Part I
Chapter 1

The base package

base-package  The R Base Package

Description
Base R functions

Details
This package contains the basic functions which let R function as a language: arithmetic, input/output, basic programming support, etc. Its contents are available through inheritance from any environment.
For a complete list of functions, use library(help = "base").

.bincode  Bin a Numeric Vector

Description
Bin a numeric vector and return integer codes for the binning.

Usage
.bincode(x, breaks, right = TRUE, include.lowest = FALSE)

Arguments

x  a numeric vector which is to be converted to integer codes by binning.
breaks a numeric vector of two or more cut points, sorted in increasing order.
right  logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa.
include.lowest  logical, indicating if an ‘x[i]’ equal to the lowest (or highest, for right = FALSE) ‘breaks’ value should be included in the first (or last) bin.
Details

This is a ‘barebones’ version of `cut.default(labels = FALSE)` intended for use in other functions which have checked the arguments passed. (Note the different order of the arguments they have in common.)

Unlike `cut`, the breaks do not need to be unique. An input can only fall into a zero-length interval if it is closed at both ends, so only if `include.lowest = TRUE` and it is the first (or last for `right = FALSE`) interval.

Value

An integer vector of the same length as `x` indicating which bin each element falls into (the leftmost bin being bin 1). NaN and NA elements of `x` are mapped to NA codes, as are values outside range of `breaks`.

See Also

cut, `tabulate`

Examples

```r
## An example with non-unique breaks:
x <- c(0, 0.01, 0.5, 0.99, 1)
b <- c(0, 0, 1, 1)
  .bincode(x, b, TRUE)
  .bincode(x, b, FALSE)
  .bincode(x, b, TRUE, TRUE)
  .bincode(x, b, FALSE, TRUE)
```

Device

Lists of Open/Active Graphics Devices

Description

A pairlist of the names of open graphics devices is stored in `.Devices`. The name of the active device (see `dev.cur`) is stored in `.Device`. Both are symbols and so appear in the base namespace.

Value

`.Device` is a length-one character vector.

`.Devices` is a pairlist of length-one character vectors. The first entry is always "null device", and there are as many entries as the maximal number of graphics devices which have been simultaneously active. If a device has been removed, its entry will be "" until the device number is reused.
Description

`.Machine` is a variable holding information on the numerical characteristics of the machine `R` is running on, such as the largest double or integer and the machine’s precision.

Usage

`.Machine`

Details

The algorithm is based on Cody’s (1988) subroutine MACHAR. As all current implementations of `R` use 32-bit integers and use IEC 60559 floating-point (double precision) arithmetic, all but the last two values are the same for almost all `R` builds.

Note that on most platforms smaller positive values than `.Machine$double.xmin` can occur. On a typical `R` platform the smallest positive double is about 5e-324.

Value

A list with components

- **double.eps** the smallest positive floating-point number `x` such that `1 + x != 1`. It equals `double.base ^ ulp.digits` if either `double.base` is 2 or `double.rounding` is 0; otherwise, it is `(double.base ^ double.ulp.digits) / 2`. Normally 2.220446e-16.

- **double.neg.eps** a small positive floating-point number `x` such that `1 - x != 1`. It equals `double.base ^ double.neg.ulp.digits` if `double.base` is 2 or `double.rounding` is 0; otherwise, it is `(double.base ^ double.neg.ulp.digits) / 2`. Normally 1.110223e-16. As `double.neg.ulp.digits` is bounded below by `-(double.digits + 3)`, `double.neg.eps` may not be the smallest number that can alter 1 by subtraction.

- **double.xmin** the smallest non-zero normalized floating-point number, a power of the radix, i.e., `double.base ^ double.min.exp`. Normally 2.225074e-308.

- **double.xmax** the largest normalized floating-point number. Typically, it is equal to `(1 - double.neg.eps) * double.base ^ double.max.exp`, but on some machines it is only the second or third largest such number, being too small by 1 or 2 units in the last digit of the significand. Normally 1.797693e+308. Note that larger unnormalized numbers can occur.

- **double.base** the radix for the floating-point representation: normally 2.

- **double.digits** the number of base digits in the floating-point significand: normally 53.

- **double.rounding** the rounding action, one of
  0 if floating-point addition chops;
  1 if floating-point addition rounds, but not in the IEEE style;
  2 if floating-point addition rounds in the IEEE style;
  3 if floating-point addition chops, and there is partial underflow;
4 if floating-point addition rounds, but not in the IEEE style, and there is partial underflow;
5 if floating-point addition rounds in the IEEE style, and there is partial underflow.
Normally 5.

double.guard the number of guard digits for multiplication with truncating arithmetic. It is 1 if floating-point arithmetic truncates and more than double digits base-
double digits participate in the post-normalization shift of the floating-point significand in multiplication, and 0 otherwise.
Normally 8.

double.ulp.digits the largest negative integer $i$ such that $1 + \text{double.base}^i \neq 1$, except that it is bounded below by $-(\text{double.digits} + 3)$. Normally -52.

double.neg.ulp.digits the largest negative integer $i$ such that $1 - \text{double.base}^i \neq 1$, except that it is bounded below by $-(\text{double.digits} + 3)$. Normally -53.

double.exponent the number of bits (decimal places if double.base is 10) reserved for the representation of the exponent (including the bias or sign) of a floating-point number. Normally 11.

double.min.exp the largest in magnitude negative integer $i$ such that double.base $^i$ is positive and normalized. Normally -1022.

double.max.exp the smallest positive power of double.base that overflows. Normally 1024.

integer.max the largest integer which can be represented. Always 2147483647.

sizeof.long the number of bytes in a C long type: 4 or 8 (most 64-bit systems, but not Windows).

sizeof.longlong the number of bytes in a C long long type. Will be zero if there is no such type, otherwise usually 8.

sizeof.longdouble the number of bytes in a C long double type. Will be zero if there is no such type (or its use was disabled when R was built), otherwise possibly 12 (most 32-bit builds) or 16 (most 64-bit builds).

sizeof.pointer the number of bytes in a C SEXP type. Will be 4 on 32-bit builds and 8 on 64-bit builds of R.

Note

sizeof.longdouble only tells you the amount of storage allocated for a long double (which are normally used internally by R for accumulators in e.g. sum, and can be read by readBin). Often what is stored is the 80-bit extended double type of IEC 60559, padded to the double alignment used on the platform — this seems to be the case for the common R platforms using ix86 and x86_64 chips.

Source

Uses a C translation of Fortran code in the reference, modified by the R Core Team to defeat over-optimization in recent compilers.
.Platform

References

See Also

.Platform for details of the platform.

Examples

```
# or for a neat printout
noquote(unlist(format(.Machine)))
```

.Platform Specific Variables

Description

.Platform is a list with some details of the platform under which R was built. This provides means to write OS-portable R code.

Usage

.Platform

Value

A list with at least the following components:

- **OS.type** character string, giving the Operating System (family) of the computer. One of "unix" or "windows".
- **file.sep** character string, giving the file separator used on your platform: "/" on both Unix-alikes and Windows (but not on the former port to Classic Mac OS).
- **dynlib.ext** character string, giving the file name extension of dynamically loadable libraries, e.g., ".dll" on Windows and ".so" or ".sl" on Unix-alikes. (Note for OS X users: these are shared objects as loaded by dyn.load and not dylibs: see dyn.load.)
- **GUI** character string, giving the type of GUI in use, or "unknown" if no GUI can be assumed. Possible values are for Unix-alikes the values given via the `--g` command-line flag ("X11", "Tk"), "AQUA" (running under R.app on OS X), "Rgui" and "RTerm" (Windows) and perhaps others under alternative front-ends or embedded R.
- **endian** character string, "big" or "little", giving the endianness of the processor in use. This is relevant when it is necessary to know the order to read/write bytes of e.g. an integer or double from/to a connection: see readBin.
- **pkgType** character string, the preferred setting for options("pkgType"). Values "source", "mac.binary.leopard" and "win.binary" are currently in use.
Abbreviate Strings

Description

Abbreviate strings to at least minlength characters, such that they remain unique (if they were), unless strict = TRUE.

Usage

abbreviate(names.arg, minlength = 4, use.classes = TRUE, dot = FALSE, strict = FALSE, method = c("left.kept", "both.sides"))
**Arguments**

- `names.arg` a character vector of names to be abbreviated, or an object to be coerced to a character vector by `as.character`.
- `minlength` the minimum length of the abbreviations.
- `use.classes` logical (currently ignored by R).
- `dot` logical: should a dot (".") be appended?
- `strict` logical: should `minlength` be observed strictly? Note that setting `strict = TRUE` may return non-unique strings.
- `method` a string specifying the method used with default "left.kept", see ‘Details’ below.

**Details**

The default algorithm (`method = "left.kept"`) used is similar to that of S. For a single string it works as follows. First all spaces at the beginning of the string are stripped. Then (if necessary) any other spaces are stripped. Next, lower case vowels are removed (starting at the right) followed by lower case consonants. Finally if the abbreviation is still longer than `minlength` upper case letters are stripped.

Characters are always stripped from the end of the word first. If an element of `names.arg` contains more than one word (words are separated by space) then at least one letter from each word will be retained.

Missing (NA) values are unaltered.

If `use.classes` is FALSE then the only distinction is to be between letters and space. This has NOT been implemented.

**Value**

A character vector containing abbreviations for the strings in its first argument. Duplicates in the original `names.arg` will be given identical abbreviations. If any non-duplicated elements have the same `minlength` abbreviations then, if `method = "both.sides"` the basic internal `abbreviate()` algorithm is applied to the characterwise reversed strings; if there are still duplicated abbreviations and if `strict = FALSE` as by default, `minlength` is incremented by one and new abbreviations are found for those elements only. This process is repeated until all unique elements of `names.arg` have unique abbreviations.

The character version of `names.arg` is attached to the returned value as a names argument: no other attributes are retained.

**Warning**

This is really only suitable for English, and does not work correctly with non-ASCII characters in multibyte locales. It will warn if used with non-ASCII characters (and required to reduce the length).

**See Also**

`substr`.
Examples

```r
x <- c("abcd", "efgh", "abce")
abbreviate(x, 2)
abbreviate(x, 2, strict = TRUE) # >> 1st and 3rd are == "ab"

(st.abb <- abbreviate(state.name, 2))
table(nchar(st.abb)) # out of 50, 3 need 4 letters:
as <- abbreviate(state.name, 3, strict = TRUE)
as[which(as == "Mss")]

## method="both.sides" helps: no 4-letters, and only 4 3-letters:
st.ab2 <- abbreviate(state.name, 2, method = "both")
table(nchar(st.ab2))
## Compare the two methods:
cbind(st.abb, st.ab2)
```

**agrep** Approximate String Matching (Fuzzy Matching)

Description

Searches for approximate matches to pattern (the first argument) within each element of the string x (the second argument) using the generalized Levenshtein edit distance (the minimal possibly weighted number of insertions, deletions and substitutions needed to transform one string into another).

Usage

```r
agrep(pattern, x, max.distance = 0.1, costs = NULL,
ignore.case = FALSE, value = FALSE, fixed = TRUE,
useBytes = FALSE)
```

Arguments

- **pattern**: a non-empty character string or a character string containing a regular expression (for fixed = FALSE) to be matched. Coerced by `as.character` to a string if possible.
- **x**: character vector where matches are sought. Coerced by `as.character` to a character vector if possible.
- **max.distance**: Maximum distance allowed for a match. Expressed either as integer, or as a fraction of the `pattern` length times the maximal transformation cost (will be replaced by the smallest integer not less than the corresponding fraction), or a list with possible components `cost`: maximum number/fraction of match cost (generalized Levenshtein distance) `all`: maximal number/fraction of all transformations (insertions, deletions and substitutions) `insertions`: maximum number/fraction of insertions `deletions`: maximum number/fraction of deletions `substitutions`: maximum number/fraction of substitutions
If cost is not given, all defaults to 10%, and the other transformation number bounds default to all. The component names can be abbreviated.

costs

a numeric vector or list with names partially matching ‘insertions’, ‘deletions’ and ‘substitutions’ giving the respective costs for computing the generalized Levenshtein distance, or NULL (default) indicating using unit cost for all three possible transformations. Coerced to integer via `as.integer` if possible.

ignore.case

if FALSE, the pattern matching is case sensitive and if TRUE, case is ignored during matching.

value

if FALSE, a vector containing the (integer) indices of the matches determined is returned and if TRUE, a vector containing the matching elements themselves is returned.

fixed

logical. If TRUE (default), the pattern is matched literally (as is). Otherwise, it is matched as a regular expression.

useBytes

logical. In a multibyte locale, should the comparison be character-by-character (the default) or byte-by-byte.

Details

The Levenshtein edit distance is used as measure of approximateness: it is the (possibly cost-weighted) total number of insertions, deletions and substitutions required to transform one string into another.

As from R 2.10.0 this uses tre by Ville Laurikari (http://laurikari.net/tre/), which supports MBCS character matching much better than the previous version.

The main effect of useBytes is to avoid errors/warnings about invalid inputs and spurious matches in multibyte locales. It inhibits the conversion of inputs with marked encodings, and is forced if any input is found which is marked as "bytes".

Value

Either a vector giving the indices of the elements that yielded a match, or, if value is TRUE, the matched elements (after coercion, preserving names but no other attributes).

Note

Since someone who read the description carelessly even filed a bug report on it, do note that this matches substrings of each element of x (just as grep does) and not whole elements. See adist in package utils, which optionally returns the offsets of the matched substrings.

Author(s)

Original version by David Meyer. Current version by Brian Ripley and Kurt Hornik.

See Also

grep
Examples

```r
agrep("lazy", "1 lazy 2")
agrep("lazy", c("1 lazy 2", "1 lazy 2"), max = list(sub = \O))
agrep("lazy", c("1 lazy", "1", "1 LAZY"), max = 2)
agrep("lazy", c("1 lazy", "1", "1 LAZY"), max = 2, value = TRUE)
agrep("lazy", c("1 lazy", "1", "1 LAZY"), max = 2, ignore.case = TRUE)
```

---

**Are All Values True?**

**Description**

Given a set of logical vectors, are all of the values true?

**Usage**

```r
all(..., na.rm = FALSE)
```

**Arguments**

- `...`: zero or more logical vectors. Other objects of zero length are ignored, and the rest are coerced to logical ignoring any class.
- `na.rm`: logical. If true NA values are removed before the result is computed.

**Details**

This is a generic function: methods can be defined for it directly or via the `summary` group generic. For this to work properly, the arguments `...` should be unnamed, and dispatch is on the first argument.

Coercion of types other than integer (raw, double, complex, character, list) gives a warning as this is often unintentional.

This is a primitive function.

**Value**

The value is a logical vector of length one.

Let `x` denote the concatenation of all the logical vectors in `...` (after coercion), after removing NAs if requested by `na.rm = TRUE`.

The value returned is TRUE if all of the values in `x` are TRUE (including if there are no values), and FALSE if at least one of the values in `x` is FALSE. Otherwise the value is NA (which can only occur if `na.rm = FALSE` and `...` contains no FALSE values and at least one NA value).

**S4 methods**

This is part of the S4 `summary` group generic. Methods for it must use the signature `x, ..., na.rm`.

**Note**

That `all(logical(\O))` is true is a useful convention: it ensures that

```r
all(all(x), all(y)) == all(x, y)
```

even if `x` has length zero.
Test if Two Objects are (Nearly) Equal

Description

all.equal(x, y) is a utility to compare R objects x and y testing ‘near equality’. If they are different, comparison is still made to some extent, and a report of the differences is returned. Don’t use all.equal directly in if expressions—either use isTRUE(all.equal(....)) or identical if appropriate.

Usage

all.equal(target, current, ...)  

## S3 method for class 'numeric'
all.equal(target, current,  
  tolerance = .Machine$double.eps ^ 0.5,  
  scale = NULL, check.attributes = TRUE, ...)  

attr.all.equal(target, current,  
  check.attributes = TRUE, check.names = TRUE, ...)  

Arguments

- target: R object.
- current: other R object, to be compared with target.
- ...: Further arguments for different methods, notably the following two, for numerical comparison:
- tolerance: numeric > 0. Differences smaller than tolerance are not considered.
- scale: numeric scalar > 0 (or NULL). See ‘Details’.
- check.attributes: logical indicating if the attributes of target and current (other than the names) should be compared.
- check.names: logical indicating if the names(.) of target and current should be compared.
Details

all.equal is a generic function, dispatching methods on the target argument. To see the available methods, use methods("all.equal"). but note that the default method also does some dispatching, e.g. using the raw method for logical targets.

Numerical comparisons for scale = NULL (the default) are done by first computing the mean absolute difference of the two numerical vectors. If this is smaller than tolerance or not finite, absolute differences are used, otherwise relative differences scaled by the mean absolute difference.

If scale is positive, absolute comparisons are made after scaling (dividing) by scale.

For complex target, the modulus (Mod) of the difference is used: all.equal.numeric is called so arguments tolerance and scale are available.

The method for the date-time class "POSIXct" by default allows a tolerance of tolerance = 0.001 seconds.

attr.all.equal is used for comparing attributes, returning NULL or a character vector.

Value

Either TRUE (NULL for attr.all.equal) or a vector of mode "character" describing the differences between target and current.

References

See Also

identical, isTRUE, ==, and all for exact equality testing.

Examples

all.equal(pi, 355/113)
# not precise enough (default tol) > relative error

d45 <- pi*(1/4 + 1:10)
stopifnot(
  all.equal(tan(d45), rep(1, 10)))
  # TRUE, but
  all.equal(tan(d45) == rep(1, 10))
  # FALSE, since not exactly
  all.equal(tan(d45), rep(1, 10), tol = 0) # to see difference

Description

Return a character vector containing all the names which occur in an expression or call.

Usage

all.names(expr, functions = TRUE, max.names = -1L, unique = FALSE)

all.vars(expr, functions = FALSE, max.names = -1L, unique = TRUE)
any

Arguments

- **expr**: an expression or call from which the names are to be extracted.
- **functions**: a logical value indicating whether function names should be included in the result.
- **max.names**: the maximum number of names to be returned. \(-1\) indicates no limit (other than vector size limits).
- **unique**: a logical value which indicates whether duplicate names should be removed from the value.

Details

These functions differ only in the default values for their arguments.

Value

A character vector with the extracted names.

See Also

- `substitute` to replace symbols with values in an expression.

Examples

```r
all.names(expression(sin(x+y)))
all.names(quote(sin(x+y))) # or a call
all.vars(expression(sin(x+y)))
```

any

Are Some Values True?

Description

Given a set of logical vectors, is at least one of the values true?

Usage

```r
any(..., na.rm = FALSE)
```

Arguments

- **...**: zero or more logical vectors. Other objects of zero length are ignored, and the rest are coerced to logical ignoring any class.
- **na.rm**: logical. If true NA values are removed before the result is computed.

Details

This is a generic function: methods can be defined for it directly or via the `Summary` group generic. For this to work properly, the arguments `...` should be unnamed, and dispatch is on the first argument.

Coercion of types other than integer (raw, double, complex, character, list) gives a warning as this is often unintentional.

This is a `primitive` function.
Value

The value is a logical vector of length one.

Let \( x \) denote the concatenation of all the logical vectors in \( \ldots \) (after coercion), after removing NAs if requested by \( \text{na.rm} = \text{TRUE} \).

The value returned is TRUE if at least one of the values in \( x \) is TRUE, and FALSE if all of the values in \( x \) are FALSE (including if there are no values). Otherwise the value is NA (which can only occur if \( \text{na.rm} = \text{FALSE} \) and \( \ldots \) contains no TRUE values and at least one NA value).

S4 methods

This is part of the S4 Summary group generic. Methods for it must use the signature \( x, \ldots, \text{na.rm} \).

References

See Also

\( \text{all} \), the ‘complement’ of any.

Examples

```r
range(x <- sort(round(stats::rnorm(10) - 1.2, 1)))
if(any(x < 0)) cat("x contains negative values
"
```

aperm

Array Transposition

Description

Transpose an array by permuting its dimensions and optionally resizing it.

Usage

```r
aperm(a, perm, ...)
```

## Default S3 method:
```r
aperm(a, perm = NULL, resize = TRUE, ...)
```

## S3 method for class 'table'
```r
aperm(a, perm = NULL, resize = TRUE, keep.class = TRUE, ...)
```

Arguments

- **a**
  the array to be transposed.
- **perm**
  the subscript permutation vector, usually a permutation of the integers \( 1:n \), where \( n \) is the number of dimensions of \( a \). When \( a \) has named dimnames, it can be a character vector of length \( n \) giving a permutation of those names. The default (used whenever \( \text{perm} \) has zero length) is to reverse the order of the dimensions.
- **resize**
  a flag indicating whether the vector should be resized as well as having its elements reordered (default TRUE).
keep.class logical indicating if the result should be of the same class as a.

Value

A transposed version of array a, with subscripts permuted as indicated by the array perm. If resize is TRUE, the array is reshaped as well as having its elements permuted, the dimnames are also permuted; if resize = FALSE then the returned object has the same dimensions as a, and the dimnames are dropped. In each case other attributes are copied from a.

The function t provides a faster and more convenient way of transposing matrices.

Author(s)

Jonathan Rougier, <J.C.Rougier@durham.ac.uk> did the faster C implementation.

t, to transpose matrices.

Examples

# interchange the first two subscripts on a 3-way array x
x <- array(1:24, 2:4)
xT <- aperm(x, c(2,1,3))
stopifnot(t(xT[,2]) == x[,2],
   t(xT[,3]) == x[,3],
   t(xT[,4]) == x[,4])

UCB <- aperm(UCBAmissions, c(2,1,3))
UCB[1,]    # UCB is still a continuity table

append Vector Merging

Description

Add elements to a vector.

Usage

append(x, values, after = length(x))
Arguments

- **x**: the vector to be modified.
- **values**: to be included in the modified vector.
- **after**: a subscript, after which the values are to be appended.

Value

A vector containing the values in `x` with the elements of `values` appended after the specified element of `x`.

References

Examples

```r
append(1:5, 0:1, after = 3)
```

---

**apply**

Apply Functions Over Array Margins

Description

Returns a vector or array or list of values obtained by applying a function to margins of an array or matrix.

Usage

```r
apply(X, MARGIN, FUN, ...)
```

Arguments

- **X**: an array, including a matrix.
- **MARGIN**: a vector giving the subscripts which the function will be applied over. E.g., for a matrix 1 indicates rows, 2 indicates columns, `c(1, 2)` indicates rows and columns. Where `X` has named dimnames, it can be a character vector selecting dimension names.
- **FUN**: the function to be applied: see ‘Details’. In the case of functions like `+`, `%*%`, etc., the function name must be backquoted or quoted.
- **...**: optional arguments to `FUN.`
apply

Details

If \( X \) is not an array but an object of a class with a non-null \( \text{dim} \) value (such as a data frame), apply attempts to coerce it to an array via \( \text{as.matrix} \) if it is two-dimensional (e.g., a data frame) or via \( \text{as.array} \).

\( \text{FUN} \) is found by a call to \( \text{match.fun} \) and typically is either a function or a symbol (e.g. a backquoted name) or a character string specifying a function to be searched for from the environment of the call to apply.

Arguments in \( \ldots \) cannot have the same name as any of the other arguments, and care may be needed to avoid partial matching to \( \text{MARGIN} \) or \( \text{FUN} \). In general-purpose code it is good practice to name the first three arguments if \( \ldots \) is passed through: this both avoids partial matching to \( \text{MARGIN} \) or \( \text{FUN} \) and ensures that a sensible error message is given if arguments named \( X \), \( \text{MARGIN} \) or \( \text{FUN} \) are passed through \( \ldots \).

Value

If each call to \( \text{FUN} \) returns a vector of length \( n \), then apply returns an array of dimension \( c(n, \text{dim}(X)[\text{MARGIN}]) \) if \( n > 1 \). If \( n \) equals 1, apply returns a vector if \( \text{MARGIN} \) has length 1 and an array of dimension \( \text{dim}(X)[\text{MARGIN}] \) otherwise. If \( n \) is 0, the result has length 0 but not necessarily the 'correct' dimension.

If the calls to \( \text{FUN} \) return vectors of different lengths, apply returns a list of length \( \text{prod(dim}(X)[\text{MARGIN}]) \) with \( \text{dim} \) set to \( \text{MARGIN} \) if this has length greater than one.

In all cases the result is coerced by \( \text{as.vector} \) to one of the basic vector types before the dimensions are set, so that (for example) factor results will be coerced to a character array.

Examples

```r
## Compute row and column sums for a matrix:
x <- cbind(x1 = 3, x2 = c(4:1, 2:5))
dimnames(x)[[1]] <- letters[1:8]  
apply(x, 2, mean, trim = .2)  
col.sums <- apply(x, 2, sum)  
row.sums <- apply(x, 1, sum)  
rbind(cbind(x, Rtot = row.sums), Ctot = c(col.sums, sum(col.sums)))
stopifnot(apply(x, 2, is.vector))
## Sort the columns of a matrix
apply(x, 2, sort)
##- function with extra args:
cave <- function(x, c1, c2) c(mean(x[c1]), mean(x[c2]))  
apply(x, 1, cave, c1 = "x1", c2 = c("x1", "x2"))
ma <- matrix(c(1:4, 1, 6:8), nrow = 2)
```
args

Argument List of a Function

Description
Displays the argument names and corresponding default values of a function or primitive.

Usage
args(name)

Arguments
name a function (a closure or a primitive). If name is a character string then the function with that name is found and used.

Details
This function is mainly used interactively to print the argument list of a function. For programming, consider using \texttt{formals} instead.

Value
For a closure, a closure with identical formal argument list but an empty (NULL) body.
For a primitive, a closure with the documented usage and NULL body. Note that some primitives do not make use of named arguments and match by position rather than name.
NULL in case of a non-function.

Examples

```r
args(c)
args(graphics::plot.default)
```

---

**Description**

These unary and binary operators perform arithmetic on numeric or complex vectors (or objects which can be coerced to them).

**Usage**

+  x
-  x
x + y
x - y
x * y
x / y
x ^ y
x %% y
x %/% y

**Arguments**

x,  y numeric or complex vectors or objects which can be coerced to such, or other objects for which methods have been written.

**Details**

The unary and binary arithmetic operators are generic functions: methods can be written for them individually or via the `Ops` group generic function. (See `Ops` for how dispatch is computed.)

If applied to arrays the result will be an array if this is sensible (for example it will not if the recycling rule has been invoked).

Logical vectors will be coerced to integer or numeric vectors, FALSE having value zero and TRUE having value one.

1 ^ y and y ^ 0 are 1, always. x ^ y should also give the proper limit result when either argument is infinite (i.e., +/- Inf).

Objects such as arrays or time-series can be operated on this way provided they are conformable.

For double arguments, %% can be subject to catastrophic loss of accuracy if x is much larger than y, and a warning is given if this is detected.

%% and x %/% y can be used for non-integer y, e.g. 1 %/% 0.2, but the results are subject to representation error and so may be platform-dependent. Because the IEC 60059 representation of 0.2 is a binary fraction slightly larger than 0.2, the answer to 1 %/% 0.2 should be 4 but most platforms give 5.

Users are sometimes surprised by the value returned, for example why (-8)^((1/3)) is NaN. For double inputs, R makes use of IEC 60559 arithmetic on all platforms, together with the C system function ‘pow’ for the ^ operator. The relevant standards define the result in many corner cases.
particular, the result in the example above is mandated by the C99 standard. On many Unix-alike systems the command `man pow` gives details of the values in a large number of corner cases.

Arithmetic on type `double` in \( \mathbb{R} \) is supposed to be done in ‘round to nearest, ties to even’ mode, but this does depend on the compiler and FPU being set up correctly.

**Value**

Unary `+` returns \( x \) unchanged (without coercing logical vectors).

Unary `-` returns a numeric or complex vector with the same attributes as \( x \): logical \( x \) are coerced to integer.

The binary operators return vectors containing the result of the element by element operations. The elements of shorter vectors are recycled as necessary (with a warning when they are recycled only fractionally). The operators are `+` for addition, `-` for subtraction, `*` for multiplication, `/` for division and `^` for exponentiation.

`%%` indicates \( x \mod y \) and `%//%` indicates integer division. It is guaranteed that \( x == (x \% y) + y \times (x \%//% y) \) (up to rounding error) unless \( y == 0 \) where the result of `%%` is `NA_integer_` or `NaN` (depending on the `typeof` of the arguments).

If either argument is complex the result will be complex, otherwise if one or both arguments are numeric, the result will be numeric. If both arguments are of type `integer`, the type of the result of `/` and `^` is `numeric` and for the other operators it is `integer` (with overflow, which occurs at \( \pm(2^{31} - 1) \), returned as `NA_integer_` with a warning).

The rules for determining the attributes of the result are rather complicated. Most attributes are taken from the longer argument. Names will be copied from the first if it is the same length as the answer, otherwise from the second if that is. If the arguments are the same length, attributes will be copied from both, with those of the first argument taking precedence when the same attribute is present in both arguments. For time series, these operations are allowed only if the series are compatible, when the class and `tsp` attribute of whichever is a time series (the same, if both are) are used. For arrays (and an array result) the dimensions and dimnames are taken from first argument if it is an array, otherwise the second.

**S4 methods**

These operators are members of the S4 `Arith` group generic, and so methods can be written for them individually as well as for the group generic (or the `Ops group generic`), with arguments `c(e1, e2)` (with `e2` missing for a unary operator).

**Implementation limits**

\( \mathbb{R} \) is dependent on OS services (and they on FPUs) for floating-point arithmetic. On all current \( \mathbb{R} \) platforms IEC 60559 (also known as IEEE 754) arithmetic is used, but some things in those standards are optional. In particular, the support for denormal numbers (those outside the range given by `.Machine`) may differ between platforms and even between calculations on a single platform.

Another potential issue is signed zeroes: on IEC 60659 platforms there are two zeroes with internal representations differing by sign. Where possible \( \mathbb{R} \) treats them as the same, but for example direct output from C code often does not do so and may output ‘\(-0.0\)’ (and on Windows whether it does so or not depends on the version of Windows). One place in \( \mathbb{R} \) where the difference might be seen is in division by zero: \( 1/x \) is Inf or -Inf depending on the sign of zero \( x \).
Note

** is translated in the parser to ^, but this was undocumented for many years. It appears as an index entry in Becker *et al* (1988), pointing to the help for deprecated but is not actually mentioned on that page. Even though it had been deprecated in S for 20 years, it was still accepted in R in 2008.

x %% 2 #-- is periodic
x %/% 5
```

---

array Multi-way Arrays

Description

Creates or tests for arrays.

Usage

```r
array(data = NA, dim = length(data), dimnames = NULL)
as.array(x, ...)
is.array(x)
```

Arguments

data a vector (including a list or expression vector) giving data to fill the array. Non-atomic classed objects are coerced by `as.vector`.

dim the dim attribute for the array to be created, that is an integer vector of length one or more giving the maximal indices in each dimension.
array

dimnames
either NULL or the names for the dimensions. This must a list (or it will be ignored) with one component for each dimension, either NULL or a character vector of the length given by dim for that dimension. The list can be named, and the list names will be used as names for the dimensions. If the list is shorter than the number of dimensions, it is extended by NULLs to the length required.

x an R object.

... additional arguments to be passed to or from methods.

Details

An array in R can have one, two or more dimensions. It is simply a vector which is stored with additional attributes giving the dimensions (attribute "dim") and optionally names for those dimensions (attribute "dimnames").

A two-dimensional array is the same thing as a matrix.

One-dimensional arrays often look like vectors, but may be handled differently by some functions: str does distinguish them in recent versions of R.

The "dim" attribute is an integer vector of length one or more containing non-negative values: the product of the values must match the length of the array.

The "dimnames" attribute is optional: if present it is a list with one component for each dimension, either NULL or a character vector of the length given by the element of the "dim" attribute for that dimension.

is.array is a primitive function.

For a list array, the print methods prints entries of length not one in the form 'integer,7' indicating the type and length.

Value

array returns an array with the extents specified in dim and naming information in dimnames. The values in data are taken to be those in the array with the leftmost subscript moving fastest. If there are too few elements in data to fill the array, then the elements in data are recycled. If data has length zero, NA of an appropriate type is used for atomic vectors (0 for raw vectors) and NULL for lists.

Unlike matrix, array does not currently remove any attributes left by as.vector from a classed list data, so can return a list array with a class attribute.

as.array is a generic function for coercing to arrays. The default method does so by attaching a dim attribute to it. It also attaches dimnames if x has names. The sole purpose of this is to make it possible to access the dim[\text{names}] attribute at a later time.

is.array returns TRUE or FALSE depending on whether its argument is an array (i.e., has a dim attribute of positive length) or not. It is generic: you can write methods to handle specific classes of objects, see InternalMethods.

Note

is.array is a primitive function.

R 2.x.y allowed (although documented not to) a zero-length dim argument, and returned a vector of length one.
as.data.frame

References

Examples

dim(as.array(letters))
array(1:3, c(2,4)) # recycle 1:3 "2 2/3 times"
# [1,] 1 3 2 1
# [2,] 2 1 3 2

as.data.frame

Coerce to a Data Frame

Description

Functions to check if an object is a data frame, or coerce it if possible.

Usage

as.data.frame(x, row.names = NULL, optional = FALSE, ...)

## S3 method for class 'character'
as.data.frame(x, ...,
              stringsAsFactors = default.stringsAsFactors())

## S3 method for class 'matrix'
as.data.frame(x, row.names = NULL, optional = FALSE, ...
              stringsAsFactors = default.stringsAsFactors())

is.data.frame(x)

Arguments

x

any R object.

row.names

NULL or a character vector giving the row names for the data frame. Missing values are not allowed.

optional

logical. If TRUE, setting row names and converting column names (to syntactic names: see make.names) is optional.

...

additional arguments to be passed to or from methods.

stringsAsFactors

logical: should the character vector be converted to a factor?
Details

`as.data.frame` is a generic function with many methods, and users and packages can supply further methods.

If a list is supplied, each element is converted to a column in the data frame. Similarly, each column of a matrix is converted separately. This can be overridden if the object has a class which has a method for `as.data.frame`: two examples are matrices of class "model.matrix" (which are included as a single column) and list objects of class "POSIXct" which are coerced to class "POSIXct".

Arrays can be converted to data frames. One-dimensional arrays are treated like vectors and two-dimensional arrays like matrices. Arrays with more than two dimensions are converted to matrices by ‘flattening’ all dimensions after the first and creating suitable column labels.

Character variables are converted to factor columns unless protected by `i`.

If a data frame is supplied, all classes preceding "data.frame" are stripped, and the row names are changed if that argument is supplied.

If `row.names = NULL`, row names are constructed from the names or dimnames of `x`, otherwise are the integer sequence starting at one. Few of the methods check for duplicated row names. Names are removed from vector columns unless `I`.

Value

`as.data.frame` returns a data frame, normally with all row names "" if optional = TRUE.

`is.data.frame` returns TRUE if its argument is a data frame (that is, has "data.frame" amongst its classes) and FALSE otherwise.

data.frame, as.data.frame.table for the table method (which has additional arguments if called directly).

as.Date  

Date Conversion Functions to and from Character

Description

Functions to convert between character representations and objects of class "Date" representing calendar dates.

Usage

```r
as.Date(x, ...)  
# S3 method for class 'character'

as.Date(x, format = "", ...)
# S3 method for class 'numeric'

as.Date(x, origin, ...)
```
as.Date

## S3 method for class 'POSIXct'

```r
as.Date(x, tz = "UTC", ...)
```

## S3 method for class 'Date'

```r
format(x, ...)
```

## S3 method for class 'Date'

```r
as.character(x, ...)
```

### Arguments

- **x**: An object to be converted.
- **format**: A character string. If not specified, it will try "%Y-%m-%d" then °%Y/%m/%d" on the first non-NA element, and give an error if neither works.
- **origin**: A Date object, or something which can be coerced by `as.Date(origin, ...)` to such an object.
- **tz**: A timezone name.
- **...**: Further arguments to be passed from or to other methods, including format for `as.character` and `as.Date` methods.

### Details

The usual vector re-cycling rules are applied to `x` and `format` so the answer will be of length that of the longer of the vectors.

Locale-specific conversions to and from character strings are used where appropriate and available. This affects the names of the days and months.

The `as.Date` methods accept character strings, factors, logical `NA` and objects of classes "POSIXlt" and "POSIXct". (The last is converted to days by ignoring the time after midnight in the representation of the time in specified timezone, default UTC.) Also objects of class "date" (from package `date`) and "dates" (from package `chron`). Character strings are processed as far as necessary for the format specified: any trailing characters are ignored.

`as.Date` will accept numeric data (the number of days since an epoch), but only if `origin` is supplied.

The `format` and `as.character` methods ignore any fractional part of the date.

### Value

The `format` and `as.character` methods return a character vector representing the date. `NA` dates are returned as `NA_character_`.

The `as.Date` methods return an object of class "Date".

### Conversion from other Systems

Most systems record dates internally as the number of days since some origin, but this is fraught with problems, including

- Is the origin day 0 or day 1? As the ‘Examples’ show, Excel manages to use both choices for its two date systems.
If the origin is far enough back, the designers may show their ignorance of calendar systems. For example, Excel’s designer thought 1900 was a leap year (claiming to copy the error from earlier DOS spreadsheets), and Matlab’s designer chose the non-existent date of ‘January 0, 0000’ (there is no such day), not specifying the calendar. (There is such a year in the ‘Gregorian’ calendar as used in ISO 8601:2004, but that does say that it is only to be used for years before 1582 with the agreement of the parties in information exchange.)

The only safe procedure is to check the other systems values for known dates: reports on the Internet (including R-help) are more often wrong than right.

Note

The default formats follow the rules of the ISO 8601 international standard which expresses a day as "2001-02-03".

If the date string does not specify the date completely, the returned answer may be system-specific. The most common behaviour is to assume that a missing year, month or day is the current one. If it specifies a date incorrectly, reliable implementations will give an error and the date is reported as NA. Unfortunately some common implementations (such as ‘glibc’) are unreliable and guess at the intended meaning.

Years before 1CE (aka 1AD) will probably not be handled correctly.

References

See Also

Date for details of the date class; locales to query or set a locale.

Your system’s help pages on strftime and strptime to see how to specify their formats. Windows users will find no help page for strptime: code based on ‘glibc’ is used (with corrections), so all the format specifiers described here are supported, but with no alternative number representation nor era available in any locale.

Examples

```r
## locale-specific version of the date
format(Sys.Date(), "%a %b %d")

## read in date info in format 'dmmmmyyyy'
## This will give NA(s) in some locales; setting the C locale
## as in the commented lines will overcome this on most systems.
## lct <- Sys.getlocale("LC_TIME"); Sys.setlocale("LC_TIME", "C")
x <- c("1jan1960", "2jan1960", "31mar1960", "30jul1960")
z <- as.Date(x, "%d%m%Y")
## Sys.setlocale("LC_TIME", lct)
z

## read in date/time info in format 'm/d/y'
dates <- c("02/27/92", "02/27/92", "01/14/92", "02/28/92", "02/01/92")
as.Date(dates, "%m/%d/%y")
```
as.environment

## date given as number of days since 1900-01-01 (a date in 1989)
as.Date(32768, origin = "1900-01-01")
## Excel is said to use 1900-01-01 as day 1 (Windows default) or
## 1904-01-01 as day 0 (Mac default), but this is complicated by Excel
## treating 1900 as a leap year.
## So for dates (post-1901) from Windows Excel
as.Date(35981, origin = "1899-12-30") # 1998-07-05
## and Mac Excel
as.Date(34519, origin = "1904-01-01") # 1998-07-05
## (these values come from http://support.microsoft.com/kb/214330)

## Experiment shows that Matlab's origin is 719529 days before ours,
## so Matlab day 734373 can be imported as
as.Date(734373, origin = "1970-01-01") - 719529
## (value from http://www.mathworks.com/help/techdoc/matlab_prog/bspgcx2-1.html)

## Timezone effect
z <- ISOdate(2010, 04, 13, c(0,12)) # midnight and midday UTC
as.Date(z) # in UTC
## these timezone names are common
as.Date(z, tz = "NZ")
as.Date(z, tz = "HST") # Hawaii

---

### as.environment

**Coerce to an Environment Object**

#### Description

A generic function coercing an R object to an environment. A number or a character string is converted to the corresponding environment on the search path.

#### Usage

```r
as.environment(x)
```

#### Arguments

- `x`
  
  an R object to convert. If it is already an environment, just return it. If it is a positive number, return the environment corresponding to that position on the search list. If it is a character string, match the string to the names on the search list. If it is a list, the equivalent of `list2env(x, parent = emptyenv())` is returned.
  
  If `is.object(x)` is true and it has a `class` for which an as.environment method is found, that is used.

#### Value

The corresponding environment object.

#### Note

This is a primitive function.
as.function

Convert Object to Function

Description

as.function is a generic function which is used to convert objects to functions.
as.function.default works on a list \( x \), which should contain the concatenation of a formal argument list and an expression or an object of mode "call" which will become the function body. The function will be defined in a specified environment, by default that of the caller.

Usage

\[
\text{as.function}(x, \ldots)
\]

## Default S3 method:
\[
\text{as.function}(x, \text{envir} = \text{parent.frame}(), \ldots)
\]

Arguments

- \( x \) : object to convert, a list for the default method.
- \( \ldots \) : additional arguments, depending on object
- \( \text{envir} \) : environment in which the function should be defined

Value

The desired function.

Note

For ancient historical reasons, \( \text{envir} = \text{NULL} \) uses the global environment rather than the base environment. Please use \( \text{envir} = \text{globalenv}() \) instead if this is what you want, as the special handling of \( \text{NULL} \) may change in a future release.
as.POSIX*

Author(s)

Peter Dalgaard

See Also

function; alist which is handy for the construction of argument lists, etc.

Examples

as.function(alist(a = , b = 2, a+b))
as.function(alist(a = , b = 2, a+b))(3)

Description

Functions to manipulate objects of classes "POSIXlt" and "POSIXct" representing calendar dates and times.

Usage

as.POSIXct(x, tz = "", ...)  
as.POSIXlt(x, tz = "", ...)  

## S3 method for class 'character'
as.POSIXlt(x, tz = "", format, ...)

## S3 method for class 'numeric'
as.POSIXlt(x, tz = "", origin, ...)

## S3 method for class 'POSIXlt'
as.double(x, ...)

Arguments

x  
An object to be converted.

tz  
A timezone specification to be used for the conversion, if one is required. System-specific (see time zones), but "" is the current timezone, and "GMT" is UTC (Universal Time, Coordinated).

...  
further arguments to be passed to or from other methods.

format  
character string giving a date-time format as used by strftime.

origin  
a date-time object, or something which can be coerced by as.POSIXct(tz = "GMT") to such an object.
Details

The `as.POSIX*` functions convert an object to one of the two classes used to represent date/times (calendar dates plus time to the nearest second). They can convert a wide variety of objects, including objects of the other class and of classes "Date", "date" (from package `date`), "chron" and "dates" (from package `chron`) to these classes. Dates without times are treated as being at midnight UTC.

They can also convert character strings of the formats "2001-02-03" and "2001/02/03" optionally followed by white space and a time in the format "14:52" or "14:52:03". (Formats such as "01/02/03" are ambiguous but can be converted via a format specification by `strptime`.) Fractional seconds are allowed. Alternatively, `format` can be specified for character vectors or factors: if it is not specified and no standard format works for all non-NA inputs an error is thrown.

If `format` is specified, remember that some of the format specifications are locale-specific, and you may need to set the LC_TIME category appropriately via `Sys.setlocale`. This most often affects the use of `%b, %B (month names) and %p (AM/PM).

Logical NAs can be converted to either of the classes, but no other logical vectors can be.

If you are given a numeric time as the number of seconds since an epoch, see the examples.

Character input is first converted to class "POSIXt" by `strptime`: numeric input is first converted to "POSIXct". Any conversion that needs to go between the two date-time classes requires a timezone: conversion from "POSIXt" to "POSIXct" will validate times in the selected timezone. One issue is what happens at transitions to and from DST, for example in the UK

```r
as.POSIXct(strptime("2011-03-27 01:30:00", "%Y-%m-%d %H:%M:%S"))
```

are respectively invalid (the clocks went forward at 1:00 GMT to 2:00 BST) and ambiguous (the clocks went back at 2:00 BST to 1:00 GMT). What happens in such cases is OS-specific: one should expect the first to be `NA`, but the second could be interpreted as either BST or GMT (and common OSES give both possible values). Note too (see `strptime`), OS facilities may not format invalid times correctly.

Value

`as.POSIXct` and `as.POSIXt` return an object of the appropriate class. If `tz` was specified, `as.POSIXt` will give an appropriate "tzone" attribute. Date-times known to be invalid will be returned as `NA`.

Note

Some of the concepts used have to be extended backwards in time (the usage is *proleptic*). For example, the origin of time for the "POSIXct" class, '1970-01-01 00:00:00 UTC', is before UTC was defined. More importantly, conversion is done assuming the Gregorian calendar which was introduced in 1582 and not used universally until the 20th century. One of the re-interpretations assumed by ISO 8601:2004 is that there was a year zero, even though current year numbering (and zero) is a much later concept (525 AD for year numbers from 1 AD).

If you want to extract specific aspects of a time (such as the day of the week) just convert it to class "POSIXt" and extract the relevant component(s) of the list, or if you want a character representation (such as a named day of the week) use the `format` method.

If a timezone is needed and that specified is invalid on your system, what happens is system-specific but attempts to set it will probably be ignored.
AsIs

See Also

DateTimeClasses for details of the classes; strptime for conversion to and from character representations.
Sys.timezone for details of the (system-specific) naming of time zones.
locales for locale-specific aspects.

Examples

(z <- Sys.time()) # the current datetime, as class "POSIXct"
unclass(z) # a large integer
floor(unclass(z)/86400) # the number of days since 1970-01-01 (UTC)
{now <- as.POSIXlt(Sys.time())} # the current datetime, as class "POSIXlt"
unlist(unclass(now)) # a list shown as a named vector
now$year + 1900 # see ?DateTimeClasses
months(now); weekdays(now) # see ?months

## suppose we have a time in seconds since 1960-01-01 00:00:00 GMT
## (the origin used by SAS)
z <- 1472562988
# ways to convert this
as.POSIXct(z, origin = "1960-01-01") # local
as.POSIXct(z, origin = "1960-01-01", tz = "GMT") # in UTC

## SPSS dates (R-help 2006-02-16)
z <- c(10485849600, 10477641600, 10561104000, 10562745600)
as.Date(as.POSIXct(z, origin = "1582-10-14", tz = "GMT"))
as.POSIXlt(Sys.time(), "GMT") # the current time in UTC

## Not run: ## These may not be correct names on your system
as.POSIXlt(Sys.time(), "America/New_York") # in New York
as.POSIXlt(Sys.time(), "EST/EDT") # alternative.
as.POSIXlt(Sys.time(), "EST") # somewhere in Eastern Canada
as.POSIXlt(Sys.time(), "HST") # in Hawaii
as.POSIXlt(Sys.time(), "Australia/Darwin")

## End(Not run)

AsIs

Inhibit Interpretation/Conversion of Objects

Description

Change the class of an object to indicate that it should be treated 'as is'.

Usage

I(x)

Arguments

x an object
**Details**

Function has two main uses.

- In function `data.frame`. Protecting an object by enclosing it in `I()` in a call to `data.frame` inhibits the conversion of character vectors to factors and the dropping of names, and ensures that matrices are inserted as single columns. I can also be used to protect objects which are to be added to a data frame, or converted to a data frame via `as.data.frame`. It achieves this by prepending the class "AsIs" to the object’s classes. Class "AsIs" has a few of its own methods, including for `[]`, `as.data.frame`, `print` and `format`.

- In function `formula`. There it is used to inhibit the interpretation of operators such as `+`, `-`, `*` and `^` as formula operators, so they are used as arithmetical operators. This is interpreted as a symbol by `terms.formula`.

**Value**

A copy of the object with class "AsIs" prepended to the class(es).

**References**

**See Also**

data.frame, formula

---

**assign**

*Assign a Value to a Name*

**Description**

Assign a value to a name in an environment.

**Usage**

```r
assign(x, value, pos = -1, envir = as.environment(pos), 
      inherits = FALSE, immediate = TRUE)
```

**Arguments**

- `x` a variable name, given as a character string. No coercion is done, and the first element of a character vector of length greater than one will be used, with a warning.
- `value` a value to be assigned to `x`.
- `pos` where to do the assignment. By default, assigns into the current environment. See ‘Details’ for other possibilities.
- `envir` the `environment` to use. See ‘Details’.
- `inherits` should the enclosing frames of the environment be inspected?
- `immediate` an ignored compatibility feature.
assign

Details

There are no restrictions on the name given as \( x \): it can be a non-syntactic name (see make.names).

The \( \text{pos} \) argument can specify the environment in which to assign the object in any of several ways: as \( \sim 1 \) (the default), as a positive integer (the position in the search list); as the character string name of an element in the search list; or as an \text{environment} (including using \text{sys.frame} to access the currently active function calls). The \text{envir} argument is an alternative way to specify an environment, but is primarily for back compatibility.

assign does not dispatch assignment methods, so it cannot be used to set elements of vectors, names, attributes, etc.

Note that assignment to an attached list or data frame changes the attached copy and not the original object: see \text{attach} and \text{with}.

Value

This function is invoked for its side effect, which is assigning \text{value} to the variable \( x \). If no \text{envir} is specified, then the assignment takes place in the currently active environment.

If \text{inherits} is \text{TRUE}, enclosing environments of the supplied environment are searched until the variable \( x \) is encountered. The value is then assigned in the environment in which the variable is encountered (provided that the binding is not locked: see \text{lockBinding}: if it is, an error is signaled). If the symbol is not encountered then assignment takes place in the user’s workspace (the global environment).

If \text{inherits} is \text{FALSE}, assignment takes place in the initial frame of \text{envir}, unless an existing binding is locked or there is no existing binding and the environment is locked (when an error is signaled).

References

See Also

\text{\textless\textgreater}, \text{get}, \text{exists}, \text{environment}.

Examples

```r
for(i in 1:6) {  # Create objects 'r.1', 'r.2', ... 'r.6' --
    nam <- paste("r", i, sep = ",")
    assign(nam, 1:i)
}
ls(pattern = "^r..$")

##-- Global assignment within a function:
myf <- function(x) {
    innerf <- function(x) assign("Global.res", x^2, envir = .GlobalEnv)
    innerf(x+1)
}
myf(3)
Global.res # 16

a <- 1:4
assign("a[1]", 2)
a[1] == 2  # FALSE
```
get("a[1]") == 2  # TRUE

---

**assignOps**

**Assignment Operators**

**Description**

Assign a value to a name.

**Usage**

\[
\begin{align*}
& x \leftarrow \text{value} \\
& x \leftarrow\text{value} \\
& \text{value} \rightarrow x \\
& \text{value} \rightarrow\rightarrow x \\
& x = \text{value}
\end{align*}
\]

**Arguments**

\[
\begin{align*}
x & \quad \text{a variable name (possibly quoted).} \\
\text{value} & \quad \text{a value to be assigned to } x.
\end{align*}
\]

**Details**

There are three different assignment operators: two of them have leftwards and rightwards forms. The operators \(\leftarrow\) and = assign into the environment in which they are evaluated. The operator \(\leftarrow\) can be used anywhere, whereas the operator = is only allowed at the top level (e.g., in the complete expression typed at the command prompt) or as one of the subexpressions in a braced list of expressions.

The operators \(\leftarrow\leftarrow\) and \(\rightarrow\rightarrow\) are normally only used in functions, and cause a search to made through parent environments for an existing definition of the variable being assigned. If such a variable is found (and its binding is not locked) then its value is redefined, otherwise assignment takes place in the global environment. Note that their semantics differ from that in the S language, but are useful in conjunction with the scoping rules of R. See ‘The R Language Definition’ manual for further details and examples.

In all the assignment operator expressions, \(x\) can be a name or an expression defining a part of an object to be replaced (e.g., z[[1]]). A syntactic name does not need to be quoted, though it can be (preferably by backticks).

The leftwards forms of assignment \(\leftarrow = \leftarrow\leftarrow\) group right to left, the other from left to right.

**Value**

\[\text{value}. \text{Thus one can use } a \leftarrow b \leftarrow c \leftarrow 6.\]

**References**

attach

See Also

assign, for “subassignment” such as x[i] <- v.[<-.environment.

attach

Attach Set of R Objects to Search Path

Description

The database is attached to the R search path. This means that the database is searched by R when evaluating a variable, so objects in the database can be accessed by simply giving their names.

Usage

attach(what, pos = 2L, name = deparse(substitute(what)),
      warn.conflicts = TRUE)

Arguments

what 'database'. This can be a data.frame or a list or a R data file created with save or NULL or an environment. See also ‘Details’.
pos integer specifying position in search() where to attach.
name name to use for the attached database. Names starting with package: are reserved for library.
warn.conflicts logical. If TRUE, warnings are printed about conflicts from attaching the database, unless that database contains an object conflicts.OK. A conflict is a function masking a function, or a non-function masking a non-function.

Details

When evaluating a variable or function name R searches for that name in the databases listed by search. The first name of the appropriate type is used.

By attaching a data frame (or list) to the search path it is possible to refer to the variables in the data frame by their names alone, rather than as components of the data frame (e.g. in the example below, height rather than women$height).

By default the database is attached in position 2 in the search path, immediately after the user’s workspace and before all previously attached packages and previously attached databases. This can be altered to attach later in the search path with the pos option, but you cannot attach at pos = 1.

The database is not actually attached. Rather, a new environment is created on the search path and the elements of a list (including columns of a data frame) or objects in a save file or an environment are copied into the new environment. If you use <<- or assign to assign to an attached database, you only alter the attached copy, not the original object. (Normal assignment will place a modified version in the user’s workspace: see the examples.) For this reason attach can lead to confusion.

One useful ‘trick’ is to use what = NULL (or equivalently a length-zero list) to create a new environment on the search path into which objects can be assigned by assign or load or sys.source.

Names starting "package:" are reserved for library and should not be used by end users. Attached files are by default given the name file:what. The name argument given for the attached environment will be used by search and can be used as the argument to as.environment.

There are hooks to attach user-defined table objects of class "UserDefinedDatabase", supported by the Omegahat package RObjectTables. See http://www.omegahat.org/RObjectTables/.
Value

The environment is returned invisibly with a "name" attribute.

Good practice

attach has the side effect of altering the search path and this can easily lead to the wrong object of a particular name being found. People do often forget to detach databases.

In interactive use, with is usually preferable to the use of attach/detach.

In programming, functions should not change the search path unless that is their purpose. Often with can be used within a function. If not, good practice is to

- Always use a distinctive name argument, and
- To immediately follow the attach call by an on.exit call to detach using the distinctive name.

This ensures that the search path is left unchanged even if the function is interrupted or if code after the attach call changes the search path.

References

See Also

library, detach, search, objects, environment, with.

Examples

```r
require(utils)

summary(women$height) # refers to variable 'height' in the data frame
attach(women)
summary(height) # The same variable now available by name
height <- height*2.54 # Don't do this. It creates a new variable
# in the user's workspace
find("height")
summary(height) # The new variable in the workspace
rm(height)
summary(height) # The original variable.
height <<- height+25.4 # Change the copy in the attached environment
find("height")
summary(height) # The changed copy
detach("women")
summary(women$height) # unchanged
```

## Not run: ## create an environment on the search path and populate it
`sys.source("myfuns.R", envir = attach(NULL, name = "myfuns"))`

## End(Not run)
**attr**  

Object Attributes

**Description**

Get or set specific attributes of an object.

**Usage**

```r
attr(x, which, exact = FALSE)
attr(x, which) <- value
```

**Arguments**

- `x`: an object whose attributes are to be accessed.
- `which`: a non-empty character string specifying which attribute is to be accessed.
- `exact`: logical: should `which` be matched exactly?
- `value`: an object, the new value of the attribute, or NULL to remove the attribute.

**Details**

These functions provide access to a single attribute of an object. The replacement form causes the named attribute to take the value specified (or create a new attribute with the value given).

The extraction function first looks for an exact match to `which` amongst the attributes of `x`, then (unless `exact = TRUE`) a unique partial match. (Setting `options(warnPartialMatchAttr = TRUE)` causes partial matches to give warnings.)

The replacement function only uses exact matches.

Note that some attributes (namely `class`, `comment`, `dim`, `dimnames`, `names`, `row.names` and `tsp`) are treated specially and have restrictions on the values which can be set. (Note that this is not true of `levels` which should be set for factors via the `levels` replacement function.)

The extractor function allows (and does not match) empty and missing values of `which`: the replacement function does not.

Both are primitive functions.

**Value**

For the extractor, the value of the attribute matched, or NULL if no exact match is found and no or more than one partial match is found.

**References**

**See Also**

- `attributes`
Examples

# create a 2 by 5 matrix
x <- 1:10
attr(x,"dim") <- c(2, 5)

Description

These functions access an object’s attributes. The first form below returns the object’s attribute list. The replacement forms uses the list on the right-hand side of the assignment as the object’s attributes (if appropriate).

Usage

attributes(obj)
attributes(obj) <- value
mostattributes(obj) <- value

Arguments

obj an object
value an appropriate named list of attributes, or NULL.

Details

Unlike `attr` it is possible to set attributes on a NULL object: it will first be coerced to an empty list.

Note that some attributes (namely `class`, `comment`, `dim`, `dimnames`, `names`, `row.names` and `tsp`) are treated specially and have restrictions on the values which can be set. (Note that this is not true of `levels` which should be set for factors via the `levels` replacement function.)

Attributes are not stored internally as a list and should be thought of as a set and not a vector. They must have unique names (and `NA` is taken as "NA", not a missing value).

Assigning attributes first removes all attributes, then sets any `dim` attribute and then the remaining attributes in the order given: this ensures that setting a `dim` attribute always precedes the `dimnames` attribute.

The `mostattributes` assignment takes special care for the `dim`, `names` and `dimnames` attributes, and assigns them only when known to be valid whereas an attributes assignment would give an error if any are not. It is principally intended for arrays, and should be used with care on classed objects. For example, it does not check that `row.names` are assigned correctly for data frames.

The names of a pairlist are not stored as attributes, but are reported as if they were (and can be set by the replacement form of `attributes`).

Both assignment and replacement forms of `attributes` are primitive functions.

References

See Also

attr.

Examples

x <- cbind(a = 1:3, pi = pi) # simple matrix with dimnames
attributes(x)

## strip an object's attributes:
attributes(x) <- NULL
x # now just a vector of length 6

mostattributes(x) <- list(mycomment = "really special", dim = 3:2,
                        dimnames = list(LETTERS[1:3], letters[1:5]), names = paste(1:6))
x # dim(), but not (dim)names

Description

autoload creates a promise-to-evaluate autoloader and stores it with name name in .AutoloadEnv
environment. When R attempts to evaluate name, autoloader is run, the package is loaded and
name is re-evaluated in the new package’s environment. The result is that R behaves as if file was
loaded but it does not occupy memory.

.Autoloaded contains the names of the packages for which autoloading has been promised.

Usage

autoload(name, package, reset = FALSE, ...)
autoloader(name, package, ...)

.AutoloadEnv
.Autoloaded

Arguments

name string giving the name of an object.
package string giving the name of a package containing the object.
reset logical: for internal use by autoloader.
... other arguments to library.

Value

This function is invoked for its side-effect. It has no return value.

See Also

delayedAssign, library
Examples

```
require(stats)
autoload("interpSpline", "splines")
search()
ls("Autoloads")
Autoloaded

x <- sort(stats::rnorm(12))
y <- x^2
is <- interpSpline(x, y)
search() ## now has splines
detach("package: splines")
search()
is2 <- interpSpline(x, y+x)
search() ## and again
detach("package: splines")
```

backsolve

Solve an Upper or Lower Triangular System

Description

Solves a triangular system of linear equations.

Usage

```
backsolve(r, x, k = ncol(r), upper.tri = TRUE, 
transpose = FALSE)
forwardsolve(l, x, k = ncol(l), upper.tri = FALSE, 
transpose = FALSE)
```

Arguments

- `r, l` an upper (or lower) triangular matrix giving the coefficients for the system to be solved. Values below (above) the diagonal are ignored.
- `x` a matrix whose columns give the right-hand sides for the equations.
- `k` The number of columns of `r` and rows of `x` to use.
- `upper.tri` logical; if `TRUE` (default), the upper triangular part of `r` is used. Otherwise, the lower one.
- `transpose` logical; if `TRUE`, solve `r' * y = x` for `y`, i.e., `t(r) %*% y == x`.

Details

Solves a system of linear equations where the coefficient matrix is upper (or ‘right’, ‘R’) or lower (‘left’, ‘L’) triangular.

```
x <- backsolve (R, b) solves Rx = b, and
x <- forwardsolve(L, b) solves Lx = b, respectively.
```

The `r/l` must have at least `k` rows and columns, and `x` must have at least `k` rows.

This is a wrapper for the level-3 BLAS routine `dtrsm`. 
**basename**

**Value**

The solution of the triangular system. The result will be a vector if \( x \) is a vector and a matrix if \( x \) is a matrix.

**References**

**See Also**

`chol`, `qr`, `solve`.

**Examples**

```r
## upper triangular matrix 'r':
r <- rbind(c(1,2,3),
c(0,1,1),
c(0,0,2))
( y <- backsolve(r, x <- c(8,4,2)) ) # -1 3 1
r %*% y # == x = (8,4,2)
backsolve(r, x, transpose = TRUE) # 8 -12 -5
```

### basename

<table>
<thead>
<tr>
<th>basename</th>
<th>Manipulate File Paths</th>
</tr>
</thead>
</table>

**Description**

`basename` removes all of the path up to and including the last path separator (if any).

`dirname` returns the part of the path up to but excluding the last path separator, or "." if there is no path separator.

**Usage**

```r
basename(path)
dirname(path)
```

**Arguments**

- `path` character vector, containing path names.

**Details**

For `dirname` tilde expansion of the path is done.

Trailing path separators are removed before dissecting the path, and for `dirname` any trailing file separators are removed from the result.
Bessel

Value
A character vector of the same length as path. A zero-length input will give a zero-length output with no error.
Paths not containing any separators are taken to be in the current directory, so dirname returns ".".
If an element of path is NA, so is the result.
"" is not a valid pathname, but is returned unchanged.

Behaviour on Windows
On Windows this will accept either \ or / as the path separator, but dirname will return a path using / (except if on a network share, when the leading \ will be preserved). Expect these only to be able to handle complete paths, and not for example just a network share or a drive.
UTF-8-encoded path names not valid in the current locale can be used.

Note
These are not wrappers for the POSIX system functions of the same names: in particular they do not have the special handling of the path "/" and of returning "." for empty strings.

See Also
file.path, path.expand.

Examples
basename(file.path("", "p1", "p2", "p3", c(“file1”, “file2”)))
dirname(file.path("", "p1", "p2", "p3", "filename"))

---

Bessel Functions

Description
Bessel Functions of integer and fractional order, of first and second kind, \( J_\nu \) and \( Y_\nu \), and Modified Bessel functions (of first and third kind), \( I_\nu \) and \( K_\nu \).

Usage

\[
\begin{align*}
\text{besselI}(x, \nu, \text{expon.scaled} = \text{FALSE}) \\
\text{besselK}(x, \nu, \text{expon.scaled} = \text{FALSE}) \\
\text{besselJ}(x, \nu) \\
\text{besselY}(x, \nu)
\end{align*}
\]

Arguments

\[
\begin{align*}
x & \quad \text{numeric, } \geq 0. \\
\nu & \quad \text{numeric; The order (maybe fractional!) of the corresponding Bessel function.} \\
expon.scaled & \quad \text{logical; if TRUE, the results are exponentially scaled in order to avoid overflow (} I_\nu \text{) or underflow (} K_\nu \text{), respectively.}
\end{align*}
\]
Details

If `expon.scaled = TRUE`, $e^{-x} I_\nu(x)$, or $e^{x} K_\nu(x)$ are returned.

For $\nu < 0$, formulae 9.1.2 and 9.6.2 from Abramowitz & Stegun are applied (which is probably suboptimal), except for `besselK` which is symmetric in $\nu$.

Value

Numeric vector with the (scaled, if `expon.scaled = TRUE`) values of the corresponding Bessel function.

The length of the result is the maximum of the lengths of the parameters. All parameters are recycled to that length.

Author(s)

Original Fortran code: W. J. Cody, Argonne National Laboratory
Translation to C and adaption to R: Martin Maechler `<maechler@stat.math.ethz.ch>`.

Source

The C code is a translation of Fortran routines from `http://www.netlib.org/specfun/ribes1`, `../rjbes1`, etc.

\begin{verbatim}
bindenv

\textbf{Binding and Environment Adjustments}

\textbf{Description}

These functions represent an experimental interface for adjustments to environments and bindings within environments. They allow for locking environments as well as individual bindings, and for linking a variable to a function.
\end{verbatim}
bindenv

Usage

```r
lockEnvironment(env, bindings = FALSE)
environmentIsLocked(env)
lockBinding(sym, env)
unlockBinding(sym, env)
bindingIsLocked(sym, env)
makeActiveBinding(sym, fun, env)
bindingIsActive(sym, env)
```

Arguments

- `env` an environment.
- `bindings` logical specifying whether bindings should be locked.
- `sym` a name object or character string
- `fun` a function taking zero or one arguments

Details

The function `lockEnvironment` locks its environment argument, which must be a normal environment (not base). (Locking the base environment and namespace may be supported later.) Locking the environment prevents adding or removing variable bindings from the environment. Changing the value of a variable is still possible unless the binding has been locked. The namespace environments of packages with namespaces are locked when loaded.

`lockBinding` locks individual bindings in the specified environment. The value of a locked binding cannot be changed. Locked bindings may be removed from an environment unless the environment is locked.

`makeActiveBinding` installs `fun` so that getting the value of `sym` calls `fun` with no arguments, and assigning to `sym` calls `fun` with one argument, the value to be assigned. This allows the implementation of things like C variables linked to R variables and variables linked to databases. It may also be useful for making thread-safe versions of some system globals.

Value

The `isLocked` functions return a length-one logical vector. The remaining functions return `NULL`, invisibly.

Author(s)

Luke Tierney

Examples

```r
# locking environments
e <- new.env()
assign("x", 1, envir = e)
get("x", envir = e)
lockEnvironment(e)
get("x", envir = e)
assign("x", 2, envir = e)
try,assign("y", 2, envir = e)) # error

# locking bindings
```
e <- new.env()
assign("x", 1, envir = e)
get("x", envir = e)
lockBinding("x", e)
try(assign("x", 2, envir = e)) # error
unlockBinding("x", e)
assign("x", 2, envir = e)
get("x", envir = e)

# active bindings
f <- local(
  x <- 1
  function(v) {
    if (missing(v))
      cat("get\n")
    else {
      cat("set\n")
      x <<- v
    }
    x
  }
)
makeActiveBinding("fred", f, .GlobalEnv)
bindingIsActive("fred", .GlobalEnv)
fred
fred <- 2
fred

---

**bitwise**

### Bitwise Logical Operations

**Description**

Logical operations on integer vectors with elements viewed as sets of bits.

**Usage**

- `bitwNot(a)`
- `bitwAnd(a, b)`
- `bitwOr(a, b)`
- `bitwXor(a, b)`
- `bitwShiftL(a, n)`
- `bitwShiftR(a, n)`

**Arguments**

- `a, b` integer vectors; numeric vectors are coerced to integer vectors.
- `n` non-negative integer vector of values up to 31.
Details

Each element of an integer vector has 32 bits.
Pairwise operations can result in integer NA.
Shifting is done assuming the values represent unsigned integers.

Value

An integer vector of length the longer of the arguments, or zero length if one is zero-length.
The output element is NA if an input is NA (after coercion) or an invalid shift.

See Also

The logical operators, !, & , |, xor.
The classes “octmode” and “hexmode” whose implementation of the standard logical operators is
based on these functions.
Package bitOps has similar functions for numeric vectors which differ in the way they treat integers
2^{31} or larger.

Examples

bitwAnd(15L, 7L)
bitwOr(15L, 7L)
bitwXor(15L, 7L)
bitwXor(-1L, 1L)

bitwShiftR(-1, 1:31) # shifts of 2^{32}-1 = 4294967295

Description

Access to and Manipulation of the Body of a Function

Get or set the body of a function.

Usage

body(fun = sys.function(sys.parent()))
body(fun, envir = environment(fun)) <- value

Arguments

fun a function object, or see ‘Details’.
envir environment in which the function should be defined.
value an object, usually a language object: see section ‘Value’.

Details

For the first form, fun can be a character string naming the function to be manipulated, which is
searched for from the parent frame. If it is not specified, the function calling body is used.
The bodies of all but the simplest are braced expressions, that is calls to ζ: see the ‘Examples’
section for how to create such a call.
Value

body returns the body of the function specified. This is normally a language object, most often a call to (), but it can also be an object (e.g. pi) to be the return value of the function.

The replacement form sets the body of a function to the object on the right hand side, and (potentially) resets the environment of the function. If value is of class "expression" the first element is used as the body: any additional elements are ignored, with a warning.

See Also

alist, args, function.

Examples

body(body)
  f <- function(x) x^5
  body(f) <- quote(5*x)
  ## or equivalently  body(f) <- expression(5*x)
  f(3) # = 125
  body(f)

  ## creating a multi-expression body
  e <- expression(y <- x^2, return(y)) # or a list
  body(f) <- as.call(c(as.name("("), e))
  f
  f(8)

bquote

Partial substitution in expressions

Description

An analogue of the LISP backquote macro. bquote quotes its argument except that terms wrapped in () are evaluated in the specified where environment.

Usage

bquote(expr, where = parent.frame())

Arguments

expr A language object.
where An environment.

Value

A language object.

See Also

quote, substitute
Examples

```r
require(graphics)

a <- 2

bquote(a == a)
quote(a == a)

bquote(a == .(a))
substitute(a == A, list(A = a))

plot(1:10, a*(1:10), main = bquote(a == .(a)))

## to set a function default arg
default <- 1
bquote( function(x, y = .(default)) x+y )
```

---

**browser**

**Environment Browser**

**Description**

Interrupt the execution of an expression and allow the inspection of the environment where `browser` was called from.

**Usage**

```r
browser(text = "", condition = NULL, expr = TRUE, skipCalls = 0L)
```

**Arguments**

- **text**: a text string that can be retrieved once the browser is invoked.
- **condition**: a condition that can be retrieved once the browser is invoked.
- **expr**: An expression, which if it evaluates to `TRUE` the debugger will invoked, otherwise control is returned directly.
- **skipCalls**: how many previous calls to skip when reporting the calling context.

**Details**

A call to `browser` can be included in the body of a function. When reached, this causes a pause in the execution of the current expression and allows access to the \( \mathcal{R} \) interpreter.

The purpose of the text and condition arguments are to allow helper programs (e.g. external debuggers) to insert specific values here, so that the specific call to browser (perhaps its location in a source file) can be identified and special processing can be achieved. The values can be retrieved by calling `browserText` and `browserCondition`.

The purpose of the `expr` argument is to allow for the illusion of conditional debugging. It is an illusion, because execution is always paused at the call to browser, but control is only passed to the evaluator described below if `expr` evaluates to `TRUE`. In most cases it is going to be more efficient to use an if statement in the calling program, but in some cases using this argument will be simpler.

The `skipCalls` argument should be used when the `browser()` call is nested within another debugging function: it will look further up the call stack to report its location.
At the browser prompt the user can enter commands or R expressions, followed by a newline. The commands are

\begin{itemize}
\item[c] (or just an empty line, by default) exit the browser and continue execution at the next statement.
\item[cont] synonym for \texttt{c}.
\item[n] enter the step-through debugger if the function is interpreted. This changes the meaning of \texttt{c}: see the documentation for \texttt{debug}. For byte compiled functions \texttt{n} is equivalent to \texttt{c}.
\item[where] print a stack trace of all active function calls.
\item[Q] exit the browser and the current evaluation and return to the top-level prompt.
\end{itemize}

(Leading and trailing whitespace is ignored, except for an empty line).

Anything else entered at the browser prompt is interpreted as an R expression to be evaluated in the calling environment: in particular typing an object name will cause the object to be printed, and \texttt{ls()} lists the objects in the calling frame. (If you want to look at an object with a name such as \texttt{n}, print it explicitly.)

The number of lines printed for the deparsed call can be limited by setting \texttt{options(deparse.max.lines)}.

Setting option "browserNLdisabled" to TRUE disables the use of an empty line as a synonym for \texttt{c}. If this is done, the user will be re-prompted for input until a valid command or an expression is entered.

This is a primitive function but does argument matching in the standard way.

References

debug, and traceback for the stack on error. \texttt{browserText} for how to retrieve the text and condition.

\begin{itemize}
\item[browserText] \texttt{Functions to Retrieve Values Supplied by Calls to the Browser}
\end{itemize}

Description

A call to browser can provide context by supplying either a text argument or a condition argument. These functions can be used to retrieve either of these arguments.

Usage

\begin{itemize}
\item[browserText(n = 1)]
\item[browserCondition(n = 1)]
\item[browserSetDebug(n = 1)]
\end{itemize}

Arguments

\begin{itemize}
\item[n] The number of contexts to skip over, it must be non-negative.
\end{itemize}
Details

Each call to browser can supply either a text string or a condition. The functions browserText and browserCondition provide ways to retrieve those values. Since there can be multiple browser contexts active at any time we also support retrieving values from the different contexts. The innermost (most recently initiated) browser context is numbered 1: other contexts are numbered sequentially. browserSetDebug provides a mechanism for initiating the browser in one of the calling functions. See sys.frame for a more complete discussion of the calling stack. To use browserSetDebug you select some calling function, determine how far back it is in the call stack and call browserSetDebug with n set to that value. Then, by typing c at the browser prompt you will cause evaluation to continue, and provided there are no intervening calls to browser or other interrupts, control will halt again once evaluation has returned to the closure specified. This is similar to the up functionality in gdb or the “step out” functionality in other debuggers.

Value

browserText returns the text, while browserCondition returns the condition from the specified browser context.

browserSetDebug returns NULL, invisibly.

Note

It may be of interest to allow for querying further up the set of browser contexts and this functionality may be added at a later date.

---

builtins

Returns the Names of All Built-in Objects

Description

Return the names of all the built-in objects. These are fetched directly from the symbol table of the R interpreter.

Usage

builtins(internal = FALSE)

Arguments

internal a logical indicating whether only ‘internal’ functions (which can be called via .Internal) should be returned.
Details

`builtins()` returns an unsorted list of the objects in the symbol table, that is all the objects in the base environment. These are the built-in objects plus any that have been added subsequently when the base package was loaded. It is less confusing to use `ls(baseenv(), all = TRUE).

`builtins(TRUE)` returns an unsorted list of the names of internal functions, that is those which can be accessed as `.Internal(foo(args ...))` for `foo` in the list.

Value

A character vector.

---

by

Apply a Function to a Data Frame Split by Factors

Description

Function `by` is an object-oriented wrapper for `tapply` applied to data frames.

Usage

`by(data, INDICES, FUN, ..., simplify = TRUE)`

Arguments

data an R object, normally a data frame, possibly a matrix.
INDICES a factor or a list of factors, each of length `nrow(data)`.
FUN a function to be applied to data frame subsets of data.
... further arguments to `FUN`.
simplify logical: see `tapply`.

Details

A data frame is split by row into data frames subsetted by the values of one or more factors, and function `FUN` is applied to each subset in turn.

Object `data` will be coerced to a data frame by the default method, but if this results in a 1-column data frame, the objects passed to `FUN` are dropped to a subsets of that column.

Value

An object of class "by", giving the results for each subset. This is always a list if `simplify` is false, otherwise a list or array (see `tapply`).

See Also

tapply, simplify2array, ave also applies a function block-wise.
Examples

```r
tmp <- with(warpbreaks,
  by(warpbreaks, tension,
    function(x) lm(breaks ~ wool, data = x)))
```

## now suppose we want to extract the coefficients by group

c

### Combine Values into a Vector or List

**Description**

This is a generic function which combines its arguments.

The default method combines its arguments to form a vector. All arguments are coerced to a common type which is the type of the returned value, and all attributes except names are removed.

**Usage**

```r
c(..., recursive = FALSE)
```

**Arguments**

- `...`: objects to be concatenated.
- `recursive`: logical. If `recursive = TRUE`, the function recursively descends through lists (and pairlists) combining all their elements into a vector.

**Details**

The output type is determined from the highest type of the components in the hierarchy `NULL < raw < logical < integer < double < complex < character < list < expression`. Pairlists are treated as lists, but non-vector components (such names and calls) are treated as one-element lists which cannot be unlisted even if `recursive = TRUE`.

c is sometimes used for its side effect of removing attributes except names, for example to turn an array into a vector. as.vector is a more intuitive way to do this, but also drops names. Note too that methods other than the default are not required to do this (and they will almost certainly preserve a class attribute).

This is a primitive function.

**Value**

NULL or an expression or a vector of an appropriate mode. (With no arguments the value is NULL.)

**S4 methods**

This function is S4 generic, but with argument list `x, ..., recursive = FALSE`).

unlist and as.vector to produce attribute-free vectors.

Examples

c(1,7:9)
c(1:5, 10.5, "next")

## uses with a single argument to drop attributes
x <- 1:4
names(x) <- letters[1:4]
x
c(x)  # has names
as.vector(x) # no names
dim(x) <- c(2,2)
x
c(x)
as.vector(x)

## append to a list:
l1 <- list(A = 1, c = "C")
## do not use
c(l1, d = 1:3) # which is == c(l1, as.list(c(d = 1:3))
## but rather
c(l1, d = list(1:3)) # c() combining two lists
c(list(A = c(B = 1)), recursive = TRUE)
c(options(), recursive = TRUE)
c(list(A = c(B = 1, C = 2), B = c(E = 7)), recursive = TRUE)

---

Function Calls

Description

Create or test for objects of mode "call".

Usage

call(name, ...)
is.call(x)
as.call(x)

Arguments

name a non-empty character string naming the function to be called.
...
arguments to be part of the call.
x an arbitrary R object.
Details

call returns an unevaluated function call, that is, an unevaluated expression which consists of the named function applied to the given arguments (name must be a quoted string which gives the name of a function to be called). Note that although the call is unevaluated, the arguments ... are evaluated.

call is a primitive, so the first argument is taken as name and the remaining arguments as arguments for the constructed call: if the first argument is named the name must partially match name.

is.call is used to determine whether x is a call (i.e., of mode "call").

Objects of mode "list" can be coerced to mode "call". The first element of the list becomes the function part of the call, so should be a function or the name of one (as a symbol; a quoted string will not do).

All three are primitive functions.

Warning

call should not be used to attempt to evade restrictions on the use of .Internal and other non-API calls.

callCC: Call With Current Continuation

Description

A downward-only version of Scheme’s call with current continuation.

Usage

callCC(fun)

Arguments

fun: function of one argument, the exit procedure.

Details

callCC provides a non-local exit mechanism that can be useful for early termination of a computation. callCC calls fun with one argument, an exit function. The exit function takes a single argument, the intended return value. If the body of fun calls the exit function then the call to callCC immediately returns, with the value supplied to the exit function as the value returned by callCC.

Author(s)

Luke Tierney

Examples

# The following all return the value 1
callCC(function(k) 1)
callCC(function(k) k(1))
callCC(function(k) (k(1); 2))
callCC(function(k) repeat k(1))

CallExternal: Modern Interfaces to C/C++ code

Description

Functions to pass R objects to compiled C/C++ code that has been loaded into R.

Usage

.Call(.NAME, ..., PACKAGE)
.External(.NAME, ..., PACKAGE)
CallExternal

Arguments

- **.NAME** a character string giving the name of a C function, or an object of class "NativeSymbolInfo", "RegisteredNativeSymbol" or "NativeSymbol" referring to such a name.

- **...** arguments to be passed to the compiled code. Up to 65 for .Call.

- **PACKAGE** if supplied, confine the search for a character string .NAME to the DLL given by this argument (plus the conventional extension, `.so`, `.dll`, ...). This argument follows ... and so its name cannot be abbreviated. This is intended to add safety for packages, which can ensure by using this argument that no other package can override their external symbols, and also speeds up the search (see ‘Note’).

Details

The functions are used to call compiled code which makes use of internal R objects, passing the arguments to the code as a sequence of R objects. They assume C calling conventions, so can usually also be used of C++ code.

For details about how to write code to use with these functions see the chapter on ‘System and foreign language interfaces’ in the ‘Writing R Extensions’ manual. They differ in the way the arguments are passed to the C code: .External allows for a variable number of arguments. These functions are primitive, and .NAME is always matched to the first argument supplied (which should not be named). For clarity, avoid using names in the arguments passed to ... that match or partially match .NAME.

Value

An R object constructed in the compiled code.

Header files for external code

Writing code for use with these functions will need to use internal R structures defined in ‘Rinternals.h’ and/or the macros in ‘Rdefines.h’.

Note

If one of these functions is to be used frequently, do specify PACKAGE (to confine the search to a single DLL) or pass .NAME as one of the native symbol objects. Searching for symbols can take a long time, especially when many namespaces are loaded.

You may see PACKAGE = "base" for symbols linked into R. Do not use this in your own code: such symbols are not part of the API and may be changed without warning.

PACKAGE = "" used to be accepted (but was undocumented): it is now an error.

References

See Also

The ‘Writing R Extensions’ manual.
capabilities  Report Capabilities of this Build of R

Description
Report on the optional features which have been compiled into this build of R.

Usage
capabilities(what = NULL)

Arguments
what character vector or NULL, specifying required components. NULL implies that all are required.

Value
A named logical vector. Current components are

- jpeg is the jpeg function operational?
- png is the png function operational?
- tiff is the tiff function operational?
- tcltk is the tcltk package operational? Note that to make use of Tk you will almost always need to check that “X11” is also available.

- X11 Are the X11 graphics device and the X11-based data editor available? This loads the X11 module if not already loaded, and checks that the default display can be contacted unless a X11 device has already been used.

- aqua Are the R.app GUI components and the quartz function operational? Only on some OS X builds. Note that this is distinct from .Platform$GUI == “AQUA”, which is true when using the Mac R.app GUI console.

- http/ftp Are url and the internal method for download.file available?
- sockets Are make.socket and related functions available?
- libxml Is there support for integrating libxml with the R event loop?
- fifo are FIFO connections supported?
- cedit Is command-line editing available in the current R session? This is false in non-interactive sessions. It will be true for the command-line interface if readline support has been compiled in and ‘--no-readline’ was not used when R was invoked.

- iconv Is internationalization conversion via iconv supported? Always true as from R 2.10.0.
- NLS Is there Natural Language Support (for message translations)?
- profmem Is there support for memory profiling? See tracemem.
- cairo Is there support the svg, cairo_pdf and cairo_ps devices, and for type = “cairo” in the X11, bmp, jpeg, png, and tiff devices?
**Note to OS X users**

Capabilities "jpeg", "png" and "tiff" refer to the X11-based versions of these devices. If capabilities("aqua") is true, then these devices with type = "quartz" will be available, and out-of-the-box will be the default type. Thus, for example, the tiff device will be available if capabilities("aqua") || capabilities("tiff") if the defaults are unchanged.

**Examples**

```
capabilities()
if(!capabilities("http/ftp"))
  warning("internal download.file() is not available")
## See also the examples for 'connections'.
```

---

**cat**  
*Concatenate and Print*

**Description**

Outputs the objects, concatenating the representations. cat performs much less conversion than print.

**Usage**

```
cat(..., file = "", sep = " ", fill = FALSE, labels = NULL, append = FALSE)
```

**Arguments**

- ...: `R` objects (see ‘Details’ for the types of objects allowed).
- file: A connection, or a character string naming the file to print to. If "" (the default), cat prints to the standard output connection, the console unless redirected by sink. If it is "|cmd", the output is piped to the command given by ‘cmd’, by opening a pipe connection.
- sep: a character vector of strings to append after each element.
- fill: a logical or (positive) numeric controlling how the output is broken into successive lines. If FALSE (default), only newlines created explicitly by "\n" are printed. Otherwise, the output is broken into lines with print width equal to the option width if fill is TRUE, or the value of fill if this is numeric. Non-positive fill values are ignored, with a warning.
- labels: character vector of labels for the lines printed. Ignored if fill is FALSE.
- append: logical. Only used if the argument file is the name of file (and not a connection or "|cmd"). If TRUE output will be appended to file; otherwise, it will overwrite the contents of file.
Details

cat is useful for producing output in user-defined functions. It converts its arguments to character vectors, concatenates them to a single character vector, appends the given sep = string(s) to each element and then outputs them.

No linefeeds are output unless explicitly requested by ‘"\n"’ or if generated by filling (if argument fill is TRUE or numeric).

If file is a connection and open for writing it is written from its current position. If it is not open, it is opened for the duration of the call in "wt" mode and then closed again.

Currently only atomic vectors and names are handled, together with NULL and other zero-length objects (which produce no output). Character strings are output ‘as is’ (unlike print.default which escapes non-printable characters and backslash — use encodeString if you want to output encoded strings using cat). Other types of R object should be converted (e.g. by as.character or format) before being passed to cat. That includes factors, which are output as integer vectors.

cat converts numeric/complex elements in the same way as print (and not in the same way as as.character which is used by the S equivalent), so options "digits" and "scipen" are relevant. However, it uses the minimum field width necessary for each element, rather than the same field width for all elements.

Value

None (invisible NULL).

Note

If any element of sep contains a newline character, it is treated as a vector of terminators rather than separators, an element being output after every vector element and a newline after the last. Entries are recycled as needed.

References

See Also

print, format, and paste which concatenates into a string.

Examples

iter <- stats::rpois(1, lambda = 10)
## print an informative message
cat("iteration = ", iter <- iter + 1, "\n")

## 'fill' and label lines:
cat(paste(letters, 100* 1:26), fill = TRUE, labels = paste0("","1:10", ":"))
**cbind**

*Combine R Objects by Rows or Columns*

**Description**

Take a sequence of vector, matrix or data frames arguments and combine by columns or rows, respectively. These are generic functions with methods for other R classes.

**Usage**

```r
cbind(..., deparse.level = 1)
rbind(..., deparse.level = 1)
```

**Arguments**

- `...`: vectors or matrices. These can be given as named arguments. Other R objects will be coerced as appropriate: see sections ‘Details’ and ‘Value’. (For the “data.frame” method of `cbind` these can be further arguments to `data.frame` such as `stringsAsFactors`.)
- `deparse.level`: integer controlling the construction of labels in the case of non-matrix-like arguments (for the default method):
  - `deparse.level = 0` constructs no labels; the default,
  - `deparse.level = 1` or `2` constructs labels from the argument names, see the ‘Value’ section below.

**Details**

The functions `cbind` and `rbind` are S3 generic, with methods for data frames. The data frame method will be used if at least one argument is a data frame and the rest are vectors or matrices.

There can be other methods; in particular, there is one for time series objects. See the section on ‘Dispatch’ for how the method to be used is selected.

In the default method, all the vectors/matrices must be atomic (see `vector`) or lists. Expressions are not allowed. Language objects (such as formulae and calls) and pairlists will be coerced to lists: other objects (such as names and external pointers) will be included as elements in a list result.

Any classes the inputs might have are discarded (in particular, factors are replaced by their internal codes).

If there are several matrix arguments, they must all have the same number of columns (or rows) and this will be the number of columns (or rows) of the result. If all the arguments are vectors, the number of columns (rows) in the result is equal to the length of the longest vector. Values in shorter arguments are recycled to achieve this length (with a warning if they are recycled only fractionally).

When the arguments consist of a mix of matrices and vectors the number of columns (rows) of the result is determined by the number of columns (rows) of the matrix arguments. Any vectors have their values recycled or subsetted to achieve this length.

For `cbind` (`rbind`), vectors of zero length (including NULL) are ignored unless the result would have zero rows (columns), for S compatibility. (Zero-extent matrices do not occur in S3 and are not ignored in R.)
Value

For the default method, a matrix combining the ... arguments column-wise or row-wise. (Exception: if there are no inputs or all the inputs are NULL, the value is NULL.)

The type of a matrix result determined from the highest type of any of the inputs in the hierarchy raw < logical < integer < double < complex < character < list.

For cbind (rbind) the column (row) names are taken from the colnames (rownames) of the arguments if these are matrix-like. Otherwise from the names of the arguments or where those are not supplied and deparse.level > 0, by deparsing the expressions given, for deparse.level = 1 only if that gives a sensible name (a 'symbol', see isSymbol).

For cbind row names are taken from the first argument with appropriate names: rownames for a matrix, or names for a vector of length the number of rows of the result.

For rbind column names are taken from the first argument with appropriate names: colnames for a matrix, or names for a vector of length the number of columns of the result.

Data frame methods

The cbind data frame method is just a wrapper for data.frame(..., check.names = FALSE). This means that it will split matrix columns in data frame arguments, and convert character columns to factors unless stringsAsFactors = FALSE is specified.

The rbind data frame method first drops all zero-column and zero-row arguments. (If that leaves none, it returns the first argument with columns otherwise a zero-column zero-row data frame.) It then takes the classes of the columns from the first data frame, and matches columns by name (rather than by position). Factors have their levels expanded as necessary (in the order of the levels of the levelsets of the factors encountered) and the result is an ordered factor if and only if all the components were ordered factors. (The last point differs from S-PLUS.) Old-style categories (integer vectors with levels) are promoted to factors.

Dispatch

The method dispatching is not done via UseMethod(), but by C-internal dispatching. Therefore there is no need for, e.g., rbind.default.

The dispatch algorithm is described in the source file ('.../src/main/bind.c') as

1. For each argument we get the list of possible class memberships from the class attribute.
2. We inspect each class in turn to see if there is an applicable method.
3. If we find an applicable method we make sure that it is identical to any method determined for prior arguments. If it is identical, we proceed, otherwise we immediately drop through to the default code.

If you want to combine other objects with data frames, it may be necessary to coerce them to data frames first. (Note that this algorithm can result in calling the data frame method if all the arguments are either data frames or vectors, and this will result in the coercion of character vectors to factors.)

References

See Also

c to combine vectors (and lists) as vectors, data.frame to combine vectors and matrices as a data frame.
Examples

m <- cbind(1, 1:7) # the '1' (= shorter vector) is recycled
m
m <- cbind(m, 8:14)[, c(1, 3, 2)] # insert a column
m
cbind(1:7, diag(3)) # vector is subset -> warning

cbind(0, cbind(HQZWL, cbind(1, 1:3)))
cbind(I = 0, X = cbind(a = 1, b = 1:3)) # use some names
xx <- data.frame(I = rep(0, 2))
cbind(xx, X = cbind(a = 1, b = 1:3)) # named differently

cbind(0, matrix(1, nrow = 0, ncol = 4)) # Warning (making sense)
dim(cbind(0, matrix(1, nrow = 2, ncol = 0))) #-> 2 x 1

## # deparse.level
dd <- 10
rbind(1:4, c = 2, "a++" = 10, dd, deparse.level = 0) # middle 2 rownames
rbind(1:4, c = 2, "a++" = 10, dd, deparse.level = 1) # 3 rownames (default)
rbind(1:4, c = 2, "a++" = 10, dd, deparse.level = 2) # 4 rownames

Description

Seeks a unique match of its first argument among the elements of its second. If successful, it returns
this element; otherwise, it performs an action specified by the third argument.

Usage

char.expand(input, target, nomatch = stop("no match"))

Arguments

input a character string to be expanded.
target a character vector with the values to be matched against.
nomatch an R expression to be evaluated in case expansion was not possible.

Details

This function is particularly useful when abbreviations are allowed in function arguments, and need
to be uniquely expanded with respect to a target table of possible values.

Value

A length-one character vector, one of the elements of target (unless nomatch is changed to be a
non-error, when it can be a zero-length character string).

See Also

charmatch and pmatch for performing partial string matching.
Examples

```r
locPars <- c("mean", "median", "mode")
char.expand("me", locPars, warning("Could not expand"))
char.expand("mo", locPars)
```

### character

<table>
<thead>
<tr>
<th>Character Vectors</th>
</tr>
</thead>
</table>

#### Description

Create or test for objects of type "character".

#### Usage

```r
character(length = 0)
as.character(x, ...)
is.character(x)
```

#### Arguments

- `length`: A non-negative integer specifying the desired length. Double values will be coerced to integer: supplying an argument of length other than one is an error.
- `x`: object to be coerced or tested.
- `...`: further arguments passed to or from other methods.

#### Details

`as.character` and `is.character` are generic: you can write methods to handle specific classes of objects, see `InternalMethods`. Further, for `as.character` the default method calls `as.vector`, so dispatch is first on methods for `as.character` and then for methods for `as.vector`.

`as.character` represents real and complex numbers to 15 significant digits (technically the compiler's setting of the ISO C constant `DBL_DIG`, which will be 15 on machines supporting IEC60559 arithmetic according to the C99 standard). This ensures that all the digits in the result will be reliable (and not the result of representation error), but does mean that conversion to character and back to numeric may change the number. If you want to convert numbers to character with the maximum possible precision, use `format`.

#### Value

- `character` creates a character vector of the specified length. The elements of the vector are all equal to "".
- `as.character` attempts to coerce its argument to character type; like `as.vector` it strips attributes including names. For lists it deparses the elements individually, except that it extracts the first element of length-one character vectors.
- `is.character` returns TRUE or FALSE depending on whether its argument is of character type or not.

#### Note

`as.character` breaks lines in language objects at 500 characters, and inserts newlines. Prior to 2.15.0 lines were truncated (at about 70 characters before 1.3.1).

See Also

paste, substr and strsplit for character concatenation and splitting, chartr for character translation and casefolding (e.g., upper to lower case) and sub, grep etc for string matching and substitutions. Note that help.search(keyword = "character") gives even more links.

deparse, which is normally preferable to as.character for language objects.

Examples

form <- y ~ a + b + c
as.character(form)  # length 3
deparse(form)  # like the input

a0 <- 11/999  # has a repeating decimal representation
(a1 <- as.character(a0))
format(a0, digits = 16)  # shows one more digit
a2 <- as.numeric(a1)
a2 - a0  # normally around -1e-17
as.character(a2)  # normally different from a1
print(c(a0, a2), digits = 16)

charmmatch

Partial String Matching

Description

charmmatch seeks matches for the elements of its first argument among those of its second.

Usage

charmmatch(x, table, nomatch = NA_integer_)

Arguments

x  the values to be matched: converted to a character vector by as.character. Long vectors are supported.

table  the values to be matched against: converted to a character vector. Long vectors are not supported.

nomatch  the (integer) value to be returned at non-matching positions.

Details

Exact matches are preferred to partial matches (those where the value to be matched has an exact match to the initial part of the target, but the target is longer).

If there is a single exact match or no exact match and a unique partial match then the index of the matching value is returned; if multiple exact or multiple partial matches are found then 0 is returned and if no match is found then nomatch is returned.

NA values are treated as the string constant "NA".
Description

Translate characters in character vectors, in particular from upper to lower case or vice versa.

Usage

```r
chartr(old, new, x)
tolower(x)
toupper(x)
casefold(x, upper = FALSE)
```

Arguments

- `x`: a character vector, or an object that can be coerced to character by `as.character`.
- `old`: a character string specifying the characters to be translated. If a character vector of length 2 or more is supplied, the first element is used with a warning.
- `new`: a character string specifying the translations. If a character vector of length 2 or more is supplied, the first element is used with a warning.
- `upper`: logical: translate to upper or lower case?.

Details

`chartr` translates each character in `x` that is specified in `old` to the corresponding character specified in `new`. Ranges are supported in the specifications, but character classes and repeated characters are not. If `old` contains more characters than `new`, an error is signaled; if it contains fewer characters, the extra characters at the end of `new` are ignored.

`tolower` and `toupper` convert upper-case characters in a character vector to lower-case, or vice versa. Non-alphabetic characters are left unchanged.

`casefold` is a wrapper for `tolower` and `toupper` provided for compatibility with S-PLUS.
Value

A character vector of the same length and with the same attributes as x (after possible coercion).

Elements of the result will be have the encoding declared as that of the current locale (see Encoding if the corresponding input had a declared encoding and the current locale is either Latin-1 or UTF-8. The result will be in the current locale’s encoding unless the corresponding input was in UTF-8, when it will be in UTF-8 when the system has Unicode wide characters.

See Also

sub and gsub for other substitutions in strings.

Examples

```r
x <- "MiXeD cAsE 123"
chartr("iXs", "why", x)
chartr("a-cX", "D-Fw", x)
tolower(x)
toupper(x)

## "Mixed Case" Capitalizing - toupper( every first letter of a word ) :

.simpleCap <- function(x) {
  s <- strsplit(x, " ")[1]
  paste(toupper(substring(s, 1, 1)), substring(s, 2),
      sep = " ", collapse = " ")
}

.simpleCap("the quick red fox jumps over the lazy brown dog")
## -> [1] "The Quick Red Fox Jumps Over The Lazy Brown Dog"

## and the better, more sophisticated version:
capwords <- function(s, strict = FALSE) {
  cap <- function(s) paste(toupper(substring(s, 1, 1)),
                         {s <- substring(s, 2); if(strict) tolower(s) else s},
                         sep = " ", collapse = " ")
  sapply(strsplit(s, split = " "), cap, USE.NAMES = !is.null(names(s)))
}
capwords(c("using AIC for model selection"))
## -> [1] "Using AIC For Model Selection"
capwords(c("using AIC", "for MODEL selection"), strict = TRUE)
## -> [1] "Using Aic "For Model Selection"

## -- Very simple insecure crypto --

rot <- function(ch, k = 13) {
  p0 <- function(...) paste(c(...), collapse = "")
  A <- c(letters, LETTERS, " ")
  I <- seq_len(k); chartr(p0(A), p0(c(A[-1], A[I])), ch)
}

pw <- "my secret pass phrase"
(crypw <- rot(pw, 13)) # -> you can send this off

## now `decrypt' :
rot(crypw, 54 - 13) # -> the original:
stopifnot(identical(pw, rot(crypw, 54 - 13)))
```
**chol**  
*The Choleski Decomposition*

**Description**

Compute the Choleski factorization of a real symmetric positive-definite square matrix.

**Usage**

```r
chol(x, ...)  
```

```r
## Default S3 method:  
chol(x, pivot = FALSE, LINPACK = FALSE, tol = -1, ...)  
```

**Arguments**

- `x` an object for which a method exists. The default method applies to numeric (or logical) symmetric, positive-definite matrices.
- `...` arguments to be based to or from methods.
- `pivot` Should pivoting be used?
- `LINPACK` logical. Should LINPACK be used (which is deprecated)?
- `tol` A numeric tolerance for use with `pivot = TRUE`, `LINPACK = FALSE`.

**Details**

`chol` is generic: the description here applies to the default method.

Note that only the upper triangular part of `x` is used, so that $R'R = x$ when `x` is symmetric.

If `pivot = FALSE` and `x` is not non-negative definite an error occurs. If `x` is positive semi-definite (i.e., some zero eigenvalues) an error will also occur as a numerical tolerance is used.

If `pivot = TRUE`, then the Choleski decomposition of a positive semi-definite `x` can be computed. The rank of `x` is returned as `attr(Q, "rank")`, subject to numerical errors. The pivot is returned as `attr(Q, "pivot")`. It is no longer the case that `t(Q) %*% Q` equals `x`. However, setting `pivot <- attr(Q, "pivot")` and `oo <- order(pivot)`, it is true that `t(Q[, oo]) %*% Q[, oo]` equals `x`, or, alternatively, `t(Q) %*% Q` equals `x[pivot, pivot]`. See the examples.

Use of `chol(pivot = FALSE, LINPACK = TRUE)` was deprecated in R 1.7.0. Pivoting with LAPACK requires LAPACK >= 3.2 and was added in R 2.15.2. The value of `tol` is passed to LAPACK, with negative values selecting the default tolerance of (usually) `nrow(x) * .Machine$doubleneg.eps * max(diag(x))`. The algorithm terminates once the pivot is less than `tol`.

The LINPACK interface is restricted to matrices `x` with less than $2^{31}$ elements.

**Value**

The upper triangular factor of the Choleski decomposition, i.e., the matrix $R$ such that $R'R = x$ (see example).

If pivoting is used, then two additional attributes "pivot" and "rank" are also returned.
**Warning**

The code does not check for symmetry.

If pivot = TRUE and x is not non-negative definite then there will be a warning message but a meaningless result will occur. So only use pivot = TRUE when x is non-negative definite by construction.

**Note**

LINPACK = TRUE, pivot = FALSE (for compatibility with R < 1.7.0) was formally deprecated in R 2.15.2.

**Source**

This is an interface to the LAPACK routines DPOTRF and DPSTRF and the LINPACK routines DPQFA and DCHDC.

LAPACK and LINPACK are from http://www.netlib.org/lapack and http://www.netlib.org/linpack and their guides are listed in the references.

**Examples**

```
( m <- matrix(c(5,1,1,3),2,2) )
( cm <- chol(m) )
t(cm) %*% cm #-- = 'm'
crossprod(cm) #-- = 'm'

# now for something positive semi-definite
x <- matrix(c(1:5, (1:5)^2), 5, 2)
x <- cbind(x, x[, 1] + 3*x[, 2])
colnames(x) <- letters[20:22]
m <- crossprod(x)
qr(m)$rank # is 2, as it should be

# chol() may fail, depending on numerical rounding:
# chol() unlike qr() does not use a tolerance.
try(chol(m))

( Q <- chol(m, pivot = TRUE) )
## we can use this by
```
chol2inv

Inverse from Choleski (or QR) Decomposition

Description
Invert a symmetric, positive definite square matrix from its Choleski decomposition. Equivalently, compute \((X'X)^{-1}\) from the \((R\) part) of the QR decomposition of \(X\).

Usage
chol2inv(x, size = NCOL(x), LINPACK = FALSE)

Arguments
- **x**: a matrix. The first `size` columns of the upper triangle contain the Choleski decomposition of the matrix to be inverted.
- **size**: the number of columns of `x` containing the Choleski decomposition.
- **LINPACK**: logical. Defunct and ignored (with a warning for true value).

Value
The inverse of the matrix whose Choleski decomposition was given.

Source
This is an interface to the LAPACK routine `dpotri`. LAPACK is from [http://www.netlib.org/lapack](http://www.netlib.org/lapack) and its guide is listed in the references.

chol, solve.

Examples
```r
cma <- chol(ma <- cbind(1, 1:3, c(1,3,7)))
ma %*% chol2inv(cma)
```

**class**

**Object Classes**

**Description**

R possesses a simple generic function mechanism which can be used for an object-oriented style of programming. Method dispatch takes place based on the class of the first argument to the generic function.

**Usage**

```r
class(x)
class(x) <- value
unclass(x)
inherits(x, what, which = FALSE)

oldClass(x)
oldClass(x) <- value
```

**Arguments**

- `x` a R object
- `what`, `value` a character vector naming classes. value can also be NULL.
- `which` logical affecting return value: see ‘Details’.

**Details**

Here, we describe the so called “S3” classes (and methods). For “S4” classes (and methods), see ‘Formal classes’ below.

Many R objects have a `class` attribute, a character vector giving the names of the classes from which the object inherits. If the object does not have a class attribute, it has an implicit class, "matrix", "array" or the result of `mode(x)` (except that integer vectors have implicit class "integer"). (Functions `oldClass` and `oldClass<-` get and set the attribute, which can also be done directly.)

When a generic function `fun` is applied to an object with class attribute `c("first", "second")`, the system searches for a function called `fun.first` and, if it finds it, applies it to the object. If no such function is found, a function called `fun.second` is tried. If no class name produces a suitable function, the function `fun.default` is used (if it exists). If there is no class attribute, the implicit class is tried, then the default method.

The function `class` prints the vector of names of classes an object inherits from. Correspondingly, `class<-` sets the classes an object inherits from. Assigning NULL removes the class attribute.

`unclass` returns (a copy of) its argument with its class attribute removed. (It is not allowed for objects which cannot be copied, namely environments and external pointers.)

`inherits` indicates whether its first argument inherits from any of the classes specified in the `what` argument. If which is TRUE then an integer vector of the same length as what is returned. Each element indicates the position in the `class(x)` matched by the element of `what`; zero indicates no match. If which is FALSE then TRUE is returned by `inherits` if any of the names in what match with any class.

All but `inherits` are primitive functions.
**Formal classes**

An additional mechanism of *formal classes*, nicknamed “S4”, is available in package **methods** which is attached by default. For objects which have a formal class, its name is returned by **class** as a character vector of length one and method dispatch can happen on *several* arguments, instead of only the first. However, S3 method selection attempts to treat objects from an S4 class as if they had the appropriate S3 class attribute, as does **inherits**. Therefore, S3 methods can be defined for S4 classes. See the ‘Classes’ and ‘Methods’ help pages for details.

The replacement version of the function sets the class to the value provided. For classes that have a formal definition, directly replacing the class this way is strongly deprecated. The expression **as**(object, value) is the way to coerce an object to a particular class.

The analogue of **inherits** for formal classes is **is**. The two functions behave consistently with one exception: S4 classes can have conditional inheritance, with an explicit test. In this case, **is** will test the condition, but **inherits** ignores all conditional superclasses.

**Note**

Functions **oldClass** and **oldClass<-** behave in the same way as functions of those names in S-PLUS 5/6, but in **R** **UseMethod** dispatches on the class as returned by **class** (with some interpolated classes: see the link) rather than **oldClass**. **However, group generics** dispatch on the **oldClass** for efficiency, and **internal generics** only dispatch on objects for which **is.object** is true.

In some versions of **R**, assigning a zero-length vector with **class** removes the class: in others it is an error (whereas it works for **oldClass**. It is clearer to always assign **NULL** to remove the class.

**See Also**

**UseMethod**, **NextMethod**, ‘group generic’, ‘internal generic’

**Examples**

```r
x <- 10
class(x) # "numeric"
oldClass(x) # NULL
inherits(x, "a") #FALSE
class(x) <- c("a", "b")
inherits(x,"a") #TRUE
inherits(x, "a", TRUE) # 1
inherits(x, c("a", "b", "c"), TRUE) # 1 2 0
```

---

**Column Indexes**

**Description**

Returns a matrix of integers indicating their column number in a matrix-like object, or a factor of column labels.

**Usage**

```r
col(x, as.factor = FALSE)
```
**Colon**

**Arguments**

- **x**: a matrix-like object, that is one with a two-dimensional `dim`.
- **as.factor**: a logical value indicating whether the value should be returned as a factor of column labels (created if necessary) rather than as numbers.

**Value**

An integer (or factor) matrix with the same dimensions as `x` and whose `i,j`-th element is equal to `j` (or the `j`-th column label).

**References**

**See Also**

- `row` to get rows.

**Examples**

```r
# extract an off-diagonal of a matrix
ma <- matrix(1:12, 3, 4)
ma[row(ma) == col(ma) + 1]

# create an identity 5-by-5 matrix
x <- matrix(0, nrow = 5, ncol = 5)
x[row(x) == col(x)] <- 1
```

---

**Colon Operator**

**Description**

Generate regular sequences.

**Usage**

```r
from:to
  a:b
```

**Arguments**

- **from**: starting value of sequence.
- **to**: (maximal) end value of the sequence.
- **a, b**: factors of the same length.
Details

The binary operator \texttt{Z} has two meanings: for factors \texttt{a:b} is equivalent to \texttt{interaction(a, b)} (but the levels are ordered and labelled differently).

For other arguments \texttt{from:to} is equivalent to \texttt{seq(from, to)}, and generates a sequence from \texttt{from} to \texttt{to} in steps of \texttt{1} or \texttt{-1}. Value \texttt{to} will be included if it differs from \texttt{from} by an integer up to a numeric fuzz of about \texttt{1e-7}. Non-numeric arguments are coerced internally (hence without dispatching methods) to numeric—complex values will have their imaginary parts discarded with a warning.

Value

For numeric arguments, a numeric vector. This will be of type \texttt{integer} if \texttt{from} is integer-valued and the result is representable in the R integer type, otherwise of type "\texttt{double}" (aka \texttt{mode "numeric"}).

For factors, an unordered factor with levels labelled as \texttt{a:b} and ordered lexicographically (that is, \texttt{1b} varies fastest).

References

(for numeric arguments: S does not have : for factors.)

See Also

\texttt{seq} (a generalization of \texttt{from:to}).

As an alternative to using : for factors, \texttt{interaction}.

For : used in the formal representation of an interaction, see \texttt{formula}.

Examples

\begin{verbatim}
1:4
pi:6 # real
6:pi # integer

f1 <- gl(2, 3); f1
f2 <- gl(3, 2); f2
f1:f2 # a factor, the "cross" f1 x f2
\end{verbatim}

\begin{Verbatim}
\texttt{colSums} \hspace{1cm} \textit{Form Row and Column Sums and Means}
\end{Verbatim}

Description

Form row and column sums and means for numeric arrays.
**Usage**

```r
colSums(x, na.rm = FALSE, dims = 1)
rowSums(x, na.rm = FALSE, dims = 1)
colMeans(x, na.rm = FALSE, dims = 1)
rowMeans(x, na.rm = FALSE, dims = 1)
```

Arguments

- **x**: an array of two or more dimensions, containing numeric, complex, integer or logical values, or a numeric data frame.
- **na.rm**: logical. Should missing values (including NaN) be omitted from the calculations?
- **dims**: integer: Which dimensions are regarded as `rows` or `columns` to sum over. For row*, the sum or mean is over dimensions `dims+1, . . .`; for col* it is over dimensions `1:dim`s.
- **X**: a numeric matrix.
- **m, n**: the dimensions of X.

**Details**

These functions are equivalent to use of `apply` with `FUN = mean` or `FUN = sum` with appropriate margins, but are a lot faster. As they are written for speed, they blur over some of the subtleties of NaN and NA. If `na.rm = FALSE` and either NaN or NA appears in a sum, the result will be one of NaN or NA, but which might be platform-dependent.

Notice that omission of missing values is done on a per-column or per-row basis, so column means may not be over the same set of rows, and vice versa. To use only complete rows or columns, first select them with `na.omit` or `complete.cases` (possibly on the transpose of x).

The versions with an initial dot in the name are ‘bare-bones’ versions for use in programming: they apply only to numeric matrices and do not name the result.

**Value**

A numeric or complex array of suitable size, or a vector if the result is one-dimensional. For the first four functions the dimnames (or names for a vector result) are taken from the original array.

If there are no values in a range to be summed over (after removing missing values with `na.rm = TRUE`), that component of the output is set to 0 (xSums) or NaN (xMeans), consistent with `sum` and `mean`.

**See Also**

`apply`, `rowsum`

**Examples**

```r
## Compute row and column sums for a matrix:
x <- cbind(x1 = 3, x2 = c(4:1, 2:5))
rowSums(x); colSums(x)
```
dimnames(x)[[1]] <- letters[1:8]
rowSums(x); colSums(x); rowMeans(x); colMeans(x)
x[] <- as.integer(x)
rowSums(x); colSums(x)
x[] <- x < 3
rowSums(x); colSums(x)
x <- cbind(x1 = 3, x2 = c(4:1, 2:5))
x[3, ] <- NA; x[4, 2] <- NA
rowSums(x); colSums(x); rowMeans(x); colMeans(x)
rowSums(x, na.rm = TRUE); colSums(x, na.rm = TRUE)
rowMeans(x, na.rm = TRUE); colMeans(x, na.rm = TRUE)

## an array
dim(UCBAmissions)
rowSums(UCBAmissions); rowSums(UCBAmissions, dims = 2)
colSums(UCBAmissions); colSums(UCBAmissions, dims = 2)

## complex case
x <- cbind(x1 = 3 + 2i, x2 = c(4:1, 2:5) - 5i)
x[3, ] <- NA; x[4, 2] <- NA
rowSums(x); colSums(x); rowMeans(x); colMeans(x)
rowSums(x, na.rm = TRUE); colSums(x, na.rm = TRUE)
rowMeans(x, na.rm = TRUE); colMeans(x, na.rm = TRUE)

commandArgs  

Extract Command Line Arguments

Description

Provides access to a copy of the command line arguments supplied when this R session was invoked.

Usage

commandArgs(trailingOnly = FALSE)

Arguments

trailingOnly  logical. Should only arguments after '--args' be returned?

Details

These arguments are captured before the standard R command line processing takes place. This means that they are the unmodified values. This is especially useful with the '--args' command-line flag to R, as all of the command line after that flag is skipped.

Value

A character vector containing the name of the executable and the user-supplied command line arguments. The first element is the name of the executable by which R was invoked. The exact form of this element is platform dependent: it may be the fully qualified name, or simply the last component (or basename) of the application, or for an embedded R it can be anything the programmer supplied. If trailingOnly = TRUE, a character vector of those arguments (if any) supplied after '--args'.
See Also

Startup BATCH

Examples

```r
commandArgs()
## Spawn a copy of this application as it was invoked,
## subject to shell quoting issues
## system(paste(commandArgs(), collapse = " "))
```

---

comment  

_Query or Set a "comment" Attribute_

Description

These functions set and query a `comment` attribute for any `R` objects. This is typically useful for `data.frame` or model fits.

Contrary to other `attributes`, the comment is not printed (by `print` or `print.default`). Assigning NULL or a zero-length character vector removes the comment.

Usage

```r
comment(x)
comment(x) <- value
```

Arguments

- `x`: any `R` object
- `value`: a character vector, or NULL.

See Also

`attributes` and `attr` for other attributes.

Examples

```r
x <- matrix(1:12, 3, 4)
comment(x) <- c("This is my very important data from experiment #0234",
                "Jun 5, 1998")
x
comment(x)
```
Comparison

Relational Operators

Description

Binary operators which allow the comparison of values in atomic vectors.

Usage

- `x < y`
- `x > y`
- `x <= y`
- `x >= y`
- `x == y`
- `x != y`

Arguments

- `x, y`  
  atomic vectors, symbols, calls, or other objects for which methods have been written.

Details

The binary comparison operators are generic functions: methods can be written for them individually or via the `Ops` group generic function. (See `Ops` for how dispatch is computed.)

Comparison of strings in character vectors is lexicographic within the strings using the collating sequence of the locale in use: see `locales`. The collating sequence of locales such as `en_US` is normally different from ‘C’ (which should use ASCII) and can be surprising. Beware of making any assumptions about the collation order: e.g. in Estonian Z comes between S and T, and collation is not necessarily character-by-character – in Danish aa sorts as a single letter, after z. In Welsh ng may or may not be a single sorting unit: if it is it follows g. Some platforms may not respect the locale and always sort in numerical order of the bytes in an 8-bit locale, or in Unicode point order for a UTF-8 locale (and may not sort in the same order for the same language in different character sets). Collation of non-letters (spaces, punctuation signs, hyphens, fractions and so on) is even more problematic.

Character strings can be compared with different marked encodings (see `Encoding`): they are translated to UTF-8 before comparison.

At least one of `x` and `y` must be an atomic vector, but if the other is a list R attempts to coerce it to the type of the atomic vector: this will succeed if the list is made up of elements of length one that can be coerced to the correct type.

If the two arguments are atomic vectors of different types, one is coerced to the type of the other, the (decreasing) order of precedence being character, complex, numeric, integer, logical and raw.

Missing values (`NA`) and `NaN` values are regarded as non-comparable even to themselves, so comparisons involving them will always result in `NA`. Missing values can also result when character strings are compared and one is not valid in the current collation locale.

Language objects such as symbols and calls are deparsed to character strings before comparison.
Comparison

Value

A logical vector indicating the result of the element by element comparison. The elements of shorter vectors are recycled as necessary.

Objects such as arrays or time-series can be compared this way provided they are conformable.

S4 methods

These operators are members of the S4 `compare` group generic, and so methods can be written for them individually as well as for the group generic (or the `Ops` group generic), with arguments `c(e1, e2).

Note

Do not use `==` and `!=` for tests, such as in `if` expressions, where you must get a single `TRUE` or `FALSE`. Unless you are absolutely sure that nothing unusual can happen, you should use the `identical` function instead.

For numerical and complex values, remember `==` and `!=` do not allow for the finite representation of fractions, nor for rounding error. Using `all.equal` with `identical` is almost always preferable. See the examples.

References

Collation of character strings is a complex topic. For an introduction see http://en.wikipedia.org/wiki/Collating_sequence. The Unicode Collation Algorithm (http://unicode.org/reports/tr10/) is likely to be increasingly influential. Where available R makes use of ICU (http://site.icu-project.org/) for collation.

See Also

`factor` for the behaviour with factor arguments.

`Syntax` for operator precedence.

`icuSetCollate` to tune the string collation algorithm when ICU is in use.

Examples

```r
x <- stats::rnorm(20)
x < 1
x[x > 0]

x1 <- 0.5 - 0.3
x2 <- 0.3 - 0.1
x1 == x2                        # FALSE on most machines
identical(all.equal(x1, x2), TRUE) # TRUE everywhere

# range of most 8-bit charsets, as well as of Latin-1 in Unicode
z <- c(32:126, 160:255)
x <- if(is16n_info()) { # MBCS
  intToUtf8(z, multiple = TRUE)
} else rawToChar(as.raw(z), multiple= TRUE)
```

## by number
complex

complex

Complex Vectors

Description

Basic functions which support complex arithmetic in R.

Usage

complex(length.out = 0L, real = numeric(), imaginary = numeric(),
       modulus = 1L, argument = 0L)
as.complex(x, ...)is.complex(x)

Re(z)
Im(z)
Mod(z)
Arg(z)
Conj(z)

Arguments

length.out numeric. Desired length of the output vector, inputs being recycled as needed.
real numeric vector.
imaginary numeric vector.
modulus numeric vector.
argument numeric vector.
x an object, probably of mode complex.
z an object of mode complex, or one of a class for which a methods has been defined.
... further arguments passed to or from other methods.

Details

Complex vectors can be created with complex. The vector can be specified either by giving its length, its real and imaginary parts, or modulus and argument. (Giving just the length generates a vector of complex zeroes.)
as.complex attempts to coerce its argument to be of complex type: like as.vector it strips attributes including names. All forms of NA and NaN are coerced to a complex NA, for which both the real and imaginary parts are NA.

Note that is.complex and is.numeric are never both TRUE.
The functions Re, Im, Mod, Arg and Conj have their usual interpretation as returning the real part, imaginary part, modulus, argument and complex conjugate for complex values. The modulus and argument are also called the polar coordinates. If \( z = x + iy \) with real \( x \) and \( y \), for \( r = Mod(z) = \sqrt{x^2 + y^2} \) and \( \theta = \arg(z) = \arctan\left(\frac{y}{x}\right) \).
\[ \sqrt{x^2 + y^2}, \text{ and } \phi = \text{Arg}(z), \] 
\[ x = r \cos(\phi) \text{ and } y = r \sin(\phi). \] 
They are all internal generic primitive functions: methods can be defined for them individually or via the Complex group generic.

In addition, the elementary trigonometric, logarithmic, exponential, square root and hyperbolic functions are implemented for complex values.

Internally, complex numbers are stored as a pair of double precision numbers, either or both of which can be NaN or plus or minus infinity.

S4 methods

as.complex is primitive and can have S4 methods set.

Re, Im, Mod, Arg and Conj constitute the S4 group generic Complex and so S4 methods can be set for them individually or via the group generic.

References

Examples

```r
require(graphics)

0i ^ (-3:3)

matrix(1i^ (-6:5), nrow = 4) # all columns are the same
0 ^ 1i # a complex NaN

## create a complex normal vector
z <- complex(real = stats::rnorm(100), imaginary = stats::rnorm(100))
## or also (less efficiently):
z2 <- 1:2 + 1i*(0:9)

## The Arg(.) is an angle:
zz <- (rep(1:4, len = 9) + 1i*(9:1))/10
zz.shift <- complex(modulus = Mod(zz), argument = Arg(zz) + pi)
plot(zz, xlim = c(-1,1), ylim = c(-1,1), col = "red", asp = 1,
    main = expression(paste("Rotation by ", "", pi == 180*o)))
abline(h = 0, v = 0, col = "blue", lty = 3)
points(zz.shift, col = "orange")
```

Description

These functions provide a mechanism for handling unusual conditions, including errors and warnings.
Usage

tryCatch(expr, ..., finally)
withCallingHandlers(expr, ...)

signalCondition(cond)

simpleCondition(message, call = NULL)
simpleError (message, call = NULL)
simpleWarning (message, call = NULL)
simpleMessage (message, call = NULL)

## S3 method for class 'condition'
as.character(x, ...)
## S3 method for class 'error'
as.character(x, ...)
## S3 method for class 'condition'
print(x, ...)
## S3 method for class 'restart'
print(x, ...)

conditionCall(c)
## S3 method for class 'condition'
conditionCall(c)
conditionMessage(c)
## S3 method for class 'condition'
conditionMessage(c)

withRestarts(expr, ...)

computeRestarts(cond = NULL)
findRestart(name, cond = NULL)
invokeRestart(r, ...)
invokeRestartInteractively(r)

isRestart(x)
restartDescription(r)
restartFormals(r)

.signalSimpleWarning(msg, call)
.handleSimpleError(h, msg, call)

Arguments

c             a condition object.
call          call expression.
cond           a condition object.
expr           expression to be evaluated.
finally        expression to be evaluated before returning or exiting.
h             function.
message        character string.
**conditions**

msg character string.

name character string naming a restart.

r restart object.

x object.

... additional arguments; see details below.

## Details

The condition system provides a mechanism for signaling and handling unusual conditions, including errors and warnings. Conditions are represented as objects that contain information about the condition that occurred, such as a message and the call in which the condition occurred. Currently conditions are S3-style objects, though this may eventually change.

Conditions are objects inheriting from the abstract class `condition`. Errors and warnings are objects inheriting from the abstract subclasses `error` and `warning`. The class `simpleError` is the class used by `stop` and all internal error signals. Similarly, `simpleWarning` is used by `warning`, and `simpleMessage` is used by `message`. The constructors by the same names take a string describing the condition as argument and an optional call. The functions `conditionMessage` and `conditionCall` are generic functions that return the message and call of a condition.

Conditions are signaled by `signalCondition`. In addition, the stop and warning functions have been modified to also accept condition arguments.

The function `tryCatch` evaluates its expression argument in a context where the handlers provided in the ... argument are available. The finally expression is then evaluated in the context in which `tryCatch` was called; that is, the handlers supplied to the current `tryCatch` call are not active when the finally expression is evaluated.

Handlers provided in the ... argument to `tryCatch` are established for the duration of the evaluation of expr. If no condition is signaled when evaluating expr then `tryCatch` returns the value of the expression.

If a condition is signaled while evaluating expr then established handlers are checked, starting with the most recently established ones, for one matching the class of the condition. When several handlers are supplied in a single `tryCatch` then the first one is considered more recent than the second. If a handler is found then control is transferred to the `tryCatch` call that established the handler, the handler found and all more recent handlers are disestablished, the handler is called with the condition as its argument, and the result returned by the handler is returned as the value of the `tryCatch` call.

Calling handlers are established by `withCallingHandlers`. If a condition is signaled and the applicable handler is a calling handler, then the handler is called by `signalCondition` in the context where the condition was signaled but with the available handlers restricted to those below the handler called in the handler stack. If the handler returns, then the next handler is tried; once the last handler has been tried, `signalCondition` returns `NULL`.

User interrupts signal a condition of class `interrupt` that inherits directly from class `condition` before executing the default interrupt action.

Restarts are used for establishing recovery protocols. They can be established using `withRestarts`. One pre-established restart is an abort restart that represents a jump to top level.

`findRestart` and `computeRestarts` find the available restarts. `findRestart` returns the most recently established restart of the specified name. `computeRestarts` returns a list of all restarts. Both can be given a condition argument and will then ignore restarts that do not apply to the condition.

`invokeRestart` transfers control to the point where the specified restart was established and calls the restart’s handler with the arguments, if any, given as additional arguments to `invokeRestart`. 
The restart argument to invokeRestart can be a character string, in which case findRestart is used to find the restart.

New restarts for withRestarts can be specified in several ways. The simplest is in name = function form where the function is the handler to call when the restart is invoked. Another simple variant is as name = string where the string is stored in the description field of the restart object returned by findRestart; in this case the handler ignores its arguments and returns NULL. The most flexible form of a restart specification is as a list that can include several fields, including handler, description, and test. The test field should contain a function of one argument, a condition, that returns TRUE if the restart applies to the condition and FALSE if it does not; the default function returns TRUE for all conditions.

One additional field that can be specified for a restart is interactive. This should be a function of no arguments that returns a list of arguments to pass to the restart handler. The list could be obtained by interacting with the user if necessary. The function invokeRestartInteractively calls this function to obtain the arguments to use when invoking the restart. The default interactive method queries the user for values for the formal arguments of the handler function.

.signalSimpleWarning and .handleSimpleError are used internally and should not be called directly.

References

The tryCatch mechanism is similar to Java error handling. Calling handlers are based on Common Lisp and Dylan. Restarts are based on the Common Lisp restart mechanism.

See Also

stop and warning signal conditions, and try is essentially a simplified version of tryCatch.

Examples

tryCatch(1, finally = print("Hello"))
e <- simpleError("test error")
## Not run:
   stop(e)
   tryCatch(stop(e), finally = print("Hello"))
tryCatch(stop("fred"), finally = print("Hello"))
## End(Not run)
tryCatch(stop(e), error = function(e) e, finally = print("Hello"))
tryCatch(stop("fred"), error = function(e) e, finally = print("Hello"))
withCallingHandlers([ warning("A"): l+2 ], warning = function(w) { })
## Not run:
{ withRestarts(stop("A"), abort = function() {}); 1 }
## End(Not run)
withRestarts(invokeRestart("foo", 1, 2), foo = function(x, y) (x + y))

## demo(error.catching)
conflicts

**Search for Masked Objects on the Search Path**

**Description**

conflicts reports on objects that exist with the same name in two or more places on the search path, usually because an object in the user’s workspace or a package is masking a system object of the same name. This helps discover unintentional masking.

**Usage**

conflicts(where = search(), detail = FALSE)

**Arguments**

- **where**: A subset of the search path, by default the whole search path.
- **detail**: If TRUE, give the masked or masking functions for all members of the search path.

**Value**

If detail = FALSE, a character vector of masked objects. If detail = TRUE, a list of character vectors giving the masked or masking objects in that member of the search path. Empty vectors are omitted.

**Examples**

```r
lm <- 1:3
comments(lm, TRUE)
## gives something like
# $.GlobalEnv
# [1] "lm"
#
# $package:base
# [1] "lm"

## Remove things from your "workspace" that mask others:
remove(list = conflicts(detail = TRUE)$$.GlobalEnv)
```

connections

**Functions to Manipulate Connections**

**Description**

Functions to create, open and close connections.
Usage

file(description = "", open = "", blocking = TRUE,
  encoding = getOption("encoding"), raw = FALSE)

url(description, open = "", blocking = TRUE,
  encoding = getOption("encoding"))

gzfile(description, open = "", encoding = getOption("encoding"),
  compression = 6)

bzfile(description, open = "", encoding = getOption("encoding"),
  compression = 9)

xzfile(description, open = "", encoding = getOption("encoding"),
  compression = 6)

unz(description, filename, open = "",
  encoding = getOption("encoding"))

pipe(description, open = "", encoding = getOption("encoding"))

fifo(description, open = "", blocking = FALSE,
  encoding = getOption("encoding"))

socketConnection(host = "localhost", port, server = FALSE,
  blocking = FALSE, open = "a+",
  encoding = getOption("encoding"),
  timeout = getOption("timeout"))

open(con, ...)  # S3 method for class 'connection'
open(con, open = "r", blocking = TRUE, ...)

close(con, ...)  # S3 method for class 'connection'
close(con, type = "rw", ...)

flush(con)

isOpen(con, rw = "")
isIncomplete(con)

Arguments

description character string. A description of the connection: see ‘Details’.
open character. A description of how to open the connection (if it should be opened
initially). See section ‘Modes’ for possible values.
blocking logical. See the ‘Blocking’ section.
encoding The name of the encoding to be used. See the ‘Encoding’ section.
raw logical. If true, a ‘raw’ interface is used which will be more suitable for argu-
ments which are not regular files, e.g. character devices. This suppresses the
check for a compressed file when opening for text-mode reading, and asserts
that the ‘file’ may not be seekable.

compression integer in 0–9. The amount of compression to be applied when writing, from
none to maximal available. For xzfile can also be negative: see the ‘Compression’ section.

timeout numeric: the timeout (in seconds) to be used for this connection. Beware that
some OSes may treat very large values as zero: however the POSIX standard
requires values up to 31 days to be supported.

filename a filename within a zip file.
host character. Host name for port.
port integer. The TCP port number.
server logical. Should the socket be a client or a server?
con a connection.
type character. Currently ignored.
rw character. Empty or "read" or "write", partial matches allowed.
... arguments passed to or from other methods.

Details

The first nine functions create connections. By default the connection is not opened (except for
socketConnection), but may be opened by setting a non-empty value of argument open.

For file the description is a path to the file to be opened or a complete URL (when it is the same
as calling url), or "" (the default) or "clipboard" (see the ‘Clipboard’ section). Use "stdin" to
refer to the C-level ‘standard input’ of the process (which need not be connected to anything in a
console or embedded version of R, and is not in Rgui on Windows). See also stdin() for the subtly
different R-level concept of stdin.

For url the description is a complete URL, including scheme (such as ‘http://’, ‘ftp://’ or
‘file://’). Proxies can be specified for HTTP and FTP url connections: see download.file.

For gzip the description is the path to a file compressed by gzip: it can also open for reading
uncompressed files and (as from R 2.10.0) those compressed by bzip2, xz or lzma.

For bzfile the description is the path to a file compressed by bzip2.

For xzfile the description is the path to a file compressed by xz (http://en.wikipedia.org/
wiki/Xz) or (for reading only) lzma (http://en.wikipedia.org/wiki/Lzma).

unz reads (only) single files within zip files, in binary mode. The description is the full path to the
zip file, with ".zip" extension if required.

For pipe the description is the command line to be piped to or from. This is run in a shell, on
Windows that specified by the COMSPEC environment variable.

For fifo the description is the path of the fifo. (Windows does not have fifos, so attempts to use this
function there are an error. It was possible to use file with fifos prior to R 2.10.0, but raw = TRUE
is now required for reading, and fifo was always the documented interface.)

All platforms support file, pipe, gzipfile, bzfile, xzfile, unzip and url("file://") connections.
The other connections may be partially implemented or not implemented at all. (They do work on
most Unix platforms, and all but fifo on Windows.)

The intention is that file and gzipfile can be used generally for text input (from files and URLs)
and binary input respectively.

open, close and seek are generic functions: the following applies to the methods relevant to con-
nections.
open opens a connection. In general functions using connections will open them if they are not open, but then close them again, so to leave a connection open call open explicitly.

close closes and destroys a connection. This will happen automatically in due course (with a warning) if there is no longer an R object referring to the connection.

A maximum of 128 connections can be allocated (not necessarily open) at any one time. Three of these are pre-allocated (see stdout). The OS will impose limits on the numbers of connections of various types, but these are usually larger than 125.

flush flushes the output stream of a connection open for write/append (where implemented, currently for file and clipboard connections, stdout and stderr).

If for a file or fifo connection the description is "", the file/fifo is immediately opened (in "w+" mode unless open = "w+b" is specified) and unlinked from the file system. This provides a temporary file/fifo to write to and then read from.

**Value**

defile, pipe, fifo, url, gzfile, bzfile, xzfile, unz and socketConnection return a connection object which inherits from class "connection" and has a first more specific class.

open and flush return NULL, invisibly.

close returns either NULL or an integer status, invisibly. The status is from when the connection was last closed and is available only for some types of connections (e.g. pipes, files and fifos): typically zero values indicate success.

isopen returns a logical value, whether the connection is currently open.

isIncomplte returns a logical value, whether the last read attempt was blocked, or for an output text connection whether there is unflushed output.

**URLs**

defurl and defile support URL schemes ‘http://’, ‘ftp://’ and ‘file:///’.

A note on ‘file://’ URLs. The most general form (from RFC1738) is ‘file://host/path/to/file’, but R only accepts the form with an empty host field referring to the local machine.

On a Unix-alike, this is then ‘file://path/to/file’, where ‘path/to/file’ is relative to ‘/’. So although the third slash is strictly part of the specification not part of the path, this can be regarded as a way to specify the file ‘/path/to/file’. It is not possible to specify a relative path using a file URL.

In this form the path is relative to the root of the filesystem, not a Windows concept. The standard form on Windows is ‘file:///d:/R/repo’: for compatibility with earlier versions of R and Unix versions, any other form is parsed as R as ‘file:///’ plus path_to_file. Also, backslashes are accepted within the path even though RFC1738 does not allow them.

No attempt is made to decode an encoded URL: call URLdecode if necessary.

Note that ‘https://’ connections are not supported except on Windows. There they are only supported if ‘--internet2’ or setInternet2(TRUE) was used (to make use of Internet Explorer internals), and then only if the certificate is considered to be valid. With that option only, the ‘http://user:pass@site’ notation for sites requiring authentication is also accepted.

Contributed package RCurl provides more comprehensive facilities to download from URLs.
Modes

Possible values for the argument open are

"r" or "rt" Open for reading in text mode.
"w" or "wt" Open for writing in text mode.
"a" or "at" Open for appending in text mode.
"rb" Open for reading in binary mode.
"wb" Open for writing in binary mode.
"ab" Open for appending in binary mode.
"r+b", "r+b" Open for reading and writing.
"w+b", "w+b" Open for reading and writing, truncating file initially.
"a+b", "a+b" Open for reading and appending.

Not all modes are applicable to all connections: for example URLs can only be opened for reading. Only file and socket connections can be opened for both reading and writing. An unsupported mode is usually silently substituted.

If a file or fifo is created on a Unix-alike, its permissions will be the maximal allowed by the current setting of umask (see Sys.umask).

For many connections there is little or no difference between text and binary modes. For file-like connections on Windows, translation of line endings (between LF and CRLF) is done in text mode only (but text read operations on connections such as readLines, scan and source work for any form of line ending). Various R operations are possible in only one of the modes: for example pushBack is text-oriented and is only allowed on connections open for reading in text mode, and binary operations such as readBin, load and save operations can only be done on binary-mode connections.

The mode of a connection is determined when actually opened, which is deferred if open = "" is given (the default for all but socket connections). An explicit call to open can specify the mode, but otherwise the mode will be "r". (gzfile, bzfile and xzfile connections are exceptions, as the compressed file always has to be opened in binary mode and no conversion of line-endings is done even on Windows, so the default mode is interpreted as "rb".) Most operations that need write access or text-only or binary-only mode will override the default mode of a non-yet-open connection.

Append modes need to be considered carefully for compressed-file connections. They do not produce a single compressed stream on the file, but rather append a new compressed stream to the file. Readers (including R) may or may not read beyond end of the first stream: currently R does so for gzfile, bzfile and xzfile connections, but earlier versions did not.

Compression

R has for a long time supported gzip and bzip2 compression, and support for xz compression (and read-only support for its precursor lzma compression) was added in R 2.10.0.

For reading, the type of compression (if any) can be determined from the first few bytes of the file, and this is exploited as from R 2.10.0. Thus for file(raw = FALSE) connections, if open is "", "r" or "rt" the connection can read any of the compressed file types as well as uncompressed files. (Using "rb" will allow compressed files to be read byte-by-byte.) Similarly, gzfile connections can read any of the forms of compression and uncompressed files in any read mode.

(The type of compression is determined when the connection is created if open is unspecified and a file of that name exists. If the intention is to open the connection to write a file with a different form
of compression under that name, specify open = "w" when the connection is created or unlink the file before creating the connection.)

For write-mode connections, compress specifies how hard the compressor works to minimize the file size, and higher values need more CPU time and more working memory (up to ca 800Mb for xzfile(compress = 9)). For xzfile negative values of compress correspond to adding the xz argument '-e': this takes more time (double?) to compress but may achieve (slightly) better compression. The default (6) has good compression and modest (100Mb memory usage): but if you are using xz compression you are probably looking for high compression.

Choosing the type of compression involves tradeoffs: gzip, bzip2 and xz are successively less widely supported, need more resources for both compression and decompression, and achieve more compression (although individual files may buck the general trend). Typical experience is that bzip2 compression is 15% better on text files than gzip compression, and xz with maximal compression 30% better. The experience with R save files is similar, but on some large `.rda` files xz compression is much better than the other two. With current computers decompression times even with compress = 9 are typically modest and reading compressed files is usually faster than uncompressed ones because of the reduction in disc activity.

**Encoding**

The encoding of the input/output stream of a connection can be specified by name in the same way as it would be given to `iconv`: see that help page for how to find out what encoding names are recognized on your platform. Additionally, "" and "native.enc" both mean the ‘native’ encoding, that is the internal encoding of the current locale and hence no translation is done.

Re-encoding only works for connections in text mode: reading from a connection with re-encoding specified in binary mode will read the stream of bytes, but mixing text and binary mode reads (e.g. mixing calls to `readLines` and `readChar`) is likely to lead to incorrect results.

The encodings "UCS-2LE" and "UTF-16LE" are treated specially, as they are appropriate values for Windows ‘Unicode’ text files. If the first two bytes are the Byte Order Mark 0xFFFE then these are removed as some implementations of `iconv` do not accept BOMs. Note that whereas most implementations will handle BOMs using encoding "UCS-2" and choose the appropriate byte order, some (including earlier versions of glibc) will not. There is a subtle distinction between "UTF-16" and "UCS-2" (see [http://en.wikipedia.org/wiki/UTF-16/UCS-2](http://en.wikipedia.org/wiki/UTF-16/UCS-2): the use of surrogate pairs is very rare so "UCS-2LE" is an appropriate first choice.

As from R 3.0.0 the encoding "UTF-8-BOM" is accepted and will remove a Byte Order Mark if present (which it often is for files and webpages generated by Microsoft applications).

Requesting a conversion that is not supported is an error, reported when the connection is opened. Exactly what happens when the requested translation cannot be done for invalid input is in general undocumented. On output the result is likely to be that up to the error, with a warning. On input, it will most likely be all or some of the input up to the error.

It may be possible to deduce the current native encoding from `Sys.getlocale("LC_CTYPE")`, but not all OSes record it.

**Blocking**

Whether or not the connection blocks can be specified for file, url (default yes) fifo and socket connections (default not).

In blocking mode, functions using the connection do not return to the R evaluator until the read/write is complete. In non-blocking mode, operations return as soon as possible, so on input they will return with whatever input is available (possibly none) and for output they will return whether or not the write succeeded.
The function `readLines` behaves differently in respect of incomplete last lines in the two modes: see its help page.

Even when a connection is in blocking mode, attempts are made to ensure that it does not block the event loop and hence the operation of GUI parts of \texttt{R}. These do not always succeed, and the whole \texttt{R} process will be blocked during a DNS lookup on Unix, for example.

Most blocking operations on HTTP/FTP URLs and on sockets are subject to the timeout set by options("timeout"). Note that this is a timeout for no response, not for the whole operation. The timeout is set at the time the connection is opened (more precisely, when the last connection of that type – `http`,'ftp' or socket – was opened).

### Fifos

Fifos default to non-blocking. That follows S version 4 and is probably most natural, but it does have some implications. In particular, opening a non-blocking fifo connection for writing (only) will fail unless some other process is reading on the fifo.

Opening a fifo for both reading and writing (in any mode: one can only append to fifos) connects both sides of the fifo to the \texttt{R} process, and provides an similar facility to `file()`.

### Clipboard

`file` can be used with description = "clipboard" in mode "r" only. This reads the X11 primary selection (see \url{http://standards.freedesktop.org/clipboards-spec/clipboards-latest.txt}), which can also be specified as "X11.primary" and the secondary selection as "X11.secondary". On most systems the clipboard selection (that used by 'Copy' from an 'Edit' menu) can be specified as "X11.clipboard".

When a clipboard is opened for reading, the contents are immediately copied to internal storage in the connection.

Unix users wishing to write to one of the selections may be able to do so via `xclip` (\url{http://sourceforge.net/projects/xclip/}), for example by `pipe("xclip -i", "w")` for the primary selection.

OS X users can use `pipe("pbpaste")` and `pipe("pbcopy", "w")` to read from and write to that system’s clipboard.

### Note

\texttt{R}'s connections are modelled on those in S version 4 (see Chambers, 1998). However \texttt{R} goes well beyond the S model, for example in output text connections and URL, compressed and socket connections.

The default open mode in \texttt{R} is "r" except for socket connections. This differs from S, where it is the equivalent of "r+", known as "."

On (rare) platforms where `vsnprintf` does not return the needed length of output there is a 100,000 byte output limit on the length of line for text output on `fifo`, `gzfile`, `bzfile` and `xzfile` connections: longer lines will be truncated with a warning.

### References

textConnection, seek, showConnections, pushBack.

Functions making direct use of connections are (text-mode) readLines, writeLines, cat, sink, scan, parse, read.dcf, dput, dump and (binary-mode) readBin, readChar, writeBin, writeChar, load and save.
capabilities to see if HTTP/FTP url, fifo and socketConnection are supported by this build of R.
gzcon to wrap gzip (de)compression around a connection.
memCompress for more ways to (de)compress and references on data compression.

Examples

```r
zz <- file("ex.data", "w") # open an output file connection
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file = zz, sep = "\n")
cat("One more line\n", file = zz)
close(zz)
readLines("ex.data")
unlink("ex.data")

zz <- gzfile("ex.gz", "w") # compressed file
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file = zz, sep = "\n")
close(zz)
readLines(zz <- gzfile("ex.gz"))
close(zz)
unlink("ex.gz")

zz <- bzfile("ex.bz2", "w") # bzip2-ed file
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file = zz, sep = "\n")
close(zz)
print(readLines(zz <- bzfile("ex.bz2")))
close(zz)
unlink("ex.bz2")

## An example of a file open for reading and writing
Tfile <- file("test1", "w+")
c(isOpen(Tfile, "r"), isOpen(Tfile, "w")) # both TRUE
cat("abc\ndef\n", file = Tfile)
readLines(Tfile)
seek(Tfile, 0, rw = "r") # reset to beginning
readLines(Tfile)
cat("ghi\n", file = Tfile)
readLines(Tfile)
close(Tfile)
unlink("test1")

## We can do the same thing with an anonymous file.
Tfile <- file()
cat("abc\ndef\n", file = Tfile)
readLines(Tfile)
close(Tfile)

## fifo example -- may fail even with OS support for fifos
if(capabilities("fifo")) {
  zz <- fifo("foo-fifo", "w+")
}
```
## Unix examples of use of pipes

```r
# read listing of current directory
readlines(pipe("ls -l"))
```

## Not run: % cat data2_

```r
450, 390, 467, 654, 30, 542, 334, 432, 421,
357, 497, 493, 550, 549, 467, 575, 578, 342,
446, 547, 534, 495, 979, 479
```

## End(Not run)

# Then read this by

```r
scan(pipe("sed -e s/\$/// data2_{"}, sep = ",")
```

## Convert decimal point to comma in output: see also write.table

```r
zz <- pipe(paste("sed s/\\\\/.,/ >", "outfile"), "w")
cat(format(round(stats::rnorm(48), 4)), fill = 70, file = zz)
close(zz)
file.show("outfile", delete.file = TRUE)
```

## Example for a machine running a finger daemon

```r
con <- socketConnection(port = 79, blocking = TRUE)
writeLines(paste0(system("whoami", intern = TRUE), "\r"), con)
gsub(" \$", "", readLines(con))
close(con)
```

## Two R processes communicating via non-blocking sockets

### R process 1

```r
con1 <- socketConnection(port = 6011, server = TRUE)
writeLines(LETTERS, con1)
close(con1)
```

### R process 2

```r
con2 <- socketConnection(Sys.info()$"nodename", port = 6011)
```

## Examples of use of encodings

```r
# write a file in UTF-8
```
### Constants

**Built-in Constants**

<table>
<thead>
<tr>

</tbody>
</table>

### Description

Constants built into R.

### Usage

LETTERS

letters

month.abb

month.name

pi

### Details

R has a small number of built-in constants.

The following constants are available:

- LETTERS: the 26 upper-case letters of the Roman alphabet;
- letters: the 26 lower-case letters of the Roman alphabet;
- month.abb: the three-letter abbreviations for the English month names;
- month.name: the English names for the months of the year;
- pi: the ratio of the circumference of a circle to its diameter.

These are implemented as variables in the base namespace taking appropriate values.

- `Quotes` for the parsing of character constants, `NumericConstants` for numeric constants.
Examples

```r
## John Machin (ca 1706) computed pi to over 100 decimal places
## using the Taylor series expansion of the second term of
pi - 4*(4.atan(1/5) - atan(1/239))

## months in English
month.name
## months in your current locale
format(ISOdate(2000, 1:12, 1), "%B")
format(ISOdate(2000, 1:12, 1), "%b")
```

Description

The R Who-is-who, describing who made significant contributions to the development of R.

Usage

```r
contributors()
```

Control

Description

These are the basic control-flow constructs of the R language. They function in much the same way as control statements in any Algol-like language. They are all reserved words.

Usage

```r
if(cond) expr
if(cond) cons.expr else alt.expr

for(var in seq) expr
while(cond) expr
repeat expr
break
next
```

Arguments

```r
cond A length-one logical vector that is not NA. Conditions of length greater than one are accepted with a warning, but only the first element is used. Other types are coerced to logical if possible, ignoring any class.

var A syntactical name for a variable.

seq An expression evaluating to a vector (including a list and an expression) or to a pairlist or NULL. A factor value will be coerced to a character vector.

expr, cons.expr, alt.expr An expression in a formal sense. This is either a simple expression or a so called compound expression, usually of the form `{ expr1 ; expr2 }`.
Details

break breaks out of a for, while or repeat loop; control is transferred to the first statement outside the inner-most loop. next halts the processing of the current iteration and advances the looping index. Both break and next apply only to the innermost of nested loops.

Note that it is a common mistake to forget to put braces ({ ... }) around your statements, e.g., after if(...) or for(...). In particular, you should not have a newline between } and else to avoid a syntax error in entering a if ... else construct at the keyboard or via source. For that reason, one (somewhat extreme) attitude of defensive programming is to always use braces, e.g., for if clauses.

The seq in a for loop is evaluated at the start of the loop; changing it subsequently does not affect the loop. If seq has length zero the body of the loop is skipped. Otherwise the variable var is assigned in turn the value of each element of seq. You can assign to var within the body of the loop, but this will not affect the next iteration. When the loop terminates, var remains as a variable containing its latest value.

Value

if returns the value of the expression evaluated, or NULL invisibly if none was (which may happen if there is no else).

for, while and repeat return NULL invisibly. for sets var to the last used element of seq, or to NULL if it was of length zero.

break and next do not return a value as they transfer control within the loop.

We are grateful to these people and other contributors (see contributors) for the ability to use their work.

**Details**

The file ‘R_HOME/COPYRIGHTS’ lists the copyrights in full detail.

---

**crossprod**

**Matrix Crossproduct**

**Description**

Given matrices x and y as arguments, return a matrix cross-product. This is formally equivalent to (but usually slightly faster than) the call t(x) %*% y (crossprod) or x %*% t(y) (tcrossprod).

**Usage**

crossprod(x, y = NULL)

tcrossprod(x, y = NULL)

**Arguments**

x, y  numeric or complex matrices: y = NULL is taken to be the same matrix as x. Vectors are promoted to single-column or single-row matrices, depending on the context.

**Value**

A double or complex matrix, with appropriate dimnames taken from x and y.

**Note**

When x or y are not matrices, they are treated as column or row matrices, but their names are usually not promoted to dimnames. Hence, currently, the last example has empty dimnames.

**References**

See Also

%% and outer product \%o\%.

Examples

\begin{verbatim}
(z <- crossprod(1:4))  # = sum(1 + 2*2 + 3*2 + 4*2)
drop(z)               # scalar
x <- 1:4; names(x) <- letters[1:4]; x
tcrossprod(as.matrix(x)) # is identical(tcrossprod(as.matrix(x)),
crossprod(t(x)))
tcrossprod(x)          # no dimnames

m <- matrix(1:6, 2,3); v <- 1:3; v2 <- 2:1
stopifnot(identical(tcrossprod(v, m), v '*' t(m)),
           identical(tcrossprod(v, m), crossprod(v, t(m))),
           identical(crossprod(m, v2), t(m) '*' v2))
\end{verbatim}

Cstack_info

Report Information on C Stack Size and Usage

Description

Report information on the C stack size and usage (if available).

Usage

Cstack_info()

Details

On most platforms, C stack information is recorded when \texttt{R} is initialized and used for stack-checking. If this information is unavailable, the size will be returned as \texttt{NA}, and stack-checking is not performed.

The information on the stack base address is thought to be accurate on Windows, Linux, OS X and FreeBSD but a heuristic is used on other platforms. Because this might be slightly inaccurate, the current usage could be estimated as negative. (The heuristic is not used on embedded uses of \texttt{R} on platforms where the stack base is not thought to be accurate.)

The 'evaluation depth' is the number of nested \texttt{R} expressions currently under evaluation: this has a limit controlled by \texttt{options(\"expressions\")}.

Value

An integer vector. This has named elements

\begin{itemize}
\item \texttt{size} The size of the stack (in bytes), or \texttt{NA} if unknown.
\item \texttt{current} The estimated current usage (in bytes), possibly \texttt{NA}.
\item \texttt{direction} 1 (stack grows down, the usual case) or \texttt{-1} (stack grows up).
\item \texttt{eval_depth} The current evaluation depth (including two calls for the call to \texttt{Cstack_info}).
\end{itemize}

Examples

Cstack_info()
Cumulative Sums, Products, and Extremes

Description

Returns a vector whose elements are the cumulative sums, products, minima or maxima of the elements of the argument.

Usage

- `cumsum(x)`
- `cumprod(x)`
- `cummax(x)`
- `cummin(x)`

Arguments

- `x`: a numeric or complex (not `cummin` or `cummax`) object, or an object that can be coerced to one of these.

Details

These are generic functions: methods can be defined for them individually or via the Math group generic.

Value

A vector of the same length and type as `x` (after coercion), except that `cumprod` returns a numeric vector for integer input (for consistency with `*`). Names are preserved.

An `NA` value in `x` causes the corresponding and following elements of the return value to be `NA`, as does integer overflow in `cumsum` (with a warning).

S4 methods

`cumsum` and `cumprod` are S4 generic functions: methods can be defined for them individually or via the Math group generic. `cummax` and `cummin` are individually S4 generic functions.

References

Examples

- `cumsum(1:10)`
- `cumprod(1:10)`
- `cummin(c(3:1, 2:0, 4:2))`
- `cummax(c(3:1, 2:0, 4:2))`
cut  

Convert Numeric to Factor

Description

cut divides the range of \( x \) into intervals and codes the values in \( x \) according to which interval they fall. The leftmost interval corresponds to level one, the next leftmost to level two and so on.

Usage

cut(\( x, \ldots \))

## Default S3 method:
cut(\( x, \text{breaks}, \text{labels} \) = NULL,
   \text{include.lowest} = \text{FALSE}, \text{right} = \text{TRUE}, \text{dig.lab} = 3,
   \text{ordered_result} = \text{FALSE}, \ldots)

Arguments

- \( x \)  
a numeric vector which is to be converted to a factor by cutting.
- \( \text{breaks} \)  
either a numeric vector of two or more unique cut points or a single number (greater than or equal to 2) giving the number of intervals into which \( x \) is to be cut.
- \( \text{labels} \)  
labels for the levels of the resulting category. By default, labels are constructed using \( "(a,b]" \) interval notation. If \( \text{labels} = \text{FALSE} \), simple integer codes are returned instead of a factor.
- \( \text{include.lowest} \)  
logical, indicating if an \( 'x[i]' \) equal to the lowest (or highest, for \( \text{right} = \text{FALSE} \)) breaks' value should be included.
- \( \text{right} \)  
logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa.
- \( \text{dig.lab} \)  
integer which is used when labels are not given. It determines the number of digits used in formatting the break numbers.
- \( \text{ordered_result} \)  
logical: should the result be an ordered factor?
- \( \ldots \)  
further arguments passed to or from other methods.

Details

When breaks is specified as a single number, the range of the data is divided into breaks pieces of equal length, and then the outer limits are moved away by 0.1% of the range to ensure that the extreme values both fall within the break intervals. (If \( x \) is a constant vector, equal-length intervals are created, one of which includes the single value.)

If a labels parameter is specified, its values are used to name the factor levels. If none is specified, the factor level labels are constructed as \( "(b1, b2]\)" \( "(b2, b3]\)" etc. for \( \text{right} = \text{TRUE} \) and as \( "[b1, b2)\)" \( "[b2, b3)\)" \( \ldots \) if \( \text{right} = \text{FALSE} \). In this case, \( \text{dig.lab} \) indicates the minimum number of digits should be used in formatting the numbers \( b1, b2, \ldots \). A larger value (up to 12) will be used if needed to distinguish between any pair of endpoints: if this fails labels such as \( "Range3\)" will be used.

The default method will sort a numeric vector of breaks, but other methods are not required to and \( \text{labels} \) will correspond to the intervals after sorting.
**Value**

A `factor` is returned, unless `labels = FALSE` which results in an integer vector of level codes. Values which fall outside the range of `breaks` are coded as `NA`, as are `NaN` and `NA` values.

**Note**

Instead of `table(cut(x, br)), hist(x, br, plot = FALSE)` is more efficient and less memory hungry. Instead of `cut(*, labels = FALSE), findInterval()` is more efficient.

**References**

**See Also**

`split` for splitting a variable according to a group factor; `factor`, `tabulate`, `table`, `findInterval`.

`quantile` for ways of choosing breaks of roughly equal content (rather than length).

`.bincode` for a bare-bones version.

**Examples**

```r
Z <- stats::rnorm(10000)
table(cut(Z, breaks = -6:6))
sum(table(cut(Z, breaks = -6:6, labels = FALSE)))
sum(graphics::hist(Z, breaks = -6:6, plot = FALSE)$counts)
```
## Sometimes the default `dig.lab` is not enough to avoid confusion:

```r
aaa <- c(1,2,3,4,5,2,3,4,5,6,7)
cut(aaa, 3)
cut(aaa, 3, dig.lab = 4, ordered = TRUE)
```

## One way to extract the breakpoints

```r
labs <- levels(cut(aaa, 3))
cbind(lower = as.numeric(sub("\((.+).+","\!", labs )"),
upper = as.numeric(sub("[+,]+,(.+)+)\]\", "\!", labs ))
```

### cut.POSIXt

*Convert a Date or Date-Time Object to a Factor*

#### Description

Method for `cut` applied to date-time objects.

#### Usage

```r
## S3 method for class 'POSIXt'
cut(x, breaks, labels = NULL, start.on.monday = TRUE,
right = FALSE, ...)
```

```r
## S3 method for class 'Date'
cut(x, breaks, labels = NULL, start.on.monday = TRUE,
right = FALSE, ...)
```

#### Arguments

- `x`  
an object inheriting from class "POSIXt" or "Date".
- `breaks`  
a vector of cut points or number giving the number of intervals which `x` is to be cut into or an interval specification, one of "sec", "min", "hour", "day", "DSTday", "week", "month", "quarter" or "year", optionally preceded by an integer and a space, or followed by "s". For "Date" objects only "day", "week", "month", "quarter" and "year" are allowed.
- `labels`  
labels for the levels of the resulting category. By default, labels are constructed from the left-hand end of the intervals (which are included for the default value of `right`). If `labels` = FALSE, simple integer codes are returned instead of a factor.
- `start.on.monday`  
logical. If `breaks` = "weeks", should the week start on Mondays or Sundays?
- `right`, ...  
arguments to be passed to or from other methods.

#### Details

Using both `right` = TRUE and `include.lowest` = TRUE will include both ends of the range of dates.

Using `breaks` = "quarter" will create intervals of 3 calendar months, with the intervals beginning on January 1, April 1, July 1 or October 1, based upon `min(x)` as appropriate.

As vector `break` will be sorted before use: `labels` will then correspond to the sorted vector.
Value

A factor is returned, unless labels = FALSE which returns the integer level codes.

See Also

seq.POSIXt, seq.Date, cut

Examples

```r
## random dates in a 10-week period
cut(ISODate(2001, 1, 1) + 70*86400*stats::runif(100), "weeks")
cut(as.Date("2001/1/1") + 70*stats::runif(100), "weeks")

# The standards all have midnight as the start of the day, but some
# people incorrectly interpret it at the end of the previous day ...
tm <- seq(as.POSIXct("2012-06-01 06:00"), by = "6 hours", length.out = 24)
aggregate(1:24, list(day = cut(tm, "days")), mean)
# and a version with midnight included in the previous day:
aggregate(1:24, list(day = cut(tm, "days", right = TRUE)), mean)
```

Description

Determine the class of an arbitrary R object.

Usage

data.class(x)

Arguments

x

an R object.

Value

character string giving the class of x.

The class is the (first element) of the class attribute if this is non-NULL, or inferred from the object’s dim attribute if this is non-NULL, or mode(x).

Simply speaking, data.class(x) returns what is typically useful for method dispatching. (Or, what the basic creator functions already and maybe eventually all will attach as a class attribute.)

Note

For compatibility reasons, there is one exception to the rule above: When x is integer, the result of data.class(x) is "numeric" even when x is classed.

See Also

class
Examples

x <- LETTERS
data.class(factor(x))  # has a class attribute
data.class(matrix(x, ncol = 13))  # has a dim attribute
data.class(list(x))  # the same as mode(x)
data.class(x)  # the same as mode(x)

stopifnot(data.class(1:2) == "numeric")  # compatibility "rule"

Description

This function creates data frames, tightly coupled collections of variables which share many of the properties of matrices and of lists, used as the fundamental data structure by most of R’s modeling software.

Usage

data.frame(..., row.names = NULL, check.rows = FALSE,
check.names = TRUE,
stringsAsFactors = default.stringsAsFactors())

default.stringsAsFactors()

Arguments

... these arguments are of either the form value or tag = value. Component names are created based on the tag (if present) or the deparsed argument itself.

row.names NULL or a single integer or character string specifying a column to be used as row names, or a character or integer vector giving the row names for the data frame.

check.rows if TRUE then the rows are checked for consistency of length and names.

check.names logical. If TRUE then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names and are not duplicated. If necessary they are adjusted (by make.names) so that they are.

stringsAsFactors logical: should character vectors be converted to factors? The ‘factory-fresh’ default is TRUE, but this can be changed by setting options(stringsAsFactors = FALSE).

Details

A data frame is a list of variables of the same number of rows with unique row names, given class "data.frame". If no variables are included, the row names determine the number of rows.

The column names should be non-empty, and attempts to use empty names will have unsupported results. Duplicate column names are allowed, but you need to use check.names = FALSE for data.frame to generate such a data frame. However, not all operations on data frames will preserve
duplicated column names: for example matrix-like subsetting will force column names in the result to be unique.

`data.frame` converts each of its arguments to a data frame by calling `as.data.frame(optional = TRUE)`. As that is a generic function, methods can be written to change the behaviour of arguments according to their classes. R comes with many such methods. Character variables passed to `data.frame` are converted to factor columns unless protected by `i` or argument `stringsAsFactors` is false. If a list or data frame or matrix is passed to `data.frame` it is as if each component or column had been passed as a separate argument (except for matrices of class "model.matrix" and those protected by `I`).

Objects passed to `data.frame` should have the same number of rows, but atomic vectors (see `is.vector`), factors and character vectors protected by `I` will be recycled a whole number of times if necessary (including as elements of list arguments).

If row names are not supplied in the call to `data.frame`, the row names are taken from the first component that has suitable names, for example a named vector or a matrix with rownames or a data frame. (If that component is subsequently recycled, the names are discarded with a warning.) If `row.names` was supplied as NULL or no suitable component was found the row names are the integer sequence starting at one (and such row names are considered to be ‘automatic’, and not preserved by `as.matrix`).

If row names are supplied of length one and the data frame has a single row, the `row.names` is taken to specify the row names and not a column (by name or number).

Names are removed from vector inputs not protected by `I`.

`default.stringsAsFactors` is a utility that takes `getOption("stringsAsFactors")` and ensures the result is TRUE or FALSE (or throws an error if the value is not NULL).

**Value**

A data frame, a matrix-like structure whose columns may be of differing types (numeric, logical, factor and character and so on).

How the names of the data frame are created is complex, and the rest of this paragraph is only the basic story. If the arguments are all named and simple objects (not lists, matrices of data frames) then the argument names give the column names. For an unnamed simple argument, a deparsed version of the argument is used as the name (with an enclosing `I(...)` removed). For a named matrix/list/data frame argument with more than one named column, the names of the columns are the name of the argument followed by a dot and the column name inside the argument: if the argument is unnamed, the argument’s column names are used. For a named or unnamed matrix/list/data frame argument that contains a single column, the column name in the result is the column name in the argument. Finally, the names are adjusted to be unique and syntactically valid unless `check.names = FALSE`.

**Note**

In versions of R prior to 2.4.0 `row.names` had to be character: to ensure compatibility with such versions of R, supply a character vector as the `row.names` argument.

**References**

data.matrix

Convert a Data Frame to a Numeric Matrix

Description

Return the matrix obtained by converting all the variables in a data frame to numeric mode and then binding them together as the columns of a matrix. Factors and ordered factors are replaced by their internal codes.

Usage

data.matrix(frame, rownames.force = NA)

Arguments

frame          a data frame whose components are logical vectors, factors or numeric vectors.
rownames.force logical indicating if the resulting matrix should have character (rather than NULL) rownames. The default, NA, uses NULL rownames if the data frame has ‘automatic’ row.names or for a zero-row data frame.

Details

Logical and factor columns are converted to integers. Any other column which is not numeric (according to is.numeric) is converted by as.numeric or, for S4 objects, as(), “numeric”). If all columns are integer (after conversion) the result is an integer matrix, otherwise a numeric (double) matrix.

Examples

L3 <- LETTERS[1:3]
fac <- sample(L3, 10, replace = TRUE)
(d <- data.frame(x = 1, y = 1:10, fac = fac))
## The "same" with automatic column names:
data.frame(1, 1:10, sample(L3, 10, replace = TRUE))

is.data.frame(d)

## do not convert to factor, using I() :
(dd <- cbind(d, char = I(letters[1:10])))
rbind(class = sapply(dd, class), mode = sapply(dd, mode))

stopifnot(1:10 == row.names(d))  # (coercion)

(d0 <- d[, FALSE])  # data frame with 0 columns and 10 rows
(d.0 <- d[FALSE, ])  # <0 rows> data frame (3 named cols)
(d00 <- d0[FALSE, ])  # data frame with 0 columns and 0 rows
Value

If `frame` inherits from class "data.frame", an integer or numeric matrix of the same dimensions as `frame`, with dimnames taken from the `row.names` (or `NULL`, depending on `row.names.force`) and names.

Otherwise, the result of `as.matrix`.

Note

The default behaviour for data frames differs from `R < 2.5.0` which always gave the result character `rownames`.

References

See Also

`as.matrix`, `data.frame`, `matrix`.

Examples

```r
DF <- data.frame(a = 1:3, b = letters[10:12],
                 c = seq(as.Date("2004-01-01"), by = "week", len = 3),
                 stringsAsFactors = TRUE)
data.matrix(DF[1:2])
data.matrix(DF)
```

---

date

System Date and Time

Description

Returns a character string of the current system date and time.

Usage

`date()`

Value

The string has the form "Fri Aug 20 11:11:00 1999", i.e., length 24, since it relies on POSIX’s `ctime` ensuring the above fixed format. Timezone and Daylight Saving Time are taken account of, but `not` indicated in the result.

The day and month abbreviations are always in English, irrespective of locale.

References

### Dates

**Date Class**

Description of the class "Date" representing calendar dates.

#### Usage

```r
# S3 method for class 'Date'
summary(object, digits = 12, ...)
```

#### Arguments

- `object` - An object summarized.
- `digits` - Number of significant digits for the computations.
- `...` - Further arguments to be passed from or to other methods.

#### Details

Dates are represented as the number of days since 1970-01-01, with negative values for earlier dates. They are always printed following the rules of the current Gregorian calendar, even though that calendar was not in use long ago (it was adopted in 1752 in Great Britain and its colonies).

It is intended that the date should be an integer, but this is not enforced in the internal representation. Fractional days will be ignored when printing. It is possible to produce fractional days via the mean method or by adding or subtracting (see `Ops.Date`).

The print methods respect `options("max.print").`

#### See Also

- `Sys.Date` for the current date.
- `Ops.Date` for operators on "Date" objects.
- `format.Date` for conversion to and from character strings.
- `axis.Date` and `hist.Date` for plotting.
- `weekdays` for convenience extraction functions.
- `seq.Date, cut.Date, round.Date` for utility operations.
- `DateTimeClasses` for date-time classes.
Examples

```r
## Not run:
(today <- Sys.Date())
format(today, "%d %b %Y") # with month as a word
(tenweeks <- seq(today, length.out=10, by="1 week")) # next ten weeks
weekdays(today)
months(tenweeks)
as.Date(.leap.seconds)

## End(Not run)
```

Description

Description of the classes "POSIXlt" and "POSIXct" representing calendar dates and times (to the nearest second).

Usage

```r
## S3 method for class 'POSIXct'
print(x, ...)

## S3 method for class 'POSIXct'
summary(object, digits = 15, ...)

time + z
z + time
time - z
time1 lop time2
```

Arguments

- `x`, `object`: An object to be printed or summarized from one of the date-time classes.
- `digits`: Number of significant digits for the computations: should be high enough to represent the least important time unit exactly.
- `...`: Further arguments to be passed from or to other methods.
- `time`: date-time objects
- `time1, time2`: date-time objects or character vectors. (Character vectors are converted by `as.POSIXct`.)
- `z`: a numeric vector (in seconds)
- `lop`: One of `==`, `!=`, `<`, `<=`, `>`, or `>=`.

Details

There are two basic classes of date/times. Class "POSIXct" represents the (signed) number of seconds since the beginning of 1970 (in the UTC timezone) as a numeric vector. Class "POSIXlt" is a named list of vectors representing...
sec 0–61: seconds
min 0–59: minutes
hour 0–23: hours
mday 1–31: day of the month
mon 0–11: months after the first of the year.
year years since 1900.
wday 0–6 day of the week, starting on Sunday.
yday 0–365: day of the year.
isdst Daylight Savings Time flag. Positive if in force, zero if not, negative if unknown.

Note that the internal list structure is somewhat hidden, as many methods, including print() or str, apply to the abstract date-time vector, as for "POSIXct". The classes correspond to the POSIX/C99 constructs of 'calendar time' (the time_t data type) and 'local time' (or broken-down time, the struct tm data type), from which they also inherit their names. The components of "POSIXlt" are integer vectors, except sec.

"POSIXct" is more convenient for including in data frames, and "POSIXlt" is closer to human-readable forms. A virtual class "POSIXt" exists from which both of the classes inherit: it is used to allow operations such as subtraction to mix the two classes. Note that length(x) is the length of the corresponding (abstract) date/time vector, also in the "POSIXlt" case.

Components wday and yday of "POSIXlt" are for information, and are not used in the conversion to calendar time. However, isdst is needed to distinguish times at the end of DST: typically 1am to 2am occurs twice, first in DST and then in standard time. At all other times isdst can be deduced from the first six values, but the behaviour if it is set incorrectly is platform-dependent.

Logical comparisons and limited arithmetic are available for both classes. One can add or subtract a number of seconds from a date-time object, but not add two date-time objects. Subtraction of two date-time objects is equivalent to using diffTime. Be aware that "POSIXlt" objects will be interpreted as being in the current timezone for these operations, unless a timezone has been specified.

"POSIXlt" objects will often have an attribute "tzname", a character vector of length 3 giving the timezone name from the TZ environment variable and the names of the base timezone and the alternate (daylight-saving) timezone. Sometimes this may just be of length one, giving the timezone name.

"POSIXct" objects may also have an attribute "tzname", a character vector of length one. If set to a non-empty value, it will determine how the object is converted to class "POSIXlt" and in particular how it is printed. This is usually desirable, but if you want to specify an object in a particular timezone but to be printed in the current timezone you may want to remove the "tzname" attribute (e.g. by c(x)).

Unfortunately, the conversion is complicated by the operation of time zones and leap seconds (24 days have been 86401 seconds long so far: the times of the extra seconds are in the object .leap.seconds). The details of this are entrusted to the OS services where possible. This always covers the period 1970–2037, and on most machines back to 1902 (when time zones were in their infancy). Outside the platform limits we use our own C code. This uses the offset from GMT in use either for 1902 (when there was no DST) or that predicted for one of 2030 to 2037 (chosen so that the likely DST transition days are Sundays), and uses the alternate (daylight-saving) timezone only if isdst is positive or (if -1) if DST was predicted to be in operation in the 2030s on that day. (There is no reason to suppose that the DST rules will remain the same in the future, and indeed the US legislated in 2005 to change its rules as from 2007, with a possible future reversion.)

It seems that some rare systems use leap seconds, but most ignore them (as required by POSIX). This is detected and corrected for at build time, so all "POSIXct" times used by R do not include
leap seconds. (Conceivably this could be wrong if the system has changed since build time, just possibly by changing locales or the ‘zoneinfo’ database.)

Using c on "POSIXlt" objects converts them to the current time zone, and on "POSIXct" objects drops any "tzname" attributes (even if they are all marked with the same time zone).

A few times have specific issues. First, the leap seconds are ignored, and real times such as "2005-12-31 23:59:60" are (probably) treated as the next second. However, they will never be generated by R, and are unlikely to arise as input. Second, on some OSes there is a problem in the POSIX/C99 standard with "1969-12-31 23:59:59 UTC", which is -1 in calendar time and that value is on those OSes also used as an error code. Thus as.POSIXct("1969-12-31 23:59:59", format = "%Y-%m-%d %H:%M:%S", tz = "UTC") may give NA, and hence as.POSIXct("1969-12-31 23:59:59", tz = "UTC") will give "1969-12-31 23:59:00". Other OSes (including the code used by R on Windows) report errors separately and so are able to handle that time as valid.

The print methods respect options("max.print").

Sub-second Accuracy

Classes "POSIXct" and "POSIXlt" are able to express fractions of a second. (Conversion of fractions between the two forms may not be exact, but will have better than microsecond accuracy.)

Fractional seconds are printed only if options("digits.secs") is set: see strftime.

Warning

Some Unix-like systems (especially Linux ones) do not have environment variable TZ set, yet have internal code that expects it (as does POSIX). We have tried to work around this, but if you get unexpected results try setting TZ. See Sys.timezone for valid settings.

References

See Also

Dates for dates without times.

as.POSIXct and as.POSIXlt for conversion between the classes.

strptime for conversion to and from character representations.

Sys.time for clock time as a "POSIXct" object.

difftime for time intervals.

cut.POSIXt, seq.POSIXt, round.POSIXt and trunc.POSIXt for methods for these classes.

weekdays for convenience extraction functions.

Examples

```
(z <- Sys.time())       # the current date, as class "POSIXct"
Sys.time() - 3600       # an hour ago

as.POSIXlt(Sys.time(), "GMT") # the current time in GMT
format(.leap.seconds, "%H:%M") # all 24 leap seconds in your timezone
print(.leap.seconds, tz = "PST/PDT") # and in Seattle's
```
## dcf

### Read and Write Data in DCF Format

#### Description

Reads or writes an R object from/to a file in Debian Control File format.

#### Usage

- **read.dcf**: `read.dcf(file, fields = NULL, all = FALSE, keep.white = NULL)
- **write.dcf**: `write.dcf(x, file = "", append = FALSE,
  indent = 0.1 * getOption("width"),
  width = 0.9 * getOption("width"),
  keep.white = NULL)

#### Arguments

- **file**: either a character string naming a file or a connection. "" indicates output to the console. For `read.dcf` this can name a compressed file (see `gzfile`).
- **fields**: Fields to read from the DCF file. Default is to read all fields.
- **all**: a logical indicating whether in case of multiple occurrences of a field in a record, all these should be gathered. If `all` is false (default), only the last such occurrence is used.
- **keep.white**: a character string with the names of the fields for which whitespace should be kept as is, or NULL (default) indicating that there are no such fields. Coerced to character if possible. For fields where whitespace is not to be kept as is, `read.dcf` removes leading and trailing whitespace, and `write.dcf` folds using `strwrap`.
- **x**: the object to be written, typically a data frame. If not, it is attempted to coerce `x` to a data frame.
- **append**: logical. If TRUE, the output is appended to the file. If FALSE, any existing file of the name is destroyed.
- **indent**: a positive integer specifying the indentation for continuation lines in output entries.
- **width**: a positive integer giving the target column for wrapping lines in the output.
Details

DCF is a simple format for storing databases in plain text files that can easily be directly read and written by humans. DCF is used in various places to store R system information, like descriptions and contents of packages.

The DCF rules as implemented in R are:

1. A database consists of one or more records, each with one or more named fields. Not every record must contain each field. Fields may appear more than once in a record.
2. Regular lines start with a non-whitespace character.
3. Regular lines are of form tag: value, i.e., have a name tag and a value for the field, separated by : (only the first : counts). The value can be empty (i.e., whitespace only).
4. Lines starting with whitespace are continuation lines (to the preceding field) if at least one character in the line is non-whitespace. Continuation lines where the only non-whitespace character is a ‘.’ are taken as blank lines (allowing for multi-paragraph field values).
5. Records are separated by one or more empty (i.e., whitespace only) lines.
6. Individual lines may not be arbitrarily long; prior to R 3.0.2 the length limit was approximately 8191 bytes per line.

Note that read.dcf(all = FALSE) reads the file byte-by-byte. This allows a ‘DESCRIPTION’ file to be read and only its ASCII fields used, or its ‘Encoding’ field used to re-encode the remaining fields.

write.dcf does not write NA fields.

Value

The default read.dcf(all = FALSE) returns a character matrix with one row per record and one column per field. Leading and trailing whitespace of field values is ignored unless a field is listed in keep.white. If a tag name is specified in the file, but the corresponding value is empty, then an empty string is returned. If the tag name of a field is specified in fields but never used in a record, then the corresponding value is NA. If fields are repeated within a record, the last one encountered is returned. Malformed lines lead to an error.

For read.dcf(all = TRUE) a data frame is returned, again with one row per record and one column per field. The columns are lists of character vectors for fields with multiple occurrences, and character vectors otherwise.

Note that an empty file is a valid DCF file, and read.dcf will return a zero-row matrix or data frame.

For write.dcf, invisible NULL.

http://www.debian.org/doc/debian-policy/ch-controlfields.html. Note that R does not require encoding in UTF-8, which is a recent Debian requirement.

See Also

write.table.
Examples

```r
## Not run:
## Create a reduced version of the 'CONTENTS' file in package 'splines'
x <- read.dcf(file = system.file("CONTENTS", package = "splines"),
              fields = c("Entry", "Description"))
write.dcf(x)

## End(Not run)
```

### Description

Set, unset or query the debugging flag on a function. The text and condition arguments are the same as those that can be supplied via a call to `browser`. They can be retrieved by the user once the browser has been entered, and provide a mechanism to allow users to identify which breakpoint has been activated.

### Usage

```r
debug(fun, text = "", condition = NULL)
debugonce(fun, text = "", condition = NULL)
undebug(fun)
isdebugged(fun)
```

### Arguments

- `fun` any interpreted R function.
- `text` a text string that can be retrieved when the browser is entered.
- `condition` a condition that can be retrieved when the browser is entered.

### Details

When a function flagged for debugging is entered, normal execution is suspended and the body of function is executed one statement at a time. A new browser context is initiated for each step (and the previous one destroyed).

At the debug prompt the user can enter commands or R expressions, followed by a newline. The commands are:

- `n` (or just an empty line, by default). Advance to the next step.
- `c` continue to the end of the current context: e.g. to the end of the loop if within a loop or to the end of the function.
- `cont` synonym for `c`.
- `where` print a stack trace of all active function calls.
- `Q` exit the browser and the current evaluation and return to the top-level prompt.
Defunct

(Leading and trailing whitespace is ignored, except for an empty line).

Anything else entered at the debug prompt is interpreted as an R expression to be evaluated in the calling environment: in particular typing an object name will cause the object to be printed, and ls() lists the objects in the calling frame. (If you want to look at an object with a name such as n, print it explicitly.)

Setting option "browserNLdisabled" to TRUE disables the use of an empty line as a synonym for n. If this is done, the user will be re-prompted for input until a valid command or an expression is entered.

To debug a function is defined inside a function, single-step though to the end of its definition, and then call debug on its name.

If you want to debug a function not starting at the very beginning, use trace(..., at = *) or setBreakpoint.

Using debug is persistent, and unless debugging is turned off the debugger will be entered on every invocation (note that if the function is removed and replaced the debug state is not preserved). Use debugonce to enter the debugger only the next time the function is invoked.

In order to debug S4 methods (see Methods), you need to use trace, typically calling browser, e.g., as trace("plot", browser, exit = browser, signature = c("track", "missing"))

The number of lines printed for the deparsed call when a function is entered for debugging can be limited by setting options(deparse.max.lines).

When debugging is enabled on a byte compiled function then the interpreted version of the function will be used until debugging is disabled.

See Also

browser, trace; traceback to see the stack after an Error: ... message; recover for another debugging approach.

Defunct

Marking Objects as Defunct

Description

When a function is removed from R it should be replaced by a function which calls .Defunct.

Usage

.DEfunct(new, package = NULL, msg)

Arguments

new character string: A suggestion for a replacement function.

package character string: The package to be used when suggesting where the defunct function might be listed.

msg character string: A message to be printed, if missing a default message is used.
delayedAssign

Details

Defunct is called from defunct functions. Functions should be listed in help("pkg-defunct") for an appropriate pkg, including base (with the alias added to the respective Rd file).

See Also

Deprecated.

base-defunct and so on which list the defunct functions in the packages.

| delayedAssign | Delay Evaluation |

Description

delayedAssign creates a promise to evaluate the given expression if its value is requested. This provides direct access to the lazy evaluation mechanism used by R for the evaluation of (interpreted) functions.

Usage

delayedAssign(x, value, eval.env = parent.frame(1), assign.env = parent.frame(1))

Arguments

- `x` a variable name (given as a quoted string in the function call)
- `value` an expression to be assigned to `x`
- `eval.env` an environment in which to evaluate `value`
- `assign.env` an environment in which to assign `x`

Details

Both `eval.env` and `assign.env` default to the currently active environment.

The expression assigned to a promise by delayedAssign will not be evaluated until it is eventually ‘forced’. This happens when the variable is first accessed.

When the promise is eventually forced, it is evaluated within the environment specified by `eval.env` (whose contents may have changed in the meantime). After that, the value is fixed and the expression will not be evaluated again.

Value

This function is invoked for its side effect, which is assigning a promise to evaluate `value` to the variable `x`.

See Also

substitute, to see the expression associated with a promise.
Examples

```r
delayedAssign("x", msg)
x <- new!
substitute(x) <- x (was 'msg' ?)
``` 

delayedAssign("x", (
  for(i in 1:3)
  cat("yippee!\n")
  10
))

x^2 #= yippee
x^2 #= simple number

e <- (function(x, y = 1, z) environment())(1+2, "y", {cat("HO! "); pi+2})
(le <- as.list(e)) # evaluates the promises
```

---

**deparse**  

**Expression Deparsing**

**Description**

Turn unevaluated expressions into character strings.

**Usage**

```r
deparse(expr, width.cutoff = 60L,
  backtick = mode(expr) %in%
  c("call", "expression", ";", "function"),
  control = c("keepInteger", "showAttributes", "keepNA"),
  nlines = -1L)
```

**Arguments**

- `expr`: any R expression.
- `width.cutoff`: integer in [20, 500] determining the cutoff (in bytes) at which line-breaking is tried.
- `backtick`: logical indicating whether symbolic names should be enclosed in backticks if they do not follow the standard syntax.
- `nlines`: integer: the maximum number of lines to produce. Negative values indicate no limit.
Details

This function turns unevaluated expressions (where ‘expression’ is taken in a wider sense than the
strict concept of a vector of mode "expression" used in expression) into character strings (a kind
of inverse to parse).

A typical use of this is to create informative labels for data sets and plots. The example shows a
simple use of this facility. It uses the functions deparse and substitute to create labels for a plot
which are character string versions of the actual arguments to the function myplot.

The default for the backtick option is not to quote single symbols but only composite expressions.
This is a compromise to avoid breaking existing code.

Using control = "all" comes closest to making deparse() an inverse of parse(). However,
not all objects are deparse-able even with this option and a warning will be issued if the function
recognizes that it is being asked to do the impossible.

Numeric and complex vectors are converted using 15 significant digits: see as.character for more
details.

width.cutoff is a lower bound for the line lengths: deparsing a line proceeds until at least
width.cutoff bytes have been output and e.g. arg = value expressions will not be split across
lines.

Note

To avoid the risk of a source attribute out of sync with the actual function definition, the source
attribute of a function will never be deparsed as an attribute.

Deparsing internal structures may not be accurate: for example the graphics display list recorded by
recordPlot is not intended to be deparsed and .Internal calls will be shown as primitive calls.

References

Brooks/Cole.

See Also

substitute, parse, expression.

Quotes for quoting conventions, including backticks.

Examples

require(stats); require(graphics)

deparse(args(lm))
deparse(args(lm), width = 500)
myplot <-
  function(x, y) {
    plot(x, y, xlab = deparse(substitute(x)),
         ylab = deparse(substitute(y)))
  }
e <- quote("foo bar")
deparse(e)
deparse(e, backtick = TRUE)
e <- quote("foo bar"+1)
deparse(e)
deparse(e, control = "all")
deparseOpts

Options for Expression Deparsing

Description

Process the deparsing options for deparse, dput and dump.

Usage

.deparseOpts(control)

Arguments

control character vector of deparsing options.

Details

This is called by deparse, dput and dump to process their control argument.

The control argument is a vector containing zero or more of the following strings. Partial string matching is used.

keepInteger Either surround integer vectors by as.integer() or use suffix L, so they are not converted to type double when parsed. This includes making sure that integer NAs are preserved (via NA_integer_ if there are no non-NA values in the vector, unless “S_compatible” is set).

quoteExpressions Surround expressions with quote(), so they are not evaluated when re-parsed.

showAttributes If the object has attributes (other than a source attribute), use structure() to display them as well as the object value. This is the default for deparse and dput.

useSource If the object has a source attribute, display that instead of deparsing the object. Currently only applies to function definitions.

warnIncomplete Some exotic objects such as environments, external pointers, etc. can not be deparsed properly. This option causes a warning to be issued if the deparser recognizes one of these situations.

Also, the parser in R < 2.7.0 would only accept strings of up to 8192 bytes, and this option gives a warning for longer strings.

keepNA Integer, real and character NAs are surrounded by coercion where necessary to ensure that they are parsed to the same type.

all An abbreviated way to specify all of the options listed above. This is the default for dump, and the options used by edit (which are fixed).

delayPromises Deparse promises in the form <promise: expression> rather than evaluating them.

The value and the environment of the promise will not be shown and the deparsed code cannot be sourced.

S_compatible Make deparsing as far as possible compatible with S and R < 2.5.0. For compatibility with S, integer values of double vectors are deparsed with a trailing decimal point. Backticks are not used.
For the most readable (but perhaps incomplete) display, use control = NULL. This displays the object’s value, but not its attributes. The default in `deparse` is to display the attributes as well, but not to use any of the other options to make the result parseable. (`dput` and `dump` do use more default options, and printing of functions without sources uses `c("keepInteger", "keepNA"`).)

Using control = "all" comes closest to making `deparse()` an inverse of `parse()`. However, not all objects are deparse-able even with this option. A warning will be issued if the function recognizes that it is being asked to do the impossible.

**Value**

A numerical value corresponding to the options selected.

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>Marking Objects as Deprecated</th>
</tr>
</thead>
</table>

**Description**

When an object is about to be removed from R it is first deprecated and should include a call to `.Deprecated`.

**Usage**

`.Deprecated(new, package=NULL, msg, old = as.character(sys.call(sys.parent()))[1L])`

**Arguments**

- **new**
  - character string: A suggestion for a replacement function.

- **package**
  - character string: The package to be used when suggesting where the deprecated function might be listed.

- **msg**
  - character string: A message to be printed, if missing a default message is used.

- **old**
  - character string specifying the function (default) or usage which is being depre-cated.

**Details**

`.Deprecated("<new name>")` is called from deprecated functions. The original help page for these functions is often available at `help("oldName-deprecated")` (note the quotes). Functions should be listed in `help("pkg-deprecated")` for an appropriate pkg, including base.

**See Also**

`Defunct`

`base-deprecated` and so on which list the deprecated functions in the packages.
Description

det calculates the determinant of a matrix. determinant is a generic function that returns separately the modulus of the determinant, optionally on the logarithm scale, and the sign of the determinant.

Usage

det(x, ...)

determinant(x, logarithm = TRUE, ...)

Arguments

x numeric matrix: logical matrices are coerced to numeric.
logarithm logical; if TRUE (default) return the logarithm of the modulus of the determinant.
...
Optional arguments. At present none are used. Previous versions of det allowed an optional method argument. This argument will be ignored but will not produce an error.

Details

The determinant function uses an LU decomposition and the det function is simply a wrapper around a call to determinant.

Often, computing the determinant is not what you should be doing to solve a given problem.

Value

For det, the determinant of x. For determinant, a list with components

modulus a numeric value. The modulus (absolute value) of the determinant if logarithm is FALSE; otherwise the logarithm of the modulus.

sign integer; either +1 or −1 according to whether the determinant is positive or negative.

Examples

(x <- matrix(1:4, ncol = 2))
unlist(determinant(x))
det(x)
det(print(cbind(1, 1:3, c(2,0,1))))
detach

Detach Objects from the Search Path

**Description**

Detach a database, i.e., remove it from the `search()` path of available R objects. Usually this is either a `data.frame` which has been attached or a package which was attached by `library`.

**Usage**

```r
detach(name, pos = 2L, unload = FALSE, character.only = FALSE, force = FALSE)
```

**Arguments**

- `name` The object to detach. Defaults to `search()[pos]`. This can be an unquoted name or a character string but not a character vector. If a number is supplied this is taken as `pos`.
- `pos` Index position in `search()` of the database to detach. When `name` is a number, `pos = name` is used.
- `unload` A logical value indicating whether or not to attempt to unload the namespace when a package is being detached. If the package has a namespace and `unload` is `TRUE`, then `detach` will attempt to unload the namespace *via `unloadNamespace`*: if the namespace is imported by another namespace or `unload` is `FALSE`, no unloading will occur.
- `character.only` a logical indicating whether `name` can be assumed to be a character string.
- `force` logical: should a package be detached even though other attached packages depend on it?

**Details**

This is most commonly used with a single number argument referring to a position on the search list, and can also be used with a unquoted or quoted name of an item on the search list such as `package:tools`.

If a package has a namespace, detaching it does not by default unload the namespace (and may not even with `unload = TRUE`), and detaching will not in general unload any dynamically loaded compiled code (DLLs). Further, registered S3 methods from the namespace will not be removed. If you use `library` on a package whose namespace is loaded, it attaches the exports of the already loaded namespace. So detaching and re-attaching a package may not refresh some or all components of the package, and is inadvisable.

**Value**

The return value is `invisible`. It is `NULL` when a package is detached, otherwise the environment which was returned by `attach` when the object was attached (incorporating any changes since it was attached).
**Good practice**

detach() without an argument removes the first item on the search path after the workspace. It is all too easy to call it too many or too few times, or to not notice that the search path has changed since an attach call.

Use of attach/detach is best avoided in functions (see the help for attach) and in interactive use and scripts it is prudent to detach by name.

**Note**

You cannot detach either the workspace (position 1) nor the base package (the last item in the search list), and attempting to do so will throw an error.

Unloading some namespaces has undesirable side effects: e.g. unloading grid closes all graphics devices, and on some systems tcltk cannot be reloaded once it has been unloaded and may crash R if this is attempted.

**References**

**See Also**

attach, library, search, objects, unloadNamespace, library.dynam.unload.

**Examples**

```r
require(splines) # package
detach(package=splines)
## or also
library(splines)
pkg <- "package:splines"

detach(pkg, character.only = TRUE)
## careful: do not do this unless 'splines' is not already attached.
library(splines)
detach(2) # 'pos' used for 'name'

## an example of the name argument to attach
## and of detaching a database named by a character vector
attach_and_detach <- function(db, pos = 2)
{
    name <- deparse(substitute(db))
    attach(db, pos = pos, name = name)
    print(search()[pos])
    detach(name, character.only = TRUE)
}
attach_and_detach(women, pos = 3)
```
Description

Extract or replace the diagonal of a matrix, or construct a diagonal matrix.

Usage

diag(x = 1, nrow, ncol)
diag(x) <- value

Arguments

x a matrix, vector or 1D array, or missing.
nrow, ncol Optional dimensions for the result when x is not a matrix.
value either a single value or a vector of length equal to that of the current diagonal.

Details

diag has four distinct usages:

1. x is a matrix, when it extracts the diagonal.
2. x is missing and nrow is specified, it returns an identity matrix.
3. x is a scalar (length-one vector) and the only argument, it returns a square identity matrix of size given by the scalar.
4. x is a numeric vector, either of length at least 2 or there were further arguments. This returns a matrix with the given diagonal and zero off-diagonal entries.

It is an error to specify nrow or ncol in the first case.

Value

If x is a matrix then diag(x) returns the diagonal of x. The resulting vector will have names if the matrix x has matching column and rownames.

The replacement form sets the diagonal of the matrix x to the given value(s).

In all other cases the value is a diagonal matrix with nrow rows and ncol columns (if ncol is not given the matrix is square). Here nrow is taken from the argument if specified, otherwise inferred from x: if that is a vector (or 1D array) of length two or more, then its length is the number of rows, but if it is of length one and neither nrow nor ncol is specified, nrow = as.integer(x).

When a diagonal matrix is returned, the diagonal elements are one except in the fourth case, when x gives the diagonal elements: it will be recycled or truncated as needed, but fractional recycling and truncation will give a warning.

Note

Using diag(x) can have unexpected effects if x is a vector that could be of length one. Use diag(x, nrow = length(x)) for consistent behaviour.
diff

Returns suitably lagged and iterated differences.

Usage

```r
apply(x, 2, function(y) diff(y, lag = 1, differences = 2))
```

Arguments

- `x`: a numeric vector or matrix containing the values to be differenced.
- `lag`: an integer indicating which lag to use.
- `differences`: an integer indicating the order of the difference.
- `...`: further arguments to be passed to or from methods.

Details

diff is a generic function with a default method and ones for classes "ts", "POSIXt" and "Date". NA's propagate.
Value

If \( x \) is a vector of length \( n \) and differences \( = 1 \), then the computed result is equal to the successive differences \( x[(1+\text{lag}):n] - x[1:(n-\text{lag})] \).

If difference is larger than one this algorithm is applied recursively to \( x \). Note that the returned value is a vector which is shorter than \( x \).

If \( x \) is a matrix then the difference operations are carried out on each column separately.

Examples

diff(1:10, 2)
diff(1:10, 2, 2)  
x <- cumsum(cumsum(1:10))
diff(x, lag = 2)
diff(x, differences = 2)

diff(.leap.seconds)

difftime

Time Intervals

Description

Time intervals creation, printing, and some arithmetic.

Usage

time1 - time2

difftime(time1, time2, tz,  
  units = c("auto", "secs", "mins", "hours",  
  "days", "weeks"))

as.difftime(tim, format = "%X", units = "auto")

## S3 method for class 'difftime'
format(x, ...)
## S3 method for class 'difftime'
units(x)
## S3 replacement method for class 'difftime'
units(x) <- value
## S3 method for class 'difftime'
as.double(x, units = "auto", ...)
**difftime**

## Arguments

- `time1, time2` date-time or date objects.
- `tz` an optional timezone specification to be used for the conversion, mainly for "POSIXt" objects.
- `units` character string. Units in which the results are desired. Can be abbreviated.
- `value` character string. Like units, except that abbreviations are not allowed.
- `tim` character string or numeric value specifying a time interval.
- `format` character specifying the format of tim: see strftime. The default is a locale-specific time format.
- `x` an object inheriting from class "difftime".
- `...` arguments to be passed to or from other methods.

## Details

Function `difftime` calculates a difference of two date/time objects and returns an object of class "difftime" with an attribute indicating the units. The `Math` group method provides `round`, `signif`, `floor`, `ceiling`, `trunc`, `abs`, and `sign` methods for objects of this class, and there are methods for the group-generic (see `Ops`) logical and arithmetic operations.

If `units = "auto"`, a suitable set of units is chosen, the largest possible (excluding "weeks") in which all the absolute differences are greater than one.

Subtraction of date-time objects gives an object of this class, by calling `difftime` with `units = "auto"`. Alternatively, as.difftime() works on character-coded or numeric time intervals; in the latter case, units must be specified, and `format` has no effect.

Limited arithmetic is available on "difftime" objects: they can be added or subtracted, and multiplied or divided by a numeric vector. In addition, adding or subtracting a numeric vector by a "difftime" object implicitly converts the numeric vector to a "difftime" object with the same units as the "difftime" object. There are methods for `mean` and `sum` (via the `Summary` group generic).

The units of a "difftime" object can be extracted by the `units` function, which also has a replacement form. If the units are changed, the numerical value is scaled accordingly. The replacement version keeps attributes such as names and dimensions.

The `as.double` method returns the numeric value expressed in the specified units. Using `units = "auto"` means the units of the object.

The `format` method simply formats the numeric value and appends the units as a text string.

The default behaviour when `time1` or `time2` was a "POSIXt" object changed in R 2.12.0: previously such objects were regarded as in the timezone given by `tz` which defaulted to the current timezone.

```r
Math(x, ...)"`
Examples

(z <- Sys.time() - 3600)
Sys.time() - z # just over 3600 seconds.

## time interval between releases of R 1.2.2 and 1.2.3.

as.difftime(c("0:3:20", "11:23:15"))
as.difftime(c("3:20", "23:15", "2:"), format=""%H:%M") # 3rd gives NA
(z <- as.difftime(c(0,30,60), units = "mins"))
as.numeric(z, units = "secs")
as.numeric(z, units = "hours")
format(z)

---

**dim**

**Dimensions of an Object**

Description

Retrieve or set the dimension of an object.

Usage

```r
dim(x)
dim(x) <- value
```

Arguments

- **x**
  - an **R** object, for example a matrix, array or data frame.

- **value**
  - For the default method, either **NULL** or a numeric vector, which is coerced to integer (by truncation).

Details

The functions **dim** and **dim<-** are **internal generic primitive** functions.

**dim** has a method for **data.frames**, which returns the lengths of the **row.names** attribute of x and of x (as the numbers of rows and columns respectively).

Value

For an array (and hence in particular, for a matrix) **dim** retrieves the **dim** attribute of the object. It is **NULL** or a vector of mode **integer**.

The replacement method changes the "**dim**" attribute (provided the new value is compatible) and removes any "**dimnames**" and "**names**" attributes.

References

See Also

ncol, nrow and dimnames.

Examples

```r
x <- 1:12 ; dim(x) <- c(3,4)
x

# simple versions of nrow and ncol could be defined as follows
nrow0 <- function(x) dim(x)[1]
col0 <- function(x) dim(x)[2]
```

Arguments

- `x` an R object, for example a matrix, array or data frame.
- `value` a possible value for `dimnames(x)`: see the ‘Value’ section.
- `sep` a character string, used to separate base symbols and digits in the constructed `dimnames`.
- `base` a non-empty list of character vectors. The list components are used in turn (and recycled when needed) to construct replacements for empty `dimnames` components. See also the examples.

Details

The functions `dimnames` and `dimnames<-` are generic.

For an `array` (and hence in particular, for a `matrix`), they retrieve or set the `dimnames` attribute (see `attributes`) of the object. A list `value` can have names, and these will be used to label the dimensions of the array where appropriate.

The replacement method for arrays/matrices coerces vector and factor elements of `value` to character, but does not dispatch methods for `as.character`. It coerces zero-length elements to `NULL`, and a zero-length list to `NULL`. If `value` is a list shorter than the number of dimensions, it is extended with `NULL`s to the needed length.

Both have methods for data frames. The `dimnames` of a data frame are its `row.names` and its `names`. For the replacement method each component of `value` will be coerced by `as.character`.

For a 1D matrix the `names` are the same thing as the (only) component of the `dimnames`. 
Both are primitive functions.

`provideDimnames(x)` provides dimnames where “missing”, such that its result has character dimnames for each component.

**Value**

The dimnames of a matrix or array can be NULL (which is not stored) or a list of the same length as `dim(x)`. If a list, its components are either NULL or a character vector with positive length of the appropriate dimension of `x`. The list can have names. It is possible that all components are NULL: such dimnames may get converted to NULL.

For the "data.frame" method both dimnames are character vectors, and the rownames must contain no duplicates nor missing values.

`provideDimnames(x)` returns `x`, with “NULL - free” dimnames, i.e. each component a character vector of correct length.

**Note**

Setting components of the dimnames, e.g., `dimnames(A)[[1]] <- value` is a common paradigm, but note that it will not work if the value assigned is NULL. Use `rownames` instead, or (as it does) manipulate the whole dimnames list.

**References**

**See Also**

`rownames, colnames; array, matrix, data.frame`.

**Examples**

```r
## simple versions of rownames and colnames
## could be defined as follows
rownames0 <- function(x) dimnames(x)[[1]]
colnames0 <- function(x) dimnames(x)[[2]]

(dn <- dimnames(A <- provideDimnames(N <- array(1:24, dim = 2:4))))
A0 <- A; dimnames(A0)[2:3] <- list(NULL)
stopifnot(identical(A0 , provideDimnames(A))
str <- function(x) utils::str(dimnames(x))
str(provideDimnames(A, base= list(letters[-(1:9)], tail(LETTERS))))
str(provideDimnames(A, base= list(letters[-(1:9)], tail(LETTERS))))
str(provideDimnames(N, base= list(letters[-(1:9)], tail(LETTERS)))) # recycling
str(provideDimnames(A, base= list(c("AA","BB")))) # recycling on both levels
```
do.call

Execute a Function Call

Description

do.call constructs and executes a function call from a name or a function and a list of arguments to be passed to it.

Usage

do.call(what, args, quote = FALSE, envir = parent.frame())

Arguments

what either a function or a non-empty character string naming the function to be called.

args a list of arguments to the function call. The names attribute of args gives the argument names.

quote a logical value indicating whether to quote the arguments.

envir an environment within which to evaluate the call. This will be most useful if what is a character string and the arguments are symbols or quoted expressions.

Details

If quote is FALSE, the default, then the arguments are evaluated (in the calling environment, not in envir). If quote is TRUE then each argument is quoted (see quote) so that the effect of argument evaluation is to remove the quotes – leaving the original arguments unevaluated when the call is constructed.

The behavior of some functions, such as substitute, will not be the same for functions evaluated using do.call as if they were evaluated from the interpreter. The precise semantics are currently undefined and subject to change.

Value

The result of the (evaluated) function call.

Warning

This should not be used to attempt to evade restrictions on the use of .Internal and other non-API calls.

References

do.call(f, list(A), envir = env)  # 2
do.call("f", list(quote(A)), envir = env)  # 100
do.call(f, list(quote(A)), envir = env)  # 10

eval(call("f", A))  # 2

eval(call("f", quote(A)))  # 2

eval(call("f", A), envir = env)  # 4

eval(call("f", quote(A)), envir = env)  # 100

double

Double-Precision Vectors

Description

Create, coerce to or test for a double-precision vector.

Usage

double(length = 0)
as.double(x, ...)
is.double(x)

single(length = 0)
as.single(x, ...)

Arguments

length A non-negative integer specifying the desired length. Double values will be coerced to integer: supplying an argument of length other than one is an error.
x object to be coerced or tested.
... further arguments passed to or from other methods.
double creates a double-precision vector of the specified length. The elements of the vector are all equal to 0. It is identical to numeric.

as.double is a generic function. It is identical to as.numeric. Methods should return an object of base type "double".

is.double is a test of double type.

R has no single precision data type. All real numbers are stored in double precision format. The functions as.single and single are identical to as.double and double except they set the attribute Csingle that is used in the .C and .Fortran interface, and they are intended only to be used in that context.

Value

double creates a double-precision vector of the specified length. The elements of the vector are all equal to 0.

as.double attempts to coerce its argument to be of double type: like as.vector it strips attributes including names. (To ensure that an object is of double type without stripping attributes, use storage.mode.) Character strings containing optional whitespace followed by either a decimal representation or a hexadecimal representation (starting with 0x or 0X) can be converted, as can special values such as "NA", "NaN", "Inf" and "infinity", irrespective of case.

as.double for factors yields the codes underlying the factor levels, not the numeric representation of the labels, see also factor.

is.double returns TRUE or FALSE depending on whether its argument is of double type or not.

Double-precision values

All R platforms are required to work with values conforming to the IEC 60559 (also known as IEEE 754) standard. This basically works with a precision of 53 bits, and represents to that precision a range of absolute values from about $2 \times 10^{-308}$ to $2 \times 10^{308}$. It also has special values NaN (many of them), plus and minus infinity and plus and minus zero (although R acts as if these are the same). There are also denormalized (or subnormal) numbers with absolute values above or below the range given above but represented to less precision.

See .Machine for precise information on these limits. Note that ultimately how double precision numbers are handled is down to the CPU/FPU and compiler.

In IEEE 754-2008/IEC60559:2011 this is called ‘binary64’ format.

Note on names

It is a historical anomaly that R has two names for its floating-point vectors, double and numeric (and formerly had real).

double is the name of the type. numeric is the name of the mode and also of the implicit class. As an S4 formal class, use "numeric".

The potential confusion is that R has used mode "numeric" to mean ‘double or integer’, which conflicts with the S4 usage. Thus is.numeric tests the mode, not the class, but as.numeric (which is identical to as.double) coerces to the class.

integer, numeric, storage.mode.

Examples

is.double(1)
all(double(3) == 0)

dput

Write an Object to a File or Recreate it

Description

Writes an ASCII text representation of an R object to a file or connection, or uses one to recreate the object.

Usage

dput(x, file = "",
control = c("keepNA", "keepInteger", "showAttributes"))

dget(file)

Arguments

x
file
control

an object.
either a character string naming a file or a connection. "" indicates output to the console.
character vector indicating deparsing options. See .deparseOpts for their description.

Details

dput opens file and deparses the object x into that file. The object name is not written (unlike dump). If x is a function the associated environment is stripped. Hence scoping information can be lost.

Deparsing an object is difficult, and not always possible. With the default control, dput() attempts to deparse in a way that is readable, but for more complex or unusual objects (see dump, not likely to be parsed as identical to the original. Use control = "all" for the most complete deparsing; use control = NULL for the simplest deparsing, not even including attributes.
drop will warn if fewer characters were written to a file than expected, which may indicate a full or corrupt file system.

To display saved source rather than deparsing the internal representation include "useSource" in control. R currently saves source only for function definitions.

Value

For dput, the first argument invisibly.

For dget, the object created.

Note

To avoid the risk of a source attribute out of sync with the actual function definition, the source attribute of a function will never be written as an attribute.

References

See Also

deparse, dump, write.

Examples

```r
## Write an ASCII version of mean to the file "foo"
dput(mean, "foo")
## And read it back into 'bar'
bar <- dget("foo")
unlink("foo")
## Create a function with comments
baz <- function(x) {
  # Subtract from one
  1-x
}
## and display it
dput(baz)
## and now display the saved source
dput(baz, control = "useSource")
```

Description

Delete the dimensions of an array which have only one level.

Usage

drop(x)
Arguments

\( x \) an array (including a matrix).

Value

If \( x \) is an object with a \texttt{dim} attribute (e.g., a matrix or \texttt{array}), then \texttt{drop} returns an object like \( x \), but with any extents of length one removed. Any accompanying \texttt{dimnames} attribute is adjusted and returned with \( x \): if the result is a vector the names are taken from the \texttt{dimnames} (if any). If the result is a length-one vector, the names are taken from the first dimension with a dimname.

Array subsetting ([) performs this reduction unless used with \texttt{drop = FALSE}, but sometimes it is useful to invoke \texttt{drop} directly.

See Also

drop1 which is used for dropping terms in models.

Examples

dim(drop(array(1:12, dim = c(1,3,1,1,2,1,2)))) # = 3 2 2
drop(1:3 %*% 2:4) # scalar product

droplevels

Description

The function \texttt{droplevels} is used to drop unused levels from a factor or, more commonly, from factors in a data frame.

Usage

\[
\begin{align*}
\text{## S3 method for class 'factor'} \\
\text{droplevels}(x, \ldots)
\end{align*}
\]

\[
\begin{align*}
\text{## S3 method for class 'data.frame'} \\
\text{droplevels}(x, \text{except}, \ldots)
\end{align*}
\]

Arguments

\( x \) an object from which to drop unused factor levels.

\( \ldots \) further arguments passed to methods

\( \text{except} \) indices of columns from which \textit{not} to drop levels

Details

The method for class "factor" is essentially equivalent to \texttt{factor(x)}.

The except argument follow the usual indexing rules.

Value

droplevels returns an object of the same class as \( x \).
Note

This function was introduced in R 2.12.0. It is primarily intended for cases where one or more factors in a data frame contains only elements from a reduced level set after subsetting. (Notice that subsetting does not in general drop unused levels). By default, levels are dropped from all factors in a data frame, but the except argument allows you to specify columns for which this is not wanted.

See Also

subset for subsetting data frames. factor for definition of factors. drop for dropping array dimensions. drop1 for dropping terms from a model. [.factor for subsetting of factors.

Examples

```r
aq <- transform(airquality, Month = factor(Month, labels = month.abb[5:9]))
aq <- subset(aq, Month != "Jul")
table(aq$Month)
table(droplevels(aq)$Month)
```

---

### dump

**Text Representations of R Objects**

**Description**

This function takes a vector of names of R objects and produces text representations of the objects on a file or connection. A dump file can usually be sourced into another R (or S) session.

**Usage**

```r
dump(list, file = "dumpdata.R", append = FALSE, control = "all", envir = parent.frame(), evaluate = TRUE)
```

**Arguments**

- **list** character. The names of one or more R objects to be dumped.
- **file** either a character string naming a file or a connection. "" indicates output to the console.
- **append** if TRUE and file is a character string, output will be appended to file; otherwise, it will overwrite the contents of file.
- **control** character vector indicating deparsing options. See .deparseOpts for their description.
- **envir** the environment to search for objects.
- **evaluate** logical. Should promises be evaluated?
Details

If some of the objects named do not exist (in scope), they are omitted, with a warning. If file is a file and no objects exist then no file is created.

sourceing may not produce an identical copy of dumped objects. A warning is issued if it is likely that problems will arise, for example when dumping exotic or complex objects (see the Note).

dump will also warn if fewer characters were written to a file than expected, which may indicate a full or corrupt file system.

A dump file can be sourced into another R (or perhaps S) session, but the function save is designed to be used for transporting R data, and will work with R objects that dump does not handle.

To produce a more readable representation of an object, use control = NULL. This will skip attributes, and will make other simplifications that make source less likely to produce an identical copy. See deparse for details.

To deparse the internal representation of a function rather than displaying the saved source, use control = c("keepInteger", "warnIncomplete", "keepNA"). This will lose all formatting and comments, but may be useful in those cases where the saved source is no longer correct.

Promises will normally only be encountered by users as a result of lazy-loading (when the default evaluate = TRUE is essential) and after the use of delayedAssign, when evaluate = FALSE might be intended.

Value

An invisible character vector containing the names of the objects which were dumped.

Note

As dump is defined in the base namespace, the base package will be searched before the global environment unless dump is called from the top level prompt or the envir argument is given explicitly.

To avoid the risk of a source attribute becoming out of sync with the actual function definition, the source attribute of a function will never be dumped as an attribute.

Currently environments, external pointers, weak references and objects of type S4 are not deparsed in a way that can be sourced. In addition, language objects are deparsed in a simple way whatever the value of control, and this includes not dumping their attributes (which will result in a warning).

References

See Also
dput, dget, write.
save for a more reliable way to save R objects.

Examples

```r
x <- 1; y <- 1:10
dump(ls(pattern = '^\[xyz\]'), "xyz.Rdmped")
print(.Last.value)
unlink("xyz.Rdmped")
```
**duplicated**  

**Determine Duplicate Elements**

**Description**

duplicated() determines which elements of a vector or data frame are duplicates of elements with smaller subscripts, and returns a logical vector indicating which elements (rows) are duplicates. anyDuplicated(.) is a “generalized” more efficient shortcut for any(duplicated(.)).

**Usage**

duplicated(x, incomparables = FALSE, ...)

## Default S3 method:
duplicated(x, incomparables = FALSE,
   fromLast = FALSE, nmax = NA, ...)

## S3 method for class 'array'
duplicated(x, incomparables = FALSE, MARGIN = 1,
   fromLast = FALSE, ...)

anyDuplicated(x, incomparables = FALSE, ...)

## Default S3 method:
anyDuplicated(x, incomparables = FALSE,
   fromLast = FALSE, ...)

## S3 method for class 'array'
anyDuplicated(x, incomparables = FALSE,
   MARGIN = 1, fromLast = FALSE, ...)

**Arguments**

- **x**  
  a vector or a data frame or an array or NULL.

- **incomparables**  
  a vector of values that cannot be compared. FALSE is a special value, meaning that all values can be compared, and may be the only value accepted for methods other than the default. It will be coerced internally to the same type as x.

- **fromLast**  
  logical indicating if duplication should be considered from the reverse side, i.e., the last (or rightmost) of identical elements would correspond to duplicated = FALSE.

- **nmax**  
  the maximum number of unique items expected.

- **MARGIN**  
  the array margin to be held fixed: see apply, and note that MARGIN = 0 maybe useful.

**Details**

These are generic functions with methods for vectors (including lists), data frames and arrays (including matrices).

For the default methods, and whenever there are equivalent method definitions for duplicated and anyDuplicated, anyDuplicated(x, ...) is a “generalized” shortcut for
any(duplicated(x, ...)), in the sense that it returns the index i of the first duplicated entry \(x[i]\) if there is one, and \(\emptyset\) otherwise. Their behaviours may be different when at least one of duplicated and anyDuplicated has a relevant method.

\[ \text{duplicated}(x, \text{fromLast} = \text{TRUE}) \text{ is equivalent to but faster than } \text{rev(duplicated}(	ext{rev}(x))). \]

The data frame method works by pasting together a character representation of the rows separated by \(\backslash\text{r}\), so may be imperfect if the data frame has characters with embedded carriage returns or columns which do not reliably map to characters.

The array method calculates for each element of the sub-array specified by \text{MARGIN} if the remaining dimensions are identical to those for an earlier (or later, when \text{fromLast} = \text{TRUE}) element (in row-major order). This would most commonly be used to find duplicated rows (the default) or columns (with \text{MARGIN} = 2). Note that \text{MARGIN} = \emptyset returns an array of the same dimensionality attributes as \(x\).

Missing values are regarded as equal, but NaN is not equal to \text{NA\_real\_}.

Values in incomparables will never be marked as duplicated. This is intended to be used for a fairly small set of values and will not be efficient for a very large set.

When used on a data frame with more than one column, or an array or matrix when comparing dimensions of length greater than one, this tests for identity of character representations. This will catch people who unwisely rely on exact equality of floating-point numbers!

Character strings will be compared as byte sequences if any input is marked as "bytes".

Except for factors, logical and raw vectors the default \text{nmax} = NA is equivalent to \text{nmax} = length\(\text{x}\). Since a hash table of size 8*\text{nmax} bytes is allocated, setting \text{nmax} suitably can save large amounts of memory. For factors it is automatically set to the smaller of length\(\text{x}\) and the number of levels plus one (for NA)

\text{Long vectors} are supported for the default method of duplicated, but may only be usable if \text{nmax} is supplied.

Value

\text{duplicated()}: For a vector input, a logical vector of the same length as \(x\). For a data frame, a logical vector with one element for each row. For a matrix or array, and when \text{MARGIN} = \emptyset, a logical array with the same dimensions and dimnames.

\text{anyDuplicated()}: a non-negative integer vector of length one.

Warning

Using this for lists is potentially slow, especially if the elements are not atomic vectors (see \text{vector}) or differ only in their attributes. In the worst case it is \(O(n^2)\).

x <- c(9:20, 1:5, 3:7, 0:8)
# extract unique elements
(xu <- x[!duplicated(x)])
# similar, same elements but different order:
(xu2 <- x[!duplicated(x, fromLast = TRUE)])
# xu == unique(x) but unique(x) is more efficient
stopifnot(identical(xu, unique(x)),
          identical(xu2, unique(x, fromLast = TRUE)))

duplicated(iris)[140:143]
duplicated(iris3, MARGIN = c(1, 3))
anyDuplicated(iris) ## 143
anyDuplicated(x)
anyDuplicated(x, fromLast = TRUE)
```

---

dyn.load Foreign Function Interface

Description

Load or unload DLLs (also known as shared objects), and test whether a C function or Fortran subroutine is available.

Usage

```r
dyn.load(x, local = TRUE, now = TRUE, ...)
dyn.unload(x)

is.loaded(symbol, PACKAGE = "", type = "")
```

Arguments

- **x** a character string giving the pathname to a DLL, also known as a dynamic shared object. (See ‘Details’ for what these terms mean.)
- **local** a logical value controlling whether the symbols in the DLL are stored in their own local table and not shared across DLLs, or added to the global symbol table. Whether this has any effect is system-dependent.
- **now** a logical controlling whether all symbols are resolved (and relocated) immediately the library is loaded or deferred until they are used. This control is useful for developers testing whether a library is complete and has all the necessary symbols, and for users to ignore missing symbols. Whether this has any effect is system-dependent.
- **symbol** a character string giving a symbol name.
if supplied, confine the search for the name to the DLL given by this argument (plus the conventional extension, ‘.so’, ‘.s1’, ‘.dll’, ...). This is intended to add safety for packages, which can ensure by using this argument that no other package can override their external symbols. This is used in the same way as in .C, .Call, .Fortran and .External functions.

type The type of symbol to look for: can be any ("", the default), "Fortran", "Call" or "External".

Details

The objects dyn.load loads are called ‘dynamically loadable libraries’ (abbreviated to ‘DLL’) on all platforms except OS X, which uses the term for a different sort of object. On Unix-alikes they are also called ‘dynamic shared objects’ (‘DSO’), or ‘shared objects’ for short. (The POSIX standards use ‘executable object file’, but no one else does.)

See ‘See Also’ and the ‘Writing R Extensions’ and ‘R Installation and Administration’ manuals for how to create and install a suitable DLL.

Unfortunately a very few platforms (e.g. Compaq Tru64) do not handle the PACKAGE argument correctly, and may incorrectly find symbols linked into R.

The additional arguments to dyn.load mirror the different aspects of the mode argument to the dlopen() routine on POSIX systems. They are available so that users can exercise greater control over the loading process for an individual library. In general, the default values are appropriate and you should override them only if there is good reason and you understand the implications.

The local argument allows one to control whether the symbols in the DLL being attached are visible to other DLLs. While maintaining the symbols in their own namespace is good practice, the ability to share symbols across related ‘chapters’ is useful in many cases. Additionally, on certain platforms and versions of an operating system, certain libraries must have their symbols loaded globally to successfully resolve all symbols.

One should be careful of the potential side-effect of using lazy loading via the now argument as FALSE. If a routine is called that has a missing symbol, the process will terminate immediately. The intended use is for library developers to call with value TRUE to check that all symbols are actually resolved and for regular users to call with FALSE so that missing symbols can be ignored and the available ones can be called.

The initial motivation for adding these was to avoid such termination in the _init() routines of the Java virtual machine library. However, symbols loaded locally may not be (read probably) available to other DLLs. Those added to the global table are available to all other elements of the application and so can be shared across two different DLLs.

Some (very old) systems do not provide (explicit) support for local/global and lazy/eager symbol resolution. This can be the source of subtle bugs. One can arrange to have warning messages emitted when unsupported options are used. This is done by setting either of the options verbose or warn to be non-zero via the options function.

There is a short discussion of these additional arguments with some example code available at http://cm.bell-labs.com/stat/duncan/R/dynload.

Value

The function dyn.load is used for its side effect which links the specified DLL to the executing R image. Calls to .C, .Call, .Fortran and .External can then be used to execute compiled C functions or Fortran subroutines contained in the library. The return value of dyn.load is an object of class DLLInfo. See getLoadedDLLs for information about this class.
The function `dyn.unload` unlinks the DLL. Note that unloading a DLL and then re-loading a DLL of the same name may or may not work: on Solaris it uses the first version loaded.

`is.loaded` checks if the symbol name is loaded *and searchable* and hence available for use as a character string value for argument `.NAME` in `.C` or `.Fortran` or `.Call` or `.External`. It will succeed if any one of the four calling functions would succeed in using the entry point unless type is specified. (See `.Fortran` for how Fortran symbols are mapped.) Note that symbols in base packages are not searchable, and other packages can be so marked.

**Warning**

Do not use `dyn.unload` on a DLL loaded by `library.dynam`; use `library.dynam.unload`. This is needed for system housekeeping.

**Note**

`is.loaded` requires the name you would give to `.C` etc and **not** (as in S) that remapped by the defunct functions `symbol.C` or `symbol.For`.

The creation of DLLs and the runtime linking of them into executing programs is very platform dependent. In recent years there has been some simplification in the process because the C subroutine call `dlopen` has become the POSIX standard for doing this. Under Unix-alikes `dyn.load` uses the `dlopen` mechanism and should work on all platforms which support it. On Windows it uses the standard mechanism (`LoadLibrary`) for loading DLLs.

The original code for loading DLLs in Unix-alikes was provided by Heiner Schwarte.

**References**

**See Also**

`library.dynam` to be used inside a package’s `.onLoad` initialization.

`SHLIB` for how to create suitable DLLs.

**Examples**

```r
## expect all of these to be false in R >= 3.0.0.
is.loaded("supsmu") # Fortran entry point in stats
is.loaded("supsmu", "stats", "Fortran")
is.loaded("PDF", type = "External") # pdf() device in grDevices
```
### Usage

eapply(env, FUN, ..., all.names = FALSE, USE.NAMES = TRUE)

### Arguments

- **env**: environment to be used.
- **FUN**: the function to be applied, found via `match.fun`. In the case of functions like `+`, `%*%`, etc., the function name must be backquoted or quoted.
- **...**: optional arguments to `FUN`.
- **all.names**: a logical indicating whether to apply the function to all values.
- **USE.NAMES**: logical indicating whether the resulting list should have names.

### Value

A named (unless `USE.NAMES = FALSE`) list. Note that the order of the components is arbitrary for hashed environments.

### See Also

- `environment`, `lapply`.

### Examples

```r
require(stats)

env <- new.env(hash = FALSE) # so the order is fixed
env$a <- 1:10
env$beta <- exp(-3:3)
env$logic <- c(TRUE, FALSE, FALSE, TRUE)
# what have we there?
utils::ls.str(env)

# compute the mean for each list element
eapply(env, mean)
unlist(eapply(env, mean, USE.NAMES = FALSE))

# median and quartiles for each element (making use of "...") passing:
eapply(env, quantile, probs = 1:3/4)
eapply(env, quantile)
```

---

### eigen

**Spectral Decomposition of a Matrix**

### Description

Computes eigenvalues and eigenvectors of numeric (double, integer, logical) or complex matrices.

### Usage

```r
eigen(x, symmetric, only.values = FALSE, EISPACK = FALSE)
```
Arguments

- **x**: a numeric or complex matrix whose spectral decomposition is to be computed. Logical matrices are coerced to numeric.
- **symmetric**: if TRUE, the matrix is assumed to be symmetric (or Hermitian if complex) and only its lower triangle (diagonal included) is used. If symmetric is not specified, the matrix is inspected for symmetry.
- **only.values**: if TRUE, only the eigenvalues are computed and returned, otherwise both eigenvalues and eigenvectors are returned.
- **EISPACK**: logical. Defunct and ignored (with a warning for true values).

Details

If symmetric is unspecified, the code attempts to determine if the matrix is symmetric up to plausible numerical inaccuracies. It is faster and surer to set the value yourself.

Computing the eigenvectors is the slow part for large matrices.

Computing the eigendecomposition of a matrix is subject to errors on a real-world computer: the definitive analysis is Wilkinson (1965). All you can hope for is a solution to a problem suitably close to x. So even though a real asymmetric x may have an algebraic solution with repeated real eigenvalues, the computed solution may be of a similar matrix with complex conjugate pairs of eigenvalues.

Value

The spectral decomposition of x is returned as components of a list with components

- **values**: a vector containing the p eigenvalues of x, sorted in decreasing order, according to Mod(values) in the asymmetric case when they might be complex (even for real matrices). For real asymmetric matrices the vector will be complex only if complex conjugate pairs of eigenvalues are detected.
- **vectors**: either a p x p matrix whose columns contain the eigenvectors of x, or NULL if only.values is TRUE. The vectors are normalized to unit length.

Recall that the eigenvectors are only defined up to a constant: even when the length is specified they are still only defined up to a scalar of modulus one (the sign for real matrices).

If r <- eigen(x), and V <- r$vectors; lam <- r$values, then

\[ A = V \Lambda V^{-1} \]

(up to numerical fuzz), where \( \Lambda = \text{diag}(\text{lam}) \).

Source

By default eigen uses the LAPACK routines DSYEVR, DGEEV, ZHEEV and ZGEEV whereas LAPACK is from http://www.netlib.org/lapack and its guide is listed in the references.

To compute the determinant of a matrix, the qr decomposition is much more efficient: det.

Examples

eigen(cbind(c(1,-1), c(-1,1)))
eigen(cbind(c(1,-1), c(-1,1)), symmetric = FALSE)
  # same (different algorithm).
eigen(cbind(1, c(1,-1)), only.values = TRUE)
eigen(cbind(-1, 2:1)) # complex values
eigen(print(cbind(c(0, 1i), c(-1i, 0)))) # Hermite ==> real Eigenvalues
  # 3 x 3:
eigen(cbind(1, 3:1, 1:3))
eigen(cbind(-1, c(1:2,0), 0:2)) # complex values

encodeString

Encode Character Vector as for Printing

Description

encodeString escapes the strings in a character vector in the same way print.default does, and optionally fits the encoded strings within a field width.

Usage

encodeString(x, width = 0, quote = "", na.encode = TRUE, justify = c("left", "right", "centre", "none"))

Arguments

x A character vector, or an object that can be coerced to one by as.character.
width integer: the minimum field width. If NULL or NA, this is taken to be the largest field width needed for any element of x.
quote character: quoting character, if any.
na.encode logical: should NA strings be encoded?
justifi character: partial matches are allowed. If padding to the minimum field width is needed, how should spaces be inserted? justify == "none" is equivalent to width = 0, for consistency with format.default.

Details

This escapes backslash and the control characters ‘\a’ (bell), ‘\b’ (backspace), ‘\f’ (formfeed), ‘\n’ (line feed), ‘\r’ (carriage return), ‘\t’ (tab) and ‘\v’ (vertical tab) as well as any non-printable characters in a single-byte locale, which are printed in octal notation (’\xyz’ with leading zeroes).

Which characters are non-printable depends on the current locale. Windows’ reporting of printable characters is unreliable, so there all other control characters are regarded as non-printable, and all
characters with codes 32–255 as printable in a single-byte locale. See \texttt{print.default} for how non-printable characters are handled in multi-byte locales.

If quote is a single or double quote any embedded quote of the same type is escaped. Note that justification is of the quoted string, hence spaces are added outside the quotes.

\textbf{Value}

A character vector of the same length as \texttt{x}, with the same attributes (including names and dimensions) but with no class set.

As from R 3.0.0, marked UTF-8 encodings are preserved.

\textbf{Note}

The default for width is different from \texttt{format.default}, which does similar things for character vectors but without encoding using escapes.

\textbf{See Also}

\texttt{print.default}

\textbf{Examples}

\begin{verbatim}
x <- "ab\bc\ndef"
print(x)
cat(x) # interprets escapes
cat(encodeString(x), "\n", sep = "") # similar to print()

factor(x) # makes use of this to print the levels

x <- c("a", "ab", "abcde")
encodeString(x, width = NA) # left justification
encodeString(x, width = NA, justify = "c")
encodeString(x, width = NA, justify = "r")
encodeString(x, width = NA, quote = "'", justify = "r")
\end{verbatim}

\begin{tabular}{|l|}
\hline
\textbf{Encoding} & \textbf{Read or Set the Declared Encodings for a Character Vector} \\
\hline
\end{tabular}

\textbf{Description}

Read or set the declared encodings for a character vector.

\textbf{Usage}

\begin{verbatim}
Encoding(x)

Encoding(x) <- value

c2native(x)
c2utf8(x)
\end{verbatim}
Encoding

Arguments

x  A character vector.
value  A character vector of positive length.

Details

Character strings in R can be declared to be in "latin1" or "UTF-8" or "bytes". These declarations can be read by Encoding, which will return a character vector of values "latin1", "UTF-8" "bytes" or "unknown", or set, when value is recycled as needed and other values are silently treated as "unknown". ASCII strings will never be marked with a declared encoding, since their representation is the same in all supported encodings. Strings marked as "bytes" are intended to be non-ASCII strings which should be manipulated as bytes, and never converted to a character encoding.

c2native and enc2utf8 convert elements of character vectors to the native encoding or UTF-8 respectively, taking any marked encoding into account. They are primitive functions, designed to do minimal copying.

There are other ways for character strings to acquire a declared encoding apart from explicitly setting it (and these have changed as R has evolved). Functions scan, read.table, readLines, and parse have an encoding argument that is used to declare encodings, iconv declares encodings from its from argument, and console input in suitable locales is also declared. intToUtf8 declares its output as "UTF-8", and output text connections (see textConnection) are marked if running in a suitable locale. Under some circumstances (see its help page) source(encoding=) will mark encodings of character strings it outputs.

Most character manipulation functions will set the encoding on output strings if it was declared on the corresponding input. These include chartr, strsplit(useBytes = FALSE), tolower and toupper as well as sub(useBytes = FALSE) and gsub(useBytes = FALSE). Note that such functions do not preserve the encoding, but if they know the input encoding and that the string has been successfully re-encoded (to the current encoding or UTF-8), they mark the output.

substr does preserve the encoding, and chartr, tolower and toupper preserve UTF-8 encoding on systems with Unicode wide characters. With their fixed and perl options, strsplit, sub and gsub will give a marked UTF-8 result if any of the inputs are UTF-8.

paste and sprintf return elements marked as bytes if any of the corresponding inputs is marked as bytes, and otherwise marked as UTF-8 of any of the inputs is marked as UTF-8.

match, pmatch, charmatch, duplicated and unique all match in UTF-8 if any of the elements are marked as UTF-8.

Value

A character vector.

Examples

### x is intended to be in latin1
x <- "fa\xe7ile"
Encoding(x)
Encoding(x) <- "latin1"
x
xx <- iconv(x, "latin1", "UTF-8")
Encoding(c(x, xx))
c(x, xx)
Encoding(xx) <- "bytes"
Description

Get, set, test for and create environments.

Usage

environment(fun = NULL)
environment(fun) <- value

is.environment(x)

.GlobalEnv
globalenv()
.BaseNamespaceEnv

emptyenv()
baseenv()

c new.env(hash = TRUE, parent = parent.frame(), size = 29L)

parent.env(env)
parent.env(env) <- value

environmentName(env)

e n v. profile(env)

Arguments

fun a function, a formula, or NULL, which is the default.

value an environment to associate with the function

x an arbitrary R object.

hash a logical, if TRUE the environment will use a hash table.

parent an environment to be used as the enclosure of the environment created.

e nv an environment

size an integer specifying the initial size for a hashed environment. An internal default value will be used if size is NA or zero. This argument is ignored if hash is FALSE.
Details

Environments consist of a frame, or collection of named objects, and a pointer to an enclosing environment. The most common example is the frame of variables local to a function call; its enclosure is the environment where the function was defined (unless changed subsequently). The enclosing environment is distinguished from the parent frame: the latter (returned by `parent.frame`) refers to the environment of the caller of a function. Since confusion is so easy, it is best never to use ‘parent’ in connection with an environment (despite the presence of the function `parent.env`).

When `get` or `exists` search an environment with the default `inherits = TRUE`, they look for the variable in the frame, then in the enclosing frame, and so on.

The global environment `.GlobalEnv`, more often known as the user’s workspace, is the first item on the search path. It can also be accessed by `globals()`. On the search path, each item’s enclosure is the next item.

The object `.BaseNamespaceEnv` is the namespace environment for the base package. The environment of the base package itself is available as `baseenv`.

If one follows the chain of enclosures found by repeatedly calling `parent.env` from any environment, eventually one reaches the empty environment `emptyenv`, into which nothing may be assigned.

The replacement function `parent.env <-` is extremely dangerous as it can be used to destructively change environments in ways that violate assumptions made by the internal C code. It may be removed in the near future.

The replacement form of `environment`, `is.environment`, `baseenv`, `emptyenv` and `globalenv` are primitive functions.

System environments, such as the base, global and empty environments, have names as do the package and namespace environments and those generated by `attach()`. Other environments can be named by giving a "name" attribute, but this needs to be done with care as environments have unusual copying semantics.

Value

If `fun` is a function or a formula then `environment(fun)` returns the environment associated with that function or formula. If `Fun` is `NULL` then the current evaluation environment is returned.

The replacement form sets the environment of the function or formula `fun` to the value given.

`is.environment(obj)` returns `TRUE` if and only if `obj` is an environment.

`new.env` returns a new (empty) environment with (by default) enclosure the parent frame.

`parent.env` returns the enclosing environment of its argument.

`parent.env <-` sets the enclosing environment of its first argument.

`environmentName` returns a character string, that given when the environment is printed or "" if it is not a named environment.

`env.profile` returns a list with the following components: `size` the number of chains that can be stored in the hash table, `nchains` the number of non-empty chains in the table (as reported by `HASHPRI`), and `counts` an integer vector giving the length of each chain (zero for empty chains). This function is intended to assess the performance of hashed environments. When `env` is a nonhashed environment, `NULL` is returned.

See Also

The \texttt{envir} argument of \texttt{eval}, \texttt{get}, and \texttt{exists}. \texttt{ls} may be used to view the objects in an environment, and hence \texttt{ls.str} may be useful for an overview. \texttt{sys.source} can be used to populate an environment.

\textbf{Examples}

\begin{verbatim}
f <- function() "top level function"

### all three give the same:
environment()
environment(f)
.GlobalEnv

ls(envir = environment(stats::approxfun(1:2, 1:2, method = "const")))

is.environment(.GlobalEnv) # TRUE

e1 <- new.env(parent = baseenv()) # this one has enclosure package:base.
e2 <- new.env(parent = e1)
assign("a", 3, envir = e1)
ls(e1)
ls(e2)
exists("a", envir = e2) # this succeeds by inheritance
exists("a", envir = e2, inherits = FALSE)
exists("+", envir = e2) # this succeeds by inheritance

eh <- new.env(hash = TRUE, size = NA)
with(env.profile(eh), stopifnot(size == length(counts)))
\end{verbatim}

\begin{table}[h]
\centering
\begin{tabular}{ll}
\hline
\textbf{EnvVar} & \textbf{Environment Variables} \\
\hline
\end{tabular}
\end{table}

\textbf{Description}

Details of some of the environment variables which affect an \proglang{R} session.

\textbf{Details}

It is impossible to list all the environment variables which can affect an \proglang{R} session: some affect the OS system functions which \proglang{R} uses, and others will affect add-on packages. But here are notes on some of the more important ones. Those that set the defaults for options are consulted only at startup (as are some of the others).

\texttt{HOME}: The user’s ‘home’ directory.

\texttt{LANGUAGE}: Optional. The language(s) to be used for message translations. This is consulted when needed.

\texttt{LC_ALL}: (etc) Optional. Use to set various aspects of the locale – see \texttt{Sys.getlocale}. Consulted at startup.

\texttt{MAKEINDEX}: The path to makeindex. If unset to a value determined when \proglang{R} was built. Used by the emulation mode of \texttt{texi2dvi} and \texttt{texi2pdf}. 

R\_BATCH: Optional – set in a batch session, that is one started by R CMD BATCH. Most often set to "", so test by something like !is.na(Sys.getenv("R\_BATCH", NA)).

R\_BROWSER: The path to the default browser. Used to set the default value of options("browser").

R\_COMPLETION: Optional. If set to FALSE, command-line completion is not used. (Not used by Mac OS GUI)

R\_DEFAULT\_PACKAGES: A comma-separated list of packages which are to be attached in every session. See options.

R\_DOC\_DIR: The location of the R ‘doc’ directory. Set by R.

R\_ENVIRON: Optional. The path to the site environment file: see Startup. Consulted at startup.

R\_GSCMD: Optional. The path to Ghostscript, used by dev2bitmap, bitmap and embedFonts. Consulted when those functions are invoked. Since it will be treated as if passed to system, spaces and shell metacharacters should be escaped.

R\_HISTFILE: Optional. The path of the history file: see Startup. Consulted at startup and when the history is saved.

R\_HISTSIZE: Optional. The maximum size of the history file, in lines. Exactly how this is used depends on the interface. For the readline command-line interface it takes effect when the history is saved (by savehistory or at the end of a session).

R\_HOME: The top-level directory of the R installation: see R.home. Set by R.

R\_INCLUDE\_DIR: The location of the R ‘include’ directory. Set by R.

R\_LIBS: Optional. Used for initial setting of .libPaths.

R\_LIBS\_SITE: Optional. Used for initial setting of .libPaths.

R\_LIBS\_USER: Optional. Used for initial setting of .libPaths.

R\_PAPERSIZE: Optional. Used to set the default for options("papersize"), e.g. used by pdf and postscript.

R\_PDFVIEWER: The path to the default PDF viewer. Used by R CMD Rd2pdf.

R\_PLATFORM: The platform – a string of the form cpu-vendor-os, see R.Version.

R\_PROFILE: Optional. The path to the site profile file: see Startup. Consulted at startup.

R\_RD4PDF: Options for pdfLaTeX processing of Rd files. Used by R CMD Rd2pdf.

R\_SHARE\_DIR: The location of the R ‘share’ directory. Set by R.

R\_TEXI2DVI\_CMD: The path to texi2dvi. Defaults to the value of TEXI2DVI, and if that is unset to a value determined when R was built. Consulted at startup to set the default for options("texi2dvi"), used by texi2dvi and texi2pdf in package tools.

R\_UNZIP\_CMD: The path to unzip. Sets the initial value for options("unzip") on a Unix-alike when namespace utils is loaded.

R\_ZIP\_CMD: The path to zip. Used by zip and by R CMD INSTALL --build on Windows.

TMPDIR, TMP, TEMP: Consulted (in that order) when setting the temporary directory for the session: see tempdir. TMPDIR is also used by some of the utilities see the help for build.

TZ: Optional. The current timezone. See Sys.timezone for the system-specific formats. Consulted as needed.

no_proxy, http_proxy, ftp_proxy: (and more). Optional. Settings for download.file: see its help for further details.
Unix-specific
Some variables set on Unix-alikes, and not (in general) on Windows.

DISPLAY: Optional: used by X11, Tk (in package tcltk), the data editor and various packages.
EDITOR: The path to the default editor: sets the default for options("editor") when namespace utils is loaded.
PAGER: The path to the pager with the default setting of options("pager"). The default value is chosen at configuration, usually as the path to less.
R_PRINTCMD: Sets the default for options("printcmd"), which sets the default print command to be used by postscript.

See Also
Sys.getenv and Sys.setenv to read and set environmental variables in an R session.

---

**eval**

Evaluate an (Unevaluated) Expression

Description
Evaluate an R expression in a specified environment.

Usage

```r
eval(expr, envir = parent.frame(),
     enclos = if(is.list(envir) || is.pairlist(envir))
           parent.frame() else baseenv())
evalq(expr, envir, enclos)
eval.parent(expr, n = 1)
local(expr, envir = new.env())
```

Arguments

- `expr` an object to be evaluated. See ‘Details’.
- `envir` the environment in which expr is to be evaluated. May also be NULL, a list, a data frame, a pairlist or an integer as specified to `sys.call`.
- `enclos` Relevant when envir is a (pair)list or a data frame. Specifies the enclosure, i.e., where R looks for objects not found in envir. This can be NULL (interpreted as the base package environment, `baseenv()`) or an environment.
- `n` number of parent generations to go back

Details
eval evaluates the expr argument in the environment specified by envir and returns the computed value. If envir is not specified, then the default is `parent.frame()` (the environment where the call to eval was made).

Objects to be evaluated can be of types call or expression or name (when the name is looked up in the current scope and its binding is evaluated), a promise or any of the basic types such as vectors, functions and environments (which are returned unchanged).
The `evalq` form is equivalent to `eval(quote(expr), ...)`. `eval` evaluates its first argument in the current scope before passing it to the evaluator: `evalq` avoids this.

`eval.parent(expr, n)` is a shorthand for `eval(expr, parent.frame(n))`.

If `envir` is a list (such as a data frame) or pairlist, it is copied into a temporary environment (with enclosure `enclos`), and the temporary environment is used for evaluation. So if `expr` changes any of the components named in the (pair)list, the changes are lost.

If `envir` is `NULL` it is interpreted as an empty list so no values could be found in `envir` and look-up goes directly to `enclos`.

`local` evaluates an expression in a local environment. It is equivalent to `evalq` except that its default argument creates a new, empty environment. This is useful to create anonymous recursive functions and as a kind of limited namespace feature since variables defined in the environment are not visible from the outside.

**Value**

The result of evaluating the object: for an expression vector this is the result of evaluating the last element.

**Note**

Due to the difference in scoping rules, there are some differences between R and S in this area. In particular, the default enclosure in S is the global environment.

When evaluating expressions in a data frame that has been passed as an argument to a function, the relevant enclosure is often the caller’s environment, i.e., one needs `eval(x, data, parent.frame())`.

**References**

**See Also**

`expression`, `quote`, `sys.frame`, `parent.frame`, `environment`.

Further, `force` to force evaluation, typically of function arguments.

**Examples**

```r
eval(2 ^ 2 ^ 3)
mEx <- expression(2^2^3); mEx; 1 + eval(mEx)
eval({ xx <- p1; xx^2 }) ; xx

a <- 3 ; aa <- 4 ; evalq(evalq(a+b+aa, list(a = 1)), list(b = 5)) # == 10
a <- 3 ; aa <- 4 ; evalq(evalq(a+b+aa, -1), list(b = 5)) # == 12

ev <- function() {
  el <- parent.frame()
  ## Evaluate a in el
  aa <- eval(expression(a), el)
  ## evaluate the expression bound to a in el
  a <- expression(x+y)
  list(aa = aa, eval = eval(a, el))
}
```
tst.ev <- function(a = 7) { x <- pi; y <- 1; ev() }
tst.ev() #> a : 7, eval : 4.14

a <- list(a = 3, b = 4)
with(a, a <- 5) # alters the copy of a from the list, discarded.

##
## Example of evalq()
##

N <- 3
eval <- new.env()
assign("N", 27, envir = env)
## this version changes the visible copy of N only, since the argument
## passed to eval is '4'.
eval(N <- 4, env)
N
evalq(N <- 5, env)
N
evalq(N, env = env)

##
## Uses of local()
##

# Mutually recursive.
# gg gets value of last assignment, an anonymous version of f.

gg <- local({
  k <- function(y)f(y)
  f <- function(x) if(x) x*k(x-1) else 1
})
sapply(1:5, gg)

# Nesting locals: a is private storage accessible to k
gg <- local({
  k <- local({
    a <- 1
    function(y)print(a <<- a+1);f(y)
  })
  f <- function(x) if(x) x*k(x-1) else 1
})
sapply(1:5, gg)
ls(envir = environment(gg))
ls(envir = environment(get("k", envir = environment(gg))))
Description

Look for an R object of the given name.

Usage

exists(x, where = -1, envir = , frame, mode = "any",
        inherits = TRUE)

Arguments

x a variable name (given as a character string).
where where to look for the object (see the details section); if omitted, the function will
        search as if the name of the object appeared unquoted in an expression.
envir an alternative way to specify an environment to look in, but it is usually simpler
        to just use the where argument.
frame a frame in the calling list. Equivalent to giving where as sys.frame(frame).
mode the mode or type of object sought: see the ‘Details’ section.
inherits should the enclosing frames of the environment be searched?

Details

The where argument can specify the environment in which to look for the object in any of several
ways: as an integer (the position in the search list); as the character string name of an element
in the search list; or as an environment (including using sys.frame to access the currently active
function calls). The envir argument is an alternative way to specify an environment, but is primarily
there for back compatibility.

This function looks to see if the name x has a value bound to it in the specified environment. If
inherits is TRUE and a value is not found for x in the specified environment, the enclosing frames
of the environment are searched until the name x is encountered. See environment and the ‘R
Language Definition’ manual for details about the structure of environments and their enclosures.

Warning: inherits = TRUE is the default behaviour for R but not for S.

If mode is specified then only objects of that type are sought. The mode may specify one of the
collections "numeric" and "function" (see mode): any member of the collection will suffice.
(This is true even if a member of a collection is specified, so for example mode = "special" will
seek any type of function.)

Value

Logical, true if and only if an object of the correct name and mode is found.

See Also

get. For quite a different kind of “existence” checking, namely if function arguments were speci-
fied, missing; and for yet a different kind, namely if a file exists, file.exists.
Examples

```r
## Define a substitute function if necessary:
if(!exists("some.fun", mode = "function"))
  some.fun <- function(x) { cat("some.fun(x)\n"); x }
search()
exists("ls", 2) # true even though ls is in pos = 3
exists("ls", 2, inherits = FALSE) # false
```

expand.grid

Create a Data Frame from All Combinations of Factors

Description

Create a data frame from all combinations of the supplied vectors or factors. See the description of
the return value for precise details of the way this is done.

Usage

```r
expand.grid(..., KEEP.OUT.ATTRS = TRUE, stringsAsFactors = TRUE)
```

Arguments

- `...` vectors, factors or a list containing these.
- `KEEP.OUT.ATTRS` a logical indicating the "out.attrs" attribute (see below) should be computed and returned.
- `stringsAsFactors` logical specifying if character vectors are converted to factors.

Value

A data frame containing one row for each combination of the supplied factors. The first factors vary
fastest. The columns are labelled by the factors if these are supplied as named arguments or named
components of a list. The row names are 'automatic'.

Attribute "out.attrs" is a list which gives the dimension and dimnames for use by predict methods.

Note

Conversion to a factor is done with levels in the order they occur in the character vectors (and not
alphabetically, as is most common when converting to factors).

expression

<table>
<thead>
<tr>
<th>expression</th>
<th>Unevaluated Expressions</th>
</tr>
</thead>
</table>

Description

Creates or tests for objects of mode "expression".

Usage

expression(...)

is.expression(x)
as.expression(x, ...)

Arguments

... expression: R objects, typically calls, symbols or constants.
as.expression: arguments to be passed to methods.
x an arbitrary R object.

Details

‘Expression’ here is not being used in its colloquial sense, that of mathematical expressions. Those are calls (see call) in R, and an R expression vector is a list of calls, symbols etc, for example as returned by parse.

As an object of mode "expression" is a list, it can be subsetted by [], [[] or $, the latter two extracting individual calls etc. The replacement forms of these operators can be used to replace or delete elements.

equation and is.expression are primitive functions. expression is ‘special’: it does not evaluate its arguments.
Value

evaluation expression returns a vector of type "expression" containing its arguments (unevaluated).

is.expression returns TRUE if expr is an expression object and FALSE otherwise.

as.expression attempts to coerce its argument into an expression object. It is generic, and only the
default method is described here. (The default method calls as.vector(type = "expression")
and so may dispatch methods for as.vector.) NULL, calls, symbols (see as.symbol) and pairlists
are returned as the element of a length-one expression vector. Atomic vectors are placed element-
by-element into an expression vector (without using any names): lists are changed type to an ex-
pression vector (keeping all attributes). Other types are not currently supported.

Extract or Replace Parts of an Object

**Description**

Operators acting on vectors, matrices, arrays and lists to extract or replace parts.

**Usage**

```r
x[i]
x[i, j, ... , drop = TRUE]
x[[i, exact = TRUE]]
x[[i, j, ... , exact = TRUE]]
x$name
ggetElement(object, name)

x[i] <- value
x[i, j, ...] <- value
x[[i]] <- value
x$i <- value
```
Arguments

\textbf{x}, \textbf{object} \quad \text{object from which to extract element(s) or in which to replace element(s).}

\textbf{i, j, ...} \quad \text{indices specifying elements to extract or replace. Indices are numeric or character vectors or empty (missing) or NULL. Numeric values are coerced to integer as by \texttt{as.integer} (and hence truncated towards zero). Character vectors will be matched to the \texttt{names} of the object (or for matrices/arrays, the \texttt{dimnames}): see 'Character indices' below for further details. For [-indexing only: \textbf{i, j, ...} can be logical vectors, indicating elements/slices to select. Such vectors are recycled if necessary to match the corresponding extent. \textbf{i, j, ...} can also be negative integers, indicating elements/slices to leave out of the selection. When indexing arrays by \texttt{[} a single argument \textbf{i} can be a matrix with as many columns as there are dimensions of \texttt{x}; the result is then a vector with elements corresponding to the sets of indices in each row of \texttt{i}. An index value of \texttt{NULL} is treated as if it were \texttt{integer}(\emptyset).

\textbf{name} \quad \text{A literal character string or a \textbf{name} (possibly \texttt{backtick} quoted). For extraction, this is normally (see under 'Environments') partially matched to the \texttt{names} of the object.}

\textbf{drop} \quad \text{For matrices and arrays. If \texttt{TRUE} the result is coerced to the lowest possible dimension (see the examples). This only works for extracting elements, not for the replacement. See \texttt{drop} for further details.}

\textbf{exact} \quad \text{Controls possible partial matching of \texttt{[} when extracting by a character vector (for most objects, but see under 'Environments'). The default is no partial matching. Value \texttt{NA} allows partial matching but issues a warning when it occurs. Value \texttt{FALSE} allows partial matching without any warning.}

\textbf{value} \quad \text{typically an array-like \texttt{R} object of a similar class as \texttt{x}.}

Details

These operators are generic. You can write methods to handle indexing of specific classes of objects, see \texttt{InternalMethods} as well as \texttt{\_data.frame} and \texttt{\_factor}. The descriptions here apply only to the default methods. Note that separate methods are required for the replacement functions \texttt{\<-}, \texttt{\[<-} and \texttt{\$<-} for use when indexing occurs on the assignment side of an expression.

The most important distinction between \texttt{[}, \texttt{\[} and \texttt{\$} is that the \texttt{[} can select more than one element whereas the other two select a single element.

The default methods work somewhat differently for atomic vectors, matrices/arrays and for recursive (list-like, see \texttt{is.recursive}) objects. \texttt{\$} is only valid for recursive objects, and is only discussed in the section below on recursive objects.

Subsetting (except by an empty index) will drop all attributes except names, \texttt{dim} and \texttt{dimnames}.

Indexing can occur on the right-hand-side of an expression for extraction, or on the left-hand-side for replacement. When an index expression appears on the left side of an assignment (known as \texttt{subassignment}) then that part of \texttt{x} is set to the value of the right hand side of the assignment. In this case no partial matching of character indices is done, and the left-hand-side is coerced as needed to accept the values. For vectors, the answer will be of the higher of the types of \texttt{x} and \texttt{value} in the hierarchy \texttt{raw < logical < integer < double < complex < character < list < expression}. Attributes are preserved (although names, \texttt{dim} and \texttt{dimnames} will be adjusted suitably). Subassignment is done sequentially, so if an index is specified more than once the latest assigned value for an index will result.

It is an error to apply any of these operators to an object which is not subsettable (e.g. a function).
Atomic vectors

The usual form of indexing is `.[]` can be used to select a single element *dropping names*, whereas `[` keeps them, e.g., in `c(abc = 123)[1]`.

The index object `i` can be numeric, logical, character or empty. Indexing by factors is allowed and is equivalent to indexing by the numeric codes (see `factor`) and not by the character values which are printed (for which use `as.character(i)`).

An empty index selects all values: this is most often used to replace all the entries but keep the attributes.

Matrices and arrays

Matrices and arrays are vectors with a dimension attribute and so all the vector forms of indexing can be used with a single index. The result will be an unnamed vector unless `x` is one-dimensional when it will be a one-dimensional array.

The most common form of indexing a `k`-dimensional array is to specify `k` indices to `. As for vector indexing, the indices can be numeric, logical, character, empty or even factor. An empty index (a comma separated blank) indicates that all entries in that dimension are selected. The argument `drop` applies to this form of indexing.

A third form of indexing is via a numeric matrix with the one column for each dimension: each row of the index matrix then selects a single element of the array, and the result is a vector. Negative indices are not allowed in the index matrix. `NA` and zero values are allowed: rows of an index matrix containing a zero are ignored, whereas rows containing an `NA` produce an `NA` in the result.

Indexing via a character matrix with one column per dimensions is also supported if the array has dimension names. As with numeric matrix indexing, each row of the index matrix selects a single element of the array. Indices are matched against the appropriate dimension names. `NA` is allowed and will produce an `NA` in the result. Unmatched indices as well as the empty string (`""`) are not allowed and will result in an error.

A vector obtained by matrix indexing will be unnamed unless `x` is one-dimensional when the row names (if any) will be indexed to provide names for the result.

Recursive (list-like) objects

Indexing by `[` is similar to atomic vectors and selects a list of the specified element(s).

Both `[[` and `$` select a single element of the list. The main difference is that `$` does not allow computed indices, whereas `[[ does. `x$`name` is equivalent to `x[['name', `exact = FALSE]]. Also, the partial matching behavior of `[[ can be controlled using the `exact` argument.

`getElement(x, name)` is a version of `x[['name', `exact = TRUE]]` which for formally classed (S4) objects returns `slot(x, `name`), hence providing access to even more general list-like objects.

`[` and `[[ are sometimes applied to other recursive objects such as calls and expressions. Pairlists are coerced to lists for extraction by `[`, but all three operators can be used for replacement.

`[[` can be applied recursively to lists, so that if the single index `i` is a vector of length `p`, `alist[[i]]` is equivalent to `alist[[i1]][[i2]][[i3]]` providing all but the final indexing results in a list.

Note that in all three kinds of replacement, a value of `NULL` deletes the corresponding item of the list. To set entries to `NULL`, you need `x[i] <- list(NULL)`.

When `$<-` is applied to a `NULL` `x`, it first coerces `x` to `list()`. This is what also happens with `[[<-` if the replacement value `value` is of length greater than one: if `value` has length 1 or 0, `x` is first coerced to a zero-length vector of the type of `value`.
Environments

Both $ and [[ can be applied to environments. Only character indices are allowed and no partial matching is done. The semantics of these operations are those of get(i, env = x, inherits = FALSE). If no match is found then NULL is returned. The replacement versions, $<-$ and [[<-, can also be used. Again, only character arguments are allowed. The semantics in this case are those of assign(i, value, env = x, inherits = FALSE). Such an assignment will either create a new binding or change the existing binding in x.

NAs in indexing

When extracting, a numerical, logical or character NA index picks an unknown element and so returns NA in the corresponding element of a logical, integer, numeric, complex or character result, and NULL for a list. (It returns Ø for a raw result.)

When replacing (that is using indexing on the lhs of an assignment) NA does not select any element to be replaced. As there is ambiguity as to whether an element of the rhs should be used or not, this is only allowed if the rhs value is of length one (so the two interpretations would have the same outcome). (The documented behaviour of S was that an NA replacement index ‘goes nowhere’ but uses up an element of value: Becker et al p. 359. However, that has not been true of other implementations.)

Argument matching

Note that these operations do not match their index arguments in the standard way: argument names are ignored and positional matching only is used. So m[j = 2, i = 1] is equivalent to m[2, 1] and not to m[1, 2].

This may not be true for methods defined for them; for example it is not true for the data.frame methods described in [.data.frame which warn if i or j is named and have undocumented behaviour in that case.

To avoid confusion, do not name index arguments (but drop and exact must be named).

S4 methods

These operators are also implicit S4 generics, but as primitives, S4 methods will be dispatched only on S4 objects x.

The implicit generics for the $ and $<-$ operators do not have name in their signature because the grammar only allows symbols or string constants for the name argument.

Character indices

Character indices can in some circumstances be partially matched (see pmatch) to the names or dimnames of the object being subsetted (but never for subassignment). Unlike S (Becker et al p. 358)), R has never used partial matching when extracting by [, and as from R 2.7.0 partial matching is not by default used by [[ (see argument exact).

Thus the default behaviour is to use partial matching only when extracting from recursive objects (except environments) by $. Even in that case, warnings can be switched on by options(warnPartialMatchDollar = TRUE).

Neither empty (""") nor NA indices match any names, not even empty nor missing names. If any object has no names or appropriate dimnames, they are taken as all "" and so match nothing.

Examples

```r
x <- 1:12
m <- matrix(1:6, nrow = 2, dimnames = list(c("a", "b"), LETTERS[1:3]))
l1 <- list(pi = pi, e = exp(1))
x[10]  # the tenth element of x
dx <- x[-1]  # delete the 1st element of x
m[1,]  # the first row of matrix m
m[, , drop = FALSE]  # is a 1-row matrix
m[, c(TRUE, FALSE, TRUE)]  # logical indexing
m[cbind(c(1,2,1),3:1)]  # matrix numeric index
ci <- cbind(c("a", "b", "a"), c("A", "C", "B"))
m[ci]  # matrix character index
m <- m[-1]  # delete the first column of m
l1[[1]]  # the first element of list l1
y <- list(1, 2, a = 4, 5)
y[c(3, 4)]  # a list containing elements 3 and 4 of y
y$a  # the element of y named a

## non-integer indices are truncated:
(i <- 3.999999999)  # "4" is printed
(1:5)[i]  # 3

## named atomic vectors, compare "[" and "[[" :
nx <- c(Abc = 123, pi = pi)
nx[1]; nx["pi"]  # keeps names, whereas "[[" does not:
nx[[1]] ; nx[["pi"]]

## recursive indexing into lists
z <- list(a = list(b = 9, c = "hello"), d = 1:5)
unlist(z)
z[[c(1, 2)]]
z[[c(1, 2, 1)]]  # both "hello"
z[[c("a", "b")]] <- "new"
unlist(z)

## check $ and [[ for environments
e1 <- new.env()
e1$a <- 10
e1["a"]
e1[["a"]]
e1[["b"]]<-20
e1$b
```
ls(e!)

## partial matching - possibly with warning:
stopifnot(identical(li$p, pi))
op <- options(warnPartialMatchDollar = TRUE)
stopifnot(identical(li$p, pi), #-- a warning
    inherits(tryCatch (li$p, warning = identity), "warning"))
## revert the warning option:
if(is.null(op[[1]])) op[[1]] <- FALSE; options(op)

---

### Extract.data.frame

**Extract or Replace Parts of a Data Frame**

**Description**

Extract or replace subsets of data frames.

**Usage**

```r
## S3 method for class 'data.frame'
x[i, j, drop = ]
## S3 replacement method for class 'data.frame'
x[i, j] <- value
## S3 method for class 'data.frame'
x[[...], exact = TRUE]]
## S3 replacement method for class 'data.frame'
x[[i, j]] <- value
## S3 replacement method for class 'data.frame'
x$name <- value
```

**Arguments**

- `x`  
  data frame.

- `i, j, ...`  
  elements to extract or replace. For `[]` and `[[`, these are numeric or character or, for `[`, only, empty. Numeric values are coerced to integer as if by `as.integer`. For replacement by `[`, a logical matrix is allowed.

- `name`  
  A literal character string or a name (possibly backtick quoted).

- `drop`  
  logical. If TRUE the result is coerced to the lowest possible dimension. The default is to drop if only one column is left, but not to drop if only one row is left.

- `value`  
  A suitable replacement value: it will be repeated a whole number of times if necessary and it may be coerced: see the Coercion section. If NULL, deletes the column if a single column is selected.

- `exact`  
  logical: see `[`, and applies to column names.
Details

Data frames can be indexed in several modes. When [ and [[ are used with a single vector index (x[i] or x[[i]]), they index the data frame as if it were a list. In this usage a drop argument is ignored, with a warning.

There is no data.frame method for $, so x$name uses the default method which treats x as a list. There is a replacement method which checks value for the correct number of rows, and replicates it if necessary.

When [ and [[ are used with two indices (x[i, j] and x[[i, j]]) they act like indexing a matrix: [[ can only be used to select one element. Note that for each selected column, xj say, typically (if it is not matrix-like), the resulting column will be xj[i], and hence rely on the corresponding [ method, see the examples section.

If [ returns a data frame it will have unique (and non-missing) row names, if necessary transforming the row names using make.unique. Similarly, if columns are selected column names will be transformed to be unique if necessary (e.g. if columns are selected more than once, or if more than one column of a given name is selected if the data frame has duplicate column names).

When drop = TRUE, this is applied to the subsetting of any matrices contained in the data frame as well as to the data frame itself.

The replacement methods can be used to add whole column(s) by specifying non-existent column(s), in which case the column(s) are added at the right-hand edge of the data frame and numerical indices must be contiguous to existing indices. On the other hand, rows can be added at any row after the current last row, and the columns will be in-filled with missing values. Missing values in the indices are not allowed for replacement.

For the replacement value can be a list: each element of the list is used to replace (part of) one column, recycling the list as necessary. If columns specified by number are created, the names (if any) of the corresponding list elements are used to name the columns. If the replacement is not selecting rows, list values can contain NULL elements which will cause the corresponding columns to be deleted. (See the Examples.)

Matrix indexing (x[i] with a logical or a 2-column integer matrix i) using [] is not recommended. For extraction, x is first coerced to a matrix. For replacement, logical matrix indices must be of the same dimension as x. Replacements are done one column at a time, with multiple type coercions possibly taking place.

Both [ and [[ extraction methods partially match row names. By default neither partially match column names, but [[ will if exact = FALSE (and with a warning if exact = NA). If you want to exact matching on row names use match, as in the examples.

Value

For [ a data frame, list or a single column (the latter two only when dimensions have been dropped). If matrix indexing is used for extraction a vector results. If the result would be a data frame an error results if undefined columns are selected (as there is no general concept of a ’missing’ column in a data frame). Otherwise if a single column is selected and this is undefined the result is NULL.

For [[ a column of the data frame or NULL (extraction with one index) or a length-one vector (extraction with two indices).

For $, a column of the data frame (or NULL).

For [<-, [[<- and $<-, a data frame.
Coercion

The story over when replacement values are coerced is a complicated one, and one that has changed during R’s development. This section is a guide only.

When `[]` and `[[` are used to add or replace a whole column, no coercion takes place but value will be replicated (by calling the generic function `rep`) to the right length if an exact number of repeats can be used.

When `[]` is used with a logical matrix, each value is coerced to the type of the column into which it is to be placed.

When `[]` and `[[` are used with two indices, the column will be coerced as necessary to accommodate the value.

Note that when the replacement value is an array (including a matrix) it is not treated as a series of columns (as `data.frame` and `as.data.frame` do) but inserted as a single column.

Warning

The default behaviour when only one row is left is equivalent to specifying `drop = FALSE`. To drop from a data frame to a list, `drop = TRUE` has to be specified explicitly.

Arguments other than `drop` and `exact` should not be named: there is a warning if they are and the behaviour differs from the description here.

See Also

`subset` which is often easier for extraction, `data.frame`, `Extract`.

Examples

```r
sw <- swiss[1:5, 1:4]  # select a manageable subset
sw[1:3]                # select columns
sw[ , 1:3]             # same
sw[4:5, 1:3]           # select rows and columns
sw[1]                  # a one-column data frame
sw[ , 1, drop = FALSE] # the same
sw[ , 1]               # a (unnamed) vector
sw[[1]]                # the same
sw[1, ]                # a one-row data frame
sw[1, , drop = TRUE]   # a list
sw["C", ]              # partially matches
sw[match("C", row.names(sw)), ] # no exact match
try(sw[, "Ferti"])) # column names must match exactly

swiss[ c(1, 1:2), ]    # duplicate row, unique row names are created
sw[sw <= 6] <- 6       # logical matrix indexing
sw
```

```
# adding a column
sw["new1"] <- LETTERS[1:5]  # adds a character column
sw[["new2"]]) <- letters[1:5] # ditto
sw[, "new3"] <- LETTERS[1:5] # ditto
```
### Extract.factor

#### Extract or Replace Parts of a Factor

**Description**

Extract or replace subsets of factors.

**Usage**

```r
# S3 method for class 'factor'

x[...], drop = FALSE

# S3 method for class 'factor'

x[[...]]

# S3 replacement method for class 'factor'

x[...] <- value

# S3 replacement method for class 'factor'

x[[...]] <- value
```

**Arguments**

- `x` a factor
- `...` a specification of indices – see `Extract`.
drop logical. If true, unused levels are dropped.

value character: a set of levels. Factor values are coerced to character.

Details

When unused levels are dropped the ordering of the remaining levels is preserved.
If value is not in levels(x), a missing value is assigned with a warning.
Any contrasts assigned to the factor are preserved unless drop = TRUE.
The [] method supports argument exact.

Value

A factor with the same set of levels as x unless drop = TRUE.

See Also

factor, Extract.

Examples

```r
## following example(factor)
(ff <- factor(substring("statistics", 1:10, 1:10), levels = letters))
ff[, drop = TRUE]
factor(letters[7:10])[2:3, drop = TRUE]
```

---

**Extremes**

### Maxima and Minima

**Description**

Returns the (parallel) maxima and minima of the input values.

**Usage**

```r
max(..., na.rm = FALSE)
min(..., na.rm = FALSE)

pmax(..., na.rm = FALSE)
pmin(..., na.rm = FALSE)

pmax.int(..., na.rm = FALSE)
pmin.int(..., na.rm = FALSE)
```

**Arguments**

- ... numeric or character arguments (see Note).
- na.rm a logical indicating whether missing values should be removed.
Details

`max` and `min` return the maximum or minimum of all the values present in their arguments, as `integer` if all are `logical` or `integer`, as `double` if all are numeric, and character otherwise.

If `na.rm` is `FALSE` an NA value in any of the arguments will cause a value of NA to be returned, otherwise NA values are ignored.

The minimum and maximum of a numeric empty set are `+Inf` and `-Inf` (in this order!) which ensures transitivity, e.g., `min(x1, min(x2)) == min(x1, x2)`. For numeric `x`, `max(x) == -Inf` and `min(x) == +Inf` whenever `length(x) == 0` (after removing missing values if requested). However, `pmax` and `pmin` return NA if all the parallel elements are NA even for `na.rm = TRUE`.

`pmax` and `pmin` take one or more vectors (or matrices) as arguments and return a single vector giving the ‘parallel’ maxima (or minima) of the vectors. The first element of the result is the maximum (minimum) of the first elements of all the arguments, the second element of the result is the maximum (minimum) of the second elements of all the arguments and so on. Shorter inputs (of non-zero length) are recycled if necessary. Attributes (see `attributes` such as `names` or `dim`) are copied from the first argument (if applicable).

`pmax.int` and `pmin.int` are faster internal versions only used when all arguments are atomic vectors and there are no classes: they drop all attributes. (Note that all versions fail for raw and complex vectors since these have no ordering.)

`max` and `min` are generic functions: methods can be defined for them individually or via the `Summary` group generic. For this to work properly, the arguments ... should be unnamed, and dispatch is on the first argument.

By definition the min/max of a numeric vector containing an NaN is NaN, except that the min/max of any vector containing an NA is NA even if it also contains an NaN. Note that `max(NA, Inf) == NA` even though the maximum would be Inf whatever the missing value actually is.

Character versions are sorted lexicographically, and this depends on the collating sequence of the locale in use: the help for ‘Comparison’ gives details. The max/min of an empty character vector is defined to be character NA. (One could argue that as "" is the smallest character element, the maximum should be "", but there is no obvious candidate for the minimum.)

Value

For `min` or `max`, a length-one vector. For `pmin` or `pmax`, a vector of length the longest of the input vectors, or length zero if one of the inputs had zero length.

The type of the result will be that of the highest of the inputs in the hierarchy integer < double < character.

For `min` and `max` if there are only numeric inputs and all are empty (after possible removal of NAs), the result is double (`Inf` or `-Inf`).

S4 methods

`max` and `min` are part of the S4 `Summary` group generic. Methods for them must use the signature `x, ..., na.rm`.

Note

‘Numeric’ arguments are vectors of type `integer` and numeric, and logical (coerced to integer). For historical reasons, `NULL` is accepted as equivalent to `integer(0)`.

`pmax` and `pmin` will also work on classed objects with appropriate methods for comparison, is.na and rep (if recycling of arguments is needed).
References

See Also

`range` *(both min and max)* and `which.min` *(which.max)* for the arg min, i.e., the location where an extreme value occurs.

`plotmath` for the use of `min` in plot annotation.

Examples

```r
require(stats); require(graphics)
min(5:1, pi) # one number
pmin(5:1, pi) # 5 numbers

x <- sort(rnorm(100)); ch <- 1.35
pmin(ch, quantile(x)) # no names
pmin(quantile(x), ch) # has names
plot(x, pmin(ch, pmax(-ch, x)), type = "b", main = "Huber's function")

cut01 <- function(x) pmax(pmin(x, 1), 0)
curve(cut01(x^2 - 1/4, -1.4, 1.5, col = 2),
col = "blue", add = TRUE, n = 500)
## pmax(), pmin() preserve attributes of *first* argument
d <- diag(x = (3:1)/4); n0 <- numeric()
stopifnot(identical(D, cut01(D)),
          identical(n0, cut01(n0)),
          identical(n0, cut01(NULL)),
          identical(n0, pmax(3:1, n0, 2)),
          identical(n0, pmax(n0, 4)))
```

factor

Factors

Description

The function `factor` is used to encode a vector as a factor (the terms ‘category’ and ‘enumerated type’ are also used for factors). If argument `ordered` is `TRUE`, the factor levels are assumed to be ordered. For compatibility with S there is also a function `ordered`.

`is.factor`, `is.ordered`, `as.factor` and `as.ordered` are the membership and coercion functions for these classes.

Usage

```r
factor(x = character(), levels, labels = levels,
       exclude = NA, ordered = is.ordered(x), nmax = NA)

ordered(x, ...)  
is.factor(x)
is.ordered(x)
```

as.factor(x)
as.ordered(x)

addNa(x, ifany = FALSE)

Arguments

x  a vector of data, usually taking a small number of distinct values.
levels  an optional vector of the values that x might have taken. The default is the unique set of values taken by as.character(x), sorted into increasing order of x. Note that this set can be specified as smaller than sort(unique(x)).
labels  either an optional vector of labels for the levels (in the same order as levels after removing those in exclude), or a character string of length 1.
exclude  a vector of values to be excluded when forming the set of levels. This should be of the same type as x, and will be coerced if necessary.
ordered  logical flag to determine if the levels should be regarded as ordered (in the order given).
nmax  an upper bound on the number of levels; see ‘Details’.
...  (in ordered(.)): any of the above, apart from ordered itself.
ifany  (only add an NA level if it is used, i.e. if any(is.na(x))).

Details

The type of the vector x is not restricted; it only must have an as.character method and be sortable (by sort.list).

Ordered factors differ from factors only in their class, but methods and the model-fitting functions treat the two classes quite differently.

The encoding of the vector happens as follows. First all the values in exclude are removed from levels. If x[i] equals levels[j], then the i-th element of the result is j. If no match is found for x[i] in levels (which will happen for excluded values) then the i-th element of the result is set to NA.

Normally the ‘levels’ used as an attribute of the result are the reduced set of levels after removing those in exclude, but this can be altered by supplying labels. This should either be a set of new labels for the levels, or a character string, in which case the levels are that character string with a sequence number appended.

factor(x, exclude = NULL) applied to a factor is a no-operation unless there are unused levels: in that case, a factor with the reduced level set is returned. If exclude is used it should also be a factor with the same level set as x or a set of codes for the levels to be excluded.

The codes of a factor may contain NA. For a numeric x, set exclude = NULL to make NA an extra level (prints as <NA>); by default, this is the last level.

If NA is a level, the way to set a code to be missing (as opposed to the code of the missing level) is to use is.na on the left-hand-side of an assignment (as in is.na(f)[i] <- TRUE; indexing inside is.na does not work). Under those circumstances missing values are currently printed as <NA>, i.e., identical to entries of level NA.

is.factor is generic: you can write methods to handle specific classes of objects, see Internal-Methods.

Where levels is not supplied, unique is called. Since factors typically have quite a small number of levels, for large vectors x it is helpful to supply nmax as an upper bound on the number of unique values.
factor returns an object of class "factor" which has a set of integer codes the length of \( x \) with a "levels" attribute of mode \texttt{character} and unique (!anyDuplicated(.)) entries. If argument \texttt{ordered} is true (or \texttt{ordered()} is used) the result has class \texttt{c("ordered", "factor")}.

Applying \texttt{factor} to an ordered or unordered factor returns a factor (of the same type) with just the levels which occur: see also \texttt{.factor} for a more transparent way to achieve this.

\texttt{is.factor} returns \texttt{TRUE} or \texttt{FALSE} depending on whether its argument is of type factor or not. Correspondingly, \texttt{is.ordered} returns \texttt{TRUE} when its argument is an ordered factor and \texttt{FALSE} otherwise.

\texttt{as.factor} coerces its argument to a factor. It is an abbreviated form of \texttt{factor}.

\texttt{as.ordered(x)} returns \( x \) if this is ordered, and \texttt{ordered(x)} otherwise.

\texttt{addNA} modifies a factor by turning \texttt{NA} into an extra level (so that \texttt{NA} values are counted in tables, for instance).

**Warning**

The interpretation of a factor depends on both the codes and the "levels" attribute. Be careful only to compare factors with the same set of levels (in the same order). In particular, \texttt{as.numeric} applied to a factor is meaningless, and may happen by implicit coercion. To transform a factor \( f \) to approximately its original numeric values, \texttt{as.numeric(levels(f))[f]} is recommended and slightly more efficient than \texttt{as.numeric(as.character(f))}.

The levels of a factor are by default sorted, but the sort order may well depend on the locale at the time of creation, and should not be assumed to be ASCII.

There are some anomalies associated with factors that have \texttt{NA} as a level. It is suggested to use them sparingly, e.g., only for tabulation purposes.

**Comparison operators and group generic methods**

There are "\texttt{factor}" and "\texttt{ordered}" methods for the \texttt{group generic Ops} which provide methods for the \texttt{Comparison} operators, and for the \texttt{min}, \texttt{max}, and \texttt{range} generics in \texttt{Summary} of "\texttt{ordered}". (The rest of the groups and the \texttt{Math} group generate an error as they are not meaningful for factors.)

Only \texttt{==} and \texttt{!=} can be used for factors: a factor can only be compared to another factor with an identical set of levels (not necessarily in the same ordering) or to a character vector. Ordered factors are compared in the same way, but the general dispatch mechanism precludes comparing ordered and unordered factors.

All the comparison operators are available for ordered factors. Collation is done by the levels of the operands: if both operands are ordered factors they must have the same level set.

**Note**

In earlier versions of \( R \), storing character data as a factor was more space efficient if there is even a small proportion of repeats. However, identical character strings now share storage, so the difference is small in most cases. (Integer values are stored in 4 bytes whereas each reference to a character string needs a pointer of 4 or 8 bytes.)

Month <- airquality$Month
table(addNA(Month))
table(addNA(Month, ifany = TRUE))

---

file.access Ascertain File Accessibility

Description

Utility function to access information about files on the user's file systems.

Usage

file.access(names, mode = 0)

Arguments

names character vector containing file names. Tilde-expansion will be done: see path.expand.
mode integer specifying access mode required: see ‘Details’.
Details

The mode value can be the exclusive or of the following values

0  test for existence.
1  test for execute permission.
2  test for write permission.
4  test for read permission.

Permission will be computed for real user ID and real group ID (rather than the effective IDs).
Please note that it is not a good idea to use this function to test before trying to open a file. On a
multi-tasking system, it is possible that the accessibility of a file will change between the time you
call file.access() and the time you try to open the file. It is better to wrap file open attempts in
try.

Value

An integer vector with values 0 for success and -1 for failure.

Note

This is intended as a replacement for the S-PLUS function access, a wrapper for the C function
of the same name, which explains the return value encoding. Note that the return value is false for
success.

See Also

file.info for more details on permissions, Sys.chmod to change permissions, and try for a ‘test
it and see’ approach.
file_test for shell-style file tests.

Examples

fa <- file.access(dir("."))
table(fa) # count successes & failures

file.choose  Choose a File Interactively

Description

Choose a file interactively.

Usage

file.choose(new = FALSE)

Arguments

new  Logical: choose the style of dialog box presented to the user: at present only
new = FALSE is used.
\textit{file.info}

**Value**

A character vector of length one giving the file path.

**See Also**

\texttt{list.files} for non-interactive selection.

---

**Description**

Utility function to extract information about files on the user's file systems.

**Usage**

\texttt{file.info(...)}

**Arguments**

... character vectors containing file paths. Tilde-expansion is done: see \texttt{path.expand}.

**Details**

What constitutes a ‘file’ is OS-dependent but includes directories. (However, directory names must not include a trailing backslash or slash on Windows.) See also the section in the help for \texttt{file.exists} on case-insensitive file systems.

The file ‘mode’ follows POSIX conventions, giving three octal digits summarizing the permissions for the file owner, the owner’s group and for anyone respectively. Each digit is the logical or of read (4), write (2) and execute/search (1) permissions.

On most systems symbolic links are followed, so information is given about the file to which the link points rather than about the link.

**Value**

A data frame with row names the file names and columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{size}</td>
<td>double: File size in bytes.</td>
</tr>
<tr>
<td>\texttt{isdir}</td>
<td>logical: Is the file a directory?</td>
</tr>
<tr>
<td>\texttt{mode}</td>
<td>integer of class &quot;octmode&quot;. The file permissions, printed in octal, for example 644.</td>
</tr>
<tr>
<td>\texttt{mtime, ctime, atime}</td>
<td>integer of class &quot;POSIXct&quot;: file modification, ‘last status change’ and last access times.</td>
</tr>
<tr>
<td>\texttt{uid}</td>
<td>integer: the user ID of the file’s owner.</td>
</tr>
<tr>
<td>\texttt{gid}</td>
<td>integer: the group ID of the file’s group.</td>
</tr>
<tr>
<td>\texttt{uname}</td>
<td>character: \texttt{uid} interpreted as a user name.</td>
</tr>
<tr>
<td>\texttt{grname}</td>
<td>character: \texttt{gid} interpreted as a group name.</td>
</tr>
</tbody>
</table>
Unknown user and group names will be NA.

Entries for non-existent or non-readable files will be NA. The uid, gid, uname and grname columns may not be supplied on a non-POSIX Unix-alike system, and will not be on Windows.

What is meant by the three file times depends on the OS and file system. On Windows native file systems ctime is the file creation time (something which is not recorded on most Unix-alike file systems). What is meant by ‘file access’ and hence the ‘last access time’ is system-dependent.

The times are reported to an accuracy of seconds, and perhaps more on some systems. However, many file systems only record times in seconds, and some (e.g. modification time on FAT systems) are recorded in increments of 2 or more seconds.

Note

Some systems allow files of more than 2Gb to be created but not accessed by the stat system call. Such files will show up as non-readable (and very likely not be readable by any of R’s input functions) – fortunately such file systems are becoming rare.

See Also

Sys.readlink to find out about symbolic links, files, file.access, list.files, and DateTimeClasses for the date formats.

Sys.chmod to change permissions.

Examples

col(finf <- file.info(dir()))  # at least six
## Not run: finf # the whole list
## Those that are more than 100 days old :
finf[difftime(Sys.time(), finf[,"mtime"], units = "days") > 100 , 1:4]

file.info("no-such-file-exists")

---

**file.path**

*Construct Path to File*

Description

Construct the path to a file from components in a platform-independent way.

Usage

file.path(..., fsep = .Platform$file.sep)

Arguments

... character vectors.

fsep the path separator to use.
Details

The implementation is designed to be fast (faster than \texttt{paste}) as this function is used extensively in R itself.

It can also be used for environment paths such as PATH and R_LIBS with \texttt{fsep = .Platform$path.sep}.

Value

A character vector of the arguments concatenated term-by-term and separated by \texttt{fsep} if all arguments have positive length; otherwise, an empty character vector (unlike \texttt{paste}).

Note

The components are separated by / (not \backslash) on Windows.

\begin{verbatim}
file.show
\end{verbatim}

\textit{Display One or More Files}

Description

Display one or more files.

Usage

\begin{verbatim}
file.show(..., header = rep("", nfiles),
     title = "R Information",
     delete.file = FALSE, pager = getOption("pager"),
     encoding = ""
)
\end{verbatim}

Arguments

\begin{itemize}
\item \ldots\hspace{1cm} one or more character vectors containing the names of the files to be displayed. Paths with have tilde expansion.
\item header\hspace{1cm} character vector (of the same length as the number of files specified in \ldots) giving a header for each file being displayed. Defaults to empty strings.
\item title\hspace{1cm} an overall title for the display. If a single separate window is used for the display, \texttt{title} will be used as the window title. If multiple windows are used, their titles should combine the title and the file-specific header.
\item delete.file\hspace{1cm} should the files be deleted after display? Used for temporary files.
\item pager\hspace{1cm} the pager to be used: not used on all platforms
\item encoding\hspace{1cm} character string giving the encoding to be assumed for the file(s).
\end{itemize}
Details

This function provides the core of the R help system, but it can be used for other purposes as well, such as `page`.

How the pager is implemented is highly system-dependent.

The basic Unix version concatenates the files (using the headers) to a temporary file, and displays it in the pager selected by the pager argument, which is a character vector specifying a system command to run on the set of files. The ‘factory-fresh’ default is to use `R_HOME/bin/pager`, which is a shell script running the command specified by the environment variable PAGER whose default is set at configuration, usually to less. On a Unix-alike more is used if pager is empty.

Most GUI systems will use a separate pager window for each file, and let the user leave it up while R continues running. The selection of such pagers could either be done using special pager names being intercepted by lower-level code (such as "internal" and "console" on Windows), or by letting pager be an R function which will be called with arguments (files, header, title, delete.file) corresponding to the first four arguments of file.show and take care of interfacing to the GUI.

The R.app GUI on OS X uses its internal pager irrespective of the setting of pager.

Not all implementations will honour delete.file. In particular, using an external pager on Windows does not, as there is no way to know when the external application has finished with the file.

Ross Ihaka, Brian Ripley.

See Also

`files`, `list.files`, `help`.

`file.edit`.

Examples

```r
file.show(file.path(R.home("doc"), "COPYRIGHTS"))
```

Description

These functions provide a low-level interface to the computer’s file system.

Usage

```r
file.create(..., showWarnings = TRUE)
file.exists(...)
file.remove(...)
file.rename(from, to)
file.append(file1, file2)
file.copy(from, to, overwrite = recursive, recursive = FALSE,
          copy.mode = TRUE)
file symlink(from, to)
file.link(from, to)
```
Arguments

... file1, file2

character vectors, containing file names or paths.

from, to
character vectors, containing file names or paths. For file.copy and file symlink to can alternatively be the path to a single existing directory.

overwrite
logical; should existing destination files be overwritten?

showWarnings
logical; should the warnings on failure be shown?

recursive
logical. If to is a directory, should directories in from be copied (and their contents)? (Like cp -R on POSIX OSes.)

copy.mode
logical: should file permission bits be copied where possible? This applies to both files and directories.

Details

The ... arguments are concatenated to form one character string: you can specify the files separately or as one vector. All of these functions expand path names: see path.expand.

file.create creates files with the given names if they do not already exist and truncates them if they do. They are created with the maximal read/write permissions allowed by the ‘umask’ setting (where relevant). By default a warning is given (with the reason) if the operation fails.

file.exists returns a logical vector indicating whether the files named by its argument exist. (Here ‘exists’ is in the sense of the system’s stat call: a file will be reported as existing only if you have the permissions needed by stat. Existence can also be checked by file.access, which might use different permissions and so obtain a different result. Note that the existence of a file does not imply that it is readable: for that use file.access.) What constitutes a ‘file’ is system-dependent, but should include directories. (However, directory names must not include a trailing backslash or slash on Windows.) Note that if the file is a symbolic link on a Unix-alike, the result indicates if the link points to an actual file, not just if the link exists. Lastly, note the different function exists which checks for existence of R objects.

file.remove attempts to remove the files named in its argument. On most Unix platforms ‘file’ includes empty directories, symbolic links, fifos and sockets. On Windows, ‘file’ means a regular file and not, say, an empty directory.

file.rename attempts to rename files (and from and to must be of the same length). Where file permissions allow this will overwrite an existing element of to. This is subject to the limitations of the OS’s corresponding system call (see something like man 2 rename on a Unix-alike): in particular in the interpretation of ‘file’: most platforms will not rename files across file systems. (On Windows, file.rename can move files but not directories between volumes.) On platforms which allow directories to be renamed, typically neither or both of from and to must a directory, and if to exists it must be an empty directory.

file.append attempts to append the files named by its second argument to those named by its first. The R subscript recycling rule is used to align names given in vectors of different lengths.

file.copy works in a similar way to file.append but with the arguments in the natural order for copying. Copying to existing destination files is skipped unless overwrite = TRUE. The to argument can specify a single existing directory. If copy.mode = TRUE (added in R 2.13.0) file read/write/execute permissions are copied where possible, restricted by ‘umask’. Other security attributes such as ACLs are not copied. On a POSIX filesystem the targets of symbolic links will be copied rather than the links themselves, and hard links are copied separately.

file.symlink and file.link make symbolic and hard links on those file systems which support them. For file.symlink the to argument can specify a single existing directory. (Unix and OS X
native filesystems support both. Windows has hard links to files on NTFS file systems and concepts related to symbolic links on recent versions: see the section below on the Windows version of this help page. What happens on a FAT or SMB-mounted file system is OS-specific.)

Value

These functions return a logical vector indicating which operation succeeded for each of the files attempted. Using a missing value for a file or path name will always be regarded as a failure.

If showWarnings = TRUE, file.create will give a warning for an unexpected failure.

Case-insensitive file systems

Case-insensitive file systems are the norm on Windows and OS X, but can be found on all OSes (for example a FAT-formatted USB drive is probably case-insensitive).

These functions will most likely match existing files regardless of case on such file systems: however this is an OS function and it is possible that file names might be mapped to upper or lower case.

setwd("..")
unlink("tmp", recursive = TRUE)
file.remove("A", "B", "C")
Manipulation of Directories and File Permissions

Description

These functions provide a low-level interface to the computer’s file system.

Usage

dir.create(path, showWarnings = TRUE, recursive = FALSE, mode = "0777")
Sys.chmod(paths, mode = "0777", use_umask = TRUE)
Sys.umask(mode = NA)

Arguments

- **path**: a character vector containing a single path name. Tilde expansion (see `path.expand`) is done.
- **paths**: character vectors containing file or directory paths. Tilde expansion (see `path.expand`) is done.
- **showWarnings**: logical; should the warnings on failure be shown?
- **recursive**: logical. Should elements of the path other than the last be created? If true, like the Unix command `mkdir -p`.
- **mode**: the mode to be used on Unix-alikes: it will be coerced by `as.octmode`. For `Sys.chmod` it is recycled along `paths`.
- **use_umask**: logical: should the mode be restricted by the `umask` setting?

Details

dir.create creates the last element of the path, unless `recursive = TRUE`. Trailing path separators are discarded. The mode will be modified by the `umask` setting in the same way as for the system function `mkdir`. What modes can be set is OS-dependent, and it is unsafe to assume that more than three octal digits will be used. For more details see your OS’s documentation on the system call `mkdir`, e.g. `man 2 mkdir` (and not that on the command-line utility of that name).

One of the idiosyncrasies of Windows is that directory creation may report success but create a directory with a different name, for example `dir.create(BgNsBI)` creates `BgNsB`. This is undocumented, and what are the precise circumstances is unknown (and might depend on the version of Windows). Also avoid directory names with a trailing space.

`Sys.chmod` sets the file permissions of one or more files. It may not be supported on a system (when a warning is issued). See the comments for `dir.create` for how modes are interpreted. Changing mode on a symbolic link is unlikely to work (nor be necessary). For more details see your OS’s documentation on the system call `chmod`, e.g. `man 2 chmod` (and not that on the command-line utility of that name). Whether this changes the permission of a symbolic link or its target is OS-dependent (although to change the target is more common, and POSIX does not support modes for symbolic links: BSD-based Unixes do, though).

`Sys.umask` sets the `umask` and returns the previous value: as a special case `mode = NA` just returns the current value. It may not be supported (when a warning is issued and "0" is returned). For more details see your OS’s documentation on the system call `umask`, e.g. `man 2 umask`.

How modes are handled depends on the file system, even on Unix-alikes (although their documentation is often written assuming a POSIX file system). So treat documentation cautiously if you are using, say, a FAT/FAT32 or network-mounted file system.
Value

dir.create and Sys.chmod return invisibly a logical vector indicating if the operation succeeded for each of the files attempted. Using a missing value for a path name will always be regarded as a failure. dir.create indicates failure if the directory already exists. If showWarnings = TRUE, dir.create will give a warning for an unexpected failure (e.g. not for a missing value nor for an already existing component for recursive = TRUE).

Sys.umask returns the previous value of the umask, as a length-one object of class "octmode": the visibility flag is off unless mode is NA.

See also the section in the help for file.exists on case-insensitive file systems for the interpretation of path and paths.

## End(Not run)

find.package    Find Packages

Description

Find the paths to one or more packages.

Usage

find.package(package, lib.loc = NULL, quiet = FALSE,
verbose = getOption("verbose"))

path.package(package, quiet = FALSE)

Arguments

package character vector: the names of packages.
lib.loc a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to checking the loaded namespace, then all libraries currently known in .libPaths().
quiet logical. Should this not give warnings or an error if the package is not found?
verbose a logical. If TRUE, additional diagnostics are printed.
Details

`find.package` returns path to the locations where the given packages are found. If `lib.loc` is `NULL`, then loaded namespaces are searched before the libraries. If a package is found more than once, the first match is used. Unless `quiet = TRUE` a warning will be given about the named packages which are not found, and an error if none are. If `verbose` is true, warnings about packages found more than once are given. For a package to be returned it must contain a either a ‘Meta’ subdirectory or a ‘DESCRIPTION’ file containing a valid version field, but it need not be installed (it could be a source package if `lib.loc` was set suitably).

`find.package` is not usually the right tool to find out if a package is available for use: the only way to do that is to use `require` to try to load it. It need not be installed for the correct platform, it might have a version requirement not met by the running version of `R`, there might be dependencies which are not available, . . . .

`path.package` returns the paths from which the named packages were loaded, or if none were named, for all currently attached packages. Unless `quiet = TRUE` it will warn if some of the packages named are not attached, and given an error if none are.

Value

A character vector of paths of package directories.

---

**findInterval**

*Find Interval Numbers or Indices*

Description

Given a vector of non-decreasing breakpoints in `vec`, find the interval containing each element of `x`; i.e., if \( i \leftarrow \text{findInterval}(x, \vec{v}) \), for each index \( j \) in \( x \) \( v_{ij} < x_j < v_{ij+1} \) where \( v_0 := -\infty, v_{N+1} := +\infty \), and \( N \leftarrow \text{length}(\vec{v}) \). At the two boundaries, the returned index may differ by 1, depending on the optional arguments `rightmost.closed` and `all.inside`.

Usage

`findInterval(x, vec, rightmost.closed = FALSE, all.inside = FALSE)`

Arguments

- `x` numeric.
- `vec` numeric, sorted (weakly) increasingly, of length `N`, say.
- `rightmost.closed` logical; if true, the rightmost interval, `vec[\text{N-1}] .. vec[\text{N}]` is treated as `closed`, see below.
- `all.inside` logical; if true, the returned indices are coerced into `1, \ldots, N-1`, i.e., `0` is mapped to `1` and `N` to `N-1`. 

---
Details

The function `findInterval` finds the index of one vector `x` in another, `vec`, where the latter must be non-decreasing. Where this is trivial, equivalent to `apply(outer(x, vec, ">="), 1, sum)`, as a matter of fact, the internal algorithm uses interval search ensuring $O(n \log N)$ complexity where $n \leftarrow \text{length}(x)$ (and $N \leftarrow \text{length}(vec)$). For (almost) sorted `x`, it will be even faster, basically $O(n)$.

This is the same computation as for the empirical distribution function, and indeed, `findInterval(t, sort(X))` is identical to $n F_n(t; X_1, \ldots, X_n)$ where $F_n$ is the empirical distribution function of $X_1, \ldots, X_n$.

When `rightmost.closed = TRUE`, the result for $x[j] = \text{vec}[N] (= \text{max vec})$, is $N - 1$ as for all other values in the last interval.

Value

vector of length `length(x)` with values in $\emptyset: N$ (and NA) where $N \leftarrow \text{length(vec)}$, or values coerced to $1:(N-1)$ if and only if `all.inside = TRUE` (equivalently coercing all `x` values inside the intervals). Note that NAs are propagated from `x`, and `Inf` values are allowed in both `x` and `vec`.

Author(s)

Martin Maechler

See Also

`approx(*, method = "constant")` which is a generalization of `findInterval()`, `ecdf` for computing the empirical distribution function which is (up to a factor of $n$) also basically the same as `findInterval()`.

Examples

```r
x <- 2:18
v <- c(5, 10, 15) # create two bins [5,10) and [10,15)
cbind(x, findInterval(x, v))

N <- 100
X <- sort(round(stats::rt(N, df = 2), 2))
tt <- c(-100, seq(-2, 2, len = 201), +100)
it <- findInterval(tt, X)
tt[it < 1 | it >= N] # only first and last are outside range(X)
```

force

Force Evaluation of an Argument

Description

Forces the evaluation of a function argument.

Usage

```r
force(x)
```
Arguments

\( x \)

a formal argument of the enclosing function.

Details

`force` forces the evaluation of a formal argument. This can be useful if the argument will be captured in a closure by the lexical scoping rules and will later be altered by an explicit assignment or an implicit assignment in a loop or an apply function.

Note

This is semantic sugar: just evaluating the symbol will do the same thing (see the examples).

`force` does not force the evaluation of other promises. (It works by forcing the promise that is created when the actual arguments of a call are matched to the formal arguments of a closure, the mechanism which implements lazy evaluation.)

Examples

```r
f <- function(y) function() y
lf <- vector("list", 5)
for (i in seq_along(lf)) lf[[i]] <- f(i)
lf[[1]]() # returns 5

g <- function(y) { force(y); function() y }
lg <- vector("list", 5)
for (i in seq_along(lg)) lg[[i]] <- g(i)
lg[[1]]() # returns 1

## This is identical to
g <- function(y) { y; function() y }
```

---

Description

Functions to make calls to compiled code that has been loaded into R.

Usage

```
.C(.NAME, ..., NAOK = FALSE, DUP = TRUE, PACKAGE, ENCODING)
.Fortran(.NAME, ..., NAOK = FALSE, DUP = TRUE, PACKAGE, ENCODING)
```

Arguments

- `.NAME` a character string giving the name of a C function or Fortran subroutine, or an object of class "NativeSymbolInfo", "RegisteredNativeSymbol" or "NativeSymbol" referring to such a name.

- `...` arguments to be passed to the foreign function. Up to 65.

- `NAOK` if TRUE then any `NA` or `NaN` or `Inf` values in the arguments are passed on to the foreign function. If FALSE, the presence of NA or NaN or Inf values is regarded as an error.
if TRUE then arguments are duplicated before their address is passed to C or Fortran.

if supplied, confine the search for a character string .NAME to the DLL given by this argument (plus the conventional extension, ‘.so’, ‘.dll’, …).

This is intended to add safety for packages, which can ensure by using this argument that no other package can override their external symbols, and also speeds up the search (see ‘Note’).

For back-compatibility, accepted but ignored.

These functions can be used to make calls to compiled C and Fortran 77 code. Later interfaces are .Call and .External which are more flexible and have better performance.

These functions are both primitive, and .NAME is always matched to the first argument supplied (which should not be named). The other named arguments follow . . . and so cannot be abbreviated. For clarity, should avoid using names in the arguments passed to . . . that match or partially match .NAME.

A list similar to the . . . list of arguments passed in (including any names given to the arguments), but reflecting any changes made by the C or Fortran code.

The mapping of the types of \( R \) arguments to C or Fortran arguments is

<table>

</tbody>
</table>

Numeric vectors in \( R \) will be passed as type double * to C (and as double precision to Fortran) unless the argument has attribute Csingle set to TRUE (use as single or single). This mechanism is only intended to be used to facilitate the interfacing of existing C and Fortran code.

The C type Rcomplex is defined in ‘Complex.h’ as a typedef struct {double r; double i;}. It may or may not be equivalent to the C99 double complex type, depending on the compiler used.

Logical values are sent as 0 (FALSE), 1 (TRUE) or INT_MIN = \(-2147483648\) (NA, but only if NAOK = TRUE), and the compiled code should return one of these three values: however non-zero values other than INT_MIN are mapped to TRUE.

Note: The C types corresponding to integer and logical are int, not long as in S. This difference matters on most 64-bit platforms, where int is 32-bit and long is 64-bit (but not on 64-bit Windows).
Note: The Fortran type corresponding to logical is integer, not logical: the difference matters on some Fortran compilers.

Missing (NA) string values are passed to .C as the string "NA". As the C char type can represent all possible bit patterns there appears to be no way to distinguish missing strings from the string "NA". If this distinction is important use .Call.

Fortran passes the first (only) character string of a character vector is passed as a C character array to Fortran: that may be usable as character*255 if its true length is passed separately. Only up to 255 characters of the string are passed back. (How well this works, and even if it works at all, depends on the C and Fortran compilers and the platform.)

Lists, functions are other R objects can (for historical reasons) be passed to .C, but the .Call interface is much preferred. All inputs apart from atomic vectors should be regarded as read-only, and all apart from vectors (including lists), functions and environments are now deprecated.

Warning

DUP = FALSE is dangerous.
People concerned about memory usage are strongly recommended to use the .Call interface instead of these interfaces.

If you pass a local variable to .C.Fortran with DUP = FALSE, your compiled code can alter the local variable and not just the copy in the return list. Worse, if you pass a local variable that is a formal parameter of the calling function, you may be able to change not only the local variable but the variable one level up. This will be very hard to trace.

With DUP = FALSE, character vectors cannot be used, and single precision values will not be returned.

It is safe and useful to set DUP = FALSE if you do not change any of the variables that might be affected, e.g.,

.C("Cfunction", input = x, output = numeric(10)).

In this case the output variable did not exist before the call so it cannot cause trouble (but as from R 2.15.1 it is not copied even with DUP = TRUE). If the input variable is not changed in the C code of Cfunction you are safe.

Fortran symbol names

All Fortran compilers known to be usable to compile R map symbol names to lower case, and so does .Fortran.

Symbol names containing underscores are not valid Fortran 77 (although they are valid in Fortran 9x). Many Fortran 77 compilers will allow them but may translate them in a different way to names not containing underscores. Such names will often work with .Fortran (since how they are translated is detected when R is built and the information used by .Fortran), but portable code should not use Fortran names containing underscores.

Use .Fortran with care for compiled Fortran 9x code: it may not work if the Fortran 9x compiler used differs from the Fortran 77 compiler used when configuring R, especially if the subroutine name is not lower-case or includes an underscore. It is also possible to use .C and do any necessary symbol-name translation yourself.

Copying of arguments

If DUP = TRUE there are up to two copies made of each argument in . . . . .

Prior to R 2.15.1 there were always two for vectors (one before calling the compiled code and one to collect the results), and this is still the case for character vectors. For other atomic vectors, the
argument is not copied before calling the compiled code if it is not otherwise used in the calling code (such as output in the example above). Non-atomic-vector objects are read-only to the C code and are never copied.

This behaviour can be changed by setting `options(CBoundsCheck = TRUE)`. In that case raw, logical, integer, double and complex vector arguments are copied both before and after calling the compiled code. The first copy made is extended at each end by guard bytes, and on return it is checked that these are unaltered. For `.C`, each element of a character vector uses guard bytes.

**Note**

If one of these functions is to be used frequently, do specify `PACKAGE` (to confine the search to a single DLL) or pass `.NAME` as one of the native symbol objects. Searching for symbols can take a long time, especially when many namespaces are loaded.

You may see `PACKAGE = "base"` for symbols linked into R. Do not use this in your own code: such symbols are not part of the API and may be changed without warning.

`PACKAGE = ""` used to be accepted (but was undocumented): it is now an error.

The way `pairlists` were passed by `.C` prior to R 2.15.0 was not as documented. This has been corrected, but the `.Call` and `.External` interfaces are much preferred for passing anything other than atomic vectors.

---

**formals**

**Access to and Manipulation of the Formal Arguments**

**Description**

Get or set the formal arguments of a function.

**Usage**

```r
formals(fun = sys.function(sys.parent()))
formals(fun, envir = environment(fun)) <- value
```

**Arguments**

- `fun` a function object, or see ‘Details’.
- `envir` environment in which the function should be defined.
- `value` a list (or pairlist) of R expressions.
Details

For the first form, fun can also be a character string naming the function to be manipulated, which is searched for from the parent frame. If it is not specified, the function calling `formals` is used.

Only closures have formals, not primitive functions.

Value

`formals` returns the formal argument list of the function specified, as a `pairlist`, or `NULL` for a non-function or primitive.

The replacement form sets the formals of a function to the list/pairlist on the right hand side, and (potentially) resets the environment of the function.

See Also

`args` for a human-readable version, `alist`, `body`, `function`.

Examples

```r
require(stats); require(graphics)
length(formals(lm))  # the number of formal arguments
names(formals(boxplot))  # formal arguments names

f <- function(x) a+b
formals(f) <- alist(a = , b = 3) # function(a, b = 3) a+b
f(2) # result = 5
```

Description

Format an R object for pretty printing.

Usage

```r
format(x, ...)
```

### Default S3 method:

```r
format(x, trim = FALSE, digits = NULL, nsmall = 0L,
       justify = c("left", "right", "centre", "none"),
       width = NULL, na.encode = TRUE, scientific = NA,
       big.mark = "",  big.interval = 3L,
       small.mark = "", small.interval = 5L,
       decimal.mark = ".", zero.print = NULL,
       drop.trailing = FALSE, ...)
```

### S3 method for class 'data.frame'

```r
format(x, ..., justify = "none")
```

### S3 method for class 'factor'

```r
format(x, ...)
```
## S3 method for class 'AsIs'

`format(x, width = 12, ...)`

### Arguments

- **x**: any R object (conceptually); typically numeric.
- **trim**: logical; if `FALSE`, logical, numeric and complex values are right-justified to a common width: if `TRUE` the leading blanks for justification are suppressed.
- **digits**: how many significant digits are to be used for numeric and complex `x`. The default, `NULL`, uses `getOption("digits")`. This is a suggestion: enough decimal places will be used so that the smallest (in magnitude) number has this many significant digits, and also to satisfy `nsmall`. (For the interpretation for complex numbers see `signif`).
- **nsmall**: the minimum number of digits to the right of the decimal point in formatting real/complex numbers in non-scientific formats. Allowed values are `0 <= nsmall <= 20`.
- **justify**: should a `character` vector be left-justified (the default), right-justified, centred or left alone.
- **width**: default method: the minimum field width or `NULL` or `0` for no restriction.
- **AsIs** method: the maximum field width for non-character objects. `NULL` corresponds to the default 12.
- **na.encode**: logical: should NA strings be encoded? Note this only applies to elements of character vectors, not to numerical or logical NAs, which are always encoded as "NA".
- **scientific**: Either a logical specifying whether elements of a real or complex vector should be encoded in scientific format, or an integer penalty (see `options("scipen")`). Missing values correspond to the current default penalty.
- **...**: further arguments passed to or from other methods.
- `big.mark`, `big.interval`, `small.mark`, `small.interval`, `decimal.mark`, `zero.print`, `drop0trailing` used for prettying (longish) decimal sequences, passed to `prettyNum`: that help page explains the details.

### Details

`format` is a generic function. Apart from the methods described here there are methods for dates (see `format.Date`), date-times (see `format.POSIXct`) and for other classes such as `format.owin` and `format.dist`.

`format.data.frame` formats the data frame column by column, applying the appropriate method of `format` for each column. Methods for columns are often similar to `as.character` but offer more control. Matrix and data-frame columns will be converted to separate columns in the result, and character columns (normally all) will be given class "AsIs".

`format.factor` converts the factor to a character vector and then calls the default method (and so `justify` applies).

`format.AsIs` deals with columns of complicated objects that have been extracted from a data frame. Character objects are passed to the default method (and so `width` does not apply). Otherwise it calls `toString` to convert the object to character (if a vector or list, element by element) and then right-justifies the result.
Justification for character vectors (and objects converted to character vectors by their methods) is done on display width (see `nchar`), taking double-width characters and the rendering of special characters (as escape sequences, including escaping backslash but not double quote: see `print.default`) into account. Thus the width is as displayed by `print(quote = FALSE)` and not as displayed by `cat`. Character strings are padded with blanks to the display width of the widest. (If `na.encode = FALSE` missing character strings are not included in the width computations and are not encoded.)

Numeric vectors are encoded with the minimum number of decimal places needed to display all the elements to at least the digits significant digits. However, if all the elements then have trailing zeroes, the number of decimal places is reduced until `nsmall` is reached or at least one element has a non-zero final digit; see also the argument documentation for `big`, `small`, `*` etc, above. See the note in `print.default` about `digits >= 16`.

Raw vectors are converted to their 2-digit hexadecimal representation by `as.character`.

**Value**

An object of similar structure to `x` containing character representations of the elements of the first argument `x` in a common format, and in the current locale’s encoding.

For character, numeric, complex or factor `x`, `dims` and `dimnames` are preserved on matrices/arrays and names on vectors: no other attributes are copied.

If `x` is a list, the result is a character vector obtained by applying `format.default(x, ...)` to each element of the list (after `unlist`ing elements which are themselves lists), and then collapsing the result for each element with `paste(collapse = "", ")`. The defaults in this case are `trim = TRUE`, `justify = "none"` since one does not usually want alignment in the collapsed strings.

**References**

**See Also**

`format.info` indicates how an atomic vector would be formatted.

`formatC`, `paste`, `as.character`, `sprintf`, `print`, `prettyNum`, `toString`, `encodeString`.

**Examples**

```r
format(1:10)
format(1:10, trim = TRUE)

zz <- data.frame("(row names)"= c("aaaaa", "b"), check.names = FALSE)
format(zz)
format(zz, justify = "left")

## use of nsmall
format(13.7)
format(13.7, nsmall = 3)
format(c(6.0, 13.1), digits = 2)
format(c(6.0, 13.1), digits = 2, nsmall = 1)

## use of scientific
format(2^31-1)
```
format(2^31-1, scientific = TRUE)

## a list
z <- list(a = letters[1:3], b = (-pi+0i)^((-2:2)/2), c = c(1,10,100,1000),
         d = c("a", "longer", "character", "string"),
         q = quote(a + b ), e = expression(1+x))
## can you find the "2" small differences?
(f1 <- format(z, digits = 2))
(f2 <- format(z, digits = 2, justify = "left", trim = FALSE))
f1 == f2 ## 2 FALSE, 4 TRUE

format.info  format(.) Information

Description

Information is returned on how `format(x, digits, nsmall)` would be formatted.

Usage

`format.info(x, digits = NULL, nsmall = 0)`

Arguments

- `x` an atomic vector; a potential argument of `format(x, ...)`
- `digits` how many significant digits are to be used for numeric and complex `x`. The default, `NULL`, uses `getOption("digits")`.
- `nsmall` (see `format(..., nsmall)`).

Value

An integer vector of length 1, 3 or 6, say `r`.

For logical, integer and character vectors a single element, the width which would be used by `format` if `width = NULL`.

For numeric vectors:

- `r[1]` width (in characters) used by `format(x)`
- `r[2]` number of digits after decimal point.
- `r[3]` in 0:2; if ≥1, exponential representation would be used, with exponent length of `r[3]+1`.

For a complex vector the first three elements refer to the real parts, and there are three further elements corresponding to the imaginary parts.

See Also

`format` (notably about `digits >= 16`), `formatC`. 
Examples

dd <- options("digits") : options(digits = 7) #-- for the following
format.info(123)  # 3 0 0
format.info(pi)   # 8 6 0
format.info(1e8)  # 5 0 1 - exponential "1e+88"
format.info(1e222) # 6 0 2 - exponential "1e+222"
x <- pi*10^c(-10,-2,0:2,8,20)
names(x) <- formatC(x, width = 1, digits = 3, format = "g")
cbind(sapply(x, format))
t(sapply(x, format.info))

## using at least 8 digits right of "."
t(sapply(x, format.info, nsmall = 8))

# Reset old options:
options(dd)

format.pval

Format P Values

Description

format.pval is intended for formatting p-values.

Usage

format.pval(pv, digits = max(1,getOption("digits") - 2),
            eps = .Machine$double.eps, na.form = "NA", ...)

Arguments

pv        a numeric vector.
digits    how many significant digits are to be used.
eps       a numerical tolerance: see ‘Details’.
na.form   character representation of NAs.
...        further arguments to be passed to format such as nsmall.

Details

format.pval is mainly an auxiliary function for print.summary.lm etc., and does separate formatting for fixed, floating point and very small values; those less than eps are formatted as "< [eps]" (where '[eps]' stands for format(eps, digits)).

Value

A character vector.

Examples

format.pval(c(stats::runif(5), pi^-100, NA))
format.pval(c(0.1, 0.0001, 1e-27))
### Description

Formatting numbers individually and flexibly, using C style format specifications.

### Usage

```r
formatC(x, digits = NULL, width = NULL,
    format = NULL, flag = "", mode = NULL,
    big.mark = ",", big.interval = 3L,
    small.mark = ",", small.interval = 5L,
    decimal.mark = ",", preserve.width = "individual",
    zero.print = NULL, dropTrailing = FALSE)
```

```r
PRETTYNum(x, big.mark = ",", big.interval = 3L,
    small.mark = ",", small.interval = 5L,
    decimal.mark = ",", preserve.width = c("common", "individual", "none",
    zero.print = NULL, dropTrailing = FALSE, is.complex = NA,
    ...)```

### Arguments

- **x**: an atomic numerical or character object, possibly complex only for `PRETTYNum()`, typically a vector of real numbers. Any class is discarded, with a warning.
- **digits**: the desired number of digits after the decimal point (`format = "f"`) or significant digits (`format = "g", "e" or = "fg"`).
- **Default**: 2 for integer, 4 for real numbers. If less than 0, the C default of 6 digits is used. If specified as more than 50, 50 will be used with a warning unless `format = "f"` where it is limited to typically 324. (Not more than 15–21 digits need be accurate, depending on the OS and compiler used. This limit is just a precaution against segfaults in the underlying C runtime.)
- **width**: the total field width; if both `digits` and `width` are unspecified, `width` defaults to 1, otherwise to `digits + 1`. `width = 0` will use `width = digits`, `width < 0` means left justify the number in this field (equivalent to `flag = "-"`). If necessary, the result will have more characters than `width`. For character data this is interpreted in characters (not bytes nor display width).
- **format**: equal to "d" (for integers), "f", "e", "E", "g", "G", "fg" (for reals), or "s" (for strings). Default is "d" for integers, "g" for reals. "f" gives numbers in the usual xxx.xxx format; "e" and "E" give n.ddde+nn or n.dddE+nn (scientific format); "g" and "G" put x[i] into scientific format only if it saves space to do so. "fg" uses fixed format as "f", but digits as the minimum number of significant digits. This can lead to quite long result strings, see examples below. Note that unlike `signif` this prints large numbers with more significant digits than digits. Trailing zeros are dropped in this format, unless `flag` contains "#".

### Notes

- The `flag` argument is used for formatting. It can contain the character "-", which indicates left justification. Other possible characters include "#", which indicates that trailing zeros are dropped, and "0", which indicates that leading zeros are added to ensure the total field width is met.

- The `mode` argument is used to specify the type of number to be formatted. This can be "i" for integers, "f" for floating point numbers, or "g" for scientific notation.

- The `preserve.width` argument is used to control how numbers are formatted. If specified as "individual", numbers will be formatted in the smallest possible field width. If specified as "common", numbers will be formatted in a uniform field width, which is at least twice the number of digits specified by `digits`. If specified as "none", no extra space will be added to the field width.

- The `dropTrailing` argument is used to control whether trailing zeros are dropped from the formatted result. If `false`, trailing zeros will be dropped. If `true`, trailing zeros will be retained.

- The `is.complex` argument is used to determine whether the input data is complex. If `true`, the input data is treated as complex and formatted accordingly. If `false`, the input data is treated as real.

- The `preserve.width` argument is used to control how numbers are formatted. If specified as "individual", numbers will be formatted in the smallest possible field width. If specified as "common", numbers will be formatted in a uniform field width, which is at least twice the number of digits specified by `digits`. If specified as "none", no extra space will be added to the field width.

- The `dropTrailing` argument is used to control whether trailing zeros are dropped from the formatted result. If `false`, trailing zeros will be dropped. If `true`, trailing zeros will be retained.

- The `is.complex` argument is used to determine whether the input data is complex. If `true`, the input data is treated as complex and formatted accordingly. If `false`, the input data is treated as real.
flag
For `formatC`, a character string giving a format modifier as in Kernighan and Ritchie (1988, page 243). "0" pads leading zeros; "-" does left adjustment, others are "+", ".", and ".#". There can be more than one of these, in any order.

mode
"double" (or "real"), "integer" or "character". Default: Determined from the storage mode of `x`.

big.mark
character; if not empty used as mark between every `big.interval` decimals before (hence big) the decimal point.

big.interval
see `big.mark` above; defaults to 3.

small.mark
character; if not empty used as mark between every `small.interval` decimals after (hence small) the decimal point.

small.interval
see `small.mark` above; defaults to 5.

decimal.mark
the character to be used to indicate the numeric decimal point.

preserve.width
string specifying if the string widths should be preserved where possible in those cases where marks (big.mark or small.mark) are added. "common", the default, corresponds to `format`-like behavior whereas "individual" is the default in `formatC()`.

zero.print
logical, character string or NULL specifying if and how zeros should be formatted specially. Useful for pretty printing 'sparse' objects.

drop.trailing
logical, indicating if trailing zeros, i.e., "0" after the decimal mark, should be removed; also drops "e+00" in exponential formats.

is.complex
optional logical, to be used when `x` is "character" to indicate if it stems from complex vector or not. By default (NA), `x` is checked to 'look like' complex.

... arguments passed to `format`.

Details
If you set `format` it overrides the setting of `mode`, so `formatC(123.45, mode = "double", format = "d")` gives 123.

The rendering of scientific format is platform-dependent: some systems use n.ddde+nnn or n.dddenn rather than n.dddenn.

`formatC` does not necessarily align the numbers on the decimal point, so `formatC(c(6.11, 13.1), digits = 2, format = "fg")` gives c("6.1", "13"). If you want common formatting for several numbers, use `format`.

`prettyNum` is the utility function for prettifying `x`. `x` can be complex (or `format(<complex>)`, here. If `x` is not a character, `format(x[1], ...)` is applied to each element, and then it is left unchanged if all the other arguments are at their defaults. Note that `prettyNum(x)` may behave unexpectedly if `x` is a character vector not resulting from something like `format(<number>):` in particular it assumes that a period is a decimal mark.

Because `gsub` is used to insert the `big.mark` and `small.mark`, special characters need escaping. In particular, to insert a single backslash, use "\\\".

In versions of R before 2.13.0, the `big.mark` would be reversed on insertion if it contained more than one character.

Value
A character object of same size and attributes as `x` (after discarding any class), in the current locale’s encoding.
Unlike `format`, each number is formatted individually. Looping over each element of `x`, the C function `sprintf(...)` is called for numeric inputs (inside the C function `str_signif`).

`formatC`: for character `x`, do simple (left or right) padding with white space.

**Note**

Prior to R 3.0.2 this copied the class of `x` to the return value and could easily create invalid objects.

**Author(s)**

`formatC` was originally written by Bill Dunlap for S-PLUS, later much improved by Martin Maechler.

It was first adapted for R by Friedrich Leisch and since much improved by the R Core team.

**References**

**See Also**

`format`,

`sprintf` for more general C like formatting.

**Examples**

```r
xx <- pi * 10^(-5:4)
cbind(format(xx, digits = 4), formatC(xx))
cbind(formatC(xx, width = 9, flag = "-"))
cbind(formatC(xx, digits = 5, width = 8, format = "f", flag = "0"))
cbind(format(xx, digits = 4), formatC(xx, digits = 4, format = "fg"))

formatC(c("a", "Abc", "no way"), width = -7)  # <= flag = "-"
formatC(c((-1:1)/6, c(1,100)*pi), width = 8, digits = 1)
```

## note that some of the results here depend on the implementation
## of long-double arithmetic, which is platform-specific.
xx <- c(1e-12, -3.98765e-10, 1.45645e-69, 1e-70, pi*1e37, 3.44e4)
##
formatC(xx)
formatC(xx, format = "fg")  # special "fixed" format.
formatC(xx[1:4], format = "f", digits = 75)  # even longer strings

formatC(c(3.24, 2.3e-6), format = "f", digits = 11, dropTrailing = TRUE)

r <- c("76491283764.97430", "29.12345678901", "-7.1234", "-100.1", "1123")
## American:
prettyNum(r, big.mark = ",")
## Some Europeans:
prettyNum(r, big.mark = "", decimal.mark = ",")

(dd <- sapply(1:10, function(i) paste((9:0)[1:i], collapse = "")))
prettyNum(dd, big.mark = "")

## examples of 'small.mark'

formatDL

Format Description Lists

Description

Format vectors of items and their descriptions as 2-column tables or LaTeX-style description lists.

Usage

formatDL(x, y, style = c("table", "list"),
width = 0.9 * getOption("width"), indent = NULL)

Arguments

x       a vector giving the items to be described, or a list of length 2 or a matrix with 2 columns giving both items and descriptions.
y       a vector of the same length as x with the corresponding descriptions. Only used if x does not already give the descriptions.
style   a character string specifying the rendering style of the description information. If "table", a two-column table with items and descriptions as columns is produced (similar to Texinfo’s @table environment. If "list", a LaTeX-style tagged description list is obtained.
width   a positive integer giving the target column for wrapping lines in the output.
indent  a positive integer specifying the indentation of the second column in table style, and the indentation of continuation lines in list style. Must not be greater than width/2, and defaults to width/3 for table style and width/9 for list style.
**Details**

After extracting the vectors of items and corresponding descriptions from the arguments, both are coerced to character vectors.

In table style, items with more than indent - 3 characters are displayed on a line of their own.

**Value**

a character vector with the formatted entries.

**Examples**

```r
## Not run:

## Use R to create the 'INDEX' for package 'splines' from its 'CONTENTS'
x <- read.dcf(file = system.file("CONTENTS", package = "splines"),
  fields = c("Entry", "Description"))
x <- as.data.frame(x)
writeLines(formatDL(x$Entry, x$Description))
## or equivalently: writeLines(formatDL(x))
## Same information in tagged description list style:
writeLines(formatDL(x$Entry, x$Description, style = "list"))
## or equivalently: writeLines(formatDL(x, style = "list"))

## End(Not run)
```

**Function Definition**

These functions provide the base mechanisms for defining new functions in the R language.

**Usage**

```r
function( arglist ) expr
return(value)
```

**Arguments**

- **arglist**: Empty or one or more name or name=expression terms.
- **expr**: An expression.
- **value**: An expression.

**Details**

The names in an argument list can be back-quoted non-standard names (see `backquote`).

If `value` is missing, NULL is returned. If it is a single expression, the value of the evaluated expression is returned. (The expression is evaluated as soon as `return` is called, in the evaluation frame of the function and before any `on.exit` expression is evaluated.)

If the end of a function is reached without calling `return`, the value of the last evaluated expression is returned.
Technical details

This type of function is not the only type in R: they are called closures (a name with origins in LISP) to distinguish them from primitive functions.

A closure has three components, its forms (its argument list), its body (expr in the ‘Usage’ section) and its environment which provides the enclosure of the evaluation frame when the closure is used.

There is an optional further component if the closure has been byte-compiled. This is not normally user-visible, but it indicated when functions are printed.

References

args, forms, body and environment for accessing the component parts of a function.

depend for debugging; using invisible inside return(.) for returning invisibly.

Examples

\[
\text{norm} \leftarrow \text{function}(x) \ \sqrt{x^2 + x^2}
\]

\[
\text{norm}(1:4)
\]

## An anonymous function:

\[
\text{function}(x, y)( z \leftarrow x^2 + y^2; x+y+z )(0:7, 1)
\]

---

funprog  
*Common Higher-Order Functions in Functional Programming Languages*

---

Description

Reduce uses a binary function to successively combine the elements of a given vector and a possibly given initial value. Filter extracts the elements of a vector for which a predicate (logical) function gives true. Find and Position give the first or last such element and its position in the vector, respectively. Map applies a function to the corresponding elements of given vectors. Negate creates the negation of a given function.

Usage

Reduce(f, x, init = FALSE, accumulate = FALSE)  
Filter(f, x)  
Find(f, x, right = FALSE, nomatch = NULL)  
Map(f, ...)  
Negate(f)  
Position(f, x, right = FALSE, nomatch = NA_integer_)
Arguments

- **f**: a function of the appropriate arity (binary for Reduce, unary for Filter, Find and Position, k-ary for Map if this is called with k arguments). An arbitrary predicate function for Negate.
- **x**: a vector.
- **init**: an R object of the same kind as the elements of x.
- **right**: a logical indicating whether to proceed from left to right (default) or from right to left.
- **accumulate**: a logical indicating whether the successive reduce combinations should be accumulated. By default, only the final combination is used.
- **nomatch**: the value to be returned in the case when “no match” (no element satisfying the predicate) is found.
- ... vectors.

Details

If **init** is given, Reduce logically adds it to the start (when proceeding left to right) or the end of x, respectively. If this possibly augmented vector **v** has \( n > 1 \) elements, Reduce successively applies **f** to the elements of **v** from left to right or right to left, respectively. I.e., a left reduce computes \( l_1 = f(v_1, v_2), l_2 = f(l_1, v_3), \ldots \), and returns \( l_{n-1} = f(l_{n-2}, v_n) \), and a right reduce does \( r_{n-1} = f(v_{n-1}, v_n), r_{n-2} = f(v_{n-2}, r_{n-1}) \), and returns \( r_1 = f(v_1, r_2) \). (E.g., if **v** is the sequence \( (2, 3, 4) \) and **f** is division, left and right reduce give \( (2/3)/4 = 1/6 \) and \( 2/(3/4) = 8/3 \), respectively.) If **v** has only a single element, this is returned; if there are no elements, NULL is returned. Thus, it is ensured that **f** is always called with 2 arguments.

The current implementation is non-recursive to ensure stability and scalability.

Reduce is patterned after Common Lisp’s reduce. A reduce is also known as a fold (e.g., in Haskell) or an accumulate (e.g., in the C++ Standard Template Library). The accumulative version corresponds to Haskell’s scan functions.

Filter applies the unary predicate function **f** to each element of x, coercing to logical if necessary, and returns the subset of x for which this gives true. Note that possible NA values are currently always taken as false; control over NA handling may be added in the future. Filter corresponds to filter in Haskell or remove-if-not in Common Lisp.

Find and Position are patterned after Common Lisp’s find-if and position-if, respectively. If there is an element for which the predicate function gives true, then the first or last such element or its position is returned depending on whether **right** is false (default) or true, respectively. If there is no such element, the value specified by **nomatch** is returned. The current implementation is not optimized for performance.

Map is a simple wrapper to mapply which does not attempt to simplify the result, similar to Common Lisp’s mapcar (with arguments being recycled, however). Future versions may allow some control of the result type.

Negate corresponds to Common Lisp’s complement. Given a (predicate) function **f**, it creates a function which returns the logical negation of what **f** returns.

Function clusterMap and mcmapply (not Windows) in package parallel provide parallel versions of Map.
Examples

## A general-purpose adder:
```haskell
add <- function(x) Reduce("+", x)
add(list(1, 2, 3))
```

## Like sum(), but can also be used for adding matrices etc., as it will
## use the appropriate '+ ' method in each reduction step.

## More generally, many generics meant to work on arbitrarily many
## arguments can be defined via reduction:
```haskell
FOO <- function(...) Reduce(FOO2, list(...))
```

## FOO() methods can then be provided via FOO2() methods.

## A general-purpose cumulative adder:
```haskell
cadd <- function(x) Reduce("+", x, accumulate = TRUE)
cadd(seq_len(7))
```

## A simple function to compute continued fractions:
```haskell
cfrac <- function(x) Reduce(function(u, v) u + 1 / v, x, right = TRUE)
```

## Continued fraction approximation for pi:
```haskell
cfrac(c(3, 7, 15, 1, 292))
```

## Continued fraction approximation for Euler's number (e):
```haskell
cfrac(c(2, 1, 2, 1, 4, 1, 1, 6, 1, 1, 8))
```

## Iterative function application:
```haskell
Funcall <- function(f, ...) f(...)
```

## Compute log(exp(acos(cos(0)))
Reduce(Funcall, list(log, exp, acos, cos), 0, right = TRUE)

## n-fold iterate of a function, functional style:
```haskell
function(x) Reduce(Funcall, rep.int(list(f), n), x, right = TRUE)
```

## Continued fraction approximation to the golden ratio:
```haskell
Iterate(function(x) 1 + 1 / x, 30)(1)
```

## which is the same as
```haskell
cfrac(rep.int(list(1, 31))
```

## Computing square root approximations for x as fixed points of the
## function t |–> (t + x / t) / 2, as a function of the initial value:
```haskell
asqrt <- function(x, n) Iterate(function(t) (t + x / t) / 2, n)
asqrt(2, 30)(10) # Starting from a positive value => +sqrt(2)
asqrt(2, 30)(-1) # Starting from a negative value => -sqrt(2)
```

## A list of all functions in the base environment:
```haskell
funs <- Filter(is.function, sapply(ls(baseenv()), get, baseenv()))
```

## Functions in base with more than 10 arguments:
```haskell
names(Filter(function(f) length(formals(args(f))) > 10, funs))
```

## Number of functions in base with a '...' argument:
```haskell
length(Filter(function(f)
    any(names(formals(args(f))) %in% "..."),
    funs))
```

## Find all objects in the base environment which are *not* functions:
```haskell
Filter(Negate(is.function), sapply(ls(baseenv()), get, baseenv()))
```
Description

A call of gc causes a garbage collection to take place. gcinfo sets a flag so that automatic collection is either silent (verbose = FALSE) or prints memory usage statistics (verbose = TRUE).

Usage

gc(verb®se = getOption("verb®se"), reset = FALSE)
gcinfo(verb®se)

Arguments

verbose logical; if TRUE, the garbage collection prints statistics about cons cells and the space allocated for vectors.
reset logical; if TRUE the values for maximum space used are reset to the current values.

Details

A call of gc causes a garbage collection to take place. This will also take place automatically without user intervention, and the primary purpose of calling gc is for the report on memory usage. However, it can be useful to call gc after a large object has been removed, as this may prompt R to return memory to the operating system.

R allocates space for vectors in multiples of 8 bytes: hence the report of "Vcells", a relict of an earlier allocator (that used a vector heap).

When gcinfo(TRUE) is in force, messages are sent to the message connection at each garbage collection of the form

Garbage collection 12 = 10+0+2 (level 0) ...
6.4 Mbytes of cons cells used (58%)
2.0 Mbytes of vectors used (32%)

Here the last two lines give the current memory usage rounded up to the next 0.1Mb and as a percentage of the current trigger value. The first line gives a breakdown of the number of garbage collections at various levels (for an explanation see the ‘R Internals’ manual).

Value

gc returns a matrix with rows "Ncells" (cons cells), usually 28 bytes each on 32-bit systems and 56 bytes on 64-bit systems, and "Vcells" (vector cells, 8 bytes each), and columns "used" and "gc trigger", each also interpreted in megabytes (rounded up to the next 0.1Mb).

If maxima have been set for either "Ncells" or "Vcells", a fifth column is printed giving the current limits in Mb (with NA denoting no limit).

The final two columns show the maximum space used since the last call to gc(reset = TRUE) (or since R started).

gcinfo returns the previous value of the flag.

See Also

The ‘R Internals’ manual.
Memory on R’s memory management, and gctorture if you are an R developer.
reg.finalizer for actions to happen at garbage collection.
Examples

```r
gc() # do it now
gcinfo(TRUE) #-- in the future, show when R does it
x <- integer(100000); for(i in 1:10) x <- c(x, i)
gcinfo(verbos = FALSE) #-- don't show it anymore

gc(TRUE)

gc(reset = TRUE)
```

Description

This function reports the time spent in garbage collection so far in the \texttt{R} session while GC timing was enabled.

Usage

```r
gc.time(on = TRUE)
```

Arguments

- \texttt{on} logical; if \texttt{TRUE}, GC timing is enabled.

Details

Due to timer resolution this may be under-estimate.

This is a \texttt{primitive}.

Value

A numerical vector of length 5 giving the user CPU time, the system CPU time, the elapsed time and children's user and system CPU times (normally both zero), of time spent doing garbage collection whilst GC timing was enabled.

Times of child processes are not available on Windows and will always be given as \texttt{NA}.

See Also

- \texttt{gc}, \texttt{proc.time} for the timings for the session.

Examples

```r
gc.time()
```
**gctorture**  
*Torture Garbage Collector*

**Description**

Provokes garbage collection on (nearly) every memory allocation. Intended to ferret out memory protection bugs. Also makes R run *very* slowly, unfortunately.

**Usage**

```
gc_torture(on = TRUE)  
gc_torture2(step, wait = step, inhibit_release = FALSE)
```

**Arguments**

- **on** logical; turning it on/off.
- **step** integer; run GC every step allocations; step 0 turns the GC torture off.
- **wait** integer; number of allocations to wait before starting GC torture.
- **inhibit_release** logical; do not release free objects for re-use: use with caution.

**Details**

Calling `gc_torture(TRUE)` instructs the memory manager to force a full GC on every allocation. `gc_torture2` provides a more refined interface that allows the start of the GC torture to be deferred and also gives the option of running a GC only every `step` allocations.

The third argument to `gc_torture2` is only used if R has been configured with a strict write barrier enabled. When this is the case all garbage collections are full collections, and the memory manager marks free nodes and enables checks in many situations that signal an error when a free node is used. This can greatly help in isolating unprotected values in C code. It does not detect the case where a node becomes free and is reallocated. The `inhibit_release` argument can be used to prevent such reallocation. This will cause memory to grow and should be used with caution and in conjunction with operating system facilities to monitor and limit process memory use.

**Value**

Previous value of first argument.

**Author(s)**

Peter Dalgaard and Luke Tierney
get  

Return the Value of a Named Object

Description

Search by name for an object (get) or zero or more objects (mget).

Usage

get(x, pos = -1, envir = as.environment(pos), mode = "any", inherits = TRUE)
mget(x, envir = as.environment(-1), mode = "any", ifnotfound, inherits = FALSE)

Arguments

x For get, an object name (given as a character string). For mget, a character vector of object names.
pos, envir where to look for the object (see 'Details'); if omitted search as if the name of the object appeared unquoted in an expression.
mode the mode or type of object sought: see the 'Details' section.
inherits should the enclosing frames of the environment be searched?
ifnotfound A list of values to be used if the item is not found: it will be coerced to a list if necessary.

Details

The pos argument can specify the environment in which to look for the object in any of several ways: as a positive integer (the position in the search list); as the character string name of an element in the search list; or as an environment (including using sys.frame to access the currently active function calls). The default of -1 indicates the current environment of the call to get. The envir argument is an alternative way to specify an environment.

These functions look to see if each of the name(s) x have a value bound to it in the specified environment. If inherits is TRUE and a value is not found for x in the specified environment, the enclosing frames of the environment are searched until the name x is encountered. See environment and the 'R Language Definition' manual for details about the structure of environments and their enclosures.

If mode is specified then only objects of that type are sought. mode here is a mixture of the meanings of typeof and mode: "function" covers primitive functions and operators, "numeric","integer" and "double" all refer to any numeric type, "symbol" and "name" are equivalent but "language" must be used (and not "call" or "("). For mget, the values of mode and ifnotfound can be either the same length as x or of length 1. The argument ifnotfound must be a list containing either the value to use if the requested item is not found or a function of one argument which will be called if the item is not found, with argument the name of the item being requested.

Value

For get, the object found. If no object is found an error results.

For mget, a named list of objects (found or specified via ifnotfound).
getDLLRegisteredRoutines

Note

The reverse of `<- get(nam)` is `assign(nam, a)`. 

`inherits = TRUE` is the default for `get` in `R` but not for `S` where it had a different meaning.

References

See Also

`exists, assign`.

Examples

```r
get("%o%")
```

```r
## test mget
e1 <- new.env()
mget(letters, e1, ifnotfound = as.list(LETTERS))
```

---

**getDLLRegisteredRoutines**

*Reflectance Information for C/Fortran routines in a DLL*

**Description**

This function allows us to query the set of routines in a DLL that are registered with R to enhance dynamic lookup, error handling when calling native routines, and potentially security in the future. This function provides a description of each of the registered routines in the DLL for the different interfaces, i.e. `.C`, `.Call`, `.Fortran` and `.External`.

**Usage**

```r
getDLLRegisteredRoutines(dll, addNames = TRUE)
```

**Arguments**

dll

a character string or DLLInfo object. The character string specifies the file name of the DLL of interest, and is given without the file name extension (e.g., the `.dll` or `.so`) and with no directory/path information. So a file `MyPackage/libs/MyPackage.so` would be specified as `MyPackage`.

The DLLInfo objects can be obtained directly in calls to `dyn.load` and `library.dynam`, or can be found after the DLL has been loaded using `getLoadedDLLs`, which returns a list of DLLInfo objects (index-able by DLL file name).

The DLLInfo approach avoids any ambiguities related to two DLLs having the same name but corresponding to files in different directories.
addNames a logical value. If this is TRUE, the elements of the returned lists are named using the names of the routines (as seen by R via registration or raw name). If FALSE, these names are not computed and assigned to the lists. As a result, the call should be quicker. The name information is also available in the NativeSymbolInfo objects in the lists.

Details

This takes the registration information after it has been registered and processed by the R internals. In other words, it uses the extended information.

There is print methods for the class, which prints only the types which have registered routines.

Value

A list of class "DLLRegisteredRoutines" with four elements corresponding to the routines registered for the .C, .Call, .Fortran and .External interfaces. Each is a list with as many elements as there were routines registered for that interface.

Each element identifies a routine and is an object of class "NativeSymbolInfo". An object of this class has the following fields:

- name the registered name of the routine (not necessarily the name in the C code).
- address the memory address of the routine as resolved in the loaded DLL. This may be NULL if the symbol has not yet been resolved.
- dll an object of class DLLInfo describing the DLL. This is same for all elements returned.
- numParameters the number of arguments the native routine is to be called with. In the future, we will provide information about the types of the parameters also.

Author(s)

Duncan Temple Lang <duncan@wald.ucdavis.edu>

References

‘Writing R Extensions Manual’ for symbol registration.

getLoadedDLLs, getNativeSymbolInfo for information on the entry points listed.

Examples

dlls <- getLoadedDLLs()
getDLLRegisteredRoutines(dlls["base"])
getDLLRegisteredRoutines("stats")
getLoadedDLLs

Get DLLs Loaded in Current Session

Description

This function provides a way to get a list of all the DLLs (see `dyn.load`) that are currently loaded in the R session.

Usage

getLoadedDLLs()

Details

This queries the internal table that manages the DLLs.

Value

An object of class "DLLInfoList" which is a list with an element corresponding to each DLL that is currently loaded in the session. Each element is an object of class "DLLInfo" which has the following entries.

- **name**: the abbreviated name.
- **path**: the fully qualified name of the loaded DLL.
- **dynamcLookup**: a logical value indicating whether R uses only the registration information to resolve symbols or whether it searches the entire symbol table of the DLL.
- **handle**: a reference to the C-level data structure that provides access to the contents of the DLL. This is an object of class "DLLHandle".

Note that the class `DLLInfo` has an overloaded method for `$` which can be used to resolve native symbols within that DLL. Therefore, one must access the R-level elements described above using `[[`, e.g. `x[['name']]` or `x[['handle']]`.

Note

We are starting to use the handle elements in the DLL object to resolve symbols more directly in R.

- `getNativeSymbolInfo`

Examples

getLoadedDLLs()
**getDescription**

Obtain a Description of one or more Native (C/Fortran) Symbols

**Description**

This finds and returns a description of one or more dynamically loaded or ‘exported’ built-in native symbols. For each name, it returns information about the name of the symbol, the library in which it is located and, if available, the number of arguments it expects and by which interface it should be called (i.e. Call, .C, .Fortran, or .External). Additionally, it returns the address of the symbol and this can be passed to other C routines. Specifically, this provides a way to explicitly share symbols between different dynamically loaded package libraries. Also, it provides a way to query where symbols were resolved, and aids diagnosing strange behavior associated with dynamic resolution.

**Usage**

```r
getDescription(name, PACKAGE, unlist = TRUE,
                withRegistrationInfo = FALSE)
```

**Arguments**

- `name` the name(s) of the native symbol(s).
- `PACKAGE` an optional argument that specifies to which DLL to restrict the search for this symbol. If this is “base”, we search in the R executable itself.
- `unlist` a logical value which controls how the result is returned if the function is called with the name of a single symbol. If `unlist` is TRUE and the number of symbol names in `name` is one, then the `getDescription` object is returned. If it is FALSE, then a list of `getDescription` objects is returned. This is ignored if the number of symbols passed in `name` is more than one. To be compatible with earlier versions of this function, this defaults to TRUE.
- `withRegistrationInfo` a logical value indicating whether, if TRUE, to return information that was registered with R about the symbol and its parameter types if such information is available, or if FALSE to return just the address of the symbol.

**Details**

This uses the same mechanism for resolving symbols as is used in all the native interfaces (.Call, etc.). If the symbol has been explicitly registered by the DLL in which it is contained, information about the number of arguments and the interface by which it should be called will be returned. Otherwise, a generic native symbol object is returned.

**Value**

Generally, a list of `getDescription` elements whose elements can be indexed by the elements of `name` in the call. Each `getDescription` object is a list containing the following elements:

- `name` the name of the symbol, as given by the name argument.
if `withRegistrationInfo` is `FALSE`, this is the native memory address of the symbol which can be used to invoke the routine, and also to compare with other symbol addresses. This is an external pointer object and of class `NativeSymbol`. If `withRegistrationInfo` is `TRUE` and registration information is available for the symbol, then this is an object of class `RegisteredNativeSymbol` and is a reference to an internal data type that has access to the routine pointer and registration information. This too can be used in calls to `.Call`, `.C`, `.Fortran` and `.External`.

A list containing 3 elements:

- **name** the short form of the library name which can be used as the value of the `PACKAGE` argument in the different native interface functions.
- **path** the fully qualified name of the DLL.
- **dynamicLookup** a logical value indicating whether dynamic resolution is used when looking for symbols in this library, or only registered routines can be located.

If the routine was explicitly registered by the dynamically loaded library, the list contains a fourth field:

- **numParameters** the number of arguments that should be passed in a call to this routine.

Additionally, the list will have an additional class, being `CRoutine`, `CallRoutine`, `FortranRoutine` or `ExternalRoutine` corresponding to the R interface by which it should be invoked.

If any of the symbols is not found, an error is raised.

If `name` contains only one symbol name and `unlist` is `TRUE`, then the single `NativeSymbolInfo` is returned rather than the list containing that one element.

**Note**

One motivation for accessing this reflectance information is to be able to pass native routines to C routines as function pointers in C. This allows us to treat native routines and R functions in a similar manner, such as when passing an R function to C code that makes callbacks to that function at different points in its computation (e.g., `nls`). Additionally, we can resolve the symbol just once and avoid resolving it repeatedly or using the internal cache.

gettext  Translate Text Messages

Description
If Native Language Support was enabled in this build of R, attempt to translate character vectors or set where the translations are to be found.

Usage
gettext(..., domain = NULL)
ngettext(n, msg1, msg2, domain = NULL)
bindtextdomain(domain, dirname = NULL)

Arguments
... One or more character vectors.
domain The ‘domain’ for the translation.
n a non-negative integer.
msg1 the message to be used in English for n = 1.
msg2 the message to be used in English for n = 0, 2, 3, ....
dirname The directory in which to find translated message catalogs for the domain.

Details
If domain is NULL or "", a domain is searched for based on the namespace which contains the function calling gettext or ngettext. If a suitable domain can be found, each character string is offered for translation, and replaced by its translation into the current language if one is found. The value (logical) NA suppresses any translation.

Conventionally the domain for R warning/error messages in package pkg is "R-pkg", and that for C-level messages is "pkg".

For gettext, leading and trailing whitespace is ignored when looking for the translation.
ngettext is used where the message needs to vary by a single integer. Translating such messages is subject to very specific rules for different languages: see the GNU Gettext Manual. The string will often contain a single instance of %d to be used in sprintf. If English is used, msg1 is returned if n == 1 and msg2 in all other cases.

Value
For gettext, a character vector, one element per string in .... If translation is not enabled or no domain is found or no translation is found in that domain, the original strings are returned.
For ngettext, a character string.
For bindtextdomain, a character string giving the current base directory, or NULL if setting it failed.
getwd

Get or Set Working Directory

Description

getwd returns an absolute filepath representing the current working directory of the R process; setwd(dir) is used to set the working directory to dir.

Usage

getwd()
setwd(dir)

Arguments

dir A character string: tilde expansion will be done.
Value

getwd returns a character string or NULL if the working directory is not available. On Windows the path returned will use / as the path separator and be encoded in UTF-8. The path will not have a trailing / unless it is the root directory (of a drive or share on Windows).

setwd returns the current directory before the change, invisibly and with the same conventions as getwd. It will give an error if it does not succeed (including if it is not implemented).

Note

Note that the return value is said to be an absolute filepath: there can be more than one representation of the path to a directory and on some OSes the value returned can differ after changing directories and changing back to the same directory (for example if symbolic links have been traversed).

See Also

list.files for the contents of a directory.
normalizePath for a ‘canonical’ path name.

Examples

```r
 WD <- getwd()
 if (!is.null(WD)) setwd(WD)
```

---

### gl

**Generate Factor Levels**

Description

Generate factors by specifying the pattern of their levels.

Usage

gl(n, k, length = n*k, labels = 1:n, ordered = FALSE)

Arguments

- **n**: an integer giving the number of levels.
- **k**: an integer giving the number of replications.
- **length**: an integer giving the length of the result.
- **labels**: an optional vector of labels for the resulting factor levels.
- **ordered**: a logical indicating whether the result should be ordered or not.

Value

The result has levels from 1 to n with each value replicated in groups of length k out to a total length of length.

gl is modelled on the GLIM function of the same name.
grep

Pattern Matching and Replacement

decription

grep, grepl, regexpr and gregexpr search for matches to argument pattern within each element of a character vector: they differ in the format of and amount of detail in the results. sub and gsub perform replacement of the first and all matches respectively.

Usage

grep(pattern, x, ignore.case = FALSE, perl = FALSE, value = FALSE, fixed = FALSE, useBytes = FALSE, invert = FALSE)

grepl(pattern, x, ignore.case = FALSE, perl = FALSE, fixed = FALSE, useBytes = FALSE)

sub(pattern, replacement, x, ignore.case = FALSE, perl = FALSE, fixed = FALSE, useBytes = FALSE)

gsub(pattern, replacement, x, ignore.case = FALSE, perl = FALSE, fixed = FALSE, useBytes = FALSE)

regexpr(pattern, text, ignore.case = FALSE, perl = FALSE, fixed = FALSE, useBytes = FALSE)

gregexpr(pattern, text, ignore.case = FALSE, perl = FALSE, fixed = FALSE, useBytes = FALSE)

regexec(pattern, text, ignore.case = FALSE, fixed = FALSE, useBytes = FALSE)

Arguments

pattern character string containing a regular expression (or character string for fixed = TRUE) to be matched in the given character vector. Coerced by as.character to a character string if possible. If a character vector of length 2 or more is supplied, the first element is used with a warning. Missing values are allowed except for regexpr and gregexpr.
grep

x, text  a character vector where matches are sought, or an object which can be coerced by as.character to a character vector. Long vectors are supported.

ignore.case  if FALSE, the pattern matching is case sensitive and if TRUE, case is ignored during matching.

perl  logical. Should perl-compatible regexps be used?

value  if FALSE, a vector containing the (integer) indices of the matches determined by grep is returned, and if TRUE, a vector containing the matching elements themselves is returned.

fixed  logical. If TRUE, pattern is a string to be matched as is. Overrides all conflicting arguments.

useBytes  logical. If TRUE the matching is done byte-by-byte rather than character-by-character. See ‘Details’.

invert  logical. If TRUE return indices or values for elements that do not match.

replacement  a replacement for matched pattern in sub and gsub. Coerced to character if possible. For fixed = FALSE this can include backreferences \1 to \9 to parenthesized subexpressions of pattern. For perl = TRUE only, it can also contain \U or \L to convert the rest of the replacement to upper or lower case and \E to end case conversion. If a character vector of length 2 or more is supplied, the first element is used with a warning. If NA, all elements in the result corresponding to matches will be set to NA.

Details

Arguments which should be character strings or character vectors are coerced to character if possible.

Each of these functions (apart from regexec, which currently does not support Perl-style regular expressions) operates in one of three modes:

1. fixed = TRUE: use exact matching.
2. perl = TRUE: use Perl-style regular expressions.
3. fixed = FALSE, perl = FALSE: use POSIX 1003.2 extended regular expressions.

See the help pages on regular expression for details of the different types of regular expressions.

The two *sub functions differ only in that sub replaces only the first occurrence of a pattern whereas gsub replaces all occurrences. If replacement contains backreferences which are not defined in pattern the result is undefined (but most often the backreference is taken to be ").

For regexpr, gregexpr and regexec it is an error for pattern to be NA, otherwise NA is permitted and gives an NA match.

The main effect of useBytes is to avoid errors/warnings about invalid inputs and spurious matches in multibyte locales, but for regexpr it changes the interpretation of the output. It inhibits the conversion of inputs with marked encodings, and is forced if any input is found which is marked as "bytes".

Caseless matching does not make much sense for bytes in a multibyte locale, and you should expect it only to work for ASCII characters if useBytes = TRUE.

regexpr and gregexpr with perl = TRUE allow Python-style named captures, but not for long vector inputs.
**Value**

`grep(value = FALSE)` returns a vector of the indices of the elements of `x` that yielded a match (or not, for `invert = TRUE`). This will be an integer vector unless the input is a *long vector*, when it will be a double vector.

`grep(value = TRUE)` returns a character vector containing the selected elements of `x` (after coercion, preserving names but no other attributes).

`grep1` returns a logical vector (match or not for each element of `x`).

For `sub` and `gsub` return a character vector of the same length and with the same attributes as `x` (after possible coercion to character). Elements of character vectors `x` which are not substituted will be returned unchanged (including any declared encoding). If `useBytes = FALSE` a non-ASCII substituted result will often be in UTF-8 with a marked encoding (e.g. if there is a UTF-8 input, and in a multibyte locale unless `fixed = TRUE`). Such strings can be re-encoded by `enc2native`.

`regexpr` returns an integer vector of the same length as `text` giving the starting position of the first match or −1 if there is none, with attribute "match.length", an integer vector giving the length of the matched text (or −1 for no match). The match positions and lengths are in characters unless `useBytes = TRUE` is used, when they are in bytes. If named capture is used there are further attributes "capture.start", "capture.length" and "capture.names".

`gregexpr` returns a list of the same length as `text` each element of which is of the same form as the return value for `regexpr`, except that the starting positions of every (disjoint) match are given.

`regexec` returns a list of the same length as `text` each element of which is either −1 if there is no match, or a sequence of integers with the starting positions of the match and all substrings corresponding to parenthesized subexpressions of `pattern`, with attribute "match.length" a vector giving the lengths of the matches (or −1 for no match).

**Warning**

POSIX 1003.2 mode of `gsub` and `gregexpr` does not work correctly with repeated word-boundaries (e.g. `pattern = \b`). Use `perl = TRUE` for such matches (but that may not work as expected with non-ASCII inputs, as the meaning of ‘word’ is system-dependent).

**Performance considerations**

If you are doing a lot of regular expression matching, including on very long strings, you will want to consider the options used. Generally PCRE will be faster than the default regular expression engine, and `fixed = TRUE` faster still (especially when each pattern is matched only a few times).

If you are working in a single-byte locale and have marked UTF-8 strings that are representable in that locale, convert them first as just one UTF-8 string will force all the matching to be done in Unicode, which attracts a penalty of around 3 × for the default POSIX 1003.2 mode.

If you can make use of `useBytes = TRUE`, the strings will not be checked before matching, and the actual matching will be faster. Often byte-based matching suffices in a UTF-8 locale since byte patterns of one character never match part of another.

**Source**

The C code for POSIX-style regular expression matching has changed over the years. As from R 2.10.0 the TRE library of Ville Laurikari (http://laurikari.net/tre/) is used. The POSIX standard does give some room for interpretation, especially in the handling of invalid regular expressions and the collation of character ranges, so the results will have changed slightly over the years.

For Perl-style matching PCRE (http://www.pcre.org) is used.

Examples
grep("[a-z]", letters)

```
txt <- c("arm","foot","lefoo","bafooobar")
if(length(i <- grep("foo", txt)))
  cat("'foo' appears at least once in\n\n\t", txt, \"
"
) i # 2 and 4
txt[i]
```

```
## Double all 'a' or 'b's; "\" must be escaped, i.e., 'doubled'
gsub("([ab])","\\\", "abc and ABC")
```

```
txt <- c("The", "licenses", "for", "most", "software", "are", "designed", "to", "take", "away", "your", "freedom", "to", "share", "and", "change", "it.", ", "By", "contrast.", "the", "GNU", "General", "Public", "License", "is", "intended", "to", "guarantee", "your", "freedom", "to", "share", "and", "change", "free", "software", "--", "to", "make", "sure", "the", "software", "is", "free", "for", "all", "its", "users")
  ( i <- grep("[gu]", txt) ) # indices
  stopifnot( txt[i] == grep("[gu]", txt, value = TRUE) )
```

```
## Note that in locales such as en_US this includes B as the
## collation order is aAaBbCcCdDeEe ...
  (ot <- sub("[b-e]","\", txt))
txt[!ot != gsub("[b-e]","\", txt)]# gsub does "global" substitution
```

```
txt.gsub("g","#", txt) !=
gsub(\"g","#", txt, ignore.case = TRUE) ] the "G" words
```

```
regexpr("en", txt)
gregexpr("e", txt)
```

```
## Using grep() for filtering
```
## Find functions with argument names matching "warn":

```r
findArgs <- function(env, pattern) {
  nms <- ls(env = as.environment(env))
  nms <- nms[is.na(match(nms, c("F","T")))] # work around "checking hack"
  aa <- sapply(nms, function(.) {
    oo <- get(.)
    if(is.function(oo)) names(formals(oo))
  })
  iw <- sapply(aa, function(a) any(grepl(pattern, a, ignore.case=TRUE)))
  aa[iw]
}
findArgs("package:base", "warn")
```

### trim trailing white space

```r
str <- "Now is the time"
sub(" +$", "", str) # spaces only
sub("\[[:space:]\]+$", ", str) # white space, POSIX-style
sub("\[\+\]+$", ", str, perl = TRUE) # Perl-style white space
```

### capitalizing

```r
txt <- "a test of capitalizing"
gsub("\[\-\]\", "\tMillard Fillmore")
gregexpr(name.rex, notables, perl = TRUE)
```

### named capture

```r
notables <- c(" Ben Franklin and Jefferson Davis",
"\tMillard Fillmore")
# name groups 'first' and 'last'
name.rex <- "(?<first>\[[:upper:]][[:lower:]]+) (?<last>\[[:upper:]][[:lower:]]+)
(parsed <- regexpr(name.rex, notables, perl = TRUE))
gregexpr(name.rex, notables, perl = TRUE)[2]
```

### Decompose a URL into its components.

```r
# Example by LT (http://www.cs.uiowa.edu/~luke/R/regexp.html).
x <- "http://stat.unm.edu:80/xyz"
m <- regexec("(\^[\-\]+://)?([^:/]+)(::([0-9]+))?(/.*)", x)
```

```r
# Element 3 is the protocol, 4 is the host, 6 is the port, and 7
# is the path. We can use this to make a function for extracting the
# parts of a URL:
URL_parts <- function(x) {
m <- regexec("(\^[\-\]+://)?([^:/]+)(::([0-9]+))?(/.*)", x)
  parts <- do.call(rbind,
    lapply(regmatches(x, m), c(3L, 4L, 6L, 7L)))
```
grepRaw

Pattern Matching for Raw Vectors

description

grepRaw searches for substring pattern matches within a raw vector x.

usage

grepRaw(pattern, x, offset = 1L, ignore.case = FALSE,
value = FALSE, fixed = FALSE, all = FALSE, invert = FALSE)

arguments

pattern raw vector containing a regular expression (or fixed pattern for fixed = TRUE) to be matched in the given raw vector. Coerced by charToRaw to a character string if possible.

x a raw vector where matches are sought, or an object which can be coerced by charToRaw to a raw vector. Long vectors are not supported.

ignore.case if FALSE, the pattern matching is case sensitive and if TRUE, case is ignored during matching.

offset An integer specifying the offset from which the search should start. Must be positive. The beginning of line is defined to be at that offset so "^" will match there.

value logical. Determines the return value: see ‘Value’.

fixed logical. If TRUE, pattern is a pattern to be matched as is.

all logical. If TRUE all matches are returned, otherwise just the first one.

invert logical. If TRUE return indices or values for elements that do not match. Ignored (with a warning) unless value = TRUE.

details

Unlike grep, seeks matching patterns within the raw vector x. This has implications especially in the all = TRUE case, e.g., patterns matching empty strings are inherently infinite and thus may lead to unexpected results.

The argument invert is interpreted as asking to return the complement of the match, which is only meaningful for value = TRUE. Argument offset determines the start of the search, not of the complement. Note that invert = TRUE with all = TRUE will split x into pieces delimited by the pattern including leading and trailing empty strings (consequently the use of regular expressions with "^" or "$" in that case may lead to less intuitive results).

Some combinations of arguments such as fixed = TRUE with value = TRUE are supported but are less meaningful.
Value

grepRaw(value = FALSE) returns an integer vector of the offsets at which matches have occurred. If all = FALSE then it will be either of length zero (no match) or length one (first matching position).

grepRaw(value = TRUE, all = FALSE) returns a raw vector which is either empty (no match) or the matched part of x.

grepRaw(value = TRUE, all = TRUE) returns a (potentially empty) list of raw vectors corresponding to the matched parts.

Source

The TRE library of Ville Laurikari (http://laurikari.net/tre/) is used except for fixed = TRUE.

See Also

regular expression (aka regexp) for the details of the pattern specification.
grep for matching character vectors.
Details

There are four groups for which S3 methods can be written, namely the "Math", "Ops", "Summary" and "Complex" groups. These are not R objects in base R, but methods can be supplied for them and base R contains factor, data.frame and difftime methods for the first three groups. (There is also a ordered method for Ops, POSIXt and Date methods for Math and Ops, package_version methods for Ops and Summary, as well as a ts method for Ops in package stats.)

1. Group "Math":
   • abs, sign, sqrt, floor, ceiling, trunc, round, signif
   • exp, log, expm1, log1p, cos, sin, tan, acos, asin, atan
cosh, sinh, tanh, acosh, asinh, atanh
   • lgamma, gamma, digamma, trigamma
   • cumsum, cumprod, cummax, cummin

Members of this group dispatch on x. Most members accept only one argument, but members log, round and signif accept one or two arguments, and trunc accepts one or more.

2. Group "Ops":
   • "+", "-", "/", "/", "/", "/", "/", "/"
   • "&", "|", ">

This group contains both binary and unary operators (+, - and !): when a unary operator is encountered the Ops method is called with one argument and e2 is missing.

The classes of both arguments are considered in dispatching any member of this group. For each argument its vector of classes is examined to see if there is a matching specific (preferred) or Ops method. If a method is found for just one argument or the same method is found for both, it is used. If different methods are found, there is a warning about ‘incompatible methods’: in that case or if no method is found for either argument the internal method is used.

If the members of this group are called as functions, any argument names are removed to ensure that positional matching is always used.

3. Group "Summary":
   • all, any
   • sum, prod
   • min, max
   • range

Members of this group dispatch on the first argument supplied.

4. Group "Complex":
   • Arg, Conj, Im, Mod, Re

Members of this group dispatch on z.

Note that a method will be used for one of these groups or one of its members only if it corresponds to a "class" attribute, as the internal code dispatches on oldClass and not on class. This is for efficiency: having to dispatch on, say, Ops.integer would be too slow.
The number of arguments supplied for primitive members of the "Math" group generic methods is not checked prior to dispatch.

There is no lazy evaluation of arguments for group-generic functions.

Technical Details

These functions are all primitive and internal generic.

The details of method dispatch and variables such as .Generic are discussed in the help for UseMethod. There are a few small differences:

- For the operators of group Ops, the object .Method is a length-two character vector with elements the methods selected for the left and right arguments respectively. (If no method was selected, the corresponding element is ".".)
- Object .Group records the group used for dispatch (if a specific method is used this is ".").

Note

Package methods does contain objects with these names, which it has re-used in confusing similar (but different) ways. See the help for that package.

See Also

methods for methods of non-internal generic functions.
S4groupGeneric for group generics for S4 methods.

Examples

```r
require(utils)

d.fr <- data.frame(x = 1:9, y = stats::rnorm(9))
class(1 + d.fr) == "data.frame" #-- add to d.f. ...

methods("Math")
methods("Ops")
methods("Summary")
methods("Complex") # none in base R
```

Description

gzcon provides a modified connection that wraps an existing connection, and decompresses reads or compresses writes through that connection. Standard gzip headers are assumed.
Usage

gzcon(con, level = 6, allowNonCompressed = TRUE)

Arguments

con           a connection.
level         integer between 0 and 9, the compression level when writing.
allowNonCompressed
              logical. When reading, should non-compressed input be allowed?

Details

If con is open then the modified connection is opened. Closing the wrapper connection will also
close the underlying connection.

Reading from a connection which does not supply a gzip magic header is equivalent to reading
from the original connection if allowNonCompressed is true, otherwise an error.

Compressed output will contain embedded NUL bytes, and so con is not permitted to be a
textConnection opened with open = "w". Use a writable rawConnection to compress data
into a variable.

The original connection becomes unusable: any object pointing to it will now refer to the modified
connection. For this reason, the new connection needs to be closed explicitly.

Value

An object inheriting from class "connection". This is the same connection number as supplied,
but with a modified internal structure. It has binary mode.

See Also

gzfile

Examples

## Uncompress a data file from a URL
z <- gzcon(url("http://www.stats.ox.ac.uk/pub/datasets/csb/ch12.dat.gz"))
# read.table can only read from a text-mode connection.
raw <- textConnection(readLines(z))
close(z)
dat <- read.table(raw)
close(raw)
dat[1:4, ]

## gzfile and gzcon can inter-work.
## Of course here one would use gzfile, but file() can be replaced by
## any other connection generator.
zz <- gzfile("ex.gz", "w")
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file = zz, sep = "\n")
close(zz)
readLines(zz <- gzcon(file("ex.gz", "rb")))
close(zz)
unlink("ex.gz")
zz <- gzcon(file("ex2.gz", "wb"))
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file = zz, sep = "\n")
close(zz)
readlines(zz <- gzfile("ex2.gz"))
close(zz)
unlink("ex2.gz")

hexmode
display Numbers in Hexadecimal

Description

Convert or print integers in hexadecimal format, with as many digits as are needed to display the largest, using leading zeroes as necessary.

Usage

as.hexmode(x)

## S3 method for class 'hexmode'
as.character(x, ...)

## S3 method for class 'hexmode'
format(x, width = NULL, upper.case = FALSE, ...)

## S3 method for class 'hexmode'
print(x, ...)

Arguments

x An object, for the methods inheriting from class "hexmode".
width NULL or a positive integer specifying the minimum field width to be used, with padding by leading zeroes.
upper.case a logical indicating whether to use upper-case letters or lower-case letters (default).
... further arguments passed to or from other methods.

Details

Class "hexmode" consists of integer vectors with that class attribute, used merely to ensure that they are printed in hex.

If width = NULL (the default), the output is padded with leading zeroes to the smallest width needed for all the non-missing elements.

as.hexmode can convert integers (of type "integer" or "double") and character vectors whose elements contain only 0-9, a-f, A-F (or are NA) to class "hexmode".

There is a ! method and |, & and xor methods: these recycle their arguments to the length of the longer and then apply the operators bitwise to each element.

See Also

octmode, sprintf for other options in converting integers to hex, strtoi to convert hex strings to integers.
Hyperbolic Functions

Description
These functions give the obvious hyperbolic functions. They respectively compute the hyperbolic cosine, sine, tangent, and their inverses, arc-cosine, arc-sine, arc-tangent (or ‘area cosine’, etc).

Usage

cosh(x)  
sinh(x)  
tanh(x)  
acosh(x)  
asinh(x)  
atanh(x)

Arguments

x a numeric or complex vector

Details
These are internal generic primitive functions: methods can be defined for them individually or via the Math group generic.

Branch cuts are consistent with the inverse trigonometric functions asin et seq, and agree with those defined in Abramowitz and Stegun, figure 4.7, page 86. The behaviour actually on the cuts follows the C99 standard which requires continuity coming round the endpoint in a counter-clockwise direction.

S4 methods
All are S4 generic functions: methods can be defined for them individually or via the Math group generic.

c
v

Convert Character Vector between Encodings

Description
This uses system facilities to convert a character vector between encodings: the ‘i’ stands for ‘internationalization’.

Usage
```
i
c
v
(x, from = "", to = ", sub = NA, mark = TRUE, toRaw = FALSE)
i

iconvlist()
```

Arguments
- **x**: A character vector, or an object to be converted to a character vector by `as.character`, or a list with NULL and raw elements as returned by `iconv(toRaw = TRUE).
- **from**: A character string describing the current encoding.
- **to**: A character string describing the target encoding.
- **sub**: character string. If not `NA` it is used to replace any non-convertible bytes in the input. (This would normally be a single character, but can be more.) If "byte", the indication is "<xx>" with the hex code of the byte.
- **mark**: logical, for expert use. Should encodings be marked?
- **toRaw**: logical. Should a list of raw vectors be returned rather than a character vector?

Details
The names of encodings and which ones are available are platform-dependent. All R platforms support "" (for the encoding of the current locale), "latin1" and "UTF-8". Generally case is ignored when specifying an encoding.

On many platforms, including Windows, `iconvlist` provides an alphabetical list of the supported encodings. On others, the information is on the man page for `iconv(5)` or elsewhere in the man pages (but beware that the system command `iconv` may not support the same set of encodings as the C functions R calls). Unfortunately, the names are rarely valid across all platforms.

Elements of `x` which cannot be converted (perhaps because they are invalid or because they cannot be represented in the target encoding) will be returned as `NA` unless `sub` is specified.

Most versions of `iconv` will allow transliteration by appending '//TRANSLIT' to the to encoding: see the examples.

Encoding "ASCII" is also accepted, and on most systems "C" and "POSIX" are synonyms for ASCII.

Any encoding bits (see `Encoding`) on elements of `x` are ignored: they will always be translated as if from `from` even if declared otherwise.
Value

If `toRaw = FALSE` (the default), the value is a character vector of the same length and the same attributes as `x` (after conversion to a character vector).

If `mark = TRUE` (the default) the elements of the result have a declared encoding if `from` is "latin1" or "UTF-8", or if `from = ""` and the current locale's encoding is detected as Latin-1 or UTF-8.

If `toRaw = TRUE`, the value is a vector of the same length and the same attributes as `x` whose elements are either `NULL` (if conversion fails) or a raw vector.

For `iconvlist()`, a character vector (typically of a few hundred elements).

Implementation Details

There are three main implementations of `iconv` in use. 'glibc' (as used on Linux) contains one. Several platforms supply GNU 'libiconv', including OS X, FreeBSD and Cygwin, in some cases with additional encodings. On Windows we use a version of Yukihiro Nakadaira's 'win_iconv', which is based on Windows' codepages. (We have added several encoding names for compatibility with other systems.) All three have `iconvlist`, ignore case in encoding names and support '/TRANSLIT' (but with different results, and for 'win_iconv' currently a 'best fit' strategy is used except for `to = "ASCII"`).

Most commercial Unixes contain an implementation of `iconv` but none we have encountered have supported the encoding names we need: the “R Installation and Administration Manual” recommends installing GNU 'libiconv' on Solaris and AIX, for example.

There are other implementations, e.g. NetBSD uses one from the Citrus project (which does not support '/TRANSLIT') and there is an older FreeBSD port ('libconv' is usually used there): it has not been reported whether or not these work with R.

Note that you cannot rely on invalid inputs being detected, especially for `to = "ASCII"` where some implementations allow 8-bit characters and pass them through unchanged or with transliteration.

Some of the implementations have interesting extra encodings: for example GNU 'libiconv' allows `to = "C99"` to use \uxxx escapes for non-ASCII characters.

Note

The only reasonably portable name for the ISO 8859-15 encoding, commonly known as 'Latin 9', is "latin-9": some platforms support "latin9" but GNU 'libiconv' does not.

See Also

`localeToCharset`, `file`.

Examples

```r
## In principle, not all systems have iconvlist
try(utils::head(iconvlist(), n = 50))

## Not run:
## convert from Latin-2 to UTF-8: two of the glibc iconv variants.
iconv(x, "ISO_8859-2", "UTF-8")
iconv(x, "LATIN2", "UTF-8")

## End(Not run)

## Both x below are in latin1 and will only display correctly in a
## locale that can represent and display latin1.
```
icuSetCollate

Setup Collation by ICU

Description

Controls the way collation is done by ICU (an optional part of the R build).

Usage

icuSetCollate(...)  

Arguments

...  

Named arguments, see 'Details'.

Details

Optionally, R can be built to collate character strings by ICU (http://site.icu-project.org). For such systems, icuSetCollate can be used to tune the way collation is done. On other builds calling this function does nothing, with a warning.

Possible arguments are

locale: A character string such as "da_DK" giving the country whose collation rules are to be used. If present, this should be the first argument.

case_first: "upper", "lower" or "default", asking for upper- or lower-case characters to be sorted first. The default is usually lower-case first, but not in all languages (see the Danish example).

alternate_handling: Controls the handling of ‘variable’ characters (mainly punctuation and symbols). Possible values are "non_ignorable" (primary strength) and "shifted" (quartenary strength).
strength: Which components should be used? Possible values "primary", "secondary", "tertiary" (default), "quaternary" and "identical".

tfrench_collation: In a French locale the way accents affect collation is from right to left, whereas in most other locales it is from left to right. Possible values "on", "off" and "default".

normalization: Should strings be normalized? Possible values are "on" and "off" (default). This affects the collation of composite characters.

case_level: An additional level between secondary and tertiary, used to distinguish large and small Japanese Kana characters. Possible values "on" and "off" (default).

hiragana_quaternary: Possible values "on" (sort Hiragana first at quaternary level) and "off". Only the first three are likely to be of interest except to those with a detailed understanding of collation and specialized requirements.

Some examples are case_level = "on", strength = "primary" to ignore accent differences and alternate_handling = "shifted" to ignore space and punctuation characters.

Note that these settings have no effect if collation is set to the C locale, unless Locale is specified.

Note

ICU is used by default wherever it is available: this include Mac OS >= 10.4 and many Linux installations.

See Also

Comparison, sort

The ICU user guide chapter on collation (http://userguide.icu-project.org/collation).

Examples

```r
## these examples depend on having ICU available, and on the locale
x <- c("Aarhus", "aarhus", "safe", "test", "Zoo")
sort(x)
icuSetCollate(case_first = "upper"); sort(x)
icuSetCollate(case_first = "lower"); sort(x)

icuSetCollate(locale = "da_DK", case_first = "default"); sort(x)
icuSetCollate(locale = "et_EE"); sort(x)
```

identical

Test Objects for Exact Equality

Description

The safe and reliable way to test two objects for being exactly equal. It returns TRUE in this case, FALSE in every other case.

Usage

`identical(x, y, num.eq = TRUE, single.NA = TRUE, attrib.as.set = TRUE, ignore.bytecode = TRUE, ignore.environment = FALSE)`
Arguments

- **x, y**: any R objects.
- **num.eq**: logical indicating if (double and complex non-NA) numbers should be compared using == (‘equal’), or by bitwise comparison. The latter (non-default) differentiates between -0 and +0.
- **single.NA**: logical indicating if there is conceptually just one numeric NA and one NaN; single.NA = FALSE differentiates bit patterns.
- **attrib.as.set**: logical indicating if attributes of x and y should be treated as unordered tagged pairlists (“sets”); this currently also applies to slots of S4 objects. It may well be too strict to set attrib.as.set = FALSE.
- **ignore.bytecode**: logical indicating if byte code should be ignored when comparing closures.
- **ignore.environment**: logical indicating if their environments should be ignored when comparing closures.

Details

A call to identical is the way to test exact equality in if and while statements, as well as in logical expressions that use && or ||. In all these applications you need to be assured of getting a single logical value.

Users often use the comparison operators, such as == or !=, in these situations. It looks natural, but it is not what these operators are designed to do in R. They return an object like the arguments. If you expected x and y to be of length 1, but it happened that one of them was not, you will not get a single FALSE. Similarly, if one of the arguments is NA, the result is also NA. In either case, the expression if(x == y).... won’t work as expected.

The function all.equal is also sometimes used to test equality this way, but was intended for something different: it allows for small differences in numeric results.

The computations in identical are also reliable and usually fast. There should never be an error. The only known way to kill identical is by having an invalid pointer at the C level, generating a memory fault. It will usually find inequality quickly. Checking equality for two large, complicated objects can take longer if the objects are identical or nearly so, but represent completely independent copies. For most applications, however, the computational cost should be negligible.

If single.NA is true, as by default, identical sees NaN as different from NA_real_, but all NaNs are equal (and all NA of the same type are equal).

Character strings are regarded as identical if they are in different marked encodings but would agree when translated to UTF-8.

If attrib.as.set is true, as by default, comparison of attributes view them as a set (and not a vector, so order is not tested).

If ignore.bytecode is true (the default), the compiled bytecode of a function (see cmpfun) will be ignored in the comparison. If it is false, functions will compare equal only if they are copies of the same compiled object (or both are uncompiled). To check whether two different compiles are equal, you should compare the results of disassemble().

Note that identical(x, y, FALSE, FALSE, FALSE, FALSE) pickily tests for exact equality.

Value

A single logical value, TRUE or FALSE, never NA and never anything other than a single value.
identity

Author(s)
John Chambers and R Core

References

See Also
all.equal for descriptions of how two objects differ; Comparison for operators that generate elementwise comparisons. isTRUE is a simple wrapper based on identical.

Examples

identical(1, NULL) # FALSE -- don't try this with ==
identical(1, 1.) # TRUE in R (both are stored as doubles)
identical(1, as.integer(1)) # FALSE, stored as different types

x <- 1.0; y <- 0.99999999999
## how to test for object equality allowing for numeric fuzz :
(E <- all.equal(x, y))
isTRUE(E) # which is simply defined to just use
identical(TRUE, E)
## If all.equal thinks the objects are different, it returns a
## character string, and the above expression evaluates to FALSE

## even for unusual R objects :
identical(.GlobalEnv, environment())

### ------ Pickyness Flags : ---------------------------

## the infamous example:
identical(0, -0.) # TRUE, i.e. not differentiated
identical(0, -0., num.eq = FALSE)
## similar:
identical(NaN, -NaN) # TRUE
identical(NaN, -NaN, single.NA = FALSE) # differ on bit-level
## for functions:
f <- function(x) x
f
g <- compiler::cmpfun(f)
g
identical(f, g)
identical(f, g, ignore.bytecode = FALSE)

----------

identity

Identity Function

Description
A trivial identity function returning its argument.
Usage

identity(x)

Arguments

x

an R object.

Description

ifelse returns a value with the same shape as test which is filled with elements selected from either yes or no depending on whether the element of test is TRUE or FALSE.

Usage

ifelse(test, yes, no)

Arguments

test

an object which can be coerced to logical mode.

yes

return values for true elements of test.

no

return values for false elements of test.

Details

If yes or no are too short, their elements are recycled. yes will be evaluated if and only if any element of test is true, and analogously for no.

Missing values in test give missing values in the result.

Value

A vector of the same length and attributes (including dimensions and "class") as test and data values from the values of yes or no. The mode of the answer will be coerced from logical to accommodate first any values taken from yes and then any values taken from no.

Warning

The mode of the result may depend on the value of test (see the examples), and the class attribute (see oldClass) of the result is taken from test and may be inappropriate for the values selected from yes and no.

Sometimes it is better to use a construction such as

(tmp <- yes; tmp[test] <- no[!test]; tmp)

, possibly extended to handle missing values in test.

References

integer

See Also

if.

Examples

x <- c(6:-4)
sqrt(x) # gives warning
sqrt(ifelse(x >= 0, x, NA)) # no warning

## Note: the following also gives the warning!
ifelse(x >= 0, sqrt(x), NA)

## example of different return modes:
yes <- 1:3
no <- pi^c(0:3)
typeof(ifelse(NA, yes, no)) # logical
typeof(ifelse(TRUE, yes, no)) # integer
typeof(ifelse(FALSE, yes, no)) # double

integer

Integer Vectors

Description

Creates or tests for objects of type "integer".

Usage

integer(length = 0)
as.integer(x, ...)
is.integer(x)

Arguments

length A non-negative integer specifying the desired length. Double values will be coerced to integer: supplying an argument of length other than one is an error.

x object to be coerced or tested.

... further arguments passed to or from other methods.

Details

Integer vectors exist so that data can be passed to C or Fortran code which expects them, and so that (small) integer data can be represented exactly and compactly.

Note that current implementations of R use 32-bit integers for integer vectors, so the range of representable integers is restricted to about $\pm 2 \times 10^9$: doubles can hold much larger integers exactly.
Value

integer creates a integer vector of the specified length. Each element of the vector is equal to 0. as.integer attempts to coerce its argument to be of integer type. The answer will be NA unless the coercion succeeds. Real values larger in modulus than the largest integer are coerced to NA (unlike S which gives the most extreme integer of the same sign). Non-integral numeric values are truncated towards zero (i.e., as.integer(x) equals trunc(x) there), and imaginary parts of complex numbers are discarded (with a warning). Character strings containing optional whitespace followed by either a decimal representation or a hexadecimal representation (starting with 0x or 0X) can be converted, as well as any allowed by the platform for real numbers. Like as.vector it strips attributes including names. (To ensure that an object x is of integer type without stripping attributes, use storage.mode(x) <- "integer".)

is.integer returns TRUE or FALSE depending on whether its argument is of integer type or not, unless it is a factor when it returns FALSE.

Note

is.integer(x) does not test if x contains integer numbers! For that, use round, as in the function is.wholenumber(x) in the examples.

References

See Also

numeric, storage.mode.

round (and ceiling and floor on that help page) to convert to integral values.

Examples

## as.integer() truncates:
x <- pi * c(-1:1, 10)
as.integer(x)

is.integer(1) # is FALSE!

is.wholenumber <-
  function(x, tol = .Machine$double.eps*0.5) abs(x - round(x)) < tol
is.wholenumber(1) # is TRUE
(x <- seq(1, 5, by = 0.5))
is.wholenumber( x ) #--> TRUE FALSE TRUE ...

interaction Compute Factor Interactions

Description

interaction computes a factor which represents the interaction of the given factors. The result of interaction is always unordered.
**interactive**

**Usage**

```
interaction(..., drop = FALSE, sep = ".", lex.order = FALSE)
```

**Arguments**

- `...`: the factors for which interaction is to be computed, or a single list giving those factors.
- `drop`: if `drop` is `TRUE`, unused factor levels are dropped from the result. The default is to retain all factor levels.
- `sep`: string to construct the new level labels by joining the constituent ones.
- `lex.order`: logical indicating if the order of factor concatenation should be lexically ordered.

**Value**

A factor which represents the interaction of the given factors. The levels are labelled as the levels of the individual factors joined by `sep` which is `.` by default.

By default, when `lex.order = FALSE`, the levels are ordered so the level of the first factor varies fastest, then the second and so on. This is the reverse of lexicographic ordering (which you can get by `lex.order = TRUE`), and differs from `:`. (It is done this way for compatibility with S.)

**References**

**See Also**

`factor`; where `f:g` is similar to `interaction(f, g, sep = ":")` when `f` and `g` are factors.

**Examples**

```
a <- gl(2, 4, 8)
b <- gl(2, 2, 8, labels = c("ctrl", "treat"))
s <- gl(2, 1, 8, labels = c("M", "F"))
interaction(a, b)
interaction(a, b, s, sep = ":")
stopifnot(identical(a:s,
    interaction(a, s, sep = ":", lex.order = TRUE)),
    identical(a:s:b,
    interaction(a, s, b, sep = ":", lex.order = TRUE)))
```

---

**interactive**

**Is R Running Interactively?**

**Description**

Return `TRUE` when R is being used interactively and `FALSE` otherwise.

**Usage**

```
interactive()
```
Details
An interactive R session is one in which it is assumed that there is a human operator to interact with, so for example R can prompt for corrections to incorrect input or ask what to do next or if it is OK to move to the next plot.

GUI consoles will arrange to start R in an interactive session. When R is run in a terminal (via Rterm.exe on Windows), it assumes that it is interactive if ‘stdin’ is connected to a (pseudo-)terminal and not if ‘stdin’ is redirected to a file or pipe. Command-line options ‘--interactive’ (Unix) and ‘--ess’ (Windows, Rterm.exe) override the default assumption. (On a Unix-alike, whether the readline command-line editor is used is not overridden by ‘--interactive’.)

Embedded uses of R can set a session to be interactive or not. Internally, whether a session is interactive determines

• how some errors are handled and reported, e.g. see stop and options("showWarnCalls").
• whether one of ‘--save’, ‘--no-save’ or ‘--vanilla’ is required, and if R ever asks whether to save the workspace.
• the choice of default graphics device launched when needed and by dev.new: see options("device")
• whether graphics devices ever ask for confirmation of a new page.

In addition, R’s own R code makes use of interactive(): for example help, debugger and install.packages do.

Note
This is a primitive function.

See Also
source, .First

Examples
.First <- function() if(interactive()) x11()

Description
.internal performs a call to an internal code which is built in to the R interpreter.

Only true R wizards should even consider using this function, and only R developers can add to the list of internal functions.

Usage
.internal(call)

Arguments
call a call expression
See Also

.Primitive, .External (the nearest equivalent available to users).

InternalMethods

Internal Generic Functions

Description

Many R-internal functions are generic and allow methods to be written for.

Details

The following primitive and internal functions are generic, i.e., you can write methods for them:

[, ., ., .<-, .[,] <-, length, length<-, dimnames, dimnames<-, dim, dim<-, names, names<-, levels<-,
c, unlist, cbind, rbind,
as.character, as.complex, as.double, as.integer, as.logical, as.raw, as.vector,
is.array, is.matrix, is.na, is.nan, is.numeric, rep, seq.int (which dispatches methods for "seq") and xtfrm

In addition, is.name is a synonym for is.symbol and dispatches methods for the latter.

Note that all of the group generic functions are also internal/primitive and allow methods to be written for them.

.S3PrimitiveGenerics is a character vector listing the primitives which are internal generic and not group generic. Currently as.vector, cbind, rbind and unlist are the internal non-primitive functions which are internally generic.

For efficiency, internal dispatch only occurs on objects, that is those for which is.object returns true.

See Also

methods for the methods which are available.

invisible

Change the Print Mode to Invisible

Description

Return a (temporarily) invisible copy of an object.

Usage

invisible(x)

Arguments

x an arbitrary R object.
Details

This function can be useful when it is desired to have functions return values which can be assigned, but which do not print when they are not assigned.

This is a primitive function.

References

See Also

withVisible, return, function.

Examples

# These functions both return their argument
f1 <- function(x) x
f2 <- function(x) invisible(x)
f1(1) # prints
f2(1) # does not

is.finite is Finite, Infinite and NaN Numbers

Description

is.finite and is.infinite return a vector of the same length as x, indicating which elements are finite (not infinite and not missing) or infinite.

Inf and -Inf are positive and negative infinity whereas NaN means ‘Not a Number’. (These apply to numeric values and real and imaginary parts of complex values but not to values of integer vectors.) Inf and NaN are reserved words in the R language.

Usage

is.finite(x)
is.infinite(x)
is.nan(x)

Inf
NaN

Arguments

x R object to be tested: the default methods handle atomic vectors.
Details

is.finite returns a vector of the same length as x the jth element of which is TRUE if x[j] is finite (i.e., it is not one of the values NA, NaN, Inf or -Inf) and FALSE otherwise. Complex numbers are finite if both the real and imaginary parts are.

is.infinite returns a vector of the same length as x the jth element of which is TRUE if x[j] is infinite (i.e., equal to one of Inf or -Inf) and FALSE otherwise. This will be false unless x is numeric or complex. Complex numbers are infinite if either the real or the imaginary part is.

is.nan tests if a numeric value is NaN. Do not test equality to NaN, or even use identical, since systems typically have many different NaN values. One of these is used for the numeric missing value NA, and is.nan is false for that value. A complex number is regarded as NaN if either the real or imaginary part is NaN but not NA. All elements of logical, integer and raw vectors are considered not to be NaN.

All three functions accept NULL as input and return a length zero result. The default methods accept character and raw vectors, and return FALSE for all entries. Prior to R version 2.14.0 they accepted all input, returning FALSE for most non-numeric values; cases which are not atomic vectors are now signalled as errors.

All three functions are generic: you can write methods to handle specific classes of objects, see InternalMethods.

Value

A logical vector of the same length as x: dim, dimnames and names attributes are preserved.

Note

In R, basically all mathematical functions (including basic Arithmetic), are supposed to work properly with +/- Inf and NaN as input or output.

The basic rule should be that calls and relations with Infs really are statements with a proper mathematical limit.

Computations involving NaN will return NaN or perhaps NA: which of those two is not guaranteed and may depend on the R platform (since compilers may re-order computations).

References

The IEC 60559 standard, also known as the ANSI/IEEE 754 Floating-Point Standard.
http://en.wikipedia.org/wiki/NaN.

The C99 function isfinite is used for is.finite if available.

See Also

NA, ‘Not Available’ which is not a number as well, however usually used for missing values and applies to many modes, not just numeric and complex.
Arithmetic, double.
Examples

\- \pi / 0 \# = \infty a non-zero number divided by zero creates infinity
\- 0 / 0 \# = \text{NaN}

\- 1/0 + 1/0 \# \infty
\- 1/0 - 1/0 \# \text{NaN}

```
stopifnot(
  1/0 == Inf,
  1/Inf == 0
)
sin(Inf)
cos(Inf)
tan(Inf)
```

is.function Is an Object of Type (Primitive) Function?

Description

Checks whether its argument is a (primitive) function.

Usage

\- is.function(x)
\- is.primitive(x)

Arguments

\- **x** an \( R \) object.

Details

is.primitive(x) tests if x is a primitive function (either a "builtin" or "special" as described for typeof)? It is a primitive function.

Value

TRUE if x is a (primitive) function, and FALSE otherwise.

Examples

\- is.function(1) \# FALSE
\- is.function(is.primitive) \# TRUE: it is a function, but ..
\- is.primitive(is.primitive) \# FALSE: it’s not a primitive one, whereas
\- is.primitive(is.function) \# TRUE: that one *is*
is.language  Is an Object a Language Object?

Description

is.language returns TRUE if x is a variable name, a call, or an expression.

Usage

is.language(x)

Arguments

x  object to be tested.

Note

This is a primitive function.

References

Examples

```r
ll <- list(a = expression(x^2 - 2*x + 1), b = as.name("Jim"),
          c = as.expression(exp(1)), d = call("sin", pi))
sapply(ll, typeof)
sapply(ll, mode)
stopifnot(sapply(ll, is.language))
```

is.object  Is an Object 'internally classed'?

Description

A function rather for internal use. It returns TRUE if the object x has the R internal OBJECT bit set, and FALSE otherwise. The OBJECT bit is set when a "class" attribute is added and removed when that attribute is removed, so this is a very efficient way to check if an object has a class attribute. (S4 objects always should.)

Usage

is.object(x)

Arguments

x  object to be tested.
is.R

Note
This is a primitive function.

See Also
class, and methods.
isS4.

Examples

is.object(1) # FALSE
is.object(as.factor(1:3)) # TRUE

is.R Are we using R, rather than S?

Description
Test if running under R.

Usage
is.R()

Details
The function has been written such as to correctly run in all versions of R, S and S-PLUS. In order for code to be runnable in both R and S dialects previous to S-PLUS 8.0, your code must either define is.R or use it as

```r
if (exists("is.R") && is.function(is.R) && is.R()) {
  ## R-specific code
} else {
  ## S-version of code
}
```

Value

is.R returns TRUE if we are using R and FALSE otherwise.

See Also
R.version, system.

Examples

```r
x <- stats::runif(20); small <- x < 0.4
## In the early years of R, 'which()' only existed in R:
if(is.R()) which(small) else seq(along = small)[small]
```
is.recursive  Is an Object Atomic or Recursive?

Description

is.atomic returns TRUE if x is an atomic vector (or NULL) and FALSE otherwise.

is.recursive returns TRUE if x has a recursive (list-like) structure and FALSE otherwise.

Usage

is.atomic(x)

is.recursive(x)

Arguments

x object to be tested.

Details

is.atomic is true for the atomic vector types ("logical", "integer", "numeric", "complex", "character" and "raw") and NULL.

Most types of objects are regarded as recursive, except for atomic vector types, NULL and symbols (as given by as.name).

These are primitive functions.

References

See Also

is.list, is.language, etc, and the demo("is.things").

Examples

require(stats)

is.a.r <- function(x) c(is.atomic(x), is.recursive(x))

is.a.r(c(a = 1, b = 3)) # TRUE FALSE
is.a.r(list()) # FALSE TRUE - a list is a list
is.a.r(list(2)) # FALSE TRUE
is.a.r(lm) # FALSE TRUE
is.a.r(y ~ x) # FALSE TRUE
is.a.r(expression(x+1)) # FALSE TRUE (nowadays)
is.single  

Is an Object of Single Precision Type?

Description
is.single reports an error. There are no single precision values in R.

Usage
is.single(x)

Arguments
x object to be tested.

References

is.unsorted  

Test if an Object is Not Sorted

Description
Test if an object is not sorted (in increasing order), without the cost of sorting it.

Usage
is.unsorted(x, na.rm = FALSE, strictly = FALSE)

Arguments
x an R object with a class or a numeric, complex, character or logical vector.
na.rm logical. Should missing values be removed before checking?
strictly logical indicating if the check should be for strictly increasing values.

Value
A length-one logical value. All objects of length 0 or 1 are sorted: the result will be NA for objects of length 2 or more except for atomic vectors and objects with a class (where the >= or > method is used to compare x[i] with x[i-1] for i in 2:length(x)).

Note
This function is designed for objects with one-dimensional indices, as described above. Data frames, matrices and other arrays may give surprising results.

See Also
sort, order.
ISOdatetime

Date-time Conversion Functions from Numeric Representations

Description

Convenience wrappers to create date-times from numeric representations.

Usage

ISOdatetime(year, month, day, hour, min, sec, tz = "")
ISOdate(year, month, day, hour = 12, min = 0, sec = 0, tz = "GMT")

Arguments

year, month, day
numerical values to specify a day.

hour, min, sec
numerical values for a time within a day. Fractional seconds are allowed.

tz
A timezone specification to be used for the conversion. "" is the current timezone and "GMT" is UTC.

Details

ISOdatetime and ISOdate are convenience wrappers for strptime that differ only in their defaults and that ISOdate sets UTC as the timezone. For dates without times it would normally be better to use the "Date" class.

The main arguments will be recycled using the usual recycling rules.

Value

An object of class "POSIXct".

See Also

DateTimeClasses for details of the date-time classes; strptime for conversions from character strings.

isS4

Test for an S4 object

Description

Tests whether the object is an instance of an S4 class.

Usage

isS4(object)

asS4(object, flag = TRUE, complete = TRUE)

asS3(object, flag = TRUE, complete = TRUE)
isSymmetric

Arguments

- object: Any R object.
- flag: Optional, logical: indicate direction of conversion.
- complete: Optional, logical: whether conversion to S3 is completed. Not usually needed, but see the details section.

Details

Note that isS4 does not rely on the methods package, so in particular it can be used to detect the need to require that package.

asS3 uses the value of complete to control whether an attempt is made to transform object into a valid object of the implied S3 class. If complete is TRUE, then an object from an S4 class extending an S3 class will be transformed into an S3 object with the corresponding S3 class (see S3Part). This includes classes extending the pseudo-classes array and matrix: such objects will have their class attribute set to NULL.

isS4 is primitive.

Value

isS4 always returns TRUE or FALSE according to whether the internal flag marking an S4 object has been turned on for this object.

asS4 and asS3 will turn this flag on or off, and asS3 will set the class from the objects .S3Class slot if one exists. Note that asS3 will not turn the object into an S3 object unless there is a valid conversion; that is, an object of type other than ”S4” for which the S4 object is an extension, unless argument complete is FALSE.

See Also

is.object for a more general test; Methods for general information on S4.

Examples

isS4(pi) # FALSE
isS4(getClass("MethodDefinition")) # TRUE

isSymmetric

Test if a Matrix or other Object is Symmetric

Description

Generic function to test if object is symmetric or not. Currently only a matrix method is implemented.

Usage

isSymmetric(object, ...)  # S3 method for class 'matrix'
isSymmetric(object, tol = 100 * .Machine$double.eps, ...)
Arguments

object any R object; a matrix for the matrix method.
tol numeric scalar $\geq 0$. Smaller differences are not considered, see all.equal.numeric.
... further arguments passed to methods; the matrix method passes these to all.equal.

Details

The matrix method is used inside eigen by default to test symmetry of matrices up to rounding error, using all.equal. It might not be appropriate in all situations.

Note that a matrix is only symmetric if its rownames and colnames are identical.

Value

logical indicating if object is symmetric or not.

See Also

eigen which calls isSymmetric when its symmetric argument is missing.

Examples

isSymmetric(D3 <- diag(3)) # -> TRUE

D3[2, 1] <- 1e-100
D3
isSymmetric(D3) # TRUE
isSymmetric(D3, tol = 0) # FALSE for zero-tolerance

jitter

'Jitter' (Add Noise) to Numbers

Description

Add a small amount of noise to a numeric vector.

Usage

jitter(x, factor = 1, amount = NULL)

Arguments

x numeric vector to which jitter should be added.
factor numeric; if positive, used as amount (see below), otherwise, if $= 0$ the default is factor $\times d/50$.
amount numeric; if positive, used as amount (see below), otherwise, if $= 0$ the default is factor $\times d/50$.

Default (NULL): factor $\times d/5$ where d is about the smallest difference between x values.
Details

The result, say \( r \), is \( r \leftarrow x + \text{runif}(n, -a, a) \) where \( n \leftarrow \text{length}(x) \) and \( a \) is the amount argument (if specified).

Let \( z \leftarrow \max(x) - \min(x) \) (assuming the usual case). The amount \( a \) to be added is either provided as positive argument amount or otherwise computed from \( z \), as follows:

If amount == 0, we set \( a \leftarrow \text{factor} \times z/50 \) (same as S).

If amount is NULL (default), we set \( a \leftarrow \text{factor} \times d/5 \) where \( d \) is the smallest difference between adjacent unique (apart from fuzz) \( x \) values.

Value

\( \text{jitter}(x, \ldots) \) returns a numeric of the same length as \( x \), but with an amount of noise added in order to break ties.

Author(s)

Werner Stahel and Martin Maechler, ETH Zurich

References

See Also

\( \text{rug} \) which you may want to combine with \( \text{jitter} \).

Examples

\( \text{round(jitter(c(rep(1, 3), rep(1.2, 4), rep(3, 3))), 3)} \)

\# These two 'fail' with S-plus 3.x:
\( \text{jitter(rep(0, 7))} \)
\( \text{jitter(rep(10000, 5))} \)

---

**kappa**

Compute or Estimate the Condition Number of a Matrix

Description

The condition number of a regular (square) matrix is the product of the norm of the matrix and the norm of its inverse (or pseudo-inverse), and hence depends on the kind of matrix-norm.

\( \text{kappa()} \) computes by default (an estimate of) the 2-norm condition number of a matrix or of the \( R \) matrix of a QR decomposition, perhaps of a linear fit. The 2-norm condition number can be shown to be the ratio of the largest to the smallest non-zero singular value of the matrix.

\( \text{rcond()} \) computes an approximation of the reciprocal condition number, see the details.
Usage

kappa(z, ...)
## Default S3 method:
kappa(z, exact = FALSE,
    norm = NULL, method = c("qr", "direct"), ...)
## S3 method for class 'lm'
kappa(z, ...)
## S3 method for class 'qr'
kappa(z, ...)

.kappa_tri(z, exact = FALSE, LINPACK = TRUE, norm = NULL, ...)

rcond(x, norm = c("O","I","1"), triangular = FALSE, ...)

Arguments

z, x  A matrix or a the result of `qr` or a fit from a class inheriting from "lm".
exact  logical. Should the result be exact?
norm  character string, specifying the matrix norm with respect to which the condition number is to be computed, see also `norm`. For `rcond`, the default is "0", meaning the One- or 1-norm. The (currently only) other possible value is "I" for the infinity norm.
method  character string, specifying the method to be used; "qr" is default for back-compatibility, mainly.
triangular  logical. If true, the matrix used is just the lower triangular part of z.
LINPACK  logical. If true and z is not complex, the Linpack routine `dtrcond` is called; otherwise the relevant Lapack routine is.
...
  further arguments passed to or from other methods; for `kappa.*()`, notably `LINPACK` when `norm` is not "2".

Details

For `kappa()`, if `exact = FALSE` (the default) the 2-norm condition number is estimated by a cheap approximation. However, the exact calculation (via `svd`) is also likely to be quick enough.

Note that the 1- and Inf-norm condition numbers are much faster to calculate, and `rcond()` computes these reciprocal condition numbers, also for complex matrices, using standard Lapack routines.

`kappa` and `rcond` are different interfaces to partly identical functionality.

.kappa_tri is an internal function called by `kappa.qr` and `kappa.default`.

Value

The condition number, `kappa`, or an approximation if `exact = FALSE`.

Author(s)

The design was inspired by (but differs considerably from) the S function of the same name described in Chambers (1992).
Source

The LAPACK routines `dtrcon` and `ztrcon` and the LINPACK routine `dtrco`.

LAPACK and LINPACK are from http://www.netlib.org/lapack and http://www.netlib.org/linpack and their guides are listed in the references.

References

See Also

`norm`, `svd` for the singular value decomposition and `qr` for the QR one.

Examples

```r
kappa(x1 <- cbind(1, 1:10)) # 15.71
kappa(x1, exact = TRUE)     # 13.68
kappa(x2 <- cbind(x1, 2:11)) # high! [x2 is singular!]

hilbert <- function(n) { i <- 1:n; 1 / outer(i - 1, i, "*") }
sv9 <- svd(h9 <- hilbert(9))$d
kappa(h9)   # pretty high!
kappa(h9, exact = TRUE) == max(sv9) / min(sv9)
kappa(h9, exact = TRUE) / kappa(h9) # 0.677 (i.e., rel.error = 32%)
```

Description

Computes the generalised kronecker product of two arrays, X and Y.

Usage

```r
kronencker(X, Y, FUN = "+", make.dimnames = FALSE, ...)
```

X %x% Y

Arguments

- **X** A vector or array.
- **Y** A vector or array.
- **FUN** a function; it may be a quoted string.
- **make.dimnames** Provide dimnames that are the product of the dimnames of X and Y.
- **...** optional arguments to be passed to FUN.
Details

If \( x \) and \( y \) do not have the same number of dimensions, the smaller array is padded with dimensions of size one. The returned array comprises submatrices constructed by taking \( x \) one term at a time and expanding that term as \( \text{FUN}(x, y, \ldots) \).

\%\% is an alias for \texttt{kronecker} (where \texttt{FUN} is hardwired to "\%\%").

Value

An array \( A \) with dimensions \( \text{dim}(X) \times \text{dim}(Y) \).

Author(s)

Jonathan Rougier

References

See Also

\texttt{outer}, on which \texttt{kronecker} is built and \%\% for usual matrix multiplication.

Examples

\begin{verbatim}
# simple scalar multiplication
( M <- matrix(1:6, ncol = 2) )
kronecker(4, M)
# Block diagonal matrix:
kronecker(diag(1, 3), M)

# ask for dimnames

fred <- matrix(1:12, 3, 4, dimnames = list(LETTERS[1:3], LETTERS[4:7]))
bill <- c("happy" = 100, "sad" = 1000)
kroner(fred, bill, make.dimnames = TRUE)

bill <- outer(bill, c("cat" = 3, "dog" = 4))
kroner(fred, bill, make.dimnames = TRUE)
\end{verbatim}

---

\texttt{110n_info}

\textit{Localization Information}

Description

Report on localization information.

Usage

\texttt{110n_info()}
labels

Value
A list with three logical components:

- **mbcs**: If a multi-byte character set in use?
- **UTF-8**: Is this a UTF-8 locale?
- **Latin-1**: Is this a Latin-1 locale?

See Also

`Sys.getlocale`, `localeconv`

Examples

```r
labels Inf_n_info()
```

Description
Find a suitable set of labels from an object for use in printing or plotting, for example. A generic function.

Usage

```r
labels(object, ...)
```

Arguments

- **object**: Any R object: the function is generic.
- **...**: further arguments passed to or from other methods.

Value
A character vector or list of such vectors. For a vector the results is the names or `seq_along(x)` and for a data frame or array it is the dimnames (with NULL expanded to `seq_len(d[1])`).

References

lapply

Apply a Function over a List or Vector

Description

lapply returns a list of the same length as X, each element of which is the result of applying FUN to the corresponding element of X.

sapply is a user-friendly version and wrapper of lapply by default returning a vector, matrix or, if simplify = "array", an array if appropriate, by applying simplify2array(). sapply(x, f, simplify = FALSE, USE.NAMES = FALSE) is the same as lapply(x, f).

vapply is similar to sapply, but has a pre-specified type of return value, so it can be safer (and sometimes faster) to use.

replicate is a wrapper for the common use of sapply for repeated evaluation of an expression (which will usually involve random number generation).

simplify2array() is the utility called from sapply() when simplify is not false and is similarly called from maply().

Usage

lapply(X, FUN, ...)

sapply(X, FUN, ..., simplify = TRUE, USE.NAMES = TRUE)

vapply(X, FUN, FUN.VALUE, ..., USE.NAMES = TRUE)

replicate(n, expr, simplify = "array")

simplify2array(x, higher = TRUE)

Arguments

X a vector (atomic or list) or an expression object. Other objects (including classed objects) will be coerced by base::as.list.

FUN the function to be applied to each element of X; see ‘Details’. In the case of functions like *, %*%, the function name must be backquoted or quoted.

... optional arguments to FUN.

simplify logical or character string; should the result be simplified to a vector, matrix or higher dimensional array if possible? For sapply it must be named and not abbreviated. The default value, TRUE, returns a vector or matrix if appropriate, whereas if simplify = "array" the result may be an array of “rank” (=length(dim(.))) one higher than the result of FUN(X[[i]])).

USE.NAMES logical; if TRUE and if X is character, use X as names for the result unless it had names already. Since this argument follows ... its name cannot be abbreviated.

FUN.VALUE a (generalized) vector; a template for the return value from FUN. See ‘Details’.

n integer: the number of replications.

eexpr the expression (language object, usually a call) to evaluate repeatedly.

x a list, typically returned from lapply().
higher logical; if true, simplify2array() will produce a ("higher rank") array when appropriate, whereas higher = FALSE would return a matrix (or vector) only. These two cases correspond to sapply(*, simplify = "array") or simplify = TRUE, respectively.

Details

FUN is found by a call to match.fun and typically is specified as a function or a symbol (e.g. a back-quoted name) or a character string specifying a function to be searched for from the environment of the call to lapply.

Function FUN must be able to accept as input any of the elements of X. If the latter is an atomic vector, FUN will always be passed a length-one vector of the same type as X.

Arguments in ... cannot have the same name as any of the other arguments, and care may be needed to avoid partial matching to FUN. In general-purpose code it is good practice to name the first two arguments X and FUN if ... is passed through: this both avoids partial matching to FUN and ensures that a sensible error message is given if arguments named X or FUN are passed through . . . .

Simplification in sapply is only attempted if X has length greater than zero and if the return values from all elements of X are all of the same (positive) length. If the common length is one the result is a vector, and if greater than one is a matrix with a column corresponding to each element of X.

Simplification is always done in vapply. This function checks that all values of FUN are compatible with the FUN.VALUE, in that they must have the same length and type. (Types may be promoted to a higher type within the ordering logical < integer < double < complex, but not demoted.)

Users of S4 classes should pass a list to lapply and vapply: the internal coercion is done by the as.list in the base namespace and not one defined by a user (e.g. by setting S4 methods on the base function).

lapply and vapply are primitive functions.

Value

For lapply, sapply(simplify = FALSE) and replicate(simplify = FALSE), a list.

For sapply(simplify = TRUE) and replicate(simplify = TRUE): if X has length zero or n = 0, an empty list. Otherwise an atomic vector or matrix or list of the same length as X (of length n for replicate). If simplification occurs, the output type is determined from the highest type of the return values in the hierarchy NULL < raw < logical < integer < double < complex < character < list < expression, after coercion of pairlists to lists.

vapply returns a vector or array of type matching the FUN.VALUE. If length(FUN.VALUE) == 1 a vector of the same length as X is returned, otherwise an array. If FUN.VALUE is not an array, the result is a matrix with length(FUN.VALUE) rows and length(X) columns, otherwise an array a with dim(a) == c(dim(FUN.VALUE), length(X)).

The (Dim)names of the array value are taken from the FUN.VALUE if it is named, otherwise from the result of the first function call. Column names of the matrix or more generally the names of the last dimension of the array value or names of the vector value are set from X as in sapply.

Note

sapply(*, simplify = FALSE, USE.NAMES = FALSE) is equivalent to lapply(*).

For historical reasons, the calls created by lapply are unevaluated, and code has been written (e.g. bquote) that relies on this. This means that the recorded call is always of the form FUN(X[[i]], ...), with i replaced by the current integer index. This is not normally a problem, but it can be if FUN uses sys.call or match.call or if it is a primitive function that makes use
of the call. This means that it is often safer to call primitive functions with a wrapper, so that e.g. lapply(1L, function(x) is.numeric(x)) is required in R 2.7.1 to ensure that method dispatch for is.numeric occurs correctly.

If expr is a function call, be aware of assumptions about where it is evaluated, and in particular what … might refer to. You can pass additional named arguments to a function call as additional named arguments to `replicate`: see ‘Examples’.

References

See Also

`apply`, `tapply`, `mapply` for applying a function to multiple arguments, and `rapply` for a recursive version of `lapply()`, `eapply` for applying a function to each entry in an environment.

Examples

```r
require(stats); require(graphics)

x <- list(a = 1:10, beta = exp(-3:3), logic = c(TRUE,FALSE,FALSE,TRUE)) # compute the list mean for each list element
lapply(x, mean)
# median and quartiles for each list element
lapply(x, quantile, probs = 1:3/4)
sapply(x, quantile)
i39 <- sapply(3:9, seq) # list of vectors
sapply(i39, fivenum)
vapply(i39, fivenum, c(Min. = 0, "1st Qu." = 0, Median = 0, "3rd Qu." = 0, Max. = 0))

## sapply(*, "array") -- artificial example
(v <- structure(10*(5:8), names = LETTERS[1:4]))
f2 <- function(x, y) outer(rep(x, length.out = 3), y)
(a2 <- sapply(v, f2, y = 2*(1:5), simplify = "array"))
a.2 <- vapply(v, f2, outer(1:3, 1:5), y = 2*(1:5))
stopifnot(dim(a2) == c(3,5,4), all.equal(a2, a.2),
         identical(dimnames(a2), list(NULL,NULL,LETTERS[1:4])))

hist(replicate(100, mean(rexp(10))))

## use of `replicate()` with parameters:
foo <- function(x = 1, y = 2) c(x, y)
# does not work: bar <- function(n, ...) replicate(n, foo(...))
bar <- function(n, x) replicate(n, foo(x = x))
bar(5, x = 3)
```

<table>
<thead>
<tr>
<th>Last.value</th>
<th>Value of Last Evaluated Expression</th>
</tr>
</thead>
</table>

---
Description

The value of the internal evaluation of a top-level \texttt{R} expression is always assigned to \texttt{.Last.value} (in package\texttt{:base}) before further processing (e.g., printing).

Usage

\texttt{.Last.value}

Details

The value of a top-level assignment is put in \texttt{.Last.value}, unlike \texttt{S}.

Do not assign to \texttt{.Last.value} in the workspace, because this will always mask the object of the same name in package\texttt{:base}.

See Also

\texttt{eval}

Examples

\begin{verbatim}
## These will not work correctly from example(),
## but they will in make check or if pasted in,
## as example() does not run them at the top level
gamma(1:15)   # think of some intensive calculation...
fac14 <- .Last.value # keep them

library("splines") # returns invisibly
.Last.value    # shows what library(.) above returned
\end{verbatim}

---

\texttt{length}  \hspace{1cm} \textit{Length of an Object}

Description

Get or set the length of vectors (including lists) and factors, and of any other \texttt{R} object for which a method has been defined.

Usage

\begin{verbatim}
length(x)
length(x) <- value
\end{verbatim}

Arguments

\begin{verbatim}
x              an \texttt{R} object. For replacement, a vector or factor.
value          a non-negative integer or double (which will be rounded down).
\end{verbatim}
Both functions are generic: you can write methods to handle specific classes of objects, see InternalMethods. `length<-` has a "factor" method.

The replacement form can be used to reset the length of a vector. If a vector is shortened, extra values are discarded and when a vector is lengthened, it is padded out to its new length with NAs (null for raw vectors).

Both are primitive functions.

The default method for `length` currently returns a non-negative integer of length 1, except for vectors of more than \(2^{31} - 1\) elements, when it returns a double.

For vectors (including lists) and factors the length is the number of elements. For an environment it is the number of objects in the environment, and NULL has length 0. For expressions and pairlists (including language objects and dotlists) it is the length of the pairlist chain. All other objects (including functions) have length one: note that for functions this differs from S.

The replacement form removes all the attributes of `x` except its names, which are adjusted (and if necessary extended by "").

Package authors have written methods that return a result of length other than one (Formula) and that return a vector of type double (Matrix), even with non-integer values (earlier versions of sets). Where a single double value is returned that can be represented as an integer it is returned as a length-one integer vector.

As from \(R\) 3.0.0, lengths can be returned as double in base \(R\).

References

See Also

`nchar` for counting the number of characters in character vectors.

Examples

```r
length(diag(4))  # = 16 (4 x 4)
length(options()) # 12 or more
length(y ~ x1 + x2 + x3) # 3
length(expression(x, {y <- x^2; y+2}, x*y)) # 3

## from example(warpbreaks)
require(stats)

fml <- lm(breaks ~ wool * tension, data = warpbreaks)
length(fml$call) # 3, `lm()` and two arguments.
length(formula(fml)) # 3, `- lhs rhs`
```
levels

Levels Attributes

Description
levels provides access to the levels attribute of a variable. The first form returns the value of the levels of its argument and the second sets the attribute.

Usage
levels(x)
levels(x) <- value

Arguments
x an object, for example a factor.
value A valid value for levels(x). For the default method, NULL or a character vector. For the factor method, a vector of character strings with length at least the number of levels of x, or a named list specifying how to rename the levels.

Details
Both the extractor and replacement forms are generic and new methods can be written for them. The most important method for the replacement function is that for factors.

For the factor replacement method, a NA in value causes that level to be removed from the levels and the elements formerly with that level to be replaced by NA.

Note that for a factor, replacing the levels via levels(x) <- value is not the same as (and is preferred to) attr(x, "levels") <- value.

The replacement function is primitive.

nlevels, relevel, reorder.

Examples
## assign individual levels
x <- gl(2, 4, 8)
levels(x)[1] <- "low"
levels(x)[2] <- "high"
x

## or as a group
y <- gl(2, 4, 8)
levels(y) <- c("low", "high")
y
## Description
.libPaths gets/sets the library trees within which packages are looked for.

## Usage
.libPaths(new)

.Library
.Library.site

## Arguments
new a character vector with the locations of R library trees. Tilde expansion (path.expand) is done, and if any element contains one of *,?[, globbing is done where supported by the platform: see Sys.glob.

## Details
.Library is a character string giving the location of the default library, the 'library' subdirectory of R_HOME.
.Library.site is a (possibly empty) character vector giving the locations of the site libraries, by default the 'site-library' subdirectory of R_HOME (which may not exist).
.libPaths is used for getting or setting the library trees that R knows about (and hence uses when looking for packages). If called with argument new, the library search path is set to the existing directories in unique(c(new, .Library.site, .Library)) and this is returned. If given no argument, a character vector with the currently active library trees is returned.

How paths new with a trailing slash are treated is OS-dependent. On a POSIX filesystem existing directories can usually be specified with a trailing slash: on Windows filepaths with a trailing slash (or backslash) are invalid and so will never be added to the library search path.
The library search path is initialized at startup from the environment variable `R_LIBS` (which should be a colon-separated list of directories at which R library trees are rooted) followed by those in environment variable `R_LIBS_USER`. Only directories which exist at the time will be included.

By default `R_LIBS` is unset, and `R_LIBS_USER` is set to directory `R/R.version$platform-library/x.y` of the home directory (or `Library/R/x.y/library` for CRAN OS X builds), for R x.y.z.

`.Library.site` can be set via the environment variable `R_LIBS_SITE` (as a non-empty colon-separated list of library trees).

Both `R_LIBS_USER` and `R_LIBS_SITE` feature possible expansion of specifiers for R version specific information as part of the startup process. The possible conversion specifiers all start with a `%` and are followed by a single letter (use `%%` to obtain `%`), with currently available conversion specifications as follows:

- `%v` R version number including the patchlevel (e.g., `2.5.0`).
- `%v` R version number excluding the patchlevel (e.g., `2.5`).
- `%p` the platform for which R was built, the value of `R.version$platform`.
- `%o` the underlying operating system, the value of `R.version$os`.
- `%a` the architecture (CPU) R was built on/for, the value of `R.version$arch`.

(See `version` for details on R version information.)

Function `.libPaths` always uses the values of `.Library` and `.Library.site` in the base namespace. `.Library.site` can be set by the site in `.Rprofile.site`, which should be followed by a call to `.libPaths(.libPaths())` to make use of the updated value.

For consistency, the paths are always normalized by `normalizePath(winslash = "/")`.

**Value**

A character vector of file paths.

**References**

**See Also**

`library`

**Examples**

`.libPaths() # all library trees R knows about`
library

Loading and Listing of Packages

Description

library and require load add-on packages.

Usage

library(package, help, pos = 2, lib.loc = NULL,
  character.only = FALSE, logical.return = FALSE,
  warn.conflicts = TRUE, quietly = FALSE,
  verbose = getOption("verbose")
)

require(package, lib.loc = NULL, quietly = FALSE,
  warn.conflicts = TRUE,
  character.only = FALSE)

Arguments

package, help the name of a package, given as a name or literal character string, or a character string, depending on whether character.only is FALSE (default) or TRUE).

pos the position on the search list at which to attach the loaded package. Can also be the name of a position on the current search list as given by search().

lib.loc a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known to .libPaths(). Non-existent library trees are silently ignored.

character.only a logical indicating whether package or help can be assumed to be character strings.

logical.return logical. If it is TRUE, FALSE or TRUE is returned to indicate success.

warn.conflicts logical. If TRUE, warnings are printed about conflicts from attaching the new package. A conflict is a function masking a function, or a non-function masking a non-function.

verbose a logical. If TRUE, additional diagnostics are printed.

quietly a logical. If TRUE, no message confirming package loading is printed, and most often, no errors/warnings are printed if package loading fails.

Details

library(package) and require(package) both load the package with name package and put it on the search list. require is designed for use inside other functions; it returns FALSE and gives a warning (rather than an error as library() does by default) if the package does not exist. Both functions check and update the list of currently loaded packages and do not reload a package which is already loaded. (If you want to reload such a package, call detach(unload = TRUE) or unloadNamespace first.) If you want to load a package without putting it on the search list, use requireNamespace.

To suppress messages during the loading of packages use suppressPackageStartupMessages: this will suppress all messages from R itself but not necessarily all those from package authors.
If `library` is called with no package or `help` argument, it lists all available packages in the libraries specified by `lib.loc`, and returns the corresponding information in an object of class "libraryIQR". The structure of this class may change in future versions. In earlier versions of R, only the names of all available packages were returned; use `.packages(all = TRUE)` for obtaining these. Note that `installed.packages()` returns even more information.

`library(help = somename)` computes basic information about the package `somename`, and returns this in an object of class "packageInfo". The structure of this class may change in future versions. When used with the default value (`NULL`) for `lib.loc`, the attached packages are searched before the libraries.

**Value**

Normally `library` returns (invisibly) the list of attached packages, but `TRUE` or `FALSE` if `logical.return` is `TRUE`. When called as `library()` it returns an object of class "libraryIQR", and for `library(help=)`, one of class "packageInfo".

`require` returns (invisibly) a logical indicating whether the required package is available.

**Licenses**

Some packages have restrictive licenses, and there is a mechanism to allow users to be aware of such licenses. If `getOption("checkPackageLicense") == TRUE`, then at first use of a package with a not-known-to-be-FOSS (see below) license the user is asked to view and accept the license: a list of accepted licenses is stored in file `~/.R/licensed`. In a non-interactive session it is an error to use such a package whose license has not already been accepted.

Free or Open Source Software (FOSS, e.g., [http://en.wikipedia.org/wiki/FOSS](http://en.wikipedia.org/wiki/FOSS)) packages are determined by the same filters used by `available.packages` but applied to just the current package, not its dependencies.

There can also be a site-wide file `R_HOME/etc/licensed.site` of packages (one per line).

**Formal methods**

`library` takes some further actions when package `methods` is attached (as it is by default). Packages may define formal generic functions as well as re-defining functions in other packages (notably `base`) to be generic, and this information is cached whenever such a package is loaded after `methods` and re-defined functions (`implicit generics`) are excluded from the list of conflicts. The caching and check for conflicts require looking for a pattern of objects; the search may be avoided by defining an object `.noGenerics` (with any value) in the package. Naturally, if the package does have any such methods, this will prevent them from being used.

**Note**

`library` and `require` can only load an `installed` package, and this is detected by having a `DESCRIPTION` file containing a 'Built:' field.

Under Unix-alikes, the code checks that the package was installed under a similar operating system as given by `R.version$platform` (the canonical name of the platform under which R was compiled), provided it contains compiled code. Packages which do not contain compiled code can be shared between Unix-alikes, but not to other OSes because of potential problems with line endings and OS-specific help files. If sub-architectures are used, the OS similarity is not checked since the OS used to build may differ (e.g. i386–pc–linux–gnu code can be built on an x86_64–unknown–linux–gnu OS).
The package name given to `library` and `require` must match the name given in the package’s `DESCRIPTION` file exactly, even on case-insensitive file systems such as are common on Windows and OS X.

The initial set of packages attached is set by `options(defaultPackages=)`: see also `Startup`.

Examples

```r
library()  # list all available packages
library(lib.loc = .Library)  # list all packages in the default library
library(help = splines)  # documentation on package 'splines'
library(splines)  # load package 'splines'
require(splines)  # the same
search()  # "splines", too
detach("package:splines")

# if the package name is in a character vector, use
pkg <- "splines"
library(pkg, character.only = TRUE)
detach(pos = match(paste("package", pkg, sep = ":"), search()))

require(pkg, character.only = TRUE)
detach(pos = match(paste("package", pkg, sep = ":"), search()))

require(nonexistent)  # FALSE
## Not run:
## if you want to mask as little as possible, use
library(mypkg, pos = "package:base")

## End(Not run)
```

---

**library.dynam**

*Loading DLLs from Packages*

Description

Load the specified file of compiled code if it has not been loaded already, or unloads it.
Usage

library.dynam(chname, package, lib.loc,
    verbose = getOption("verbose"),
    file.ext = .Platform$dynlib.ext, ...)

library.dynam.unload(chname, libpath,
    verbose = getOption("verbose"),
    file.ext = .Platform$dynlib.ext)

.dynLibs(new)

Arguments

chname a character string naming a DLL (also known as a dynamic shared object or library) to load.
package a character vector with the name of package.
lib.loc a character vector describing the location of R library trees to search through.
libpath the path to the loaded package whose DLL is to be unloaded.
verbose a logical value indicating whether an announcement is printed on the console before loading the DLL. The default value is taken from the verbose entry in the system options.
file.ext the extension (including `.' if used) to append to the file name to specify the library to be loaded. This defaults to the appropriate value for the operating system.
... additional arguments needed by some libraries that are passed to the call to dyn.load to control how the library and its dependencies are loaded.
new a list of "DLLInfo" objects corresponding to the DLLs loaded by packages. Can be missing.

Details

See dyn.load for what sort of objects these functions handle.
library.dynam is designed to be used inside a package rather than at the command line, and should really only be used inside .onLoad. The system-specific extension for DLLs (e.g., `.so` or `.sl` on Unix-alike systems, `.dll` on Windows) should not be added.
library.dynam.unload is designed for use in .onUnload: it unloads the DLL and updates the value of .dynLibs()
.dynLibs is used for getting (with no argument) or setting the DLLs which are currently loaded by packages (using library.dynam).

Value

If chname is not specified, library.dynam returns an object of class "DLLInfoList" corresponding to the DLLs loaded by packages.
If chname is specified, an object of class "DLLInfo" that identifies the DLL and which can be used in future calls is returned invisibly. Note that the class "DLLInfo" has a method for $ which can be used to resolve native symbols within that DLL.
library.dynam.unload invisibly returns an object of class "DLLInfo" identifying the DLL successfully unloaded.
.dynLibs returns an object of class "DLLInfoList" corresponding to its current value.

Warning

Do not use dyn.unload on a DLL loaded by library.dynam: use library.dynam.unload to ensure that .dynLibs gets updated. Otherwise a subsequent call to library.dynam will be told the object is already loaded.

Note that whether or not it is possible to unload a DLL and then reload a revised version of the same file is OS-dependent: see the ‘Value’ section of the help for dyn.unload.

Description
Functions to construct, coerce and check for both kinds of R lists.

Usage

```
list(...)  
pairlist(...)  

as.list(x, ...)  
## S3 method for class 'environment'  
as.list(x, all.names = FALSE, ...)  

as.pairlist(x)  

is.list(x)  
is.pairlist(x)  
alist(...)  
```

Arguments

```
...  
objects, possibly named.  

x  
object to be coerced or tested.  

class(x)  
a logical indicating whether to copy all values or (default) only those whose  
names do not begin with a dot.  
```

Details

Almost all lists in R internally are Generic Vectors, whereas traditional dotted pair lists (as in LISP)  
remain available but rarely seen by users (except as formals of functions).

The arguments to list or pairlist are of the form value or tag = value. The functions return  
a list or dotted pair list composed of its arguments with each value either tagged or untagged,  
depending on how the argument was specified.

alist handles its arguments as if they described function arguments. So the values are not evaluated,  
and tagged arguments with no value are allowed whereas list simply ignores them. alist is  
most often used in conjunction with formals.

as.list attempts to coerce its argument to a list. For functions, this returns the concatenation of  
the list of formal arguments and the function body. For expressions, the list of constituent elements  
is returned. as.list is generic, and as the default method calls as.vector(mode = "list")  
for a non-list, methods for as.vector may be invoked. as.list turns a factor into a list of one-element  
factors. Attributes may be dropped unless the argument already is a list or expression.  
(This is inconsistent with functions such as as.character which always drop attributes, and is for  
efficiency since lists can be expensive to copy.)

is.list returns TRUE if and only if its argument is a list or a pairlist of length > 0.  
is.pairlist returns TRUE if and only if the argument is a pairlist or NULL (see below).
The "environment" method for `as.list` copies the name-value pairs (for names not beginning with a dot) from an environment to a named list. The user can request that all named objects are copied. The list is in no particular order (the order depends on the order of creation of objects and whether the environment is hashed). No enclosing environments are searched. (Objects copied are duplicated so this can be an expensive operation.) Note that there is an inverse operation, the `as.environment()` method for list objects.

An empty pairlist, `pairlist()` is the same as `NULL`. This is different from `list()`.

`as.pairlist` is implemented as `as.vector(x, "pairlist")`, and hence will dispatch methods for the generic function `as.vector`. Lists are copied element-by-element into a pairlist and the names of the list used as tags for the pairlist: the return value for other types of argument is undocumented.

`list`, `is.list` and `is.pairlist` are primitive functions.

References

See Also

`vector("list", length)` for creation of a list with empty components; `c`, for concatenation; `formals.unlist` is an approximate inverse to `as.list()`.

`'plotmath'` for the use of `list` in plot annotation.

Examples

```r
require(graphics)

# create a plotting structure
pts <- list(x = cars[,1], y = cars[,2])
plot(pts)

is.pairlist(.Options) # a user-level pairlist

## "pre-allocate" an empty list of length 5
vector("list", 5)

# Argument lists
f <- function() x
# Note the specification of a "..." argument:
formals(f) <- al <- alist(x = , y = 2*3, ... = )
f
al

## environment->list coercion

el <- new.env()
el$a <- 10
el$b <- 20
as.list(el)
```
list.files

List the Files in a Directory/Folder

Description

These functions produce a character vector of the names of files or directories in the named directory.

Usage

*list.files*(path = ".", pattern = NULL, all.files = FALSE,
full.names = FALSE, recursive = FALSE,
ignore.case = FALSE, include.dirs = FALSE, no.. = FALSE)

*dir*(path = ".", pattern = NULL, all.files = FALSE,
full.names = FALSE, recursive = FALSE,
ignore.case = FALSE, include.dirs = FALSE, no.. = FALSE)

*list.dirs*(path = ".", full.names = TRUE, recursive = TRUE)

Arguments

- **path**: a character vector of full path names; the default corresponds to the working directory, `getwd()`. Tilde expansion (see `path.expand`) is performed. Missing values will be ignored.
- **pattern**: an optional regular expression. Only file names which match the regular expression will be returned.
- **all.files**: a logical value. If FALSE, only the names of visible files are returned. If TRUE, all file names will be returned.
- **full.names**: a logical value. If TRUE, the directory path is prepended to the file names to give a relative file path. If FALSE, the file names (rather than paths) are returned.
- **recursive**: logical. Should the listing recurse into directories?
- **ignore.case**: logical. Should pattern-matching be case-insensitive?
- **include.dirs**: logical. Should subdirectory names be included in recursive listings? (They always are in non-recursive ones).
- **no..**: logical. Should both "." and ".." be excluded also from non-recursive listings?

Value

A character vector containing the names of the files in the specified directories, or "" if there were no files. If a path does not exist or is not a directory or is unreadable it is skipped, with a warning.
The files are sorted in alphabetical order, on the full path if full.names = TRUE.
*list.dirs* implicitly has all.files = TRUE, and if recursive = TRUE, the answer includes path itself (provided it is a readable directory).

Note

File naming conventions are platform dependent. The pattern matching works with the case of file names as returned by the OS.

On a POSIX filesystem recursive listings will follow symbolic links to directories.
list2env

Description

From a named list x, create an environment containing all list components as objects, or “multi-assign” from x into a pre-existing environment.

Usage

list2env(x, envir = NULL, parent = parent.frame(),
hash = (length(x) > 100), size = max(29L, length(x)))

Arguments

x a list, where names(x) must not contain empty ("") elements.
envir an environment or NULL.
parent (for the case envir = NULL): a parent frame aka enclosing environment, see new.env.
hash (for the case envir = NULL): logical indicating if the created environment should use hashing, see new.env.
size (in the case envir = NULL, hash = TRUE): hash size, see new.env.

Details

This will be very slow for large inputs unless hashing is used on the environment.
Environments must have uniquely named entries, but named lists need not: where the list has duplicate names it is the last element with the name that is used. Empty names throw an error.
Value

An environment, either newly created (as by `new.env`) if the `envir` argument was `NULL`, otherwise the updated environment `envir`. Since environments are never duplicated, the argument `envir` is also changed.

Author(s)

Martin Maechler

See Also

`environment`, `new.env`, `as.environment`; further, `assign`.

The (semantical) “inverse”: `as.list.environment`.

Examples

```r
L <- list(a = 1, b = 2:4, p = pi, ff = gl(3, 4, labels = LETTERS[1:3]))
e <- list2env(L)
ls(e)
stopifnot(ls(e) == sort(names(L)),
     identical(L$e, e$)) # "$" working for environments as for lists

## consistency, when we do the inverse:
l1 <- as.list(e) # -> dispatching to the as.list.environment() method
rbind(names(L), names(l1)) # not in the same order, typically,
# but the same content:
stopifnot(identical(L [sort.list(names(L))],
     l1[sort.list(names(l1))]))

## now add to e -- can be seen as a fast "multi-assign":
list2env(list(abc = LETTERS, note = "just an example",
     df = data.frame(x = rnorm(20), y = rbinom(20, 1, pr = 0.2)),
     envir = e),
utils::ls.str(e)
```

load

Reload Saved Datasets

Description

Reload datasets written with the function `save`.

Usage

```r
load(file, envir = parent.frame(), verbose = FALSE)
```

Arguments

- **file**: a (readable binary-mode) connection or a character string giving the name of the file to load (when tilde expansion is done).
- **envir**: the environment where the data should be loaded.
- **verbose**: should item names be printed during loading?
Details

load can load R objects saved in the current or any earlier format. It can read a compressed file (see save) directly from a file or from a suitable connection (including a call to ur1).

A not-open connection will be opened in mode "rb" and closed after use. Any connection other than a gzfile or gzcon connection will be wrapped in gzcon to allow compressed saves to be handled: note that this leaves the connection in an altered state (in particular, binary-only), and that it needs to be closed explicitly (it will not be garbage-collected).

Only R objects saved in the current format (used since R 1.4.0) can be read from a connection. If no input is available on a connection a warning will be given, but any input not in the current format will result in an error.

Loading from an earlier version will give a warning about the 'magic number': magic numbers 1971:1977 are from R < 0.99.0, and RD[ABX] from R 0.99.0 to R 1.3.1. These are all obsolete, and you are strongly recommended to re-save such files in a current format.

The verbose argument is mainly intended for debugging. If it is TRUE, then as objects from the file are loaded, their names will be printed to the console. If verbose is set to an integer value greater than one, additional names corresponding to attributes and other parts of individual objects will also be printed. Larger values will print names to a greater depth.

Objects can be saved with references to namespaces, usually as part of the environment of a function or formula. As from R 3.1.0 such objects can be loaded even if the namespace is not available: it is replaced by a reference to the global environment with a warning. The warning identifies the first object with such a reference (but there may be more than one).

Value

A character vector of the names of objects created, invisibly.

Warning

Saved R objects are binary files, even those saved with ascii = TRUE, so ensure that they are transferred without conversion of end of line markers. load tries to detect such a conversion and gives an informative error message.

See Also

save, download.file.

For other interfaces to the underlying serialization format, see unserialize and readRDS.

Examples

```r
## save all data
xx <- pi # to ensure there is some data
save(list = ls(all = TRUE), file= "all.RData")
rm(xx)

## restore the saved values to the current environment
local({
   load("all.RData")
   ls()
})

## restore the saved values to the user's workspace
load("all.RData", .GlobalEnv)
```
### locales

**Query or Set Aspects of the Locale**

Get details of or set aspects of the locale for the R process.

**Usage**

```r
Sys.getlocale(category = "LC_ALL")
Sys.setlocale(category = "LC_ALL", locale = "")
```

**Arguments**

- **category** character string. The following categories should always be supported: "LC_ALL", "LC_COLLATE", "LC_TYPE", "LC_MONETARY", "LC_NUMERIC" and "LC_TIME". Some systems (not Windows) will also support "LC_MESSAGES", "LC_PAPER" and "LC_MEASUREMENT".
- **locale** character string. A valid locale name on the system in use. Normally "" (the default) will pick up the default locale for the system.

**Details**

The locale describes aspects of the internationalization of a program. Initially most aspects of the locale of R are set to "C" (which is the default for the C language and reflects North-American usage). R sets "LC_CTYPE" and "LC_COLLATE", which allow the use of a different character set and alphabetic comparisons in that character set (including the use of `sort`), "LC_MONETARY" (for use by `Sys.localeconv`) and "LC_TIME" may affect the behaviour of `as.POSIXct` and `strptime` and functions which use them (but not `date`).

The first seven categories described here are those specified by POSIX. "LC_MESSAGES" will be "C" on systems that do not support message translation, and is not supported on Windows. Trying to use an unsupported category is an error for `Sys.setlocale`.

Note that setting category "LC_ALL" sets only "LC_COLLATE", "LC_CTYPE", "LC_MONETARY" and "LC_TIME".

Attempts to set an invalid locale are ignored. There may or may not be a warning, depending on the OS.

Attempts to change the character set (by `Sys.setlocale("LC_TYPE", ...`) if that implies a different character set) during a session may not work and are likely to lead to some confusion.

Note that the `LANGUAGE` environment variable has precedence over "LC_MESSAGES" in selecting the language for message translation on most R platforms.
locales

Value

A character string of length one describing the locale in use (after setting for Sys.setlocale), or an empty character string if the current locale settings are invalid or NULL if locale information is unavailable.

For category = "LC_ALL" the details of the string are system-specific: it might be a single locale name or a set of locale names separated by "/" (Solaris, OS X) or ";" (Windows, Linux). For portability, it is best to query categories individually: it is not necessarily the case that the result of foo <- Sys.getlocale() can be used in Sys.setlocale("LC_ALL", locale = foo).

Warning

Setting "LC_NUMERIC" may cause R to function anomalously, so gives a warning. Input conversions in R itself are unaffected, but the reading and writing of ASCII save files will be, as may packages.

Setting it temporarily on a Unix-alike to produce graphical or text output may work well enough, but options(OutDec) is often preferable.

Almost all the output routines used by R itself under Windows ignore the setting of "LC_NUMERIC" since they make use of the Trio library which is not internationalized.

Note

Changing the values of locale categories whilst R is running ought to be noticed by the OS services, and usually is but exceptions have been seen (usually in collation services).

See Also

strptime for uses of category = "LC_TIME". Sys.localeconv for details of numerical and monetary representations.

110n_info gives some summary facts about the locale and its encoding.

The 'R Installation and Administration’ manual for background on locales and how to find out locale names on your system.

Examples

Sys.getlocale()
Sys.getlocale("LC_TIME")
## Not run:
Sys.setlocale("LC_TIME", "de")  # Solaris: details are OS-dependent
Sys.setlocale("LC_TIME", "de_DE.utf8")  # Modern Linux etc.
Sys.setlocale("LC_TIME", "de_DE.UTF-8")  # ditto
Sys.setlocale("LC_TIME", "de_DE")  # Mac OS X, in UTF-8
Sys.setlocale("LC_TIME", "German")  # Windows

## End(Not run)
Sys.getlocale("LC_PAPER")  # may or may not be set

## Not run:
Sys.setlocale("LC_COLLATE", "C")  # turn off locale-specific sorting,
                                    # usually, but not on all platforms

## End(Not run)
Description

log computes logarithms, by default natural logarithms, \( \log_\theta \) computes common (i.e., base 10) logarithms, and \( \log_2 \) computes binary (i.e., base 2) logarithms. The general form \( \log(x, \text{ base}) \) computes logarithms with base base.

\( \log_1p(x) \) computes \( \log(1 + x) \) accurately also for \(|x| \ll 1\) (and less accurately when \( x \approx -1\)).

exp computes the exponential function.

expm1(x) computes \( \exp(x) - 1 \) accurately also for \(|x| \ll 1\).

Usage

\[
\begin{align*}
\log(x, \text{ base } = \exp(1)) & \\
\logb(x, \text{ base } = \exp(1)) & \\
\log_\theta(x) & \\
\log_2(x) & \\
\log_1p(x) & \\
\exp(x) & \\
\expm1(x) & 
\end{align*}
\]

Arguments

- x a numeric or complex vector.
- base a positive or complex number: the base with respect to which logarithms are computed. Defaults to \( e=\exp(1) \).

Details

All except \( \logb \) are generic functions: methods can be defined for them individually or via the \texttt{Math} group generic.

\( \log_\theta \) and \( \log_2 \) are only convenience wrappers, but \( \log \) to bases 10 and 2 (whether computed via \( \log \) or the wrappers) will be computed more efficiently and accurately where supported by the OS. Methods can be set for them individually (and otherwise methods for \( \log \) will be used).

\( \logb \) is a wrapper for \( \log \) for compatibility with S. If (S3 or S4) methods are set for \( \log \) they will be dispatched. Do not set S4 methods on \( \logb \) itself.

All except \( \log \) are \texttt{primitive} functions.

Value

A vector of the same length as \( x \) containing the transformed values. \( \log(0) \) gives \(-\mathit{Inf}\), and \( \log(x) \) for negative values of \( x \) is \( \mathit{NaN} \). \( \exp(-\mathit{Inf}) \) is 0.

For complex inputs to the \( \log \) functions, the value is a complex number with imaginary part in the range \([-\pi, \pi]\): which end of the range is used might be platform-specific.
S4 methods

exp, expm1, log, log10, log2 and log1p are S4 generic and are members of the Math group generic. Note that this means that the S4 generic for log has a signature with only one argument, x, but that base can be passed to methods (but will not be used for method selection). On the other hand, if you only set a method for the Math group generic then base argument of log will be ignored for your class.

Source

log1p and expm1 may be taken from the operating system, but if not available there are based on the Fortran subroutine dlnrel by W. Fullerton of Los Alamos Scientific Laboratory (see http://www.netlib.org/slatec/fnlib/dlnrel.f and (for small x) a single Newton step for the solution of log1p(y) = x respectively.

References

See Also

Trig, sqrt, Arithmetic.

Examples

log(exp(3))
log10(107) # = 7
x <- 10^-(1+2*1:9)
cbind(x, log(1+x), log1p(x), exp(x)-1, expm1(x))

Logic Logical Operators

Description

These operators act on raw, logical and number-like vectors.

Usage

! x
x & y
x && y
x | y
x || y
xor(x, y)
isTRUE(x)
Arguments

x, y  
raw or logical or ‘number-like’ vectors (i.e., of types double (class numeric), integer and complex), or objects for which methods have been written.

Details

! indicates logical negation (NOT).

& and && indicate logical AND and | and || indicate logical OR. The shorter form performs elementwise comparisons in much the same way as arithmetic operators. The longer form evaluates left to right examining only the first element of each vector. Evaluation proceeds only until the result is determined. The longer form is appropriate for programming control-flow and typically preferred in if clauses.

xor indicates elementwise exclusive OR.

isTRUE(x) is an abbreviation of identical(TRUE, x), and so is true if and only if x is a length-one logical vector whose only element is TRUE and which has no attributes (not even names).

Numeric and complex vectors will be coerced to logical values, with zero being false and all non-zero values being true. Raw vectors are handled without any coercion for !, & and | and xor, with these operators being applied bitwise (so ! is the 1s-complement).

The operators !, & and | are generic functions: methods can be written for them individually or via the Ops (or S4 Logic, see below) group generic function. (See Ops for how dispatch is computed.)

NA is a valid logical object. Where a component of x or y is NA, the result will be NA if the outcome is ambiguous. In other words NA & TRUE evaluates to NA, but NA & FALSE evaluates to FALSE. See the examples below.

See Syntax for the precedence of these operators: unlike many other languages (including S) the AND and OR operators do not have the same precedence (the AND operators have higher precedence than the OR operators).

Value

For !, a logical or raw vector of the same length as x: names, dims and dimnames are copied from x.

For |, &, and xor a logical or raw vector. The elements of shorter vectors are recycled as necessary (with a warning when they are recycled only fractionally). The rules for determining the attributes of the result are rather complicated. Most attributes are taken from the longer argument, the first if they are of the same length. Names will be copied from the first if it is the same length as the answer, otherwise from the second if that is. For time series, these operations are allowed only if the series are compatible, when the class and tsp attribute of whichever is a time series (the same, if both are) are used. For arrays (and an array result) the dimensions and dimnames are taken from first argument if it is an array, otherwise the second.

For ||, && and isTRUE, a length-one logical vector.

S4 methods

!, & and | are S4 generics, the latter two part of the Logic group generic (and hence methods need argument names e1, e2).

References

Logical Vectors

Description

Create or test for objects of type "logical", and the basic logical constants.

Usage

```
TRUE
FALSE
T; F
```

```
logical(length = 0)
as.logical(x, ...)
is.logical(x)
```

Arguments

**length**  
A non-negative integer specifying the desired length. Double values will be coerced to integer: supplying an argument of length other than one is an error.

**x**  
object to be coerced or tested.

**...**  
进一步的参数传递到或从其他方法。

Details

TRUE and FALSE are reserved words denoting logical constants in the R language, whereas T and F are global variables whose initial values set to these. All four are logical(1) vectors. Logical vectors are coerced to integer vectors in contexts where a numerical value is required, with TRUE being mapped to 1L, FALSE to 0L and NA to NA_integer_.

Examples

```
y <- 1 + (x <- stats::rpois(50, lambda = 1.5) / 4 - 1)  
x[(x > 0) & (x < 1)]  # all x values between 0 and 1
if (any(x == 0) || any(y == 0)) "zero encountered"

## construct truth tables :

x <- c(NA, FALSE, TRUE)
names(x) <- as.character(x)
outer(x, x, "&")  ## AND table
outer(x, x, "|")  ## OR table
```

See Also

TRUE or logical.

any and all for OR and AND on many scalar arguments.

Syntax for operator precedence.

bitwAnd for bitwise versions for integer vectors.
Value

logical creates a logical vector of the specified length. Each element of the vector is equal to FALSE.

as.logical attempts to coerce its argument to be of logical type. For factors, this uses the levels (labels). Like as.vector it strips attributes including names. Character strings c("T", "TRUE", "True", "true") are regarded as true, c("F", "FALSE", "False", "false") as false, and all others as NA.

is.logical returns TRUE or FALSE depending on whether its argument is of logical type or not.

References

See Also

NA, the other logical constant.
Matrix algebra

It is now possible to use \( m \times n \) matrices with more than 2 billion elements. Whether matrix algebra (including \%\%, crossprod, svd, qr, solve and eigen) will actually work is somewhat implementation dependent, including the Fortran compiler used and if an external BLAS or LAPACK is used. An efficient parallel BLAS implementation will often be important to obtain usable performance. For example on one particular platform chol on a 47,000 square matrix took about 5 hours with the internal BLAS, 21 minutes using an optimized BLAS on one core, and 2 minutes using an optimized BLAS on 16 cores.

---

```r
lower.tri
```

### Lower and Upper Triangular Part of a Matrix

#### Description

Returns a matrix of logicals the same size of a given matrix with entries TRUE in the lower or upper triangle.

#### Usage

```r
lower.tri(x, diag = FALSE)
upper.tri(x, diag = FALSE)
```

#### Arguments

- `x`: a matrix.
- `diag`: logical. Should the diagonal be included?

#### See Also

`diag`, `matrix`.

#### Examples

```r
(m2 <- matrix(1:20, 4, 5))
lower.tri(m2)
m2[lower.tri(m2)] <- NA
m2
```

---

```r
ls
```

### List Objects

#### Description

`ls` and `objects` return a vector of character strings giving the names of the objects in the specified environment. When invoked with no argument at the top level prompt, `ls` shows what data sets and functions a user has defined. When invoked with no argument inside a function, `ls` returns the names of the function’s local variables: this is useful in conjunction with `browser`.
Usage

```r
ls(name, pos = -1L, envir = as.environment(pos),
   all.names = FALSE, pattern)
```

```r
objects(name, pos = -1L, envir = as.environment(pos),
          all.names = FALSE, pattern)
```

Arguments

- **name**: which environment to use in listing the available objects. Defaults to the current environment. Although called `name` for back compatibility, in fact this argument can specify the environment in any form; see the ‘Details’ section.
- **pos**: an alternative argument to `name` for specifying the environment as a position in the search list. Mostly there for back compatibility.
- **envir**: an alternative argument to `name` for specifying the environment. Mostly there for back compatibility.
- **all.names**: a logical value. If `TRUE`, all object names are returned. If `FALSE`, names which begin with a `'
'` are omitted.
- **pattern**: an optional regular expression. Only names matching `pattern` are returned. `grep` can be used to convert wildcard patterns to regular expressions.

Details

The `name` argument can specify the environment from which object names are taken in one of several forms: as an integer (the position in the search list); as the character string name of an element in the search list; or as an explicit environment (including using `sys.frame` to access the currently active function calls). By default, the environment of the call to `ls` or `objects` is used. The `pos` and `envir` arguments are an alternative way to specify an environment, but are primarily there for back compatibility.

Note that the order of the resulting strings is locale dependent, see `Sys.getlocale`.

References

See Also

`grep` for more details on ‘regular expressions’; `class`, `methods`, etc., for object-oriented programming.

Examples

```
.OB <- 1
ls(pattern = "0")
ls(pattern = "0", all.names = TRUE)  # also shows ".[foo]"
```

# shows an empty list because inside myfunc no variables are defined
myfunc <- function() {ls()}
myfunc()

# define a local variable inside myfunc
myfunc <- function() { y <- 1; ls() }
myfunc()  # shows "y"

## make.names

### Description

Make syntactically valid names out of character vectors.

### Usage

```r
make.names(names, unique = FALSE, allow_ = TRUE)
```

### Arguments

- **names**: character vector to be coerced to syntactically valid names. This is coerced to character if necessary.
- **unique**: logical; if TRUE, the resulting elements are unique. This may be desired for, e.g., column names.
- **allow_**: logical. For compatibility with R prior to 1.9.0.

### Details

A syntactically valid name consists of letters, numbers and the dot or underline characters and starts with a letter or the dot not followed by a number. Names such as ".2way" are not valid, and neither are the reserved words.

The definition of a letter depends on the current locale, but only ASCII digits are considered to be digits.

The character "X" is prepended if necessary. All invalid characters are translated to ".". A missing value is translated to "NA". Names which match R keywords have a dot appended to them. Duplicated values are altered by `make.unique`.

### Value

A character vector of same length as `names` with each changed to a syntactically valid name, in the current locale's encoding.

### Warning

Some OSes, notably FreeBSD, report extremely incorrect information about which characters are alphabetic in some locales (typically, all multi-byte locales including UTF-8 locales). However, R provides substitutes on Windows, OS X and AIX.

### Note

Prior to R version 1.9.0, underscores were not valid in variable names, and code that relies on them being converted to dots will no longer work. Use `allow_ = FALSE` for back-compatibility. `allow_ = FALSE` is also useful when creating names for export to applications which do not allow underline in names (for example, S-PLUS and some DBMSs).
See Also

`make.unique.names`, `character.data.frame`.

Examples

```r
make.names(c("a and b", "a-and-b"), unique = TRUE)
# [1] "a.and.b" "a.and.b.1"
make.names(c("a and b", "a_and_b"), unique = TRUE)
# [1] "a.and.b" "a_and_b"
make.names(c("a and b", "a_and_b"), unique = TRUE, allow_ = FALSE)
# [1] "a.and.b" "a.and.b.1"

state.name[make.names(state.name) != state.name] # those 10 with a space
```

Description

Makes the elements of a character vector unique by appending sequence numbers to duplicates.

Usage

```r
make.unique(names, sep = ".")
```

Arguments

- `names`: a character vector
- `sep`: a character string used to separate a duplicate name from its sequence number.

Details

The algorithm used by `make.unique` has the property that `make.unique(c(A, B)) == make.unique(c(make.unique(A), B))`. In other words, you can append one string at a time to a vector, making it unique each time, and get the same result as applying `make.unique` to all of the strings at once.

If character vector `A` is already unique, then `make.unique(c(A, B))` preserves `A`.

Value

A character vector of same length as `names` with duplicates changed, in the current locale’s encoding.

`make.names`
**mapply**

Apply a Function to Multiple List or Vector Arguments

**Description**

mapply is a multivariate version of sapply. mapply applies FUN to the first elements of each ... argument, the second elements, the third elements, and so on. Arguments are recycled if necessary.

**Usage**

```r
mapply(FUN, ..., MoreArgs = NULL, SIMPLIFY = TRUE,
       USE.NAMES = TRUE)
```

**Arguments**

- **FUN** function to apply, found via `match.fun`.
- **...** arguments to vectorize over (vectors or lists of strictly positive length, or all of zero length). See also ‘Details’.
- **MoreArgs** a list of other arguments to FUN.
- **SIMPLIFY** logical or character string; attempt to reduce the result to a vector, matrix or higher dimensional array; see the simplify argument of `sapply`.
- **USE.NAMES** logical; use names if the first ... argument has names, or if it is a character vector, use that character vector as the names.

**Details**

mapply calls FUN for the values of ... (re-cycled to the length of the longest, unless any have length zero), followed by the arguments given in MoreArgs. The arguments in the call will be named if ... or MoreArgs are named.

Arguments with classes in ... will be accepted, and their subsetting and length methods will be used.

**Value**

A list, or for SIMPLIFY = TRUE, a vector, array or list.

**See Also**

- sapply, after which mapply() is modelled.
- outer, which applies a vectorized function to all combinations of two arguments.

**Examples**

```r
c(make.unique(c("a", "a", "a"))
c(make.unique(c(make.unique(c("a", "a")), "a")))
c(make.unique(c("a", "a", "a.2", "a"))
c(make.unique(c(make.unique(c("a", "a")), "a.2", "a")))

c(rbind(data.frame(x = 1), data.frame(x = 2), data.frame(x = 3)))
c(rbind(rbind(data.frame(x = 1), data.frame(x = 2)), data.frame(x = 3)))
```
Examples

maply(rep, 1:4, 4:1)
maply(rep, times = 1:4, x = 4:1)
maply(rep, times = 1:4, MoreArgs = list(x = 42))
maply(function(x, y) seq_len(x) + y, c(a = 1, b = 2, c = 3), # names from first
c(A = 10, B = 0, C = -10))
word <- function(C, k) paste(rep.int(C, k), collapse = "")
utils::str(maply(word, LETTERS[1:6], 6:1, SIMPLIFY = FALSE))

margin.table

Compute table margin

Description

For a contingency table in array form, compute the sum of table entries for a given index.

Usage

margin.table(x, margin = NULL)

Arguments

x
an array
margin
index number (1 for rows, etc.)

Details

This is really just apply(x, margin, sum) packaged up for newbies, except that if margin has
length zero you get sum(x).

Value

The relevant marginal table. The class of x is copied to the output table, except in the summation
case.

Author(s)

Peter Dalgaard

See Also

prop.table and addmargins.

Examples

m <- matrix(1:4, 2)
margin.table(m, 1)
margin.table(m, 2)
**mat.or.vec**

*Create a Matrix or a Vector*

**Description**

*mat.or.vec* creates an *nr* by *nc* zero matrix if *nc* is greater than 1, and a zero vector of length *nr* if *nc* equals 1.

**Usage**

```r
mat.or.vec(nr, nc)
```

**Arguments**

- `nr`, `nc`: numbers of rows and columns.

**Examples**

```r
mat.or.vec(3, 1)
mat.or.vec(3, 2)
```

---

**match**

*Value Matching*

**Description**

*match* returns a vector of the positions of (first) matches of its first argument in its second.

%in% is a more intuitive interface as a binary operator, which returns a logical vector indicating if there is a match or not for its left operand.

**Usage**

```r
match(x, table, nomatch = NA_integer_, incomparables = NULL)
```

```r
x %in% table
```

**Arguments**

- `x`: vector or NULL: the values to be matched. Long vectors are supported.
- `table`: vector or NULL: the values to be matched against. Long vectors are not supported.
- `nomatch`: the value to be returned in the case when no match is found. Note that it is coerced to integer.
- `incomparables`: a vector of values that cannot be matched. Any value in *x* matching a value in this vector is assigned the *nomatch* value. For historical reasons, FALSE is equivalent to NULL.
Details

%in% is currently defined as
```
"%in%" <- function(x, table) match(x, table, nomatch = 0) > 0
```
Factors, raw vectors and lists are converted to character vectors, and then `x` and `table` are coerced to a common type (the later of the two types in R's ordering, logical < integer < numeric < complex < character) before matching. If `incomparables` has positive length it is coerced to the common type.

Matching for lists is potentially very slow and best avoided except in simple cases.

Exactly what matches what is to some extent a matter of definition. For all types, `NA` matches `NA` and no other value. For real and complex values, `NaN` values are regarded as matching any other `NaN` value, but not matching `NA`.

That `%in%` never returns `NA` makes it particularly useful in `if` conditions.

Character strings will be compared as byte sequences if any input is marked as “bytes”.

Value

A vector of the same length as `x`.

`match`: An integer vector giving the position in `table` of the first match if there is a match, otherwise `nomatch`.

If `x[i]` is found to equal `table[j]` then the value returned in the `i`-th position of the return value is `j`, for the smallest possible `j`. If no match is found, the value is `nomatch`.

%in%: A logical vector, indicating if a match was located for each element of `x`: thus the values are `TRUE` or `FALSE` and never `NA`.

References

See Also

`pmatch` and `charmatch` for (partial) string matching, `match.arg`, etc for function argument matching. `findInterval` similarly returns a vector of positions, but finds numbers within intervals, rather than exact matches.

`is.element` for an S-compatible equivalent of `%in%`.

Examples

```r
## The intersection of two sets can be defined via match():
## Simple version:
## intersect <- function(x, y) y[match(x, y, nomatch = 0)]
intersect <- function(x, y) y[match(x, y, nomatch = 0)]
intersect # the R function in base, slightly more careful
intersect(1:10, 7:20)

1:10 %in% c(1,3,5,9)
sstr <- c("c","ab","B","bba","c","NA","@","bla","a","Ba","%")
sstr[sstr %in% c(letters, LETTERS)]

"%w/o%" <- function(x, y) x[!x %in% y] #-- x without y
(1:10) "%w/o%" c(3,7,12)
```
Description

match.arg matches arg against a table of candidate values as specified by choices, where NULL means to take the first one.

Usage

match.arg(arg, choices, several.ok = FALSE)

Arguments

arg a character vector (of length one unless several.ok is TRUE) or NULL.
choices a character vector of candidate values
several.ok logical specifying if arg should be allowed to have more than one element.

Details

In the one-argument form match.arg(arg), the choices are obtained from a default setting for the formal argument arg of the function from which match.arg was called. (Since default argument matching will set arg to choices, this is allowed as an exception to the 'length one unless several.ok is TRUE' rule, and returns the first element.)

Matching is done using pmatch, so arg may be abbreviated.

Value

The unabbreviated version of the exact or unique partial match if there is one; otherwise, an error is signalled if several.ok is false, as per default. When several.ok is true and more than one element of arg has a match, all unabbreviated versions of matches are returned.

See Also

pmatch, match.fun, match.call.

Examples

require(stats)
## Extends the example for 'switch'
center <- function(x, type = c("mean", "median", "trimmed")) {
  type <- match.arg(type)
  switch(type,
    mean = mean(x),
    median = median(x),
    trimmed = mean(x, trim = .1))
}
x <- rcauchy(10)
center(x, "t") # Works
center(x, "med") # Works
try(center(x, "m")) # Error
stopifnot(identical(center(x), center(x, "mean")),

```r
center(x, "m"), center(x, "mean"),
```
identical(center(x, NULL), center(x, "mean"))

## Allowing more than one match:
match.arg(c("gauss", "rect", "ep"),
          c("gaussian", "epanechnikov", "rectangular", "triangular"),
          several.ok = TRUE)

### Argument Matching

**Description**

match.call returns a call in which all of the specified arguments are specified by their full names.

**Usage**

match.call(definition = NULL, call = sys.call(sys.parent()),
            expand.dots = TRUE)

**Arguments**

- **definition**: a function, by default the function from which match.call is called. See details.
- **call**: an unevaluated call to the function specified by definition, as generated by call.
- **expand.dots**: logical. Should arguments matching ... in the call be included or left as a ... argument?

**Details**

'function' on this help page means an interpreted function (also known as a 'closure'); match.call does not support primitive functions (where argument matching is normally positional).

match.call is most commonly used in two circumstances:

- To record the call for later re-use: for example most model-fitting functions record the call as element call of the list they return. Here the default expand.dots = TRUE is appropriate.
- To pass most of the call to another function, often model.frame. Here the common idiom is that expand.dots = FALSE is used, and the ... element of the matched call is removed. An alternative is to explicitly select the arguments to be passed on, as is done in lm.

Calling match.call outside a function without specifying definition is an error.

**Value**

An object of class call.

**References**

**See Also**

sys.call() is similar, but does not expand the argument names; call, pmatch, match.arg, match.fun.
**match.fun**

**Examples**

```r
match.call(get, call("get", "abc", i = FALSE, p = 3))
## -> get(x = "abc", pos = 3, inherits = FALSE)
fun <- function(x, lower = 0, upper = 1) {
  structure((x - lower) / (upper - lower), CALL = match.call())
}
fun(4 * atan(1), u = pi)
```

**Description**

When called inside functions that take a function as argument, extract the desired function object while avoiding undesired matching to objects of other types.

**Usage**

```r
match.fun(FUN, descend = TRUE)
```

**Arguments**

- `FUN` item to match as function: a function, symbol or character string. See ‘Details’.
- `descend` logical; control whether to search past non-function objects.

**Details**

`match.fun` is not intended to be used at the top level since it will perform matching in the *parent* of the caller.

If `FUN` is a function, it is returned. If it is a symbol (for example, enclosed in backquotes) or a character vector of length one, it will be looked up using `get` in the environment of the parent of the caller. If it is of any other mode, it is attempted first to get the argument to the caller as a symbol (using `substitute` twice), and if that fails, an error is declared.

If `descend = TRUE`, `match.fun` will look past non-function objects with the given name; otherwise if `FUN` points to a non-function object then an error is generated.

This is used in base functions such as `apply`, `lapply`, `outer`, and `sweep`.

**Value**

A function matching `FUN` or an error is generated.

**Bugs**

The descend argument is a bit of misnomer and probably not actually needed by anything. It may go away in the future.

It is impossible to fully foolproof this. If one attaches a list or data frame containing a length-one character vector with the same name as a function, it may be used (although namespaces will help).

**Author(s)**

Peter Dalgaard and Robert Gentleman, based on an earlier version by Jonathan Rougier.
MathFun

Miscellaneous Mathematical Functions

Description

abs(x) computes the absolute value of x, sqrt(x) computes the (principal) square root of x, \( \sqrt{x} \).

The naming follows the standard for computer languages such as C or Fortran.

Usage

abs(x)
sqrt(x)

Arguments

x

a numeric or complex vector or array.

Details

These are internal generic primitive functions: methods can be defined for them individually or via the Math group generic. For complex arguments (and the default method), \( z \), abs(\( z \)) \( \equiv |z| \) and \( \text{sqrt}(z) \equiv z^0.5 \).

abs(x) returns an integer vector when x is integer or logical.

S4 methods

Both are S4 generic and members of the Math group generic.

References

See Also

Arithmetic for simple, \texttt{log} for logarithmic, \texttt{sin} for trigonometric, and \texttt{Special} for special mathematical functions.

'\texttt{plotmath}' for the use of \texttt{sqrt} in plot annotation.

Examples

```r
require(stats) # for spline
require(graphics)
xx <- -9:9
plot(xx, sqrt(abs(xx)), col = "red")
lines(spline(xx, sqrt(abs(xx)), n=101), col = "pink")
```

---

\texttt{matmult} \hspace{1cm} \textit{Matrix Multiplication}

Description

Multiplies two matrices, if they are conformable. If one argument is a vector, it will be promoted to either a row or column matrix to make the two arguments conformable. If both are vectors it will return the inner product (as a matrix).

Usage

```
x \%\%\% y
```

Arguments

```
x, y     numeric or complex matrices or vectors.
```

Details

When a vector is promoted to a matrix, its names are not promoted to row or column names, unlike \texttt{as.matrix}.

This operator is S4 generic but not S3 generic. S4 methods need to be written for a function of two arguments named \texttt{x} and \texttt{y}.

Value

A double or complex matrix product. Use \texttt{drop} to remove dimensions which have only one level.

References

See Also

\texttt{matrix}, \texttt{Arithmetic}, \texttt{diag}.
### Examples

```
x <- 1:4
(z <- x %*% x)  # scalar ("inner") product (1 x 1 matrix)
drop(z)        # as scalar

y <- diag(x)
z <- matrix(1:12, ncol = 3, nrow = 4)
y %*% z
y %*% x
x %*% z
```

### Description

`matrix` creates a matrix from the given set of values.

`as.matrix` attempts to turn its argument into a matrix.

`is.matrix` tests if its argument is a (strict) matrix.

### Usage

```
matrix(data = NA, nrow = 1, ncol = 1, byrow = FALSE,
       dimnames = NULL)
as.matrix(x, ...)
## S3 method for class 'data.frame'
as.matrix(x, rownames.force = NA, ...)
is.matrix(x)
```

### Arguments

- **data**: an optional data vector (including a list or expression vector). Non-atomic classed R objects are coerced by `as.vector` and all attributes discarded.
- **nrow**: the desired number of rows.
- **ncol**: the desired number of columns.
- **byrow**: logical. If FALSE (the default) the matrix is filled by columns, otherwise the matrix is filled by rows.
- **dimnames**: A `dimnames` attribute for the matrix: NULL or a list of length 2 giving the row and column names respectively. An empty list is treated as `NULL`, and a list of length one as row names. The list can be named, and the list names will be used as names for the dimensions.
- **x**: an R object.
- **...**: additional arguments to be passed to or from methods.
- **rownames.force**: logical indicating if the resulting matrix should have character (rather than NULL) rownames. The default, NA, uses NULL rownames if the data frame has ‘automatic’ row.names or for a zero-row data frame.
Details

If one of nrow or ncol is not given, an attempt is made to infer it from the length of data and the other parameter. If neither is given, a one-column matrix is returned.

If there are too few elements in data to fill the matrix, then the elements in data are recycled. If data has length zero, NA of an appropriate type is used for atomic vectors (0 for raw vectors) and NULL for lists.

is.matrix returns TRUE if x is a vector and has a "dim" attribute of length 2) and FALSE otherwise. Note that a data.frame is not a matrix by this test. The function is generic: you can write methods to handle specific classes of objects, see InternalMethods.

as.matrix is a generic function. The method for data frames will return a character matrix if there is only atomic columns and any non-(numeric/logical/complex) column, applying as.vector to factors and format to other non-character columns. Otherwise, the usual coercion hierarchy (logical < integer < double < complex) will be used, e.g., all-logical data frames will be coerced to a logical matrix, mixed logical-integer will give a integer matrix, etc.

The default method for as.matrix calls as.vector(x), and hence e.g. coerces factors to character vectors.

When coercing a vector, it produces a one-column matrix, and promotes the names (if any) of the vector to the rownames of the matrix.

is.matrix is a primitive function.

The print method for a matrix gives a rectangular layout with dimnames or indices. For a list matrix, the entries of length not one are printed in the form ‘integer,7’ indicating the type and length.

Note

If you just want to convert a vector to a matrix, something like

```r
dim(x) <- c(nx, ny)
dimnames(x) <- list(row_names, col_names)
```

will avoid duplicating x.

References

See Also

data.matrix, which attempts to convert to a numeric matrix.

A matrix is the special case of a two-dimensional array.

Examples

```r
is.matrix(as.matrix(1:10))
!is.matrix(warpbreaks) # data.frame, NOT matrix!
warpbreaks[1:10,]
as.matrix(warpbreaks[1:10,]) # using as.matrix.data.frame(.) method
```

```r
## Example of setting row and column names
mdat <- matrix(c(1,2,3, 11,12,13), nrow = 2, ncol = 3, byrow = TRUE,
```
maxCol

Find Maximum Position in Matrix

Description
Find the maximum position for each row of a matrix, breaking ties at random.

Usage

maxCol(m, ties.method = c("random", "first", "last"))

Arguments

m
numerical matrix

ties.method
a character string specifying how ties are handled, "random" by default; can be abbreviated; see 'Details'.

Details

When ties.method = "random", as per default, ties are broken at random. In this case, the determination of a tie assumes that the entries are probabilities: there is a relative tolerance of $10^{-5}$, relative to the largest (in magnitude, omitting infinity) entry in the row.

If ties.method = "first", maxCol returns the column number of the first of several maxima in every row, the same as which.max(m, 1, which.max).

Correspondingly, ties.method = "last" returns the last of possibly several indices.

Value

index of a maximal value for each row, an integer vector of length nrow(m).

References

See Also

which.max for vectors.

Examples

```r
library(stats)

# create a matrix with some missing values
mdat <- matrix(c(3, 2, 5, 4, NA, 6, 7, 8, 9), nrow = 3, byrow = TRUE)

# find the maximum position in each row
maxCol(mdat)
```

```r
# create a matrix
swiss <- as.matrix(swiss)

# find the maximum position in each row
maxCol(swiss)
```

```r
# set seed for reproducibility
set.seed(1)

# create a matrix with random numbers
x <- runif(12)
y <- runif(12)
z <- runif(12)

# find the maximum position in each row
maxCol(rbind(x, y, z))
```

```r
# not run

```

```r
# not run
```
### mean

#### Description

Generic function for the (trimmed) arithmetic mean.

#### Usage

```r
mean(x, ...)  
```

#### Arguments

- **x**: An R object. Currently there are methods for numeric/logical vectors and date, date-time and time interval objects. Complex vectors are allowed for `trim = 0`, only.
- **trim**: the fraction (0 to 0.5) of observations to be trimmed from each end of `x` before the mean is computed. Values of `trim` outside that range are taken as the nearest endpoint.
- **na.rm**: a logical value indicating whether NA values should be stripped before the computation proceeds.
- `...`: further arguments passed to or from other methods.

#### Value

If `trim` is zero (the default), the arithmetic mean of the values in `x` is computed, as a numeric or complex vector of length one. If `x` is not logical (coerced to numeric), numeric (including integer) or complex, `NA_real_` is returned, with a warning.

If `trim` is non-zero, a symmetrically trimmed mean is computed with a fraction of `trim` observations deleted from each end before the mean is computed.

#### References

memCompress

In-memory Compression and Decompression

Description

In-memory compression or decompression for raw vectors.

Usage

```r
memCompress(from, type = c("gzip", "bzip2", "xz", "none"))

memDecompress(from, type = c("unknown", "gzip", "bzip2", "xz", "none"), asChar = FALSE)
```

Arguments

- `from` A raw vector. For `memCompress` a character vector will be converted to a raw vector with character strings separated by `\n`.
- `type` character string, the type of compression. May be abbreviated to a single letter, defaults to the first of the alternatives.
- `asChar` logical: should the result be converted to a character string?

Details

type = "none" passes the input through unchanged, but may be useful if type is a variable.
type = "unknown" attempts to detect the type of compression applied (if any): this will always succeed for bzip2 compression, and will succeed for other forms if there is a suitable header. It will auto-detect the 'magic' header ("\x1f\x8b") added to files by the gzip program (and to files written by `gzfile`), but `memCompress` does not add such a header.
bzip2 compression always adds a header ("BZh").
Compressing with type = "xz" is equivalent to compressing a file with `xz -9e` (including adding the 'magic' header): decompression should cope with the contents of any file compressed with `xz` version 4.999 and some versions of lzma. There are other versions, in particular 'raw' streams, that are not currently handled.
All the types of compression can expand the input: for "gzip" and "bzip" the maximum expansion is known and so `memCompress` can always allocate sufficient space. For "xz" it is possible (but extremely unlikely) that compression will fail if the output would have been too large.
Value

A raw vector or a character string (if asChar = TRUE).

See Also

connections.

Examples

```r
txt <- readLines(file.path(R.home("doc"), "COPYING"))
sum(nchar(txt))
txt.gz <- memCompress(txt, "g")
length(txt.gz)
txt2 <- strsplit(memDecompress(txt.gz, "g", asChar = TRUE), "\n")[[1]]
stopifnot(identical(txt, txt2))
txt.bz2 <- memCompress(txt, "b")
length(txt.bz2)
## can auto-detect bzip2:
txt3 <- strsplit(memDecompress(txt.bz2, asChar = TRUE), "\n")[[1]]
stopifnot(identical(txt, txt3))

## xz compression is only worthwhile for large objects
txt.xz <- memCompress(txt, "xz")
length(txt.xz)
txt3 <- strsplit(memDecompress(txt.xz, asChar = TRUE), "\n")[[1]]
stopifnot(identical(txt, txt3))
```

---

Memory

Memory Available for Data Storage

---

Description

How R manages its workspace.

Details

R has a variable-sized workspace. There are (rarely-used) command-line options to control its minimum size, but no longer any to control the maximum size.

R maintains separate areas for fixed and variable sized objects. The first of these is allocated as an array of cons cells (Lisp programmers will know what they are, others may think of them as the building blocks of the language itself, parse trees, etc.), and the second are thrown on a heap of 'Vcells' of 8 bytes each. Each cons cell occupies 28 bytes on a 32-bit build of R, (usually) 56 bytes on a 64-bit build.

The default values are (currently) an initial setting of 350k cons cell sand 6Mb of vector heap. Note that the areas are not actually allocated initially: rather these values are the sizes for triggering garbage collection. These values can be set by the command line options ‘--min-nsize’ and ‘--min-vsize’ (or if they are not used, the environment variables RFSIZE and R_VSIZE) when R
Memory-limits

is started. Thereafter \texttt{R} will grow or shrink the areas depending on usage, never decreasing below the initial values.

How much time \texttt{R} spends in the garbage collector will depend on these initial settings and on the trade-off the memory manager makes, when memory fills up, between collecting garbage to free up unused memory and growing these areas. The strategy used for growth can be specified by setting the environment variable \texttt{R\_GC\_MEM\_GROW} to an integer value between 0 and 3. This variable is read at start-up. Higher values grow the heap more aggressively, thus reducing garbage collection time but using more memory.

You can find out the current memory consumption (the heap and cons cells used as numbers and megabytes) by typing \texttt{gc()} at the \texttt{R} prompt. Note that following \texttt{gcinfo(TRUE)}, automatic garbage collection always prints memory use statistics.

The command-line option ‘\texttt{--max-ppsize}’ controls the maximum size of the pointer protection stack. This defaults to 50000, but can be increased to allow deep recursion or large and complicated calculations to be done. \textit{Note} that parts of the garbage collection process goes through the full reserved pointer protection stack and hence becomes slower when the size is increased. Currently the maximum value accepted is 500000.

\textbf{See Also}

An Introduction to \textit{R} for more command-line options.

\texttt{Memory-limits} for the design limitations.

\texttt{gc} for information on the garbage collector and total memory usage, \texttt{object.size(a)} for the (approximate) size of \texttt{R} object \texttt{a}. \texttt{memory.profile} for profiling the usage of cons cells.
Error messages beginning cannot allocate vector of size indicate a failure to obtain memory, either because the size exceeded the address-space limit for a process or, more likely, because the system was unable to provide the memory. Note that on a 32-bit build there may well be enough free memory available, but not a large enough contiguous block of address space into which to map it.

There are also limits on individual objects. The storage space cannot exceed the address limit, and if you try to exceed that limit, the error message begins cannot allocate vector of length. The number of bytes in a character string is limited to $2^{31} - 1 \approx 2 \times 10^9$, which is also the limit on each dimension of an array.

Unix

The address-space limit is system-specific: 32-bit OSes imposes a limit of no more than 4Gb: it is often 3Gb. Running 32-bit executables on a 64-bit OS will have similar limits: 64-bit executables will have an essentially infinite system-specific limit (e.g. 128Tb for Linux on x86_64 cpus).

See the OS/shell’s help on commands such as limit or ulimit for how to impose limitations on the resources available to a single process. For example a bash user could use

```
ulimit -t 600 -v 4000000
```

whereas a csh user might use

```
limit cputime 10m
limit vmemoryuse 4096m
```

to limit a process to 10 minutes of CPU time and (around) 4Gb of virtual memory. (There are other options to set the RAM in use, but they are not generally honoured.)

Windows

The address-space limit is 2Gb under 32-bit Windows unless the OS’s default has been changed to allow more (up to 3Gb). See [http://www.microsoft.com/whdc/system/platform/server/PAE/PAEmem.mspx](http://www.microsoft.com/whdc/system/platform/server/PAE/PAEmem.mspx) and [http://msdn.microsoft.com/en-us/library/bb613473(VS.85).aspx](http://msdn.microsoft.com/en-us/library/bb613473(VS.85).aspx). Under most 64-bit versions of Windows the limit for a 32-bit build of R is 4Gb: for the oldest ones it is 2Gb. The limit for a 64-bit build of R (imposed by the OS) is 8Tb.

It is not normally possible to allocate as much as 2Gb to a single vector in a 32-bit build of R even on 64-bit Windows because of preallocations by Windows in the middle of the address space.

Under Windows, R imposes limits on the total memory allocation available to a single session as the OS provides no way to do so: see memory.size and memory.limit.

* object.size(a) for the (approximate) size of R object a.
**memory.profile**  
*Profile the Usage of Cons Cells*

**Description**
Lists the usage of the cons cells by SEXP type.

**Usage**
```r
memory.profile()
```

**Details**
The current types and their uses are listed in the include file `Rinternals.h`.

**Value**
A vector of counts, named by the types. See `typeof` for an explanation of types.

**See Also**
- `gc` for the overall usage of cons cells. `Rprofmem` and `tracemem` allow memory profiling of specific code or objects, but need to be enabled at compile time.

**Examples**
```r
memory.profile()
```

---

**merge**  
*Merge Two Data Frames*

**Description**
Merge two data frames by common columns or row names, or do other versions of database *join* operations.

**Usage**
```r
merge(x, y, ...)
```

```r
## Default S3 method:
merge(x, y, ...)
```

```r
## S3 method for class 'data.frame'
merge(x, y, by = intersect(names(x), names(y)),
      by.x = by, by.y = by, all = FALSE, all.x = all, all.y = all,
      sort = TRUE, suffixes = c(".x", ".y"),
      incomparables = NULL, ...)
```
merge

Arguments

- **x, y**: data frames, or objects to be coerced to one.
- **by, by.x, by.y**: specifications of the columns used for merging. See ‘Details’.
- **all**: logical; all = L is shorthand for all.x = L and all.y = L, where L is either TRUE or FALSE.
- **all.x**: logical; if TRUE, then extra rows will be added to the output, one for each row in x that has no matching row in y. These rows will have NAs in those columns that are usually filled with values from y. The default is FALSE, so that only rows with data from both x and y are included in the output.
- **all.y**: logical; analogous to all.x.
- **sort**: logical. Should the result be sorted on the by columns?
- **suffixes**: a character vector of length 2 specifying the suffixes to be used for making unique the names of columns in the result which not used for merging (appearing in by etc).
- **incomparables**: values which cannot be matched. See match.
- **...**: arguments to be passed to or from methods.

Details

merge is a generic function whose principal method is for data frames: the default method coerces its arguments to data frames and calls the "data.frame" method.

By default the data frames are merged on the columns with names they both have, but separate specifications of the columns can be given by by.x and by.y. The rows in the two data frames that match on the specified columns are extracted, and joined together. If there is more than one match, all possible matches contribute one row each. For the precise meaning of ‘match’, see match.

Columns to merge on can be specified by name, number or by a logical vector: the name "row.names" or the number 0 specifies the row names. If specified by name it must correspond uniquely to a named column in the input.

If by or both by.x and by.y are of length 0 (a length zero vector or NULL), the result, r, is the Cartesian product of x and y, i.e., dim(r) = c(nrow(x)*nrow(y), ncol(x) + ncol(y)).

If all.x is true, all the non matching cases of x are appended to the result as well, with NA filled in the corresponding columns of y; analogously for all.y.

If the columns in the data frames not used in merging have any common names, these have suffixes (".x" and ".y" by default) appended to try to make the names of the result unique. If this is not possible, an error is thrown.

The complexity of the algorithm used is proportional to the length of the answer.

In SQL database terminology, the default value of all = FALSE gives a natural join, a special case of an inner join. Specifying all.x = TRUE gives a left (outer) join, all.y = TRUE a right (outer) join, and both (all = TRUE a (full) outer join. DBMSes do not match NULL records, equivalent to incomparables = NA in R.

Value

A data frame. The rows are by default lexicographically sorted on the common columns, but for sort = FALSE are in an unspecified order. The columns are the common columns followed by the remaining columns in x and then those in y. If the matching involved row names, an extra character column called Row. names is added at the left, and in all cases the result has ‘automatic’ row names.
Note

This is intended to work with data frames with vector-like columns: some aspects work with data frames containing matrices, but not all.

See Also

data.frame, by, cbind.
dendrogram for a class which has a merge method.

Examples

```r
## use character columns of names to get sensible sort order
authors <- data.frame(
  surname = I(c("Tukey", "Venables", "Tierney", "Ripley", "McNeil")),
  nationality = c("US", "Australia", "US", "UK", "Australia"),
  deceased = c("yes", rep("no", 4)))
books <- data.frame(
  name = I(c("Tukey", "Venables", "Tierney",
              "Ripley", "Ripley", "McNeil", "R Core")),
  title = c("Exploratory Data Analysis",
            "Modern Applied Statistics ...",
            "LISP-STAT",
            "Spatial Statistics", "Stochastic Simulation",
            "Interactive Data Analysis",
            "An Introduction to R"),
  other.author = c(NA, "Ripley", NA, NA, NA, NA,
                   "Venables & Smith"))

(m1 <- merge(authors, books, by.x = "surname", by.y = "name"))
(m2 <- merge(books, authors, by.x = "name", by.y = "surname"))
stopifnot(as.character(m1[, 1]) == as.character(m2[, 1]),
          all.equal(m1[, -1], m2[, -1][ names(m1)[-1 ] ]),
          dim(merge(m1, m2, by = integer(0))) == c(36, 10))

## "R core" is missing from authors and appears only here :
merge(authors, books, by.x = "surname", by.y = "name", all = TRUE)

## example of using 'incomparables'
x <- data.frame(k1 = c(NA,NA,NA,3,4,5), k2 = c(1,NA,NA,4,5), data = 1:5)
y <- data.frame(k1 = c(NA,2,NA,4,5), k2 = c(NA,NA,3,4,5), data = 1:5)
merge(x, y, by = c("k1","k2"))  # NA's match
merge(x, y, by = c("k1","k2"), incomparables = NA)
merge(x, y, by = "k1")  # NA's match, so 6 rows
merge(x, y, by = "k2", incomparables = NA)  # 2 rows
```

---

**message**

**Diagnostic Messages**

### Description

Generate a diagnostic message from its arguments.
**Usage**

```r
message(..., domain = NULL, appendLF = TRUE)
suppressMessages(expr)

packageStartupMessage(..., domain = NULL, appendLF = TRUE)
suppressPackageStartupMessages(expr)

.makeMessage(..., domain = NULL, appendLF = FALSE)
```

**Arguments**

- `...` zero or more objects which can be coerced to character (and which are pasted together with no separator) or (for `message` only) a single condition object.
- `domain` see `gettext`. If `NA`, messages will not be translated, see also the note in `stop`.
- `appendLF` logical: should messages given as a character string have a newline appended?
- `expr` expression to evaluate.

**Details**

`message` is used for generating ‘simple’ diagnostic messages which are neither warnings nor errors, but nevertheless represented as conditions. Unlike warnings and errors, a final newline is regarded as part of the message, and is optional. The default handler sends the message to the `stderr()` connection.

If a condition object is supplied to `message` it should be the only argument, and further arguments will be ignored, with a warning.

While the message is being processed, a `muffleMessage` restart is available.

`suppressMessages` evaluates its expression in a context that ignores all ‘simple’ diagnostic messages.

`packageStartupMessage` is a variant whose messages can be suppressed separately by `suppressPackageStartupMessages`. (They are still messages, so can be suppressed by `suppressMessages`.)

`.makeMessage` is a utility used by `message`, `warning` and `stop` to generate a text message from the `...` arguments by possible translation (see `gettext`) and concatenation (with no separator).

**See Also**

- `warning` and `stop` for generating warnings and errors; `conditions` for condition handling and recovery.
- `gettext` for the mechanisms for the automated translation of text.

**Examples**

```r
message("ABC", "DEF")
suppressMessages(message("ABC"))

testit <- function() {
  message("testing package startup messages")
  packageStartupMessage("initializing ...", appendLF = FALSE)
  Sys.sleep(1)
  packageStartupMessage(" done")
}
```
Does a Formal Argument have a Value?

Description

missing can be used to test whether a value was specified as an argument to a function.

Usage

missing(x)

Arguments

x a formal argument.

Details

missing(x) is only reliable if x has not been altered since entering the function: in particular it will always be false after x <- match.arg(x).

The example shows how a plotting function can be written to work with either a pair of vectors giving x and y coordinates of points to be plotted or a single vector giving y values to be plotted against their indices.

Currently missing can only be used in the immediate body of the function that defines the argument, not in the body of a nested function or a local call. This may change in the future.

This is a ‘special’ primitive function: it must not evaluate its argument.

References

See Also

substitute for argument expression; NA for missing values in data.

Examples

```r
myplot <- function(x, y) {
  if(missing(y)) {
    y <- x
    x <- 1:length(y)
  }
  plot(x, y)
}
```
The (Storage) Mode of an Object

Description
Get or set the type or storage mode of an object.

Usage

\[
\text{mode}(x) \\
\text{mode}(x) \leftarrow \text{value} \\
\text{storage.mode}(x) \\
\text{storage.mode}(x) \leftarrow \text{value}
\]

Arguments

- \text{x} \quad \text{any R object.}
- value \quad \text{a character string giving the desired mode or ‘storage mode’ (type) of the object.}

Details
Both \text{mode} and \text{storage.mode} return a character string giving the (storage) mode of the object — often the same — both relying on the output of \text{typeof}(x)$, see the example below.

\text{mode}(x) \leftarrow "\text{newmode}" changes the mode of object \text{x} to \text{newmode}. This is only supported if there is an appropriate \text{as.newmode} function, for example "logical", "integer", "double", "complex", "raw", "character", "list", "expression", "name", "symbol" and "function". Attributes are preserved (but see below).

\text{storage.mode}(x) \leftarrow "\text{newmode}" is a more efficient \textit{primitive} version of \text{mode}\leftarrow, which works for "newmode" which is one of the internal types (see \text{typeof}), but not for "single". Attributes are preserved.

As storage mode "single" is only a pseudo-mode in \text{R}, it will not be reported by \text{mode} or \text{storage.mode}: use \text{attr(object, "Csingle")} to examine this. However, \text{mode}\leftarrow can be used to set the mode to "single", which sets the real mode to "double" and the "Csingle" attribute to \text{TRUE}. Setting any other mode will remove this attribute.

Note (in the examples below) that some \text{calls} have mode "(" which is \text{S} compatible.

Mode names

Modes have the same set of names as types (see \text{typeof}) except that
- types "integer" and "double" are returned as "numeric".
- types "special" and "builtin" are returned as "function".
- type "symbol" is called mode "name".
- type "language" is returned as "(" or "call".

References
**See Also**

*typeof* for the R-internal 'mode', *attributes*.

**Examples**

```r
require(stats)

sapply(options(), mode)
cex3 <- c("NULL", "1", "1:1", "l1", "list()", "data.frame(x = 1)",
  "pairlist(pi)", "c", "lm", "formals(lm)[[]]", "formals(lm)[2]",
  "y ~ x", "expression(l1)[1]", "(y ~ x)[1]",
  "expression(x <- pi)[1][1][1]"
le3 <- sapply(cex3, function(x) eval(parse(text = x)))
mex3 <- t(sapply(le3,
  function(x) c(typeof(x), storage.mode(x), mode(x))))
dimnames(mex3) <- list(cex3, c("typeof(.)", "storage.mode(.)","mode(.)"))
mex3

## This also makes a local copy of 'pi':
storage.mode(pi) <- "complex"
storage.mode(pi)
rm(pi)
```

---

**NA**

‘Not Available’ / Missing Values

**Description**

NA is a logical constant of length 1 which contains a missing value indicator. NA can be coerced to any other vector type except raw. There are also constants `NA_integer_`, `NA_real_`, `NA_complex_` and `NA_character_` of the other atomic vector types which support missing values: all of these are reserved words in the R language.

The generic function `is.na` indicates which elements are missing.

The generic function `is.na<-` sets elements to NA.

**Usage**

```r
NA
is.na(x)
## S3 method for class 'data.frame'
is.na(x)

is.na(x) <- value
```

**Arguments**

- **x**: an R object to be tested: the default method handles atomic vectors, lists and pairlists.
- **value**: a suitable index vector for use with x.
Details

The NA of character type is distinct from the string "NA". Programmers who need to specify an explicit string NA should use `NA_character_` rather than "NA", or set elements to NA using `is.na<-`. is.na(x) works elementwise when x is a list. It is generic: you can write methods to handle specific classes of objects, see `InternalMethods`. A complex value is regarded as NA if either its real or imaginary part is NA or NaN.

Function `is.na<-` may provide a safer way to set missingness. It behaves differently for factors, for example.

Computations using NA will normally result in NA: a possible exception is where NaN is also involved, in which case either might result.

Value

The default method for `is.na` applied to an atomic vector returns a logical vector of the same length as its argument x, containing TRUE for those elements marked NA or, for numeric or complex vectors, NaN (!) and FALSE otherwise. dim, dimnames and names attributes are preserved.

The default methods also works for lists and pairlists:
For is.na, elementwise the result is false unless that element is a length-one atomic vector and the single element of that vector is regarded as NA or NaN (note that any is.na methods for the class of the atomic vector is ignored).

The data frame method for `is.na` returns a logical matrix with the same dimensions as the data frame, and with dimnames taken from the row and column names of the data frame.

References

See Also

`NaN`, `is.nan`, etc., and the utility function `complete.cases`.

`na.action, na.omit, na.fail` on how methods can be tuned to deal with missing values.

Examples

```r
is.na(c(1, NA))    #> FALSE TRUE
is.na(paste(c(1, NA))) #> FALSE FALSE

xx <- c(0:4)
is.na(xx) <- c(2, 4)
xx    #> 0 NA 2 NA 4
```
Description

A ‘name’ (also known as a ‘symbol’) is a way to refer to \( \mathbb{R} \) objects by name (rather than the value of the object, if any, bound to that name).

\( \text{as} \).name and \( \text{as} \).symbol are identical: they attempt to coerce the argument to a name.

\( \text{is} \).symbol and the identical \( \text{is} \).name return TRUE or FALSE depending on whether the argument is a name or not.

Usage

\[
\text{as} \).symbol(x) \\
\text{is} \).symbol(x)
\]

\[
\text{as} \).name(x) \\
\text{is} \).name(x)
\]

Arguments

\( x \) object to be coerced or tested.

Details

Names are limited to 10,000 bytes (and were to 256 bytes in versions of \( \mathbb{R} \) before 2.13.0).

\( \text{as} \).name first coerces its argument internally to a character vector (so methods for \( \text{as} \).character are not used). It then takes the first element and provided it is not ‘\'', returns a symbol of that name (and if the element is \text `{NA,character}_`, the name is ‘NA’).

\( \text{as} \).name is implemented as \( \text{as} \).vector(x, "symbol"), and hence will dispatch methods for the generic function \( \text{as} \).vector.

\( \text{is} \).name and \( \text{is} \).symbol are primitive functions.

Value

For \( \text{as} \).name and \( \text{as} \).symbol, an \( \mathbb{R} \) object of type "symbol" (see \text `typeof`).

For \( \text{is} \).name and \( \text{is} \).symbol, a length-one logical vector with value TRUE or FALSE.

Note

The term ‘symbol’ is from the LISP background of \( \mathbb{R} \), whereas ‘name’ has been the standard S term for this.

References

names

See Also
call, is.language. For the internal object mode, typeof.
plotmath for another use of 'symbol'.

Examples

an <- as.name("arrg")
is.name(an) # TRUE
mode(an) # name
typeof(an) # symbol

Description

Functions to get or set the names of an object.

Usage

names(x)
names(x) <- value

Arguments

x an R object.
value a character vector of up to the same length as x, or NULL.

Details

names is a generic accessor function, and names<-. is a generic replacement function. The default methods get and set the "names" attribute of a vector (including a list) or pairlist.

If value is shorter than x, it is extended by character NAs to the length of x.

It is possible to update just part of the names attribute via the general rules: see the examples. This works because the expression there is evaluated as z <- "names<-"(z, "[<""(names(z), 3, "c2")].

The name "" is special: it is used to indicate that there is no name associated with an element of a (atomic or generic) vector. Subscripting by "" will match nothing (not even elements which have no name).

A name can be character NA, but such a name will never be matched and is likely to lead to confusion.

Both are primitive functions.

Value

For names, NULL or a character vector of the same length as x. (NULL is given if the object has no names, including for objects of types which cannot have names.)

For names<-, the updated object. (Note that the value of names(x) <- value is that of the assignment, value, not the return value from the left-hand side.)
nargs

The Number of Arguments to a Function

Description

When used inside a function body, nargs returns the number of arguments supplied to that function, including positional arguments left blank.

Usage

nargs()
Details

The count includes empty (missing) arguments, so that `foo(x, , z)` will be considered to have three arguments (see ‘Examples’). This can occur in rather indirect ways, so for example `x[]` might dispatch a call to `[.some_method`(x, ) which is considered to have two arguments.

This is a primitive function.

References

See Also

`args, formals` and `sys.call`.

Examples

```r
tst <- function(a, b = 3, ...) { nargs() } 
tst() # 0 
tst(clicketyclack) # 1 (even non-existing) 
tst(c1, a2, rr3) # 3

foo <- function(x, y, z, w) { 
  cat("call was ", deparse(match.call()), ", \n", sep = ")
  nargs()
} 
foo() # 0 
foo(, , 3) # 3 
foo(z = 3) # 1, even though this is the same call 

nargs() # not really meaningful
```

Usage

`nchar(x, type = "chars", allowNA = FALSE)`

`nzchar(x)`
Arguments

x character vector, or a vector to be coerced to a character vector. Giving a factor is an error.

type character string: partial matching to one of "bytes", "chars", "width". See ‘Details’.

allowNA logical: should NA be returned for invalid multibyte strings or "bytes"-encoded strings (rather than throwing an error)?

Details

The ‘size’ of a character string can be measured in one of three ways

bytes The number of bytes needed to store the string (plus in C a final terminator which is not counted).
chars The number of human-readable characters.
width The number of columns cat will use to print the string in a monospaced font. The same as chars if this cannot be calculated.

These will often be the same, and almost always will be in single-byte locales. There will be differences between the first two with multibyte character sequences, e.g. in UTF-8 locales.

The internal equivalent of the default method of as.character is performed on x (so there is no method dispatch). If you want to operate on non-vector objects passing them through deparse first will be required.

Value

For nchar, an integer vector giving the sizes of each element, currently always 2 for missing values (for NA).

If allowNA = TRUE and an element is invalid in a multi-byte character set such as UTF-8, its number of characters and the width will be NA. Otherwise the number of characters will be non-negative, so !is.na(nchar(x, "chars", TRUE)) is a test of validity.

A character string marked with "bytes" encoding has a number of bytes, but neither a known number of characters nor a width, so the latter two types are NA if allowNA = TRUE, otherwise an error.

Names, dims and dimnames are copied from the input.

For nzchar, a logical vector of the same length as x, true if and only if the element has non-zero length.

Note

This does not by default give the number of characters that will be used to print the string. Use encodeString to find the characters used to print the string. Where character strings have been marked as UTF-8, the number of characters and widths will be computed in UTF-8, even though printing may use escapes such as ‘<U+2642>’ in a non-UTF-8 locale.

References

The Number of Levels of a Factor

Description

Return the number of levels which its argument has.

Usage

nlevels(x)

Arguments

x an object, usually a factor.

Details

This is usually applied to a factor, but other objects can have levels.

The actual factor levels (if they exist) can be obtained with the levels function.

Value

The length of levels(x), which is zero if x has no levels.

See Also

levels, factor.

Examples

nlevels(gl(3, 7)) # = 3
noquote

*Class for ‘no quote’ Printing of Character Strings*

**Description**

Print character strings without quotes.

**Usage**

```r
noquote(obj)
```

```r
## S3 method for class 'noquote'
print(x, ...)
```

```r
## S3 method for class 'noquote'
c(..., recursive = FALSE)
```

**Arguments**

- `obj` any R object, typically a vector of character strings.
- `x` an object of class "noquote".
- `...` further options passed to next methods, such as `print`.
- `recursive` for compatibility with the generic `c` function.

**Details**

`noquote` returns its argument as an object of class "noquote". There is a method for `c()` and subscript method ("[.noquote") which ensures that the class is not lost by subsetting. The print method (`print.noquote`) prints character strings *without* quotes ("...").

These functions exist both as utilities and as an example of using (S3) `class` and object orientation.

**Author(s)**

Martin Maechler <maechler@stat.math.ethz.ch>

**See Also**

`methods, class, print`

**Examples**

```r
g <- quote(letters)
noq <- noquote(g)
noq
noq[1:4] <- "oh"
noq[1:12]

cmp.logical <- function(log.v)
{
  ## Purpose: compact printing of logics
  log.v <- as.logical(log.v)
  log.v
}`
Computes a matrix norm of \( x \) using Lapack. The norm can be the one ("O") norm, the infinity ("I") norm, the Frobenius ("F") norm, the maximum modulus ("M") among elements of a matrix, or the "spectral" or "2"-norm, as determined by the value of type.

Usage

\[
\text{norm}(x, \text{type} = c("O", "I", "F", "M", "2"))
\]

Arguments

- \( x \): numeric matrix; note that packages such as Matrix define more norm() methods.
- \( \text{type} \): character string, specifying the type of matrix norm to be computed. A character indicating the type of norm desired.
  - "O", "0" or "1" specifies the one norm, (maximum absolute column sum);
  - "I" or "i" specifies the infinity norm (maximum absolute row sum);
  - "F" or "f" specifies the Frobenius norm (the Euclidean norm of \( x \) treated as if it were a vector);
  - "M" or "m" specifies the maximum modulus of all the elements in \( x \); and
  - "2" specifies the "spectral" or 2-norm, which is the largest singular value (svd) of \( x \).
  
The default is "O". Only the first character of type[1] is used.

Details

The base method of norm() calls the Lapack function dlang.

Note that the 1-, Inf- and "M" norm is faster to calculate than the Frobenius one.

Value

The matrix norm, a non-negative number.

Source

Except for norm = "2", the LAPACK routine DLANGE.

LAPACK is from http://www.netlib.org/lapack.

References

normalizePath

See Also

rcond for the (reciprocal) condition number.

Examples

```r
(x1 <- chind(1, 1:10))
norm(x1)
norm(x1, "I")
norm(x1, "M")
stopifnot(all.equal(norm(x1, "F"),
                   sqrt(sum(x1^2))))

hilbert <- function(n) { i <- 1:n; 1 / outer(i - 1, i, "+") }
h9 <- hilbert(9)
## all 5 types of norm:
(nTyp <- eval(formals(base::norm)$type))
sapply(nTyp, norm, x = h9)
```

normalizePath

Express File Paths in Canonical Form

Description

Convert file paths to canonical form for the platform, to display them in a user-understandable form and so that relative and absolute paths can be compared.

Usage

```r
normalizePath(path, winslash = "\\", mustWork = NA)
```

Arguments

- `path`: character vector of file paths.
- `winslash`: the separator to be used on Windows – ignored elsewhere. Must be one of `c("/", "\\")`.
- `mustWork`: logical: if TRUE then an error is given if the result cannot be determined; if NA then a warning.

Details

Tilde-expansion (see `path.expand`) is first done on paths (as from R 2.13.0).

Where the Unix-alike platform supports it attempts to turn paths into absolute paths in their canonical form (no `’/’, ’..’` nor symbolic links). It relies on the POSIX system function `realpath`: if the platform does not have that (we know of no current example) then the result will be an absolute path but might not be canonical. Even where `realpath` is used the canonical path need not be unique, for example via hard links or multiple mounts.

On Windows it converts relative paths to absolute paths, converts short names for path elements to long names and ensures the separator is that specified by `winslash`. It will match paths case-insensitively and return the canonical case. UTF-8-encoded paths not valid in the current locale can be used.

`mustWork = FALSE` is useful for expressing paths for use in messages.
Value

A character vector.

If an input is not a real path the result is system-dependent (unless `mustWork = TRUE`, when this should be an error). It will be either the corresponding input element or a transformation of it into an absolute path.

Converting to an absolute file path can fail for a large number of reasons. The most common are

- One of more components of the file path does not exist.
- A component before the last is not a directory, or there is insufficient permission to read the directory.
- For a relative path, the current directory cannot be determined.
- A symbolic link points to a non-existent place or links form a loop.
- The canonicalized path would be exceed the maximum supported length of a file path.

Examples

```r
# random tempdir
cat(normalizePath(c(R.home(), tempdir())), sep = "\n")
```

---

### NotYet

#### Not Yet Implemented Functions and Unused Arguments

**Description**

In order to pinpoint missing functionality, the **R** core team uses these functions for missing **R** functions and not yet used arguments of existing **R** functions (which are typically there for compatibility purposes).

You are very welcome to contribute your code …

**Usage**

```r
.NotYetImplemented()
.NotYetUsed(arg, error = TRUE)
```

**Arguments**

- `arg`: an argument of a function that is not yet used.
- `error`: a logical. If TRUE, an error is signalled; if FALSE; only a warning is given.

**See Also**

the contrary, [Deprecated](https://rdrr.io/users/) and [Defunct](https://rdrr.io/users/) for outdated code.

**Examples**

```r
require(graphics)
require(stats)
plot.mlm # to see how the "NotYetImplemented"
          # reference is made automagically
try(plot.mlm())

barplot(1:5, inside = TRUE) # 'inside' is not yet used
```
**nrow**  
*The Number of Rows/Columns of an Array*

**Description**

`nrow` and `ncol` return the number of rows or columns present in `x`. `NCOL` and `NROW` do the same treating a vector as 1-column matrix.

**Usage**

```r
nrow(x)
ncol(x)
NCOL(x)
NROW(x)
```

**Arguments**

- **x**  
  a vector, array or data frame

**Value**

an `integer` of length 1 or `NULL`.

**References**

**See Also**

`dim` which returns all dimensions; `array`, `matrix`.

**Examples**

```r
ma <- matrix(1:24, 3, 4)
nrow(ma)  # 3
ncol(ma)  # 4

ncol(array(1:24, dim = 2:4))  # 3, the second dimension
NCOL(1:12)  # 1
NROW(1:12)  # 12
```
Double Colon and Triple Colon Operators

Description
Accessing exported and internal variables in a namespace.

Usage
pkg::name
pkg:::name

Arguments
pkg  package name: symbol or literal character string.
name  variable name: symbol or literal character string.

Details
For a package `pkg`, `pkg::name` returns the value of the exported variable `name` in namespace `pkg`, whereas `pkg:::name` returns the value of the internal variable `name`. The namespace will be loaded if it was not loaded before the call, but the package will not be attached to the search path.

Specifying a variable or package that does not exist is an error.

Note that `pkg::name` does not access the objects in the environment `package::pkg` (which does not exist until the package’s namespace is attached): the latter may contain objects not exported from the namespace. It can access datasets made available by lazy-loading.

Note
It is typically a design mistake to use `:::` in your code since the corresponding object has probably been kept internal for a good reason. Consider contacting the package maintainer if you feel the need to access the object for anything but mere inspection.

See Also
`get` to access an object masked by another of the same name.

Examples
base::log
base::"+

## Beware -- use ':::' at your own risk! (see "Details")
stats:::coef.default
Description

Packages can supply functions to be called when loaded, attached, detached or unloaded.

Usage

```
.onLoad(libname, pkgname)
.onAttach(libname, pkgname)
.onUnload(libpath)
.onDetach(libpath)
.Last.lib(libpath)
```

Arguments

- `libname` a character string giving the library directory where the package defining the namespace was found.
- `pkgname` a character string giving the name of the package.
- `libpath` a character string giving the complete path to the package.

Details

After loading, `loadNamespace` looks for a hook function named `.onLoad` and calls it (with two unnamed arguments) before sealing the namespace and processing exports.

When the package is attached (via `library` or `attachNamespace`), the hook function `.onAttach` is looked for and if found is called (with two unnamed arguments) before the package environment is sealed.

If a function `.onDetach` (as from R 3.0.0) is in the namespace or `.Last.lib` is exported from the package, it will be called (with a single argument) when the package is detached. Beware that it might be called if `.onAttach` has failed, so it should be written defensively. (It is called within `tryCatch`, so errors will not stop the package being detached.)

If a namespace is unloaded (via `unloadNamespace`), a hook function `.onUnload` is run (with a single argument) before final unloading.

Note that the code in `.onLoad` and `.onUnload` should not assume any package except the base package is on the search path. Objects in the current package will be visible (unless this is circumvented), but objects from other packages should be imported or the double colon operator should be used.

`.onLoad`, `.onUnload` and `.onAttached` are looked for as internal objects in the namespace and should not be exported (whereas `.Last.lib` should be).

Anything needed for the functioning of the namespace should be handled at load/unload times by the `.onLoad` and `.onUnload` hooks. For example, DLLs can be loaded (unless done by a useDynLib directive in the 'NAMESPACE' file) and initialized in `.onLoad` and unloaded in `.onUnload`. Use `.onAttach` only for actions that are needed only when the package becomes visible to the user (for example a start-up message) or need to be run after the package environment has been created.
**Good practice**

Loading a namespace should where possible be silent, with startup messages given by `.onAttach`. These messages (and any essential ones from `.onLoad`) should use `packageStartupMessage` so they can be silenced where they would be a distraction.

There should be no calls to `library` nor `require` in these hooks. The way for a package to load other packages is via the `Depends` field in the `DESCRIPTION` file: this ensures that the dependence is documented and packages are loaded in the correct order. Loading a namespace should not change the search path, so rather than attach a package, dependence of a namespace on another package should be achieved by (selectively) importing from the other package’s namespace.

Uses of `library` with argument `help` to display basic information about the package should use `format` on the computed package information object and pass this to `packageStartupMessage`.

There should be no calls to `installed.packages` in startup code: it is potentially very slow and may fail in versions of R before 2.14.2 if package installation is going on in parallel. See its help page for alternatives.

Compiled code should be loaded (e.g. `library.dynam`) in `.onLoad` or a `useDynLib` directive in the `NAMESPACE` file, and not in `.onAttach`. Similarly, compiled code should not be unloaded (e.g. `library.dynam.unload`) in `.Last.lib` nor `.onDetach`, only in `.onUnload`.

**See Also**

`setHook` shows how users can set hooks on the same events, and lists the sequence of events involving all of the hooks.

---

**ns-load**

*Loading and Unloading Name Spaces*

**Description**

Functions to load and unload name spaces.

**Usage**

```r
attachNamespace(ns, pos = 2L, depends = NULL)
loadNamespace(package, lib.loc = NULL,
    keep.source = getOption("keep.source.pkgs"),
    partial = FALSE, versionCheck = NULL)
requireNamespace(package, ..., quietly = FALSE)
loadedNamespaces()
unloadNamespace(ns)
```

**Arguments**

- `ns`  
  string or name space object.
- `pos`  
  integer specifying position to attach.
- `depends`  
  `NULL` or a character vector of dependencies to be recorded in object `.Depends` in the package.
- `package`  
  string naming the package/name space to load.
- `lib.loc`  
  character vector specifying library search path.
keep.source  Now ignored except during package installation. For more details see this argument to library.
partial     logical; if true, stop just after loading code.
versionCheck NULL or a version specification (a list with components op and version)).
quietly     logical: should progress and error messages be suppressed?
...     further arguments to be passed to loadNamespace.

Details

The functions loadNamespace and attachNamespace are usually called implicitly when library is used to load a name space and any imports needed. However it may be useful at times to call these functions directly.

loadNamespace loads the specified name space and registers it in an internal data base. A request to load a name space when one of that name is already loaded has no effect. The arguments have the same meaning as the corresponding arguments to library, whose help page explains the details of how a particular installed package comes to be chosen. After loading, loadNamespace looks for a hook function named .onLoad as an internal variable in the name space (it should not be exported). Partial loading is used to support installation with lazy-loading.

loadNamespace does not attach the name space it loads to the search path. attachNamespace can be used to attach a frame containing the exported values of a name space to the search path (but this is almost always done via library). The hook function .onAttach is run after the name space exports are attached.

requireNamespace is a wrapper for loadNamespace analogous to require that returns a logical value.

loadedNamespaces returns a character vector of the names of the loaded name spaces.

unloadNamespace can be used to attempt to force a name space to be unloaded. If the name space is attached, it is first detached, thereby running a .onDetach or .Last.lib function in the name space if one is exported. An error is signaled and the name space is not unloaded if the name space is imported by other loaded name spaces. If defined, a hook function .onUnload is run before removing the name space from the internal registry.

See the comments in the help for detach about some issues with unloading and reloading name spaces.

Value

attachNamespace returns invisibly the package environment it adds to the search path.

loadNamespace returns the name space environment, either one already loaded or the one the function causes to be loaded.

requireNamespace returns TRUE if it succeeds or FALSE.

loadedNamespaces returns a character vector.

unloadNamespace returns NULL, invisibly.

Author(s)

Luke Tierney and R-core
**ns-topenv**

**Top Level Environment**

**Description**

Finding the top level environment.

**Usage**

```r
topenv(envir = parent.frame(),
    matchThisEnv = getOption("topLevelEnvironment"))
```

**Arguments**

- `envir` environment.
- `matchThisEnv` return this environment, if it matches before any other criterion is satisfied. The default, the option ‘toplevelEnvironment’, is set by `sys.source`, which treats a specific environment as the top level environment. Supplying the argument as `NULL` means it will never match.

**Details**

topenv returns the first top level environment found when searching `envir` and its enclosing environments. An environment is considered top level if it is the internal environment of a namespace, a package environment in the search path, or `.GlobalEnv`.

**Examples**

```r
topenv(.GlobalEnv)
topenv(new.env())
```

---

**NULL**

**The Null Object**

**Description**

NULL represents the null object in R: it is a reserved word. NULL is often returned by expressions and functions whose value is undefined.

- `as.null` ignores its argument and returns the value NULL.
- `is.null` returns TRUE if its argument is NULL and FALSE otherwise.

**Usage**

```r
NULL
as.null(x, ...)
is.null(x)
```
Arguments

- **x**: an object to be tested or coerced.
- **...**: ignored.

Details

NULL can be indexed (see Extract) in just about any syntactically legal way: whether is makes sense or not, the result is always NULL. Objects with value NULL can be changed by replacement operators and will be coerced to the type of the right-hand side.

NULL is also used as the empty pairlist.

Note

is.null is a primitive function.

References

Examples

```r
is.null(list())  # FALSE (on purpose!)
is.null(integer(0)) # FALSE
is.null(logical(0)) # FALSE
as.null(list(a = 1, b = "c"))
```

---

**numeric**  
**Numeric Vectors**

Description

Creates or coerces objects of type "numeric". **is.numeric** is a more general test of an object being interpretable as numbers.

Usage

```r
numeric(length = 0)
as.numeric(x, ...)
is.numeric(x)
```

Arguments

- **length**: A non-negative integer specifying the desired length. Double values will be coerced to integer: supplying an argument of length other than one is an error.
- **x**: object to be coerced or tested.
- **...**: further arguments passed to or from other methods.
numeric

Details

numeric is identical to double (and real). It creates a double-precision vector of the specified length with each element equal to 0.

as.numeric is a generic function, but S3 methods must be written for as.double. It is identical to as.double.

is.numeric is an internal generic primitive function: you can write methods to handle specific classes of objects, see InternalMethods. It is not the same as is.double. Factors are handled by the default method, and there are methods for classes "Date", "POSIXt" and "difftime" (all of which return false). Methods for is.numeric should only return true if the base type of the class is double or integer and values can reasonably be regarded as numeric (e.g. arithmetic on them makes sense, and comparison should be done via the base type).

Value

for numeric and as.numeric see double.

The default method for is.numeric returns TRUE if its argument is of mode "numeric" (type "double" or type "integer") and not a factor, and FALSE otherwise. That is, is.integer(x) || is.double(x),or (mode(x) == "numeric") && !is.factor(x).

S4 methods

as.numeric and is.numeric are internally S4 generic and so methods can be set for them via setMethod.

To ensure that as.numeric and as.double remain identical, S4 methods can only be set for as.numeric.

Note on names

It is a historical anomaly that R has two names for its floating-point vectors, double and numeric (and formerly had real).

double is the name of the type. numeric is the name of the mode and also of the implicit class. As an S4 formal class, use “numeric”.

The potential confusion is that R has used mode “numeric” to mean ‘double or integer’, which conflicts with the S4 usage. Thus is.numeric tests the mode, not the class, but as.numeric (which is identical to as.double) coerces to the class.

References

See Also

double, integer, storage.mode.

Examples

as.numeric(c("-1"," 2.7 ","B")) # (-0.1, 2.7, NA) + warning
as.numeric(factor(5:10))
Numeric Constants

Description

How \( \mathbb{R} \) parses numeric constants.

Details

\( \mathbb{R} \) parses numeric constants in its input in a very similar way to C99 floating-point constants. \( \text{Inf} \) and \( \text{NaN} \) are numeric constants (with \text{typeof(.)} "double"). In text input (e.g. in \text{scan} and \text{as.double}), these are recognized ignoring case as \text{infinity} as an alternative to \text{inf}. \text{NA_real_} and \text{NA_integer_} are constants of types "double" and "integer" representing missing values. All other numeric constants start with a digit or period and are either a decimal or hexadecimal constant optionally followed by \( \ell \).

Hexadecimal constants start with \text{0x} or \text{0X} followed by a nonempty sequence from \text{0-9 a-f A-F}. which is interpreted as a hexadecimal number, optionally followed by a binary exponent. A binary exponent consists of a \( p \) or \( P \) followed by an optional plus or minus sign followed by a non-empty sequence of (decimal) digits, and indicates multiplication by a power of two. Thus \text{0x123p456} is \( 291 \times 2^{456} \).

Decimal constants consist of a nonempty sequence of digits possibly containing a period (the decimal point), optionally followed by a decimal exponent. A decimal exponent consists of an \text{e} or \text{E} followed by an optional plus or minus sign followed by a non-empty sequence of digits, and indicates multiplication by a power of ten.

Values which are too large or too small to be representable will overflow to \text{Inf} or underflow to \( \text{0.0} \).

A numeric constant immediately followed by \text{i} is regarded as an imaginary \text{complex} number.

An numeric constant immediately followed by \text{L} is regarded as an \text{integer} number when possible (and with a warning if it contains a "\.").

Only the ASCII digits \text{0–9} are recognized as digits, even in languages which have other representations of digits. The 'decimal separator' is always a period and never a comma.

Note that a leading plus or minus is not regarded by the parser as part of a numeric constant but as a unary operator applied to the constant.

Note

When a string is parsed to input a numeric constant, the number may or may not be representable exactly in the C double type used. If not one of the nearest representable numbers will be returned.

\( \mathbb{R} \)'s own C code is used to convert constants to binary numbers, so the effect can be expected to be the same on all platforms implementing full IEC 600559 arithmetic (the most likely area of difference being the handling of numbers less than \text{Machine$double$.xmin}). The same code is used by \text{scan}.

See Also

\text{Syntax}.

\text{Quotes} for the parsing of character constants,
numeric_version

Examples

```r
typeof(2)  # remember elementary math?
identical(1L, as.integer(1))

# You can combine the "0x" prefix with the "L" suffix:
identical(0x1L, as.integer(15))
```

---

**numeric_version**  

**Numeric Versions**

**Description**

A simple S3 class for representing numeric versions including package versions, and associated methods.

**Usage**

```r
numeric_version(x, strict = TRUE)
package_version(x, strict = TRUE)
R_system_version(x, strict = TRUE)
getRversion()
```

**Arguments**

- `x`  
  A character vector with suitable numeric version strings (see ‘Details’); for `package_version`, alternatively an R version object as obtained by `R.version`.

- `strict`  
  A logical indicating whether invalid numeric versions should results in an error (default) or not.

**Details**

Numeric versions are sequences of one or more non-negative integers, usually (e.g., in package ‘DESCRIPTION’ files) represented as character strings with the elements of the sequence concatenated and separated by single ‘.’ or ‘-‘ characters. R package versions consist of at least two such integers, an R system version of exactly three (major, minor and patchlevel). Functions `numeric_version`, `package_version` and `R_system_version` create a representation from such strings (if suitable) which allows for coercion and testing, combination, comparison, summaries (min/max), inclusion in data frames, subscripting, and printing. The classes can hold a vector of such representations.

`getRversion` returns the version of the running R as an R system version object.

The `[` operator extracts or replaces a single version. To access the integers of a version use two indices: see the examples.

**See Also**

`compareVersion`
Examples

```r
x <- package_version(c("1.2-4", "1.2-3", "2.1"))
x <- "1.4-2.3"
c(min(x), max(x))
x[2, 2]
x$major
x$minor

if(getRversion() <= "2.5.0") {  ## work around missing feature
  cat("Your version of R, ", as.character(getRversion()),
      ", is outdated.\n", 
      "Now trying to work around that ...\n", sep = "")
}
x[[c(1, 3)]] # '4' as a numeric vector, same as x[1, 3]
x[1, 3]      # 4 as an integer
x[[2, 3]] <- 0 # zero the patchlevel
x[[c(2, 3)]] <- 0 # same
x
x[[3]] <- "2.2.3"; x
```

---

**octmode**

**Display Numbers in Octal**

Description

Convert or print integers in octal format, with as many digits as are needed to display the largest, using leading zeroes as necessary.

Usage

```r
as.octmode(x)
```

## S3 method for class 'octmode'
```r
as.character(x, ...)
```

## S3 method for class 'octmode'
```r
format(x, width = NULL, ...)
```

## S3 method for class 'octmode'
```r
print(x, ...)
```

Arguments

- **x**: An object, for the methods inheriting from class "octmode".
- **width**: NULL or a positive integer specifying the minimum field width to be used, with padding by leading zeroes.
- **...**: further arguments passed to or from other methods.
on.exit

Details

Class "octmode" consists of integer vectors with that class attribute, used merely to ensure that they are printed in octal notation, specifically for Unix-like file permissions such as 755. Subsetting ([) works too.

If \texttt{width} = \texttt{NULL} (the default), the output is padded with leading zeroes to the smallest width needed for all the non-missing elements.

\texttt{as.octmode} can convert integers (of type "integer" or "double") and character vectors whose elements contain only digits 0-7 (or are \texttt{NA}) to class "octmode".

There is a \texttt{!} method and \texttt{\&}, \texttt{\&\&} and \texttt{\texttt{xor}} methods: these recycle their arguments to the length of the longer and then apply the operators bitwise to each element.

See Also

These are auxiliary functions for \texttt{file.info}.

\texttt{hexmode}, \texttt{sprintf} for other options in converting integers to octal, \texttt{strtoi} to convert octal strings to integers.

Examples

\begin{verbatim}
(on <- as.octmode(c(16, 32, 127:129))) # "020" "040" "177" "200" "201"
unclass(on[3:4]) # subsetting

## manipulate file modes
fmode <- as.octmode("170")
(fmode | "644") & "755"

umask <- Sys.umask(NA) # depends on platform
c(fmode, "666", "755") & !umask
\end{verbatim}

\begin{tabular}{ll}
\hline
on.exit & \textit{Function Exit Code} \\
\hline
\end{tabular}

Description

\texttt{on.exit} records the expression given as its argument as needing to be executed when the current function exits (either naturally or as the result of an error). This is useful for resetting graphical parameters or performing other cleanup actions.

If no expression is provided, i.e., the call is \texttt{on.exit()}, then the current \texttt{on.exit} code is removed.

Usage

\begin{verbatim}
on.exit(expr = NULL, add = FALSE)
\end{verbatim}

Arguments

\begin{verbatim}
expr an expression to be executed.
add if TRUE, add expr to be executed after any previously set expressions; otherwise (the default) expr will overwrite any previously set expressions.
\end{verbatim}
Details

Where `expr` was evaluated changed in R 2.8.0, and the following applies only to that and later versions.

The `expr` argument passed to `on.exit` is recorded without evaluation. If it is not subsequently removed/replaced by another `on.exit` call in the same function, it is evaluated in the evaluation frame of the function when it exits (including during standard error handling). Thus any functions or variables in the expression will be looked for in the function and its environment at the time of exit: to capture the current value in `expr` use `substitute` or similar.

This is a ‘special’ primitive function: it only evaluates the argument `add`.

Value

Invisible `NULL`.

References

See Also

`sys.on.exit` which returns the expression stored for use by `on.exit()` in the function in which `sys.on.exit()` is evaluated.

Examples

```r
require(graphics)

opar <- par(mai = c(1,1,1,1))
on.exit(par(opar))
```

---

**Ops.Date**

*Operators on the Date Class*

Description

Operators for the "Date" class.

There is an `Ops` method and specific methods for `+` and `-` for the `Date` class.

Usage

```r
date + x
x + date
date - x
date1 lop date2
```
Arguments

date date objects
date1, date2 date objects or character vectors. (Character vectors are converted by as.Date.)
x a numeric vector (in days) or an object of class "difftime", rounded to the nearest whole day.
lop One of ==, !=, <, <=, > or >=.

Details

x does not need to be integer if specified as a numeric vector, but see the comments about fractional days in the help for Dates.

Examples

(z <- Sys.Date())
z + 10
z < c("2009-06-01", "2010-01-01", "2015-01-01")

options

Options Settings

Description

Allow the user to set and examine a variety of global options which affect the way in which \texttt{R} computes and displays its results.

Usage

options(...)
getOption(x, default = NULL)

Arguments

... any options can be defined, using name = value. However, only the ones below are used in base \texttt{R}.
Options can also be passed by giving a single unnamed argument which is a named list.
x a character string holding an option name.
default if the specified option is not set in the options list, this value is returned. This facilitates retrieving an option and checking whether it is set and setting it separately if not.

Details

Invoking \texttt{options()} with no arguments returns a list with the current values of the options. Note that not all options listed below are set initially. To access the value of a single option, one should use, e.g., getOption("width") rather than options("width") which is a list of length one.
Value

For `getOption`, the current value set for option `x`, or `NULL` if the option is unset.

For `options()`, a list of all set options sorted by name. For `options(name)`, a list of length one containing the set value, or `NULL` if it is unset. For uses setting one or more options, a list with the previous values of the options changed (returned invisibly).

Options used in base R

- `add.smooth`: typically logical, defaulting to `TRUE`. Could also be set to an integer for specifying how many (simulated) smooths should be added. This is currently only used by `plot.lm`.
- `browserNdized`: logical: whether newline is disabled as a synonym for "n" is the browser.
- `checkPackageLicense`: logical, not set by default. If true, `library` asks a user to accept any non-standard license at first use.
- `check.bounds`: logical, defaulting to `FALSE`. If true, a warning is produced whenever a vector (atomic or `list`) is extended, by something like `x <- 1:3; x[5] <- 6`.
- `CBoundsCheck`: logical, controlling whether `.C` and `.Fortran` make copies to check for array overruns on the atomic vector arguments.
- Initially set from value of the environment variable `R_C_BOUNDS_CHECK` (set to yes to enable).
- `continue`: a non-empty string setting the prompt used for lines which continue over one line.
- `defaultPackages`: the packages that are attached by default when R starts up. Initially set from value of the environment variable `R_DEFAULT_PACKAGES`, or if that is unset to `c("datasets", "utils", "grDevices", "graphics", "stats", "methods")`. (Set `R_DEFAULT_PACKAGES` to `NULL` or a comma-separated list of package names.) A call to `options` should be in your `.Rprofile` file to ensure that the change takes effect before the base package is initialized (see `Startup`).
- `deparse.cutoff`: integer value controlling the printing of language constructs which are deparsed. Default `60`.
- `deparse.max.lines`: controls the number of lines used when deparsing in `traceback`, `browser`, and upon entry to a function whose debugging flag is set. Initially unset, and only used if set to a positive integer.
- `digits`: controls the number of digits to print when printing numeric values. It is a suggestion only. Valid values are `1...22` with default `7`. See the note in `print.default` about values greater than `15`.
- `digitssecs`: controls the maximum number of digits to print when formatting time values in seconds. Valid values are `0...6` with default `0`. See `strftime`.
- `download.file.extra`: Extra command-line argument(s) for non-default methods: see `download.file`.
- `download.file.method`: Method to be used for `download.file`. Currently download methods "internal", "wget" and "lynx" are available. There is no default for this option, when `method = "auto"` is chosen: see `download.file`.
- `echo`: logical. Only used in non-interactive mode, when it controls whether input is echoed. Command-line option ‘--slave’ sets this to FALSE, but otherwise it starts the session as TRUE.
- `encoding`: The name of an encoding, default "native.enc". See `connections`.
- `error`: either a function or an expression governing the handling of non-catastrophic errors such as those generated by `stop` as well as by signals and internally detected errors. If the option is a function, a call to that function, with no arguments, is generated as the expression. The default value is `NULL`: see `stop` for the behaviour in that case. The functions `dump.frames` and `recover` provide alternatives that allow post-mortem debugging. Note that these need to be specified as e.g. `options(error = utils::recover)` in startup files such as `.Rprofile`. 
expressions: sets a limit on the number of nested expressions that will be evaluated. Valid values are 25...500000 with default 5000. If you increase it, you may also want to start \texttt{R} with a larger protection stack; see ‘--max-ppsize’ in Memory. Note too that you may cause a segfault from overflow of the C stack, and on OSes where it is possible you may want to increase that. Once the limit is reached an error is thrown. The current number under evaluation can be found by calling \texttt{Cstack_info}.

keep.source: When TRUE, the source code for functions (newly defined or loaded) is stored internally allowing comments to be kept in the right places. Retrieve the source by printing or using \texttt{deparse(fn, control = "useSource"). The default is \texttt{interactive()}, i.e., TRUE for interactive use.

keep.source.pkgs: As for keep.source, used only when packages are installed. Defaults to FALSE unless the environment variable \texttt{R\_KEEP\_PKG\_SOURCE} is set to yes.

max.print: integer, defaulting to 99999. \texttt{print} or \texttt{show} methods can make use of this option, to limit the amount of information that is printed, to something in the order of (and typically slightly less than) \texttt{max.print entries}.

OutDec: character string containing a single-byte character. The character to be used as the decimal point in output conversions, that is in printing, plotting and as.character but not deparsing.

pager: the command used for displaying text files by \texttt{file.show}.Defaults to \texttt{R\_HOME/bin/pager}, which selects a pager via the PAGER environment variable (and that usually defaults to less). Can be a character string or an \texttt{R} function, in which case it needs to accept the arguments (files, header,title, delete.file) corresponding to the first four arguments of \texttt{file.show}.

class.size: the default paper format used by \texttt{postscript}; set by environment variable \texttt{R\_PAPERSIZE} when \texttt{R} is started: if that is unset or invalid it defaults to a value derived from the locale category \texttt{LC\_PAPER}, or if that is unavailable to a default set when \texttt{R} was built.

pdfviewer: default PDF viewer. The default is set from the environment variable \texttt{R\_PDFVIEWER}, the default value of which is set when \texttt{R} is configured.

printcmd: the command used by \texttt{postscript} for printing; set by environment variable \texttt{R\_PRINTCMD} when \texttt{R} is started. This should be a command that expects either input to be piped to \texttt{stdin} or to be given a single filename argument. Usually set to \texttt{"lpr\"} on a Unix-alike.

prompt: a non-empty string to be used for \texttt{R}'s prompt; should usually end in a blank (" ").

rl.word_breaks: Used for the readline-based terminal interface. Default value
" \t\n"\'\'=\+\%\%;\%\{(\}\)". This is the set of characters use to break the input line up into tokens for object- and file-name completion. Those who do not use spaces around operators may prefer
" \t\n"\'\'=\+\%\%;\%\{(\}\)" which was the default in \texttt{R} 2.5.0. (The default in pre-2.5.0 versions of \texttt{R} was
" \t\n"\'\'=\+\%\%;\%\{(\}\)"

scipen: integer. A penalty to be applied when deciding to print numeric values in fixed or exponential notation. Positive values bias towards fixed and negative towards scientific notation: fixed notation will be preferred unless it is more than \texttt{scipen} digits wider.

showWarnCalls,showErrorCalls: a logical. Should warning and error messages show a summary of the call stack? By default error calls are shown in non-interactive sessions.

showCalls: integer. Controls how long the sequence of calls must be (in bytes) before ellipses are used. Defaults to 40 and should be at least 30 and no more than 500.
show.error.locations: Should source locations of errors be printed? If set to TRUE or "top", the source location that is highest on the stack (the most recent call) will be printed. "bottom" will print the location of the earliest call found on the stack. Integer values can select other entries. The value 0 corresponds to "top" and positive values count down the stack from there. The value -1 corresponds to "bottom" and negative values count up from there.

show.error.messages: a logical. Should error messages be printed? Intended for use with try or a user-installed error handler.

stringsAsFactors: The default setting for arguments of data.frame and read.table.

texi2dvi: used by functions texi2dvi and texi2pdf in package tools. Set at startup from the environment variable R_TEXI2DVICTM.

timeout: integer. The timeout for some Internet operations, in seconds. Default 60 seconds. See download.file and connections.

toplevelEnvironment: see toplevel and sys.source.

useFancyQuotes: controls the use of directional quotes in sQuote, dQuote and in rendering text help (see Rd2txt in package tools). Can be TRUE, FALSE, "TeX" or "UTF-8".

verbose: logical. Should R report extra information on progress? Set to TRUE by the command-line option --verbose.

warn: sets the handling of warning messages. If warn is negative all warnings are ignored. If warn is zero (the default) warnings are stored until the top-level function returns. If 10 or fewer warnings were signalled they will be printed otherwise a message saying how many were signalled. An object called last.warning is created and can be printed through the function warnings. If warn is one, warnings are printed as they occur. If warn is two or larger all warnings are turned into errors.

warnPartialMatchArgs: logical. If true, warns if partial matching is used in argument matching.

warnPartialMatchAttr: logical. If true, warns if partial matching is used in extracting attributes via attr.

warnPartialMatchDollar: logical. If true, warns if partial matching is used for extraction by $.

warning.expression: an R code expression to be called if a warning is generated, replacing the standard message. If non-null it is called irrespective of the value of option warn.

warning.length: sets the truncation limit for error and warning messages. A non-negative integer, with allowed values 100...8170, default 1000.

nwarnings: the limit for the number of warnings kept when warn = 0, default 50. This will discard messages if called whilst they are being collected.

width: controls the maximum number of columns on a line used in printing vectors, matrices and arrays, and when filling by cat.

Columns are normally the same as characters except in CJK languages.

You may want to change this if you re-size the window that R is running in. Valid values are 10...10000 with default normally 80. (The limits on valid values are in file ‘Print.h’ and can be changed by re-compiling R.) Some R consoles automatically change the value when they are resized.

See the examples on Startup for one way to set this automatically from the terminal width when R is started.

The ‘factory-fresh’ default settings of some of these options are

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>add.smooth</td>
<td>TRUE</td>
</tr>
<tr>
<td>check.bounds</td>
<td>FALSE</td>
</tr>
</tbody>
</table>
Others are set from environment variables or are platform-dependent.

**Options set in package grDevices**

These will be set when package `grDevices` (or its namespace) is loaded if not already set.

- `bitmapType`: (Unix-only) character. The default type for the bitmap devices such as `png`. Defaults to "cairo" on systems where that is available, or to "quartz" on OS X where that is available.
- `device`: a character string giving the name of a function, or the function object itself, which when called creates a new graphics device of the default type for that session. The value of this option defaults to the normal screen device (e.g., `X11`, `windows` or `quartz`) for an interactive session, and `pdf` in batch use or if a screen is not available. If set to the name of a device, the device is looked for first from the global environment (that is down the usual search path) and then in the `grDevices` namespace.

The default values in interactive and non-interactive sessions are configurable via environment variables `R_INTERACTIVE_DEVICE` and `R_DEFAULT_DEVICE` respectively.

- `device.ask.default`: logical. The default for `devAskNewPage("ask")` when a device is opened.

**Other options used by package graphics**

- `max.contour.segments`: positive integer, defaulting to 25000 if not set. A limit on the number of segments in a single contour line in `contour` or `contourLines`.

**Options set in package stats**

These will be set when package `stats` (or its namespace) is loaded if not already set.

- `contrasts`: the default `contrasts` used in model fitting such as with `aov` or `lm`. A character vector of length two, the first giving the function to be used with unordered factors and the second the function to be used with ordered factors. By default the elements are named `c("unordered", "ordered")`, but the names are unused.
na.action: the name of a function for treating missing values (NA’s) for certain situations.

show.coef.Pvalues: logical, affecting whether P values are printed in summary tables of coefficients. See printCoefmat.

show.nls.convergence: logical, should nls convergence messages be printed for successful fits?

show.signif.stars: logical, should stars be printed on summary tables of coefficients? See printCoefmat.

ts.eps: the relative tolerance for certain time series (ts) computations. Default 1e-05.

ts.S.compat: logical. Used to select S compatibility for plotting time-series spectra. See the description of argument log in plot.spec.

Options set in package utils

These will be set when package utils (or its namespace) is loaded if not already set.

BioC_mirror: The URL of a Bioconductor mirror for use by setRepositories, e.g. the default "http://www.bioconductor.org" or the European mirror "http://bioconductor.statistik.tu-dortmund.de". Can be set by chooseBioCmirror.

browser: default HTML browser used by help.start() and browseURL on UNIX, or a non-default browser on Windows. Alternatively, an R function that is called with a URL as its argument.

ccaddress: default Cc: address used by create.post (and hence bug.report and help.request). Can be FALSE or "".

citation.bibtex.max: default 1; the maximal number of bibentries (bibentry) in a citation for which the bibtex version is printed in addition to the text one.

dc.cellwidth: integer: the cell widths (number of characters) to be used in the data editor dataentry. If this is unset (the default), 0, negative or NA, variable cell widths are used.

demo.ask: default for the ask argument of demo.

demo: a non-empty string, or a function that is called with a file path as argument. Sets the default text editor, e.g., for edit. Set from the environment variable EDITOR on UNIX, or if unset VISUAL or vi.

demo.ports: optional integer vector for setting ports of the internal HTTP server, see startDynamicHelp.

demo.search.types: default types of documentation to be searched by help.search and ??.

demo.try.all.packages: default for an argument of help.

demo_type: default for an argument of help, used also as the help type by ?.

HTTPUserAgent: string used as the user agent in HTTP requests. If NULL, HTTP requests will be made without a user agent header. The default is R (<version> <platform> <arch> <os>)

install.lock: logical: should per-directory package locking be used by install.packages?

Most useful for binary installs on OS X and Windows, but can be used in a startup file for source installs via R CMD INSTALL. For binary installs, can also be the character string "pkgloack".

internet.info: The minimum level of information to be printed on URL downloads etc. Default is 2, for failure causes. Set to 1 or 0 to get more information.

mailer: default emailing method used by create.post and hence bug.report and help.request.
options

menu.graphics: Logical: should graphical menus be used if available?. Defaults to TRUE. Currently applies to select.list, chooseCRANmirror, setRepositories and to select from multiple (text) help files in help.

pkgType: The default type of packages to be downloaded and installed – see install.packages. Possible values are "source" (the default except under the CRAN OS X build) and "mac.binary.". Windows uses "win.binary". ("mac.binary.leopard" and "mac.binary.universal" are no longer in use.)

repos: URLs of the repositories for use by update.packages. Defaults to c(CRAN="@CRAN"), a value that causes some utilities to prompt for a CRAN mirror. To avoid this do set the CRAN mirror, by something like local({r <- getOption("repos"); r["CRAN"] <- "http://my.local.cran"; options(repos = r)}).

Note that you can add more repositories (Bioconductor and Omegahat, notably) using setRepositories().

SweaveHooks, SweaveSyntax: see Sweave.

unzip: a character string, the path of the command used for unzipping help files, or "internal". Defaults to the value of R_UNZIPOCMD, which is set in ‘etc/Renviron’ if an unzip command was found during configuration.

Options set in package parallel

These will be set when package parallel (or its namespace) is loaded if not already set.

mc.cores: a integer giving the maximum allowed number of additional R processes allowed to be run in parallel to the current R process. Defaults to the setting of the environment variable MC_CORES if set. Most applications which use this assume a limit of 2 if it is unset.

Options used on Unix only

dvips.cmd: character string giving a command to be used in the (deprecated) off-line printing of help pages via PostScript. Defaults to "dvips".

Options used on Windows only

warn.FPU: logical, by default undefined. If true, a warning is produced whenever dyn.load repairs the control word damaged by a buggy DLL.

Note

For compatibility with S there is a visible object .Options whose value is a pairlist containing the current options() (in no particular order). Assigning to it will make a local copy and not change the original.

References

Examples

```r
op <- options(); utils::str(op) # op is a named list

getOption("width") == options()$width # the latter needs more memory
options(digits = 15)
p1

# set the editor, and save previous value
old.o <- options(editor = "nedit")
old.o

options(check.bounds = TRUE, warn = 1)
x <- NULL; x[4] <- "yes" # gives a warning

options(digits = 5)
print(1e5)
options(scipen = 3); print(1e5)

options(op) # reset (all) initial options
options("digits")

## Not run: ## set contrast handling to be like S
options(contrasts = c("contr.helmert", "contr.poly"))

## End(Not run)

## Not run: ## on error, terminate the R session with error status 66
options(error = quote(q("no", status = 66, runLast = FALSE)))
stop("test it")

## End(Not run)

## Not run: ## Set error actions for debugging:
## enter browser on error, see ?recover:
## allows to call debugger() afterwards, see ?debugger:
## A possible setting for non-interactive sessions
options(error = quote((dump.frames(to.file = TRUE); q())))

## End(Not run)

# Compare the two ways to get an option and use it
# accounting for the possibility it might not be set.
if(as.logical(getOption("performCleanup", TRUE)))
  cat("do cleanup\n")

## Not run:
# a clumsier way of expressing the above w/o the default.
tmp <- getOption("performCleanup")
if(is.null(tmp))
  tmp <- TRUE
if(tmp)
  cat("do cleanup\n")

## End(Not run)
```
order

Ordering Permutation

Description

order returns a permutation which rearranges its first argument into ascending or descending order, breaking ties by further arguments. sort.list is the same, using only one argument. See the examples for how to use these functions to sort data frames, etc.

Usage

order(..., na.last = TRUE, decreasing = FALSE)

sort.list(x, partial = NULL, na.last = TRUE, decreasing = FALSE,
method = c("shell", "quick", "radix"))

Arguments

... a sequence of numeric, complex, character or logical vectors, all of the same length, or a classed R object.
x an atomic vector.
partial vector of indices for partial sorting. (Non-NULL values are not implemented.)
decreasing logical. Should the sort order be increasing or decreasing?
na.last for controlling the treatment of NAs. If TRUE, missing values in the data are put last; if FALSE, they are put first; if NA, they are removed (see ‘Note’.)
method the method to be used: partial matches are allowed. The default is "shell" except for some special cases: see ‘Details’.

Details

In the case of ties in the first vector, values in the second are used to break the ties. If the values are still tied, values in the later arguments are used to break the tie (see the first example). The sort used is stable (except for method = "quick"), so any unresolved ties will be left in their original ordering.

Complex values are sorted first by the real part, then the imaginary part.
The sort order for character vectors will depend on the collating sequence of the locale in use: see Comparison.

The default method for sort.list is a good compromise. Method "quick" is only supported for numeric x with na.last = NA, and is not stable, but will be substantially faster for long vectors. Method "radix" is only implemented for integer x with a range of less than 100,000. For such x it is very fast (and stable), and hence is ideal for sorting factors—as from R 3.0.0 it is the default method for factors with less than 100,000 levels.

partial = NULL is supported for compatibility with other implementations of S, but no other values are accepted and ordering is always complete.

For a classed R object, the sort order is taken from xtfrm: as its help page notes, this can be slow unless a suitable method has been defined or is.numeric(x) is true. For factors, this sorts on the internal codes, which is particularly appropriate for ordered factors.
Value

An integer vector unless any of the inputs has $2^{31}$ or more elements, when it is a double vector.

Note

`sort.list` can get called by mistake as a method for `sort` with a list argument, and gives a suitable error message for list `x`.

There is a historical difference in behaviour for `na.last = NA`: `sort.list` removes the NAs and then computes the order amongst the remaining elements: `order` computes the order amongst the non-NA elements of the original vector. Thus

\[
x[order(x, na.last = NA)]
\]

\[
zz <- x[!is.na(x)]; zz[sort.list(x, na.last = NA)]
\]

both sort the non-NA values of `x`.

References

See Also

`sort`, `rank`, `xtfrm`.

Examples

```r
require(stats)

(iii <- order(x <- c(1,1,3;1,1:4,3), y <- c(9,9:1), z <- c(2,1:9)))
## 6 5 2 1 7 4 10 8 3 9
rbind(x, y, z)[,iii] # shows the reordering (ties via 2nd & 3rd arg)

## Suppose we wanted descending order on y.
## A simple solution for numeric 'y' is
rbind(x, y, z)[, order(x, -y, z)]
## More generally we can make use of `xtfrm`
cy <- as.character(y)
rbind(x, y, z)[, order(x, -xtfrm(cy), z)]

## Sorting data frames:
dd <- transform(data.frame(x, y, z),
  z = factor(z, labels = LETTERS[9:1]))
## Either as above (for factor 'z' : using internal coding):
dd[ order(x, -y, z), ]
## or along 1st column, ties along 2nd, ... *arbitrary* no.
c[columns]:
dd[ do.call(order, dd), ]

set.seed(1) # reproducible example:
d4 <- data.frame(x = round( rnorm(100)), y = round(10*runif(100)),
  z = round( 8*runorm(100)), u = round(50*runif(100)))
(d4s <- d4[ do.call(order, d4), ])
(i <- which(diff(d4s[, 3]) == 0))
# in 2 places, needed 3 cols to break ties:
d4s[ rbind(i, i+1), ]
```
## Description
The outer product of the arrays X and Y is the array A with dimension 
c(dim(X), dim(Y)) where element A[c(arrayindex.x, arrayindex.y)]
= FUN(X[arrayindex.x], Y[arrayindex.y], ...).

## Usage
outer(X, Y, FUN = "*", ...)  
X %o% Y

## Arguments
- `X, Y`  
  First and second arguments for function FUN. Typically a vector or array.
- `FUN`  
  a function to use on the outer products, found via `match.fun` (except for the special case "*").
- `...`  
  optional arguments to be passed to FUN.
**Details**

X and Y must be suitable arguments for FUN. Each will be extended by rep to length the products of the lengths of X and Y before FUN is called.

FUN is called with these two extended vectors as arguments. Therefore, it must be a vectorized function (or the name of one), expecting at least two arguments.

Where they exist, the [dim]names of X and Y will be copied to the answer, and a dimension assigned which is the concatenation of the dimensions of X and Y (or lengths if dimensions do not exist).

FUN = "x" is handled internally as a special case, via as.vector(X) %*% t(as.vector(Y)), and is intended only for numeric vectors and arrays.

%*% is binary operator providing a wrapper for outer(x, y, "x").

**Author(s)**

Jonathan Rougier

**References**

**See Also**

%*% for usual (inner) matrix vector multiplication; kronecker which is based on outer: Vectorize for vectorizing a non-vectorized function.

**Examples**

```r
x <- 1:9; names(x) <- x
# Multiplication & Power Tables
x %*% x
y <- 2:8; names(y) <- paste(y, ":", sep = "")
outer(y, x, "*")

outer(month.abb, 1999:2003, FUN = "paste")

## three way multiplication table:
x %*% x %*% y[1:3]
```

---

**Parentheses and Braces**

**Description**

Open parenthesis, (, and open brace, {, are *Primitive* functions in R.

Effectively, ( is semantically equivalent to the identity function(x) x, whereas { is slightly more interesting, see examples.

**Usage**

```
( ... )
```

```
{ ... }
```
Value

For `, the result of evaluating the argument. This has visibility set, so will auto-print if used at top-level.

For `, the result of the last expression evaluated. This has the visibility of the last evaluation.

References

`if`, `return`, etc for other objects used in the R language itself.

Syntax for operator precedence.

Examples

```r
f <- get(""

\begin{verbatim}
e <- expression(3 + 2 * 4)
identical(f(e), e)

\text{do <- get(""
\text{do(x <- 3, y <- 2*x-3, 6-x-y); x; y}

\text{## note the differences}
\text{(2+3)
\text{(2+3; 4+5)
\text{invisible(2+3))
\text{invisible(2+3))
\end{verbatim}
```

```
parse                  Parse Expressions
```

Description

`parse` returns the parsed but unevaluated expressions in a list.

Usage

```r
parse(file = "", n = NULL, text = NULL, prompt = "?",
      keep.source =getOption("keep.source"), srcfile,
      encoding = "unknown")
```

Arguments

- `file`  
  a connection, or a character string giving the name of a file or a URL to read the expressions from. If `file` is "" and `text` is missing or `NULL` then input is taken from the console.

- `n`  
  integer (or coerced to integer). The maximum number of expressions to parse. If `n` is `NULL` or negative or NA the input is parsed in its entirety.
text character vector. The text to parse. Elements are treated as if they were lines of a file. Other R objects will be coerced to character if possible.
prompt the prompt to print when parsing from the keyboard. NULL means to use R’s prompt, getOption("prompt").
keep.source a logical value; if TRUE, keep source reference information.
srcfile NULL, a character vector, or a srcfile object. See the ‘Details’ section.
encoding encoding to be assumed for input strings. If the value is "latin1" or "UTF-8" it is used to mark character strings as known to be in Latin-1 or UTF-8: it is not used to re-encode the input. To do the latter, specify the encoding as part of the connection con or via options(encoding=); see the example under file.

Details

If text has length greater than zero (after coercion) it is used in preference to file.
All versions of R accept input from a connection with end of line marked by LF (as used on Unix), CRLF (as used on DOS/Windows) or CR (as used on classic Mac OS). The final line can be incomplete, that is missing the final EOL marker.
See source for the limits on the size of functions that can be parsed (by default).
When input is taken from the console, n = NULL is equivalent to n = 1, and n < 0 will read until an EOF character is read. (The EOF character is Ctrl-Z for the Windows front-ends.) The line-length limit is 4095 bytes when reading from the console (which may impose a lower limit: see ‘An Introduction to R’).
The default for srcfile is set as follows. If keep.source is not TRUE, srcfile defaults to a character string, either "<text>" or one derived from file. When keep.source is TRUE, if text is used, srcfile will be set to a srcfilecopy containing the text. If a character string is used for file, a srcfile object referring to that file will be used.
When srcfile is a character string, error messages will include the name, but source reference information will not be added to the result. When srcfile is a srcfile object, source reference information will be retained.

Value

An object of type "expression", with up to n elements if specified as a non-negative integer.
When srcfile is non-NULL, a "srcref" attribute will be attached to the result containing a list of srcref records corresponding to each element, a "srcfile" attribute will be attached containing a copy of srcfile, and a "wholeSrcref" attribute will be attached containing a srcref record corresponding to all of the parsed text. Detailed parse information will be stored in the "srcfile" attribute, to be retrieved by getParseData.
A syntax error (including an incomplete expression) will throw an error.
Character strings in the result will have a declared encoding if encoding is "latin1" or "UTF-8", or if text is supplied with every element of known encoding in a Latin-1 or UTF-8 locale.

Partial parsing

When a syntax error occurs during parsing, parse signals an error. The partial parse data will be stored in the srcfile argument if it is a srcfile object and the text argument was used to supply the text. In other cases it will be lost when the error is triggered.
The partial parse data can be retrieved using getParseData applied to the srcfile object. Because parsing was incomplete, it will typically include references to "parent" entries that are not present.
References

See Also

`scan`, `source`, `eval`, `deparse`.

The source reference information can be used for debugging (see e.g. `setBreakpoint`) and profiling (see `Rprof`). It can be examined by `getSrcRef` and related functions. More detailed information is available through `getParseData`.

Examples

```r
cat("x <- c(1, 4)\n x ^ 3 -10 ; outer(1:7, 5:9)\n", file = "xyz.Rdmped")
# parse 3 statements from the file "xyz.Rdmped"
parse(file = "xyz.Rdmped", n = 3)
unlink("xyz.Rdmped")

# A partial parse with a syntax error
txt <- "
x <- 1
an error"
"sf <- srcfile("txt")
try(parse(text = txt, srcfile = sf))
getParseData(sf)
```

---

### paste

**Concatenate Strings**

**Description**

Concatenate vectors after converting to character.

**Usage**

```r
paste(..., sep = " ", collapse = NULL)
paste0(..., collapse = NULL)
```

**Arguments**

- `...`: one or more R objects, to be converted to character vectors.
- `sep`: a character string to separate the terms. Not `NA_character_`.
- `collapse`: an optional character string to separate the results. Not `NA_character_`.  

Details

`paste` converts its arguments (via `as.character`) to character strings, and concatenates them (separating them by the string given by `sep`). If the arguments are vectors, they are concatenated term-by-term to give a character vector result. Vector arguments are recycled as needed, with zero-length arguments being recycled to "".

Note that `paste()` coerces `NA_character_`, the character missing value, to "NA" which may seem undesirable, e.g., when pasting two character vectors, or very desirable, e.g. in `paste("the value of p is ", p)`.

`paste0(..., collapse)` is equivalent to `paste(..., sep = "", collapse)`, slightly more efficiently.

If a value is specified for `collapse`, the values in the result are then concatenated into a single string, with the elements being separated by the value of `collapse`.

Value

A character vector of the concatenated values. This will be of length zero if all the objects are, unless `collapse` is non-NULL in which case it is a single empty string.

If any input into an element of the result is in UTF-8 (and none are declared with encoding "bytes"), that element will be in UTF-8, otherwise in the current encoding in which case the encoding of the element is declared if the current locale is either Latin-1 or UTF-8, at least one of the corresponding inputs (including separators) had a declared encoding and all inputs were either ASCII or declared.

If an input into an element is declared with encoding "bytes", no translation will be done of any of the elements and the resulting element will have encoding "bytes". If `collapse` is non-NULL, this applies also to the second, collapsing, phase, but some translation may have been done in pasting object together in the first phase.

String manipulation with `as.character`, `substr`, `nchar`, `strsplit`; further, `cat` which concatenates and writes to a file, and `sprintf` for C like string construction.

'plotmath' for the use of `paste` in plot annotation.

Examples

```r
paste(1:12) # same as as.character(1:12)
paste("A", 1:6, sep = "")
stopifnot(identical(paste("A", 1:6, sep = ""),

    paste0("A", 1:6)))
paste("Today is", date())
```
path.expand  Expand File Paths

Description
Expand a path name, for example by replacing a leading tilde by the user's home directory (if defined on that platform).

Usage
path.expand(path)

Arguments
path character vector containing one or more path names.

Details
On some Unix builds of R, a leading ~user will expand to the home directory of user, but not on Unix versions without readline installed, nor if R is invoked with '--no-readline'.
In an interactive session capabilities("cedit") will report if readline is available.

See Also
basename, normalizePath.

Examples
path.expand("~/foo")

pmatch Partial String Matching

Description
pmatch seeks matches for the elements of its first argument among those of its second.

Usage
pmatch(x, table, nomatch = NA_integer_, duplicates.ok = FALSE)

Arguments
x the values to be matched: converted to a character vector by as.character. Long vectors are supported.

table the values to be matched against: converted to a character vector. Long vectors are not supported.

nomatch the value to be returned at non-matching or multiply partially matching positions. Note that it is coerced to integer.

duplicates.ok should elements be in table be used more than once?
Details

The behaviour differs by the value of duplicates.ok. Consider first the case if this is true. First exact matches are considered, and the positions of the first exact matches are recorded. Then unique partial matches are considered, and if found recorded. (A partial match occurs if the whole of the element of \( x \) matches the beginning of the element of \( \text{table} \).) Finally, all remaining elements of \( x \) are regarded as unmatched. In addition, an empty string can match nothing, not even an exact match to an empty string. This is the appropriate behaviour for partial matching of character indices, for example.

If duplicates.ok is FALSE, values of \( \text{table} \) once matched are excluded from the search for subsequent matches. This behaviour is equivalent to the \( \text{R} \) algorithm for argument matching, except for the consideration of empty strings (which in argument matching are matched after exact and partial matching to any remaining arguments).

\text{charmatch} \text{ is similar to } \text{pmatch with duplicates.ok true}, \text{ the differences being that it differentiates between no match and an ambiguous partial match, it does match empty strings, and it does not allow multiple exact matches.}

\text{NA values are treated as if they were the string constant "NA".}

Value

An integer vector (possibly including NA if \( \text{nomatch} = \text{NA} \)) of the same length as \( x \), giving the indices of the elements in \( \text{table} \) which matched, or \( \text{nomatch} \).

References

See Also

Examples

\begin{verbatim}
pmatch("", ") # returns NA
pmatch("m", c("mean", "median", "mode")) # returns NA
pmatch("med", c("mean", "median", "mode")) # returns 2

pmatch(c("", "ab", "ab"), c("abc", "ab"), dup = FALSE)
pmatch(c("", "ab", "ab"), c("abc", "ab"), dup = TRUE) # compare
charmatch(c("", "ab", "ab"), c("abc", "ab"))
\end{verbatim}
**polyroot**

*Find Zeros of a Real or Complex Polynomial*

**Description**
Find zeros of a real or complex polynomial.

**Usage**
```
polyroot(z)
```

**Arguments**
- `z` the vector of polynomial coefficients in increasing order.

**Details**
A polynomial of degree \( n - 1 \),

\[
p(x) = z_1 + z_2 x + \cdots + z_n x^{n-1}
\]

is given by its coefficient vector \( z[1:n] \). `polyroot` returns the \( n - 1 \) complex zeros of \( p(x) \) using the Jenkins-Traub algorithm.

If the coefficient vector \( z \) has zeroes for the highest powers, these are discarded.
There is no maximum degree, but numerical stability may be an issue for all but low-degree polynomials.

**Value**
A complex vector of length \( n - 1 \), where \( n \) is the position of the largest non-zero element of \( z \).

**Source**
C translation by Ross Ihaka of Fortran code in the reference, with modifications by the R Core Team.

**References**

**See Also**
- `uniroot` for numerical root finding of arbitrary functions; `complex` and the zero example in the demos directory.

**Examples**
```
polyroot(c(1, 2, 1))
round(polyroot(choose(8, 0:8)), 11) # guess what!
for (n1 in 1:4) print(polyroot(1:n1), digits = 4)
polyroot(c(1, 2, 1, 0, 0)) # same as the first
```
pos.to.env  
**Convert Positions in the Search Path to Environments**

**Description**

Returns the environment at a specified position in the search path.

**Usage**

```r
pos.to.env(x)
```

**Arguments**

- `x` an integer between 1 and `length(search())`, the length of the search path, or -1.

**Details**

Several R functions for manipulating objects in environments (such as `get` and `ls`) allow specifying environments via corresponding positions in the search path. `pos.to.env` is a convenience function for programmers which converts these positions to corresponding environments; users will typically have no need for it. It is primitive.

-1 is interpreted as the environment the function is called from.

This is a primitive function.

**Examples**

```r
pos.to.env(1) # R_GlobalEnv
# the next returns the base environment
pos.to.env(length(search()))
```

---

pretty  
**Pretty Breakpoints**

**Description**

Compute a sequence of about n+1 equally spaced ‘round’ values which cover the range of the values in `x`. The values are chosen so that they are 1, 2 or 5 times a power of 10.

**Usage**

```r
pretty(x, ...)
```

```
## Default S3 method:
pretty(x, n = 5, min.n = n %% 3, shrink.sml = 0.75,
   high.u.bias = 1.5, u5.bias = .5 + 1.5*high.u.bias,
   eps.correct = 0, ...)
```
Arguments

- **x**: an object coercible to numeric by `as.numeric`.
- **n**: integer giving the desired number of intervals. Non-integer values are rounded down.
- **min.n**: nonnegative integer giving the minimal number of intervals. If `min.n == 0`, `pretty()` may return a single value.
- **shrink.sm**: positive numeric by which a default scale is shrunk in the case when `range(x)` is very small (usually 0).
- **high.u.bias**: non-negative numeric, typically > 1. The interval unit is determined as {1,2,5,10} times `b`, a power of 10. Larger `high.u.bias` values favor larger units.
- **u5.bias**: non-negative numeric multiplier favoring factor 5 over 2. Default and ‘optimal’: `u5.bias = .5 + 1.5*high.u.bias`.
- **eps.correct**: integer code, one of {0,1,2}. If non-0, an epsilon correction is made at the boundaries such that the result boundaries will be outside `range(x)`; in the small case, the correction is only done if `eps.correct >= 2`.

Details

`pretty` ignores non-finite values in `x`.

Let `d <- max(x) - min(x) >= 0`. If `d` is not (very close) to 0, we let `c <- d/n`, otherwise more or less `c <- max(abs(range(x)))*shrink.sm / min.n`. Then, the 10 base `b` is \(10^\lfloor \log_{10}(c) \rfloor\) such that `b <= c < 10b`.

Now determine the basic unit `u` as one of {1,2,5,10} `b`, depending on `c/b` \(\in [1, 10)\) and the two ‘bias’ coefficients, `h = high.u.bias` and `f = u5.bias`.

References

See Also

`axTicks` for the computation of pretty axis tick locations in plots, particularly on the log scale.

Examples

```r
pretty(1:15) # 0 2 4 6 8 10 12 14 16
pretty(1:15, h = 2) # 0 5 10 15
pretty(1:15, n = 4) # 0 5 10 15
pretty(1:15 * 2) # 0 5 10 15 20 25 30
pretty(1:20) # 0 5 10 15 20
pretty(1:20, n = 2) # 0 10 20
pretty(1:20, n = 10) # 0 2 4 ... 20

for(k in 5:11) {
  cat("k=", k, ", k: "); print(diff(range(pretty(100 + c(0, pi*10^-k))))))
}
```

```r
##-- more bizarre, when min(x) == max(x):
```
Primitive

Description

.Primitive looks up by name a ‘primitive’ (internally implemented) function.

Usage

.Primitive(name)

Arguments

name name of the R function.

Details

The advantage of .Primitive over .Internal functions is the potential efficiency of argument passing, and that positional matching can be used where desirable, e.g. in switch. For more details, see the ‘R Internals Manual’.

All primitive functions are in the base namespace.

This function is almost never used: ‘name’ or, more carefully, get(name, envir = baseenv()) work equally well and do not depend on knowing which functions are primitive (which does change as R evolves).

Note

Prior to R 2.14.2 this could also be used to retrieve .Internal functions: this was unintentional.

See Also

.Internal.

Examples

mysqrt <- .Primitive("sqrt")
c
.Internal # this one *must* be primitive!

`if` # need backticks
**print**

**Print Values**

**Description**

`print` prints its argument and returns it *invisibly* (via `invisible(x)`). It is a generic function which means that new printing methods can be easily added for new *classes*.

**Usage**

```r
print(x, ...)  # S3 method for class 'factor'
print(x, quote = FALSE, max.levels = NULL,
      width = getOption("width"), ...)
```

```r
## S3 method for class 'table'
print(x, digits = getOption("digits"), quote = FALSE,
      na.print = ",", zero.print = "0", justify = "none", ...)
```

```r
## S3 method for class 'function'
print(x, useSource = TRUE, ...)
```

**Arguments**

- `x` an object used to select a method.
- `...` further arguments passed to or from other methods.
- `quote` logical, indicating whether or not strings should be printed with surrounding quotes.
- `max.levels` integer, indicating how many levels should be printed for a factor; if 0, no extra "Levels" line will be printed. The default, NULL, entails choosing max.levels such that the levels print on one line of width width.
- `width` only used when max.levels is NULL, see above.
- `digits` minimal number of *significant* digits, see `print.default`.
- `na.print` character string (or NULL) indicating *NA* values in printed output, see `print.default`.
- `zero.print` character specifying how zeros (0) should be printed; for sparse tables, using "." can produce stronger results.
- `justify` character indicating if strings should left- or right-justified or left alone, passed to `format`.
- `useSource` logical indicating if internally stored source should be used for printing when present, e.g., if `options(keep.source = TRUE)` has been in use.

**Details**

The default method, `print.default` has its own help page. Use `methods("print")` to get all the methods for the print generic.

`print.factor` allows some customization and is used for printing *ordered* factors as well.
print.data.frame for printing tables allows other customization. As of R 3.0.0, it only prints a description in case of a table with 0-extents (this can happen if a classifier has no valid data).

See noquote as an example of a class whose main purpose is a specific print method.

References

See Also

The default method print.default, and help for the methods above; further options, noquote.

For more customizable (but cumbersome) printing, see cat, format or also write. For a simple prototypical print method, see .print.via.format in package tools.

Examples

require(stats)

ts(1:20) #-- print is the "Default function" --> print.ts(.) is called
for(i in 1:3) print(1:i)

## Printing of factors
attenu$station ## 117 levels --> 'max.levels' depending on width

## ordered factors: levels "11 < 12 < .."
esoph$agegp[1:12]
esoph$alcgp[1:12]

## Printing of sparse (contingency) tables
set.seed(521)
t1 <- round(abs(rt(200, df = 1.8)))
t2 <- round(abs(rt(200, df = 1.4)))
table(t1, t2) # simple
print(table(t1, t2), zero.print = ".") # nicer to read

## Corner cases with empty extents:
table(1, NA) # < table of extent 1 x 0 >

print.data.frame Printing Data Frames

Description

Print a data frame.

Usage

## S3 method for class 'data.frame'
print(x, ..., digits = NULL,
   quote = FALSE, right = TRUE, row.names = TRUE)
Arguments

x  object of class `data.frame`.

... optional arguments to `print` or `plot` methods.

digits the minimum number of significant digits to be used: see `print.default`.

quote logical, indicating whether or not entries should be printed with surrounding quotes.

right logical, indicating whether or not strings should be right-aligned. The default is right-alignment.

row.names logical (or character vector), indicating whether (or what) row names should be printed.

Details

This calls `format` which formats the data frame column-by-column, then converts to a character matrix and dispatches to the `print` method for matrices.

When `quote = TRUE` only the entries are quoted not the row names nor the column names.

See Also

data.frame.

Examples

```r
(dd <- data.frame(x = 1:8, f = gl(2, 4), ch = I(letters[1:8])))
# print() with defaults
print(dd, quote = TRUE, row.names = FALSE)
# suppresses row.names and quotes all entries
```

print.default  Default Printing

Description

`print.default` is the `default` method of the generic `print` function which prints its argument.

Usage

```r
## Default S3 method:
print(x, digits = NULL, quote = TRUE,
    na.print = NULL, print.gap = NULL, right = FALSE,
    max = NULL, useSource = TRUE, ...)
```

Arguments

x  the object to be printed.

digits a non-null value for `digits` specifies the minimum number of significant digits to be printed in values. The default, `NULL`, uses `getOption("digits")`. (For the interpretation for complex numbers see `signif`) Non-integer values will be rounded down, and only values greater than or equal to 1 and no greater than 22 are accepted.
print.default

quote  logical, indicating whether or not strings (`characters`) should be printed with
surrounding quotes.

na.print  a character string which is used to indicate `NA` values in printed output, or `NULL` (see `Details`).

print.gap  a non-negative integer \( \leq 1024 \), or `NULL` (meaning 1), giving the spacing between
adjacent columns in printed vectors, matrices and arrays.

right  logical, indicating whether or not strings should be right aligned. The default is
left alignment.

max  a non-null value for `max` specifies the approximate maximum number of entries
to be printed. The default, `NULL`, uses `getOption("max.print")`; see that help
page for more details.

useSource  logical, indicating whether to use source references or copies rather than deparsing
language objects. The default is to use the original source if it is available.

...  further arguments to be passed to or from other methods. They are ignored in
this function.

Details

The default for printing NAs is to print `NA` (without quotes) unless this is a character `NA` and `quote = FALSE`, when `<NA>` is printed.

The same number of decimal places is used throughout a vector. This means that `digits` specifies the minimum number of significant digits to be used, and that at least one entry will be encoded with that minimum number. However, if all the encoded elements then have trailing zeroes, the number of decimal places is reduced until at least one element has a non-zero final digit. Decimal points are only included if at least one decimal place is selected.

Attributes are printed respecting their class(es), using the values of `digits` to `print.default`, but using the default values (for the methods called) of the other arguments.

Option `width` controls the printing of vectors, matrices and arrays, and option `deparse.cutoff` controls the printing of language objects such as calls and formulae.

When the `methods` package is attached, `print` will call `show` for `R` objects with formal classes if called with no optional arguments.

Large number of digits

Note that for large values of `digits`, currently for `digits \geq 16`, the calculation of the number of significant digits will depend on the platform’s internal (C library) implementation of `‘sprintf()’` functionality.

Single-byte locales

If a non-printable character is encountered during output, it is represented as one of the ANSI escape sequences (`\a`, `\b`, `\f`, `\n`, `\r`, `\t`, `\v`, `\\`, `\` and `\0`: see Quotes), or failing that as a 3-digit octal code: for example the UK currency pound sign in the C locale (if implemented correctly) is printed as `\243`. Which characters are non-printable depends on the locale. (Because some versions of Windows get this wrong, all bytes with the upper bit set are regarded as printable on Windows in a single-byte locale.)
Unicode and other multi-byte locales

In all locales, the characters in the ASCII range (‘\0x00’ to ‘\0x7F’) are printed in the same way, as-is if printable, otherwise via ANSI escape sequences or 3-digit octal escapes as described for single-byte locales.

Multi-byte non-printing characters are printed as an escape sequence of the form ‘\uxxxx’ or ‘\Uxxxxxxxx’ (in hexadecimal). This is the internal code for the wide-character representation of the character. If this is not known to be the Unicode point, a warning is issued. The only known exceptions are certain Japanese ISO2022 locales on commercial Unixes, which use a concatenation of the bytes: it is unlikely that R compiles on such a system.

It is possible to have a character string in a character vector that is not valid in the current locale. If a byte is encountered that is not part of a valid character it is printed in hex in the form ‘\xab’ and this is repeated until the start of a valid character. (This will rapidly recover from minor errors in UTF-8.)

See Also

The generic print, options. The "noquote" class and print method.
encodeString, which encodes a character vector the way it would be printed.

Examples

```R
pi
print(pi, digits = 16)
LETTERS[1:16]
print(LETTERS, quote = FALSE)

M <- cbind(i = 1, matrix(1:10000, ncol = 10,
                       dimnames = list(NULL, LETTERS[1:10])))
utils::head(M)  # makes more sense than
print(M, max = 1000)  # prints 90 rows and a message about omitting 910
```

prmatrix

Print Matrices, Old-style

Description

An earlier method for printing matrices, provided for S compatibility.

Usage

```R
prmatrix(x, rowlab =, collab =,
         quote = TRUE, right = FALSE, na.print = NULL, ...)
```

Arguments

- `x` numeric or character matrix.
- `rowlab`, `collab` (optional) character vectors giving row or column names respectively. By default, these are taken from `dimnames(x)`.
- `quote` logical; if TRUE and `x` is of mode "character", quotes (""") are used.
- `right` if TRUE and `x` is of mode "character", the output columns are right-justified.
na.print how NAs are printed. If this is non-null, its value is used to represent NA.
... arguments for print methods.

Details

prmatrix is an earlier form of print.matrix, and is very similar to the S function of the same name.

Value

Invisibly returns its argument, x.

References

See Also

print.default, and other print methods.

Examples

```r
prmatrix(m6 <- diag(6), rowlab = rep("", 6), collab = rep("", 6))

chm <- matrix(scan(system.file("help", "AnIndex", package = "splines"),
                    what = ""), , 2, byrow = TRUE)
chm  # uses print.matrix()
prmatrix(chm, collab = paste("Column", 1:3), right = TRUE, quote = FALSE)
```

---

**proc.time**

**Running Time of R**

Description

proc.time determines how much real and CPU time (in seconds) the currently running R process has already taken.

Usage

```r
proc.time()
```

Details

proc.time returns five elements for backwards compatibility, but its print method prints a named vector of length 3. The first two entries are the total user and system CPU times of the current R process and any child processes on which it has waited, and the third entry is the ‘real’ elapsed time since the process was started.
Value

An object of class "proc_time" which is a numeric vector of length 5, containing the user, system, and total elapsed times for the currently running R process, and the cumulative sum of user and system times of any child processes spawned by it on which it has waited. (The print method uses the summary method to combine the child times with those of the main process.)

The definition of 'user' and 'system' times is from your OS. Typically it is something like

The 'user time' is the CPU time charged for the execution of user instructions of the calling process. The 'system time' is the CPU time charged for execution by the system on behalf of the calling process.

Times of child processes are not available on Windows and will always be given as NA.

The resolution of the times will be system-specific and on Unix-alikes times are rounded down to milliseconds. On modern systems they will be that accurate, but on older systems they might be accurate to 1/100 or 1/60 sec. They are typically available to 10ms on Windows.

This is a primitive function.

References

See Also

system.time for timing an R expression, gc.time for how much of the time was spent in garbage collection.

Examples

## Not run:
## a way to time an R expression: system.time is preferred
ptm <- proc.time()
for (i in 1:50) mad(stats::runif(500))
proc.time() - ptm

## End(Not run)

prod

Product of Vector Elements

description

prod returns the product of all the values present in its arguments.

Usage

prod(..., na.rm = FALSE)

Arguments

... numeric or complex or logical vectors.

na.rm logical. Should missing values be removed?
Details

If `na.rm` is FALSE an NA value in any of the arguments will cause a value of NA to be returned, otherwise NA values are ignored.

This is a generic function: methods can be defined for it directly or via the `Summary` group generic. For this to work properly, the arguments ... should be unnamed, and dispatch is on the first argument.

Logical true values are regarded as one, false values as zero. For historical reasons, `NULL` is accepted and treated as if it were `numeric(0)`.

Value

The product, a numeric (of type "double") or complex vector of length one. **NB:** the product of an empty set is one, by definition.

S4 methods

This is part of the S4 `summary` group generic. Methods for it must use the signature `xL NNNL naNrm`.

References

See Also

`sum`, `cumprod`, `cumsum`.

‘plotmath’ for the use of `prod` in plot annotation.

Examples

```r
print(prod(1:7)) == print(gamma(8))
```

---

**prop.table**

*Express Table Entries as Fraction of Marginal Table*

Description

This is really `sweep(x, margin, margin.table(x, margin), "/")` for newbies, except that if `margin` has length zero, then one gets `x/sum(x)`.

Usage

`prop.table(x, margin = NULL)`

Arguments

- `x` table
- `margin` index, or vector of indices to generate margin for
pushBack

Value
Table like x expressed relative to margin

Author(s)
Peter Dalgaard

See Also
margin.table

Examples
```r
m <- matrix(1:4, 2)
m
prop.table(m, 1)
```

Description
Functions to push back text lines onto a connection, and to enquire how many lines are currently pushed back.

Usage
```r
pushBack(data, connection, newline = TRUE)
pushBackLength(connection)
clearPushBack(connection)
```

Arguments
- `data` a character vector.
- `connection` A connection.
- `newline` logical. If true, a newline is appended to each string pushed back.

Details
Several character strings can be pushed back on one or more occasions. The occasions form a stack, so the first line to be retrieved will be the first string from the last call to pushBack. Lines which are pushed back are read prior to the normal input from the connection, by the normal text-reading functions such as `readLines` and `scan`.

Pushback is only allowed for readable connections in text mode.

Not all uses of connections respect pushbacks, in particular the input connection is still wired directly, so for example parsing commands from the console and `scan("")` ignore pushbacks on stdin.

When character strings with a marked encoding (see Encoding) are pushed back they are converted to the current encoding. This may involve representing characters as ‘\uU+xxxx’ if they cannot be converted.
Value

pushBack and clearPushBack() return nothing, invisibly.
pushBackLength returns number of lines currently pushed back.

See Also

connections, readLines.

Examples

zz <- textConnection(LETTERS)
readLines(zz, 2)
pushBack(c("aa", "bb"), zz)
pushBackLength(zz)
readLines(zz, 1)
pushBackLength(zz)
readLines(zz, 1)
readLines(zz, 1)
close(zz)

qr

The QR Decomposition of a Matrix

Description

qr computes the QR decomposition of a matrix.

Usage

qr(x, ...)  
## Default S3 method: 
qr(x, tol = 1e-07 , LAPACK = FALSE, ...)

qr.coef(qr, y)
qr.qy(qr, y)
qr.qty(qr, y)
qr.resid(qr, y)
qr.fitted(qr, y, k = qr$rank)
qr.solve(a, b, tol = 1e-7)
## S3 method for class 'qr'
solve(a, b, ...)

is.qr(x)
as.qr(x)

Arguments

x a numeric or complex matrix whose QR decomposition is to be computed. Logical matrices are coerced to numeric.

tol the tolerance for detecting linear dependencies in the columns of x. Only used if LAPACK is false and x is real.
qr

- **qr**: a QR decomposition of the type computed by `qr`.
- **y, b**: a vector or matrix of right-hand sides of equations.
- **a**: a QR decomposition or (``qr.solve`` only) a rectangular matrix.
- **k**: effective rank.
- **LAPACK**: logical. For real `x`, if true use LAPACK otherwise use LINPACK (the default).
- **...**: further arguments passed to or from other methods

**Details**

The QR decomposition plays an important role in many statistical techniques. In particular it can be used to solve the equation \( Ax = b \) for given matrix \( A \), and vector \( b \). It is useful for computing regression coefficients and in applying the Newton-Raphson algorithm.

The functions `qr.coef`, `qr.resid`, and `qr.fitted` return the coefficients, residuals and fitted values obtained when fitting \( y \) to the matrix with QR decomposition `qr`. (If pivoting is used, some of the coefficients will be NA.) `qr.qty` and `qr.qry` return \( Q^\top y \) and \( t(Q) y \), where \( Q \) is the (complete) \( Q \) matrix.

All the above functions keep dimnames (and names) of \( x \) and \( y \) if there are any.

The functions `qr.solve` is the method for `solve` for `qr` objects. `qr.solve` solves systems of equations via the QR decomposition: if \( a \) is a QR decomposition it is the same as `solve.qr`, but if \( a \) is a rectangular matrix the QR decomposition is computed first. Either will handle over- and under-determined systems, providing a least-squares fit if appropriate.

`is.qr` returns `TRUE` if `x` is a list with components named `qr`, `rank` and `qraux` and `FALSE` otherwise. It is not possible to coerce objects to mode "qr". Objects either are QR decompositions or they are not.

The LINPACK interface is restricted to matrices \( x \) with less than \( 2^{31} \) elements. `qr.fitted` and `qr.resid` only support the LINPACK interface.

**Value**

The QR decomposition of the matrix as computed by LINPACK or LAPACK. The components in the returned value correspond directly to the values returned by DQRDC/DGEQP3/ZGEQP3.

- **qr**: a matrix with the same dimensions as \( x \). The upper triangle contains the \( R \) of the decomposition and the lower triangle contains information on the \( Q \) of the decomposition (stored in compact form). Note that the storage used by DQRDC and DGEQP3 differs.
- **qraux**: a vector of length `ncol(x)` which contains additional information on \( Q \).
- **rank**: the rank of \( x \) as computed by the decomposition: always full rank in the LAPACK case.
- **pivot**: information on the pivoting strategy used during the decomposition.

Non-complex QR objects computed by LAPACK have the attribute "useLAPACK" with value `TRUE`.

**Note**

To compute the determinant of a matrix (do you really need it?), the QR decomposition is much more efficient than using Eigen values (`eigen`). See `det`.

Using LAPACK (including in the complex case) uses column pivoting and does not attempt to detect rank-deficient matrices.
Source

For qr, the LINPACK routine DQRDC and the LAPACK routines DGEQP3 and ZGEQP3. Further LINPACK and LAPACK routines are used for qr.coef, qr.qy and qr.aty.

LAPACK and LINPACK are from http://www.netlib.org/lapack and http://www.netlib.org/linpack and their guides are listed in the references.

#--> 9

###-- Solve linear equation system H %*% x = y :
y <- 1:9/10

x <- qr.solve(h9, y, tol = 1e-10) # or equivalently:
x <- qr.coef(qrh9, y) #-- is == but much better than

#-- solve(h9) %*% y

h9 %*% x

# = y

### over determined system

A <- matrix(runif(12), 4)
b <- 1:4

qr.solve(A, b) # or solve(qr(A), b)
solve(qr(A, LAPACK = TRUE), b)

# this is a least-squares solution, cf. lm(b ~ 0 + A)

### under determined system

A <- matrix(runif(12), 3)
b <- 1:3

qr.solve(A, b)
solve(qr(A, LAPACK = TRUE), b)

# solutions will have one zero, not necessarily the same one
Reconstruct the Q, R, or X Matrices from a QR Object

Description

Returns the original matrix from which the object was constructed or the components of the decomposition.

Usage

- `qr.X(qr, complete = FALSE, ncol =)`
- `qr.Q(qr, complete = FALSE, Dvec =)`
- `qr.R(qr, complete = FALSE, ...)

Arguments

- **qr**: object representing a QR decomposition. This will typically have come from a previous call to `qr` or `lsfit`.
- **complete**: logical expression of length 1. Indicates whether an arbitrary orthogonal completion of the Q or X matrices is to be made, or whether the R matrix is to be completed by binding zero-value rows beneath the square upper triangle.
- **ncol**: integer in the range 1:nrow(qr$qr). The number of columns to be in the reconstructed X. The default when complete is FALSE is the first min(ncol(X), nrow(X)) columns of the original X from which the qr object was constructed. The default when complete is TRUE is a square matrix with the original X in the first ncol(X) columns and an arbitrary orthogonal completion (unitary completion in the complex case) in the remaining columns.
- **Dvec**: vector (not matrix) of diagonal values. Each column of the returned Q will be multiplied by the corresponding diagonal value. Defaults to all 1s.
- ... potentially further arguments, passed potentially to non-default methods.

Value

- `qr.X` returns X, the original matrix from which the qr object was constructed, provided ncol(X) <= nrow(X). If complete is TRUE or the argument ncol is greater than ncol(X), additional columns from an arbitrary orthogonal (unitary) completion of X are returned.
- `qr.Q` returns part or all of Q, the order-nrow(X) orthogonal (unitary) transformation represented by qr. If complete is TRUE, Q has nrow(X) columns. If complete is FALSE, Q has ncol(X) columns. When Dvec is specified, each column of Q is multiplied by the corresponding value in Dvec.
- `qr.R` returns R. This may be pivoted, e.g., if a <- qr(x) then x[, a$pivot] = QR. The number of rows of R is either nrow(X) or ncol(X) (and may depend on whether complete is TRUE or FALSE).

- `qr`, `qr.aux`
Examples

```r
p <- ncol(x <- LifeCycleSavings[, -1]) # not the 'sr'
grstr <- qr(x) # dim(x) == c(n,p)
grstr $ rank # = 4 = p
Q <- qr.Q(grstr) # dim(Q) == dim(x)
R <- qr.R(grstr) # dim(R) == ncol(x)
X <- qr.X(grstr) # X == x
range(X - as.matrix(x)) # ~ < 6e-12
## X == Q %*% R if there has been no pivoting, as here:
all.equal(unname(X),
    unname(Q %*% R))
# example of pivoting
x <- cbind(int = 1,
    b1 = rep(1:0, each = 3), b2 = rep(0:1, each = 3),
    c1 = rep(c(1,0,0), 2), c2 = rep(c(0,1,0), 2),
    c3 = rep(c(0,0,1),2))
x # is singular, columns "b2" and "c3" are "extra"
a <- qr(x)
zapsmall(qr.R(a)) # columns are int b1 c1 c2 b2 c3 a$pivot
pivl <- sort.list(a$pivot) # the inverse permutation
all.equal(x, qr.Q(a) %*% qr.R(a)) # no, no stopifnot(
    all.equal(x[, a$pivot], qr.Q(a) %*% qr.R(a)),
    all.equal(x[, qr.Q(a) %*% qr.R(a)[, pivl]]) # TRUE too!
```

Description

The function `quit` or its alias `q` terminate the current R session.

Usage

```r
quit(save = "default", status = 0, runLast = TRUE)
q(save = "default", status = 0, runLast = TRUE)
```

Arguments

- `save` a character string indicating whether the environment (workspace) should be saved, one of "no", "yes", "ask" or "default".
- `status` the (numerical) error status to be returned to the operating system, where relevant. Conventionally 0 indicates successful completion.
- `runLast` should `.Last()` be executed?

Details

save must be one of "no", "yes", "ask" or "default". In the first case the workspace is not saved, in the second it is saved and in the third the user is prompted and can also decide not to quit. The default is to ask in interactive use but may be overridden by command-line arguments (which must be supplied in non-interactive use).
Immediately before terminating, \texttt{.Last()} is executed if the function \texttt{.Last} exists and \texttt{runLast} is true. If in interactive use there are errors in the \texttt{.Last} function, control will be returned to the command prompt, so do test the function thoroughly. There is a system analogue, \texttt{.Last.sys()}, which is run after \texttt{.Last()} if \texttt{runLast} is true.

Exactly what happens at termination of an R session depends on the platform and GUI interface in use. A typical sequence is to run \texttt{.Last()} and \texttt{.Last.sys()} (unless \texttt{runLast} is false), to save the workspace if requested (and in most cases also to save the session history: see \texttt{savehistory}), then run any finalizers (see \texttt{reg.finalizer}) that have been set to be run on exit, close all open graphics devices, remove the session temporary directory and print any remaining warnings (e.g. from \texttt{.Last()} and device closure).

Some error statuses are used by R itself. The default error handler for non-interactive use effectively calls \texttt{q("no", 1, FALSE)} and returns error code 1. Error status 2 is used for R ‘suicide’, that is a catastrophic failure, and other small numbers are used by specific ports for initialization failures. It is recommended that users choose statuses of 10 or more.

Valid values of \texttt{status} are system-dependent, but 0:255 are normally valid. (Many OSes will report the last byte of the value, that is report the number modulo 256. But not all.)

\section*{Note}

The R.app GUI on OS X has its own version of these functions with slightly different behaviour for the save argument (the ‘Startup’ preferences for this action are taken into account).

\section*{See Also}

\texttt{.First} for setting things on startup.

\section*{Examples}

\begin{verbatim}
## Not run: ## Unix-flavour example
.Last <- function() {
  cat("Now sending PDF graphics to the printer:\n")
  system("lpr Rplots.pdf")
  cat("bye bye...\n")
} quit("yes")
## End(Not run)
\end{verbatim}
Details

Three types of quotes are part of the syntax of R: single and double quotation marks and the backtick (or back quote, ‘``’). In addition, backslash is used to escape the following character inside character constants.

Character constants

Single and double quotes delimit character constants. They can be used interchangeably but double quotes are preferred (and character constants are printed using double quotes), so single quotes are normally only used to delimit character constants containing double quotes.

Backslash is used to start an escape sequence inside character constants. Escaping a character not in the following table is an error.

Single quotes need to be escaped by backslash in single-quoted strings, and double quotes in double-quoted strings.

<table>
<thead>
<tr>
<th>Escape</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘\n’</td>
<td>newline</td>
</tr>
<tr>
<td>‘\r’</td>
<td>carriage return</td>
</tr>
<tr>
<td>‘\t’</td>
<td>tab</td>
</tr>
<tr>
<td>‘\b’</td>
<td>backspace</td>
</tr>
<tr>
<td>‘\a’</td>
<td>alert (bell)</td>
</tr>
<tr>
<td>‘\f’</td>
<td>form feed</td>
</tr>
<tr>
<td>‘\v’</td>
<td>vertical tab</td>
</tr>
</tbody>
</table>
| ‘\\’    | backslash ‘‘
| ‘\’      | ASCII apostrophe ‘’’’                  |
| ‘\”’     | ASCII quotation mark ‘”’              |
| ‘\n\n’   | character with given octal code (1, 2 or 3 digits) |
| ‘\xnn’   | character with given hex code (1 or 2 hex digits) |
| ‘\uunn’  | Unicode character with given code (1–4 hex digits) |
| ‘\Unnnnnn’ | Unicode character with given code (1–8 hex digits) |

Alternative forms for the last two are ‘\u{nnnn}’ and ‘\U{nnnnnnnn}’. All except the Unicode escape sequences are also supported when reading character strings by scan and read.table if allowEscapes = TRUE. Unicode escapes can be used to enter Unicode characters not in the current locale’s charset (when the string will be stored internally in UTF-8).

The parser does not allow the use of both octal/hex and Unicode escapes in a single string.

These forms will also be used by print.default when outputting non-printable characters (including backslash).

Embedded nuls are not allowed in character strings, so using escapes (such as ‘\0’) for a nul will result in the string being truncated at that point (usually with a warning).

Names and Identifiers

Identifiers consist of a sequence of letters, digits, the period (.) and the underscore. They must not start with a digit nor underscore, nor with a period followed by a digit. Reserved words are not valid identifiers.

The definition of a letter depends on the current locale, but only ASCII digits are considered to be digits.

Such identifiers are also known as syntactic names and may be used directly in R code. Almost always, other names can be used provided they are quoted. The preferred quote is the backtick
(```", and `deparse` will normally use it, but under many circumstances single or double quotes can be used (as a character constant will often be converted to a name). One place where backticks may be essential is to delimit variable names in formulae: see `formula`.

`Syntax` for other aspects of the syntax.

`sQuote` for quoting English text.

`shQuote` for quoting OS commands.

The ‘R Language Definition’ manual.

<table>
<thead>
<tr>
<th>R.Version</th>
<th>Version Information</th>
</tr>
</thead>
</table>

**Description**

`R.Version()` provides detailed information about the version of R running.

`R.version` is a variable (a `list`) holding this information (and `version` is a copy of it for S compatibility).

**Usage**

`R.Version()
R.version
R.version.string
version`

**Value**

`R.Version` returns a list with character-string components

- `platform` the platform for which R was built. A triplet of the form CPU-VENDOR-OS, as determined by the configure script. E.g. "i586-unknown-linux" or "i386-pc-mingw32".
- `arch` the architecture (CPU) R was built on/for.
- `os` the underlying operating system
- `system` CPU and OS, separated by a comma.
- `status` the status of the version (e.g., "Alpha")
- `major` the major version number
- `minor` the minor version number, including the patchlevel
- `year` the year the version was released
- `month` the month the version was released
- `day` the day the version was released
- `svn rev` the Subversion revision number, which should be either "unknown" or a single number. (A range of numbers or a number with ‘M’ or ‘S’ appended indicates inconsistencies in the sources used to build this version of R.)
- `language` always "R".
- `version.string` a `character` string concatenating some of the info above, useful for plotting, etc.

`R.version` and `version` are lists of class "simple.list" which has a print method.
Note

Do not use R.version$os to test the platform the code is running on: use .Platform$OS.type instead. Slightly different versions of the OS may report different values of R.version$os, as may different versions of R.

R.version.string is a copy of R.version$version.string for simplicity and backwards compatibility.

See Also

sessionInfo which provides additional information; getRversion typically used inside R code, .Platform.

Examples

```
require(graphics)

R.version$os # to check how lucky you are ...
plot(0) # any plot
mtext(R.version.string, side = 1, line = 4, adj = 1) # a useful bottom-right note
```

Description

.Random.seed is an integer vector, containing the random number generator (RNG) state for random number generation in R. It can be saved and restored, but should not be altered by the user. 
RNGkind is a more friendly interface to query or set the kind of RNG in use. 
RNGversion can be used to set the random generators as they were in an earlier R version (for reproducibility). 
set.seed is the recommended way to specify seeds.

Usage

```
.Random.seed <- c(rng.kind, n1, n2, ...)
RNGkind(kind = NULL, normal.kind = NULL)
RNGversion(vstr)
set.seed(seed, kind = NULL, normal.kind = NULL)
```

Arguments

- **kind**: character or NULL. If kind is a character string, set R’s RNG to the kind desired. Use “default” to return to the R default. See ‘Details’ for the interpretation of NULL.
- **normal.kind**: character string or NULL. If it is a character string, set the method of Normal generation. Use “default” to return to the R default. NULL makes no change.
- **seed**: a single value, interpreted as an integer, or NULL (see ‘Details’).
- **vstr**: a character string containing a version number, e.g., ”1.6.2″
random

rng.kind integer code in \( \emptyset : k \) for the above kind.
n1, n2, ... integers. See the details for how many are required (which depends on rng.kind).

**Details**

The currently available RNG kinds are given below. kind is partially matched to this list. The default is "Mersenne-Twister".

"Wichmann-Hill" The seed, \( \cdot . \text{Random. seed}[-1] \equiv r[1:3] \) is an integer vector of length 3, where each \( r[i] \) is in \( 1 : (p[i] - 1) \), where \( p \) is the length 3 vector of primes, \( p = (30269, 30307, 30323) \). The Wichmann–Hill generator has a cycle length of \( 6.9536 \times 10^{12} \) (\( = \prod (p-1)/4 \), see *Applied Statistics* (1984) 33, 123 which corrects the original article).

"Marsaglia-Multicarry": A *multiply-with-carry* RNG is used, as recommended by George Marsaglia in his post to the mailing list 'sci.stat.math'. It has a period of more than \( 2^{9536} \) and has passed all tests (according to Marsaglia). The seed is two integers (all values allowed).

"Super-Duper": Marsaglia's famous Super-Duper from the 70's. This is the original version which does not pass the MTUPLE test of the Diehard battery. It has a period of \( \approx 4.6 \times 10^{18} \) for most initial seeds. The seed is two integers (all values allowed for the first seed: the second must be odd).

We use the implementation by Reeds et al. (1982–84).

The two seeds are the Tausworthe and congruence long integers, respectively. A one-to-one mapping to S's \( \cdot \text{Random. seed}[1:12] \) is possible but we will not publish one, not least as this generator is not exactly the same as that in recent versions of S-PLUS.

"Mersenne-Twister": From Matsumoto and Nishimura (1998). A twisted GFSR with period \( 2^{19937} - 1 \) and equidistribution in 623 consecutive dimensions (over the whole period). The 'seed' is a 624-dimensional set of 32-bit integers plus a current position in that set.

"Knuth-TAOCP-2802": A 32-bit integer GFSR using lagged Fibonacci sequences with subtraction. That is, the recurrence used is

\[
X_j = (X_{j-100} - X_{j-37}) \mod 2^{30}
\]

and the 'seed' is the set of the 100 last numbers (actually recorded as 101 numbers, the last being a cyclic shift of the buffer). The period is around \( 2^{129} \).

The 2002 version was not backwards compatible with the earlier version: the initialization of the GFSR from the seed was altered. R did not allow you to choose consecutive seeds, the reported 'weakness', and already scrambled the seeds.

Initialization of this generator is done in interpreted R code and so takes a short but noticeable time.

"L'Ecuyer-CMRG": A ‘combined multiple-recursive generator’ from L’Ecuyer (1999), each element of which is a feedback multiplicative generator with three integer elements: thus the seed is a (signed) integer vector of length 6. The period is around \( 2^{191} \).

The 6 elements of the seed are internally regarded as 32-bit unsigned integers. Neither the first three nor the last three should be all zero, and they are limited to less than 4294967087 and 4294944443 respectively.

This is not particularly interesting of itself, but provides the basis for the multiple streams used in package parallel.

"user-supplied": Use a user-supplied generator. See Random.user for details.
normal.kind can be "Kinderman-Ramage", "Buggy Kinderman-Ramage" (not for set.seed), "Ahrens-Dieter", "Box-Muller", "Inversion" (the default), or "user-supplied". (For inversion, see the reference in qnorm.) The Kinderman-Ramage generator used in versions prior to 1.7.1 (now called "Buggy") had several approximation errors and should only be used for reproduction of old results. The "Box-Muller" generator is stateful as pairs of normals are generated and returned sequentially. The state is reset whenever it is selected (even if it is the current normal generator) and when kind is changed.

set.seed uses a single integer argument to set as many seeds as are required. It is intended as a simple way to get quite different seeds by specifying small integer arguments, and also as a way to get valid seed sets for the more complicated methods (especially "Mersenne-Twister" and "Knuth-TAOCP"). There is no guarantee that different values of seed will seed the RNG differently, although any exceptions would be extremely rare. If called with seed == NULL it re-initializes (see ‘Note’) as if no seed had yet been set.

The use of kind = NULL or normal.kind = NULL in RNGkind or set.seed selects the currently-used generator (including that used in the previous session if the workspace has been restored): if no generator has been used it selects "default".

**Value**

set.seed is an integer vector whose first element codes the kind of RNG and normal generator. The lowest two decimal digits are in 0: (k-1) where k is the number of available RNGs. The hundreds represent the type of normal generator (starting at 0).

In the underlying C, .Random.seed[-1] is unsigned; therefore in R, .Random.seed[-1] can be negative, due to the representation of an unsigned integer by a signed integer.

RNGkind returns a two-element character vector of the RNG and normal kinds selected before the call, invisibly if either argument is not NULL. A type starts a session as the default, and is selected either by a call to RNGkind or by setting .Random.seed in the workspace.

RNGversion returns the same information as RNGkind about the defaults in a specific R version.

set.seed returns NULL, invisibly.

**Note**

Initially, there is no seed; a new one is created from the current time (and since R 2.14.0, the process ID) when one is required. Hence different sessions will give different simulation results, by default. However, the seed might be restored from a previous session if a previously saved workspace is restored.

.Random.seed saves the seed set for the uniform random-number generator, at least for the system generators. It does not necessarily save the state of other generators, and in particular does not save the state of the Box--Muller normal generator. If you want to reproduce work later, call set.seed (preferably with explicit values for kind and normal.kind) rather than set.Random.seed.

The object .Random.seed is only looked for in the user’s workspace.

Do not rely on randomness of low-order bits from RNGs. Most of the supplied uniform generators return 32-bit integer values that are converted to doubles, so they take at most 2^{32} distinct values and long runs will return duplicated values (Wichmann-Hill is the exception, and all give at least 30 varying bits.)

sample for random sampling with and without replacement.

Distributions for functions for random-variate generation from standard distributions.

Examples

```r
require(stats)

## the default random seed is 626 integers, so only print a few
runif(1); .Random.seed[1:6]; runif(1); .Random.seed[1:6]
## If there is no seed, a "random" new one is created:
rm(.Random.seed); runif(1); .Random.seed[1:6]

ok <- RNGkind()
RNGkind(" Wich") # (partial string matching on 'kind')

## This shows how 'runif(.)' works for Wichmann-Hill,
## using only R functions:
```
Description

Function `RNGkind` allows user-coded uniform and normal random number generators to be supplied. The details are given here.

Details

A user-specified uniform RNG is called from entry points in dynamically-loaded compiled code. The user must supply the entry point `user_unif_rand`, which takes no arguments and returns a pointer to a double. The example below will show the general pattern.

Optionally, the user can supply the entry point `user_unif_init`, which is called with an unsigned int argument when `RNGkind` (or `set.seed`) is called, and is intended to be used to initialize the user’s RNG code. The argument is intended to be used to set the ‘seeds’; it is the seed argument to `set.seed` or an essentially random seed if `RNGkind` is called.

If only these functions are supplied, no information about the generator’s state is recorded in `.Random.seed`. Optionally, functions `user_unif_nseed` and `user_unif_seedloc` can be supplied which are called with no arguments and should return pointers to the number of seeds and to an integer (specifically, ‘Int32’) array of seeds. Calls to `GetRNGstate` and `PutRNGstate` will then copy this array to and from `.Random.seed`.

A user-specified normal RNG is specified by a single entry point `user_norm_rand`, which takes no arguments and returns a pointer to a double.
Warning

As with all compiled code, mis-specifying these functions can crash R. Do include the ‘R_ext/Random.h’ header file for type checking.

Examples

```c
static int32 seed;
static double res;
static int nseed = 1;

double * user_unif_rand()
{
    seed = 69069 * seed + 1;
    res = seed * 2.32830643653869e-10;
    return &res;
}

void user_unif_init(Int32 seed_in) { seed = seed_in; }
int * user_unif_nseed() { return &nseed; }
int * user_unif_seedloc() { return (int *) &seed; }

/* ratio-of-uniforms for normal */
#include <math.h>
static double x;

double * user_norm_rand()
{
    double u, v, z;
    do {
        u = unif_rand();
        v = 0.057764 * (2. * unif_rand() - 1);
        x = v/u; z = 0.25 * x * x;
        if (z < 1. - u) break;
        if (z > 0.259/u + 0.35) continue;
    } while (z > -log(u));
    return &x;
}
```

## Use under Unix:

R CMD SHLIB urand.c
c

dyn.load("urand.so")
RNGkind("user")
runif(10)
Random.seed
RNGkind(, "user")
rnorm(10)
RNGkind()
[1] "user-supplied" "user-supplied"

## End(Not run)
**range**

**Range of Values**

**Description**

`range` returns a vector containing the minimum and maximum of all the given arguments.

**Usage**

```
range(..., na.rm = FALSE)
```

```r
## Default S3 method:
range(..., na.rm = FALSE, finite = FALSE)
```

**Arguments**

- `...` : any numeric or character objects.
- `na.rm` : logical, indicating if NA’s should be omitted.
- `finite` : logical, indicating if all non-finite elements should be omitted.

**Details**

`range` is a generic function: methods can be defined for it directly or via the `Summary` group generic. For this to work properly, the arguments `...` should be unnamed, and dispatch is on the first argument.

If `na.rm` is `FALSE`, NA and NaN values in any of the arguments will cause NA values to be returned, otherwise NA values are ignored.

If `finite` is `TRUE`, the minimum and maximum of all finite values is computed, i.e., `finite = TRUE` includes `na.rm = TRUE`.

A special situation occurs when there is no (after omission of NAs) nonempty argument left, see `min`.

**S4 methods**

This is part of the S4 `Summary` group generic. Methods for it must use the signature `x, ..., na.rm`.

**References**

**See Also**

`min`, `max`.

The `extendrange()` utility in package `grDevices`. 
**rank**

**Examples**

```r
(r.x <- range(stats::rnorm(100)))

diff(r.x) # the SAMPLE range

x <- c(NA, 1:3, -1:1/0); x
range(x)
range(x, na.rm = TRUE)
range(x, finite = TRUE)
```

<table>
<thead>
<tr>
<th>rank</th>
<th>Sample Ranks</th>
</tr>
</thead>
</table>

**Description**

Returns the sample ranks of the values in a vector. Ties (i.e., equal values) and missing values can be handled in several ways.

**Usage**

```r
rank(x, na.last = TRUE,
     ties.method = c("average", "first", "random", "max", "min"))
```

**Arguments**

- `x`: a numeric, complex, character or logical vector.
- `na.last`: for controlling the treatment of `NA`s. If TRUE, missing values in the data are put last; if FALSE, they are put first; if NA, they are removed; if "keep" they are kept with rank NA.
- `ties.method`: a character string specifying how ties are treated, see 'Details'; can be abbreviated.

**Details**

If all components are different (and no NAs), the ranks are well defined, with values in `seq_len(x)`. With some values equal (called 'ties'), the argument `ties.method` determines the result at the corresponding indices. The "first" method results in a permutation with increasing values at each index set of ties. The "random" method puts these in random order whereas the default, "average", replaces them by their mean, and "max" and "min" replaces them by their maximum and minimum respectively, the latter being the typical sports ranking.

NA values are never considered to be equal: for `na.last = TRUE` and `na.last = FALSE` they are given distinct ranks in the order in which they occur in x.

NB: rank is not itself generic but `xtfrm` is, and `rank(xtfrm(x), ....)` will have the desired result if there is a `xtfrm` method. Otherwise, `rank` will make use of `==`, `>`, `is.na` and extraction methods for classed objects, possibly rather slowly.

**Value**

A numeric vector of the same length as `x` with names copied from `x` (unless `na.last = NA`, when missing values are removed). The vector is of integer type unless `x` is a long vector or `ties.method = "average"` when it is of double type (whether or not there are any ties).
rapply

Recursively Apply a Function to a List

Description

rapply is a recursive version of lapply.

Usage

rapply(object, f, classes = "ANY", deflt = NULL,
how = c("unlist", "replace", "list"), ...)

Arguments

object A list.
f A function of a single argument.
classes A character vector of class names, or "ANY" to match any class.
deflt The default result (not used if how = "replace").
how A character string matching the three possibilities given: see 'Details'.
... additional arguments passed to the call to f.
Details

This function has two basic modes. If how = "replace", each element of the list which is not itself a list and has a class included in classes is replaced by the result of applying f to the element.

If the mode is how = "list" or how = "unlist", the list is copied, all non-list elements which have a class included in classes are replaced by the result of applying f to the element and all others are replaced by deflt. Finally, if how = "unlist", unlist(recursive = TRUE) is called on the result.

The semantics differ in detail from lapply: in particular the arguments are evaluated before calling the C code.

Value

If how = "unlist", a vector, otherwise a list of similar structure to object.

References

(rapply is only described briefly there.)

See Also

lapply, dendrapply.

Examples

```r
X <- list(list(a = pi, b = list(c = 1:1)), d = "a test")
rapply(X, function(x) x, how = "replace")
rapply(X, sqrt, classes = "numeric", how = "replace")
rapply(X, nchar, classes = "character",
       deflt = as.integer(NA), how = "list")
rapply(X, nchar, classes = "character",
       deflt = as.integer(NA), how = "unlist")
rapply(X, nchar, classes = "character", how = "unlist")
rapply(X, log, classes = "numeric", how = "replace", base = 2)
```

Description

Creates or tests for objects of type "raw".

Usage

```r
raw(length = 0)
as.raw(x)
is.raw(x)
```

Arguments

- `length` desired length.
- `x` object to be coerced.
Details

The raw type is intended to hold raw bytes. It is possible to extract subsequences of bytes, and to replace elements (but only by elements of a raw vector). The relational operators (see Comparison) work, as do the logical operators (see Logic) with a bitwise interpretation.

A raw vector is printed with each byte separately represented as a pair of hex digits. If you want to see a character representation (with escape sequences for non-printing characters) use rawToChar.

Coercion to raw treats the input values as representing small (decimal) integers, so the input is first coerced to integer, and then values which are outside the range [0 ... 255] or are NA are set to 0 (the null byte).

as.raw and is.raw are primitive functions.

Value

raw creates a raw vector of the specified length. Each element of the vector is equal to 0. Raw vectors are used to store fixed-length sequences of bytes.

as.raw attempts to coerce its argument to be of raw type. The (elementwise) answer will be 0 unless the coercion succeeds (or if the original value successfully coerces to 0).

is.raw returns true if and only if typeof(x) == "raw".

See Also

charToRaw, rawShift, etc.
& for bitwise operations on raw vectors.

Examples

```r
xx <- raw(2)
x[1] <- as.raw(40)    # NB, not just 40.
x[2] <- charToRaw("A")
xx

x <- "A test string"
y <- charToRaw(x)
is.vector(y)    # TRUE
rawToChar(y)
is.raw(x)
is.raw(y)

isASCII <- function(txt) all(charToRaw(txt) <= as.raw(127))
isASCII(x)    # true
isASCII("\x9c25.63")    # false (in Latin-1, this is an amount in UK pounds)
```

rawConnection

Raw Connections

Description

Input and output raw connections.
Usage

```
rawConnection(object, open = "r")
```

```
rawConnectionValue(con)
```

Arguments

- **object**: character or raw vector. A description of the connection. For an input this is an R raw vector object, and for an output connection the name for the connection.
- **open**: character. Any of the standard connection open modes.
- **con**: An output raw connection.

Details

An input raw connection is opened and the raw vector is copied at the time the connection object is created, and close destroys the copy.

An output raw connection is opened and creates an R raw vector internally. The raw vector can be retrieved via `rawConnectionValue`.

If a connection is open for both input and output the initial raw vector supplied is copied when the connections is open.

Value

For `rawConnection`, a connection object of class "rawConnection" which inherits from class "connection".

For `rawConnectionValue`, a raw vector.

Note

As output raw connections keep the internal raw vector up to date call-by-call, they are relatively expensive to use (although over-allocation is used), and it may be better to use an anonymous `file()` connection to collect output.

On (rare) platforms where `vsnprintf` does not return the needed length of output there is a 100,000 character limit on the length of line for output connections: longer lines will be truncated with a warning.

See Also

- `connections`, `showConnections`.

Examples

```
zz <- rawConnection(raw(0), "r+") # start with empty raw vector
writeBin(LETTERS, zz)
seek(zz, 0)
readlines(zz) # raw vector has embedded nuls
seek(zz, 0)
writeBin(letters[1:3], zz)
rawConnectionValue(zz)
close(zz)
```
rawConversion  

Convert to or from Raw Vectors

Description
Conversion and manipulation of objects of type "raw".

Usage

charToRaw(x)
rawToChar(x, multiple = FALSE)

rawShift(x, n)

rawToBits(x)
intToBits(x)
packBits(x, type = c("raw", "integer"))

Arguments
x object to be converted or shifted.
multiple logical: should the conversion be to a single character string or multiple individual characters?
n the number of bits to shift. Positive numbers shift right and negative numbers shift left: allowed values are \(-8 \ldots 8\).
type the result type.

Details
packBits accepts raw, integer or logical inputs, the last two without any NAs.

Value
charToRaw converts a length-one character string to raw bytes. It does so without taking into account any declared encoding (see Encoding).

rawToChar converts raw bytes either to a single character string or a character vector of single bytes (with "" for \(0\)). (Note that a single character string could contain embedded nuls; only trailing nuls are allowed and will be removed.) In either case it is possible to create a result which is invalid in a multibyte locale, e.g. one using UTF-8. Long vectors are allowed if multiple is true.

rawShift(x, n) shift the bits in \(x\) by \(n\) positions to the right, see the argument \(n\), above.

rawToBits returns a raw vector of 8 times the length of a raw vector with entries 0 or 1. intToBits returns a raw vector of 32 times the length of an integer vector with entries 0 or 1. (Non-integral numeric values are truncated to integers.) In both cases the unpacking is least-significant bit first.

packBits packs its input (using only the lowest bit for raw or integer vectors) least-significant bit first to a raw or integer vector.
RdUtils

Utilities for Processing Rd Files

Description

Utilities for converting files in R documentation (Rd) format to other formats or create indices from them, and for converting documentation in other formats to Rd format.

Usage

R CMD Rdconv [options] file
R CMD Rd2pdf [options] files

Arguments

file the path to a file to be processed.
files a list of file names specifying the R documentation sources to use, by either giving the paths to the files, or the path to a directory with the sources of a package.
options further options to control the processing, or for obtaining information about usage and version of the utility.
readBin

Transfer Binary Data To and From Connections

Description

Read binary data from a connection, or write binary data to a connection.

Usage

readBin(con, what, n = 1L, size = NA_integer_, signed = TRUE, endian = .Platform$endian)

writeBin(object, con, size = NA_integer_, endian = .Platform$endian, useBytes = FALSE)

Arguments

con A connection object or a character string naming a file or a raw vector.
what Either an object whose mode will give the mode of the vector to be read, or a character vector of length one describing the mode: one of "numeric", "double", "integer", "int", "logical", "complex", "character", "raw".
n integer. The (maximal) number of records to be read. You can use an overestimate here, but not too large as storage is reserved for n items.
size integer. The number of bytes per element in the byte stream. The default, NA_integer_, uses the natural size. Size changing is not supported for raw and complex vectors.
signed logical. Only used for integers of sizes 1 and 2, when it determines if the quantity on file should be regarded as a signed or unsigned integer.
endian The endian-ness ("big" or "little") of the target system for the file. Using "swap" will force swapping endian-ness.
object An R object to be written to the connection.
useBytes See writeLines.

See Also

The chapter “Processing Rd format” in the “Writing R Extensions” manual.
Details

These functions are intended to be used with binary-mode connections. If con is a character string, the functions call file to obtain a binary-mode file connection which is opened for the duration of the function call.

If the connection is open it is read/written from its current position. If it is not open, it is opened for the duration of the call in an appropriate mode (binary read or write) and then closed again. An open connection must be in binary mode.

If readBin is called with con a raw vector, the data in the vector is used as input. If writeBin is called with con a raw vector, it is just an indication that a raw vector should be returned.

If size is specified and not the natural size of the object, each element of the vector is coerced to an appropriate type before being written or as it is read. Possible sizes are 1, 2, 4 and possibly 8 for integer or logical vectors, and 4, 8 and possibly 12/16 for numeric vectors. (Note that coercion occurs as signed types except if signed = FALSE when reading integers of sizes 1 and 2.) Changing sizes is unlikely to preserve NAs, and the extended precision sizes are unlikely to be portable across platforms.

readBin and writeBin read and write C-style zero-terminated character strings. Input strings are limited to 10000 characters. readChar and writeChar can be used to read and write fixed-length strings. No check is made that the string is valid in the current locale.

Handling R’s missing and special (Inf, -Inf and NaN) values is discussed in the ‘R Data Import/Export’ manual.

Only $2^{31} - 1$ bytes can be written in a single call (and that is the maximum capacity of a raw vector).

Value

For readBin, a vector of appropriate mode and length the number of items read (which might be less than n).

For writeBin, a raw vector (if con is a raw vector) or invisibly NULL.

Note

Integer read/writes of size 8 will be available if either C type long is of size 8 bytes or C type long long exists and is of size 8 bytes.

Real read/writes of size sizeof(long double) (usually 12 or 16 bytes) will be available only if that type is available and different from double.

If readBin(what = character()) is used incorrectly on a file which does not contain C-style character strings, warnings (usually many) are given. From a file or connection, the input will be broken into pieces of length 10000 with any final part being discarded.

Using these functions on a text-mode connection may work but should not be mixed with text-mode access to the connection, especially if the connection was opened with an encoding argument.

See Also

The ‘R Data Import/Export’ manual.

readChar to read/write fixed-length strings.
connections, readLines, writeLines.

.Machine for the sizes of long, long long and long double.
Examples

```r
zz <- file("testbin", "wb")
writeBin(1:10, zz)
writeBin(pi, zz, endian = "swap")
writeBin(pi, zz, size = 4)
writeBin(pi^2, zz, size = 4, endian = "swap")
writeBin(pi*3L, zz)
writeBin("A test of a connection", zz)
z <- paste("A very long string", 1:100, collapse = " + ")
writeBin(z, zz)
if(.Machine$sizeof.long == 8 || .Machine$sizeof.longlong == 8)
  writeBin(as.integer(5*(1:10)), zz, size = 8)
if((z <- .Machine$sizeof.longdouble) > 8)
  writeBin((pi/3)^1:10, zz, size = s)
close(zz)

zz <- file("testbin", "rb")
readBin(zz, integer(), 4)
readBin(zz, integer(), 6)
readBin(zz, numeric(), 1, endian = "swap")
readBin(zz, numeric(), size = 4)
readBin(zz, numeric(), size = 4, endian = "swap")
readBin(zz, complex(), 1)
readBin(zz, character(), 1)
z2 <- readBin(zz, character(), 1)
if(.Machine$sizeof.long == 8 || .Machine$sizeof.longlong == 8)
  readBin(zz, integer(), 10, size = 8)
if((z <- .Machine$sizeof.longdouble) > 8)
  readBin(zz, numeric(), 10, size = s)
close(zz)
unlink("testbin")
stopifnot(z2 == z)

## signed vs unsigned ints
zz <- file("testbin", "wb")
x <- as.integer(seq(0, 255, 32))
writeBin(x, zz, size = 1)
writeBin(x, zz, size = 1)
x <- as.integer(seq(0, 60000, 10000))
writeBin(x, zz, size = 2)
writeBin(x, zz, size = 2)
close(zz)
zz <- file("testbin", "rb")
readBin(zz, integer(), 8, size = 1)
readBin(zz, integer(), 8, size = 1, signed = FALSE)
readBin(zz, integer(), 7, size = 2)
readBin(zz, integer(), 7, size = 2, signed = FALSE)
close(zz)
unlink("testbin")

## use of raw
z <- writeBin(pi^1:5, raw(), size = 4)
readBin(z, numeric(), 5, size = 4)
z <- writeBin(c("a", "test", "of", "character"), raw())
readBin(z, character(), 4)
```
**readChar**

Transfer Character Strings To and From Connections

**Description**

Transfer character strings to and from connections, without assuming they are null-terminated on the connection.

**Usage**

```r
readChar(con, nchars, useBytes = FALSE)
writeChar(object, con, nchars = nchar(object, type = "chars"),
          eos = "", useBytes = FALSE)
```

**Arguments**

- `con`: A connection object, or a character string naming a file, or a raw vector.
- `nchars`: integer vector, giving the lengths in characters of (unterminated) character strings to be read or written. Elements must be >= 0 and not NA.
- `useBytes`: logical: For `readChar`, should `nchars` be regarded as a number of bytes not characters in a multi-byte locale? For `writeChar`, see `writelines`.
- `object`: A character vector to be written to the connection, at least as long as `nchars`.
- `eos`: 'end of string': character string. The terminator to be written after each string, followed by an ASCII null; use NULL for no terminator at all.

**Details**

These functions complement `readBin` and `writeBin` which read and write C-style zero-terminated character strings. They are for strings of known length, and can optionally write an end-of-string mark. They are intended only for character strings valid in the current locale.

These functions are intended to be used with binary-mode connections. If `con` is a character string, the functions call `file` to obtain a binary-mode file connection which is opened for the duration of the function call.

If the connection is open it is read/written from its current position. If it is not open, it is opened for the duration of the call in an appropriate mode (binary read or write) and then closed again. An open connection must be in binary mode.

If `readChar` is called with `con` a raw vector, the data in the vector is used as input. If `writeChar` is called with `con` a raw vector, it is just an indication that a raw vector should be returned.

Character strings containing ASCII null(s) will be read correctly by `readChar` but truncated at the first null with a warning.

If the character length requested for `readChar` is longer than the data available on the connection, what is available is returned. For `writeChar` if too many characters are requested the output is zero-padded, with a warning.

Missing strings are written as NA.
Value

For `readChar`, a character vector of length the number of items read (which might be less than `length(nchars)`).

For `writeChar`, a raw vector (if `con` is a raw vector) or invisibly `NULL`.

Note

Earlier versions of R allowed embedded null bytes within character strings, but not R >= 2.8.0. `readChar` was commonly used to read fixed-size zero-padded byte fields for which `readBin` was unsuitable. `readChar` can still be used for such fields if there are no embedded nulls: otherwise `readBin(what = "raw")` provides an alternative.

`nchars` will be interpreted in bytes not characters in a non-UTF-8 multi-byte locale, with a warning.

There is little validity checking of UTF-8 reads.

Using these functions on a text-mode connection may work but should not be mixed with text-mode access to the connection, especially if the connection was opened with an encoding argument.

See Also

The ‘R Data Import/Export’ manual.

`connections`, `readLines`, `writeLines`, `readBin`  

Examples

```r
## test fixed-length strings
zz <- file("testchar", "wb")
x <- c("a", "this will be truncated", "abc")
nc <- c(3, 10, 3)
writeChar(x, zz, nc, eos = NULL)
writeChar(x, zz, eos = "\n")
close(zz)

zz <- file("testchar", "rb")
readChar(zz, nc)
readChar(zz, nchar(x)+3) # need to read the terminator explicitly
close(zz)
unlink("testchar")
```

**readline**

Read a Line from the Terminal

Description

`readline` reads a line from the terminal (in interactive use).

Usage

`readline(prompt = "")`

Arguments

`prompt` the string printed when prompting the user for input. Should usually end with a space " ".

Details

The prompt string will be truncated to a maximum allowed length, normally 256 chars (but can be changed in the source code).
This can only be used in an interactive session.

Value

A character vector of length one. Both leading and trailing spaces and tabs are stripped from the result.
In non-interactive use the result is as if the response was RETURN and the value is "".

See Also

readLines for reading text lines from connections, including files.

Examples

```r
fun <- function() {
  ANSWER <- readline("Are you a satisfied R user? ")
  # a better version would check the answer less cursorily, and
  # perhaps re-prompt
  if (substr(ANSWER, 1, 1) == "n")
    cat("This is impossible. YOU LIED!
"
  else
    cat("I knew it.
"
}
if(interactive()) fun()
```

readLines

Read Text Lines from a Connection

Description

Read some or all text lines from a connection.

Usage

```r
readLines(con = stdin(), n = -1L, ok = TRUE, warn = TRUE,
encoding = "unknown")
```

Arguments

- `con` a connection object or a character string.
- `n` integer. The (maximal) number of lines to read. Negative values indicate that one should read up to the end of input on the connection.
- `ok` logical. Is it OK to reach the end of the connection before `n > 0` lines are read? If not, an error will be generated.
- `warn` logical. Warn if a text file is missing a final EOL.
- `encoding` encoding to be assumed for input strings. It is used to mark character strings as known to be in Latin-1 or UTF-8: it is not used to re-encode the input. To do the latter, specify the encoding as part of the connection `con` or via `options(encoding=)`: see the example under file.
Details

If the con is a character string, the function calls file to obtain a file connection which is opened for the duration of the function call. This can be a compressed file.

If the connection is open it is read from its current position. If it is not open, it is opened in "rt" mode for the duration of the call and then closed again.

If the final line is incomplete (no final EOL marker) the behaviour depends on whether the connection is blocking or not. For a non-blocking text-mode connection the incomplete line is pushed back, silently. For all other connections the line will be accepted, with a warning.

Whatever mode the connection is opened in, any of LF, CRLF or CR will be accepted as the EOL marker for a line.

If con is a not-already-open connection with a non-default encoding argument, the text is converted to UTF-8 and declared as such (and the encoding argument to readLines is ignored). See the examples.

Value

A character vector of length the number of lines read.

The elements of the result have a declared encoding if encoding is "latin1" or "UTF-8".

Note

The default connection, stdin, may be different from con = "stdin": see file.

See Also

connections, writeLines, readBin, scan

Examples

cat("TITLE extra line", "2 3 5 7", ",", "11 13 17", file = "ex.data", sep = "\n")
readlines("ex.data", n = -1)
unlink("ex.data") # tidy up

## difference in blocking

cat("123\nabc", file = "test")
readlines("test") # line with a warning

con <- file("test", "r", blocking = FALSE)
readlines(con) # empty

cat(" def\n", file = "test!", append = TRUE)
readlines(con) # gets both
close(con)

unlink("test") # tidy up

## Not run:
# read a 'Windows Unicode' file
A <- readlines(file("Unicode.txt", encoding = "UCS-2LE"))
unique(Encoding(A)) # will most likely be UTF-8

## End(Not run)
Description

Functions to write a single \texttt{R} object to a file, and to restore it.

Usage

\begin{verbatim}
saveRDS(object, file = "", ascii = FALSE, version = NULL, 
        compress = TRUE, refhook = NULL)
\end{verbatim}

\begin{verbatim}
readRDS(file, refhook = NULL)
\end{verbatim}

Arguments

- \texttt{object} \texttt{R} object to serialize.
- \texttt{file} a \texttt{connection} or the name of the file where the \texttt{R} object is saved to or read from.
- \texttt{ascii} a logical. If \texttt{TRUE}, an ASCII representation is written; otherwise (default except for text-mode connections), a binary one is used. See the comments in the help for \texttt{save}.
- \texttt{version} the workspace format version to use. \texttt{NULL} specifies the current default version (2). Versions prior to 2 are not supported, so this will only be relevant when there are later versions.
- \texttt{compress} a logical specifying whether saving to a named file is to use "gzip" compression, or one of "gzip", "bzip2" or "xz" to indicate the type of compression to be used. Ignored if \texttt{file} is a connection.
- \texttt{refhook} a hook function for handling reference objects.

Details

These functions provide the means to save a single \texttt{R} object to a connection (typically a file) and to restore the object, quite possibly under a different name. This differs from \texttt{save} and \texttt{load}, which save and restore one or more named objects into an environment. They are widely used by \texttt{R} itself, for example to store metadata for a package and to store the \texttt{help.search} databases: the ".rds" file extension is most often used.

Functions \texttt{serialize} and \texttt{unserialize} provide a slightly lower-level interface to serialization: objects serialized to a connection by \texttt{serialize} can be read back by \texttt{readRDS} and conversely.

All of these interfaces use the same serialization format, which has been used since \texttt{R} 1.4.0 (but extended from time to time as new object types have been added to \texttt{R}). However, \texttt{save} writes a single line header (typically \texttt{"RDS\n"}) before the serialization of a single object (a pairlist of all the objects to be saved).

Compression is handled by the connection opened when \texttt{file} is a file name, so is only possible when \texttt{file} is a connection if handled by the connection. So e.g. \texttt{url} connections will needed to be wrapped in a call to \texttt{gzcon}.

If a connection is supplied it will be opened (in binary mode) for the duration of the function if not already open: if it is already open it must be in binary mode for \texttt{saveRDS(ascii = FALSE)} (the default).
Value

For `readRDS`, an `R` object.
For `saveRDS`, `NULL` invisibly.

See Also

`serialize`, `save` and `load`.

The ‘`R Internals’` manual for details of the format used.

Examples

```r
## save a single object to file
saveRDS(women, "women.rds")
## restore it under a different name
women2 <- readRDS("women.rds")
identical(women, women2)
## or examine the object via a connection, which will be opened as needed.
con <- gzfile("women.rds")
str(readRDS(con))
close(con)

## Less convenient ways to restore the object
## which demonstrate compatibility with unserialize()
con <- gzfile("women.rds", "rb")
identical(unserialize(con), women)
close(con)
con <- gzfile("women.rds", "rb")
wm <- readBin(con, "raw", n = 1e4) # size is a guess
close(con)
identical(unserialize(wm), women)

## Format compatibility with serialize():
con <- file("women2", "w")
serialize(women, con) # ASCII, uncompressed
close(con)
identical(women, readRDS("women2"))
con <- bzfie("women3", "w")
serialize(women, con) # binary, bzip2-compressed
close(con)
identical(women, readRDS("women2"))
```

---

### readRenviror

**Set Environment Variables from a File**

**Description**

Read as file such as `.Renviron` or `Renviron.site` in the format described in the help for `Startup`, and set environment variables as defined in the file.
Recall

Usage

\texttt{readRenviron(path)}

Arguments

\texttt{path} \hspace{1cm} \text{A length-one character vector giving the path to the file. Tilde-expansion is performed where supported.}

Value

Scalar logical indicating if the file was read successfully. Returned invisibly. If the file cannot be opened for reading, a warning is given.

See Also

\texttt{Startup} for the file format.

Examples

\begin{verbatim}
## Not run:
## re-read a startup file (or read it in a vanilla session)
readRenviron("~/\.Renviron")

## End(Not run)
\end{verbatim}

---

### Recursive Calling

**Description**

Recall is used as a placeholder for the name of the function in which it is called. It allows the definition of recursive functions which still work after being renamed, see example below.

**Usage**

\texttt{Recall(...)}

**Arguments**

\texttt{...} \hspace{1cm} \text{all the arguments to be passed.}

**Note**

Recall will not work correctly when passed as a function argument, e.g. to the apply family of functions.

**See Also**

\texttt{do.call} and \texttt{call}.

\texttt{local} for another way to write anonymous recursive functions.
Examples

```r
## A trivial (but inefficient!) example:
fib <- function(n)
  if(n<=2) { if(n>=0) 1 else 0 } else Recall(n-1) + Recall(n-2)
fibonacci <- fib; rm(fib)
## renaming wouldn't work without Recall
fibonacci(10) # 55
```

---

**reg.finalizer**  
*Finalization of Objects*

**Description**

Registers an \texttt{R} function to be called upon garbage collection of object or (optionally) at the end of an \texttt{R} session.

**Usage**

```r
reg.finalizer(e, f, onexit = FALSE)
```

**Arguments**

- \textbf{e}  
  Object to finalize. Must be an environment or an external pointer.

- \textbf{f}  
  Function to call on finalization. Must accept a single argument, which will be the object to finalize.

- \textbf{onexit}  
  logical: should the finalizer be run if the object is still uncollected at the end of the \texttt{R} session?

**Value**

`NULL`.

**Note**

The purpose of this function is mainly to allow objects that refer to external items (a temporary file, say) to perform cleanup actions when they are no longer referenced from within \texttt{R}. This only makes sense for objects that are never copied on assignment, hence the restriction to environments and external pointers.

**See Also**

- \texttt{gc} and \texttt{Memory} for garbage collection and memory management.

**Examples**

```r
f <- function(e) print("cleaning....")
g <- function(x){ e <- environment(); reg.finalizer(e, f) }
g()
invisible(gc()) # trigger cleanup
```
Regular Expressions as used in R

Description

This help page documents the regular expression patterns supported by grep and related functions grepl, regexpr, gregexpr, sub and gsub, as well as by strsplit.

Details

A ‘regular expression’ is a pattern that describes a set of strings. Two types of regular expressions are used in R, extended regular expressions (the default) and Perl-like regular expressions used by perl = TRUE. There is also fixed = TRUE which can be considered to use a literal regular expression.

Other functions which use regular expressions (often via the use of grep) include apropos, browseEnv, help.search, list.files and ls. These will all use extended regular expressions.

Patterns are described here as they would be printed by cat: (do remember that backslashes need to be doubled when entering R character strings, e.g. from the keyboard).

Do not assume that long regular expressions will be accepted: the POSIX standard only requires up to 256 bytes.

Extended Regular Expressions

This section covers the regular expressions allowed in the default mode of grep, regexpr, gregexpr, sub, gsub and strsplit. They use an implementation of the POSIX 1003.2 standard: that allows some scope for interpretation and the interpretations here are those used as from R 2.10.0.

Regular expressions are constructed analogously to arithmetic expressions, by using various operators to combine smaller expressions. The whole expression matches zero or more characters (read ‘character’ as ‘byte’ if useBytes = TRUE).

The fundamental building blocks are the regular expressions that match a single character. Most characters, including all letters and digits, are regular expressions that match themselves. Any metacharacter with special meaning may be quoted by preceding it with a backslash. The metacharacters in EREs are ‘.’, \ | ( ) [ { ^ $ * + ? , but note that whether these have a special meaning depends on the context.

Escaping non-metacharacters with a backslash is implementation-dependent. The current implementation interprets ‘\a’ as ‘BEL’, ‘\e’ as ‘ESC’, ‘\f’ as ‘FF’, ‘\n’ as ‘LF’, ‘\r’ as ‘CR’ and ‘\t’ as ‘TAB’. (Note that these will be interpreted by R’s parser in literal character strings.)

A character class is a list of characters enclosed between ‘[’ and ‘]’ which matches any single character in that list; unless the first character of the list is the caret ‘^’, when it matches any character not in the list. For example, the regular expression ‘[0123456789]’ matches any single digit, and ‘[^abc]’ matches anything except the characters ‘a’, ‘b’ or ‘c’. A range of characters may be specified by giving the first and last characters, separated by a hyphen. (Because their interpretation is locale- and implementation-dependent, they are best avoided.) The only portable way to specify all ASCII letters is to list them all as the character class ‘[ABCDEFGHIJKLMNOPQRSTUVWXYZabcdefghijklmnopqrstuvwxyz]’.

(From the current implementation uses numerical order of the encoding: prior to R 2.10.0 locale-specific collation was used, and might be again.)
Certain named classes of characters are predefined. Their interpretation depends on the *locale* (see *locales*); the interpretation below is that of the POSIX locale.

- `[:alnum:]` Alphanumeric characters: `[:alpha:]` and `[:digit:]`.
- `[:alpha:]` Alphabetic characters: `[:lower:]` and `[:upper:]`.
- `[:blank:]` Blank characters: space and tab, and possibly other locale-dependent characters such as non-breaking space.
- `[:cntrl:]` Control characters. In ASCII, these characters have octal codes 000 through 037, and 177 (DEL). In another character set, these are the equivalent characters, if any.
- `[:digit:]` Digits: '0 1 2 3 4 5 6 7 8 9'.
- `[:graph:]` Graphical characters: `[:alnum:]` and `[:punct:]`.
- `[:lower:]` Lower-case letters in the current locale.
- `[:print:]` Printable characters: `[:alnum:]` , `[:punct:]` and space.
- `[:punct:]` Punctuation characters:
  - `! " # $ % & ' ( ) * + , - . / : ; < = > ? [ \ ] ^ _ ` { } ~`.
- `[:space:]` Space characters: tab, newline, vertical tab, form feed, carriage return, space and possibly other locale-dependent characters.
- `[:upper:]` Upper-case letters in the current locale.
- `[:xdigit:]` Hexadecimal digits:
  - '0 1 2 3 4 5 6 7 8 9 A B C D E F a b c d e f'.

For example, `[:alnum:]` means `[0-9A-Za-z]`, except the latter depends upon the locale and the character encoding, whereas the former is independent of locale and character set. (Note that the brackets in these class names are part of the symbolic names, and must be included in addition to the brackets delimiting the bracket list.) Most metacharacters lose their special meaning inside a character class. To include a literal `]`, place it first in the list. Similarly, to include a literal `^`, place it anywhere but first. Finally, to include a literal `~`, place it first or last (or, for Perl = TRUE only, precede it by a backslash). (Only `^ ~ M | }` are special inside character classes.)

The period `.` matches any single character. The symbol `\w` matches a ‘word’ character (a synonym for `[:alnum:]`) and `\W` is its negation. Symbols `\d`, `\s`, `\D` and `\S` denote the digit and space classes and their negations.

The caret `^` and the dollar sign `$` are metacharacters that respectively match the empty string at the beginning and end of a line. The symbols `\c` and `\e` match the empty string at the beginning and end of a word. The symbol `\b` matches the empty string at either edge of a word, and `\B` matches the empty string provided it is not at an edge of a word. (The interpretation of ‘word’ depends on the locale and implementation.)

A regular expression may be followed by one of several repetition quantifiers:

- `?` The preceding item is optional and will be matched at most once.
- `*` The preceding item will be matched zero or more times.
- `+` The preceding item will be matched one or more times.
- `{n}` The preceding item is matched exactly n times.
- `{n,}` The preceding item is matched n or more times.
- `{n,m}` The preceding item is matched at least n times, but not more than m times.
By default repetition is greedy, so the maximal possible number of repeats is used. This can be changed to ‘minimal’ by appending ? to the quantifier. (There are further quantifiers that allow approximate matching: see the TRE documentation.)

Regular expressions may be concatenated; the resulting regular expression matches any string formed by concatenating the substrings that match the concatenated subexpressions.

Two regular expressions may be joined by the infix operator ‘|’; the resulting regular expression matches any string matching either subexpression. For example, ‘abba|cde’ matches either the string abba or the string cde. Note that alternation does not work inside character classes, where ‘|’ has its literal meaning.

Repetition takes precedence over concatenation, which in turn takes precedence over alternation. A whole subexpression may be enclosed in parentheses to override these precedence rules.

The backreference ‘\N’, where ‘N = 1 \ldots 9’, matches the substring previously matched by the Nth parenthesized subexpression of the regular expression. (This is an extension for extended regular expressions: POSIX defines them only for basic ones.)

Perl-like Regular Expressions

The perl = TRUE argument to grep, regexpr, gregexpr, sub, gsub and strsplit switches to the PCRE library that implements regular expression pattern matching using the same syntax and semantics as Perl 5.10, with just a few differences.

For complete details please consult the man pages for PCRE, especially man pcrepattern and man pcreapi, on your system or from the sources at http://www.pcre.org. If PCRE support was compiled from the sources within R, the PCRE version is 8.12 as described here.

Perl regular expressions can be computed byte-by-byte or (UTF-8) character-by-character: the latter is used in all multibyte locales and if any of the inputs are marked as UTF-8 (see Encoding).

All the regular expressions described for extended regular expressions are accepted except ‘|\’ and ‘|^’: in Perl all backslashd metacharacters are alphanumeric and backslashd symbols always are interpreted as a literal character. ‘{’ is not special if it would be the start of an invalid interval specification. There can be more than 9 backreferences (but the replacement in sub can only refer to the first 9).

Character ranges are interpreted in the numerical order of the characters, either as bytes in a single-byte locale or as Unicode points in UTF-8 mode. So in either case ‘[A-Za-z]’ specifies the set of ASCII letters.

In UTF-8 mode the named character classes only match ASCII characters: see ‘\p’ below for an alternative.

The construct ‘(?i)’ is used for Perl extensions in a variety of ways depending on what immediately follows the ‘?’.

Perl-like matching can work in several modes, set by the options ‘(?i)’ (caseless, equivalent to Perl’s ‘/i’), ‘(?m)’ (multiline, equivalent to Perl’s ‘/m’), ‘(?s)’ (single line, so a dot matches all characters, even new lines: equivalent to Perl’s ‘/s’)) and ‘(?x)’ (extended, whitespace data characters are ignored unless escaped and comments are allowed: equivalent to Perl’s ‘/x’). These can be concatenated, so for example, ‘(?i|m)’ sets caseless multiline matching. It is also possible to unset these options by preceding the letter with a hyphen, and to combine setting and unsetting such as ‘(?i|m=)’. These settings can be applied within patterns, and then apply to the remainder of the pattern. Additional options not in Perl include ‘(?U)’ to set ‘ungreedy’ mode (so matching is minimal unless ‘?’ is used as part of the repetition quantifier, when it is greedy). Initially none of these options are set.

If you want to remove the special meaning from a sequence of characters, you can do so by putting them between ‘\Q’ and ‘\E’. This is different from Perl in that ‘$’ and ‘@’ are handled as literals in ‘\Q...\E’ sequences in PCRE, whereas in Perl, ‘$’ and ‘@’ cause variable interpolation.
The escape sequences `\d`, `\s` and `\w` represent any decimal digit, space character and ‘word’ character (letter, digit or underscore in the current locale: in UTF-8 mode only ASCII letters and digits are considered) respectively, and their upper-case versions represent their negation. Unlike POSIX, vertical tab is not regarded as a space character. Sequences `\h`, `\v`, `\H` and `\V` match horizontal and vertical space or the negation. (In UTF-8 mode, these do match non-ASCII Unicode points.)

There are additional escape sequences: `\cx` is `cntrl-x` for any ‘x’, `\ddd` is the octal character (for up to three digits unless interpretable as a backreference, as `\1` to `\7` always are), and `\xhh` specifies a character by two hex digits. In a UTF-8 locale, `\x{h...}` specifies a Unicode point by one or more hex digits. (Note that some of these will be interpreted by R’s parser in literal character strings.)

Outside a character class, `\A` matches at the start of a subject (even in multiline mode, unlike `~`). `\Z` matches at the end of a subject or before a newline at the end, `\z` matches only at end of a subject, and `\G` matches at first matching position in a subject (which is subtly different from Perl’s end of the previous match). `\C` matches a single byte, including a newline, but its use is warned against. In UTF-8 mode, `\R` matches any Unicode newline character (not just CR), and `\X` matches any number of Unicode characters that form an extended Unicode sequence.

In UTF-8 mode, some Unicode properties are supported via `\p{xx}` and `\P{xx}` which match characters with and without property `xx` respectively. For a list of supported properties see the PCRE documentation, but for example `\u` is ‘upper case letter’ and `Sc` is ‘currency symbol’.

The sequence ‘(?#’ marks the start of a comment which continues up to the next closing parenthesis. Nested parentheses are not permitted. The characters that make up a comment play no part at all in the pattern matching.

If the extended option is set, an unescaped ‘#’ character outside a character class introduces a comment that continues up to the next newline character in the pattern.

The pattern ‘(?:...)' groups characters just as parentheses do but does not make a backreference. Patterns ‘(?=...)' and ‘(?!...)’ are zero-width positive and negative lookahead assertions: they match if an attempt to match the ... forward from the current position would succeed (or not), but use up no characters in the string being processed. Patterns ‘(?<=...)' and ‘(?<...)’ are the lookbehind equivalents: they do not allow repetition quantifiers nor ‘\C’ in ..... regexpr and gregexpr support ‘named capture’. If groups are named, e.g., "(?<first>[A-Z][a-z]+)" then the positions of the matches are also returned by name. (Named backreferences are not supported by sub.)

Atomic grouping, possessive qualifiers and conditional and recursive patterns are not covered here.

Extract or Replace Matched Substrings

Description

Extract or replace matched substrings from match data obtained by `regexp`, `gregexpr` or `regexec`.

Usage

\[
\text{regmatches}(x, m, \text{invert} = \text{FALSE}) \\
\text{regmatches}(x, m, \text{invert} = \text{FALSE}) \leftarrow \text{value}
\]

Arguments

- `x`: a character vector
- `m`: an object with match data
- `invert`: a logical: if `TRUE`, extract the non-matched substrings.
- `value`: an object with suitable replacement values for the matched or non-matched substrings (see Details).

Details

If `invert` is `TRUE` (default), `regmatches` extracts the matched substrings as specified by the match data. For vector match data (as obtained from `regexp`), empty matches are dropped; for list match data, empty matches give empty components (zero-length character vectors).

If `invert` is `FALSE`, `regmatches` extracts the non-matched substrings, i.e., the strings are split according to the matches similar to `strsplit` (for vector match data, at most a single split is performed).

Note that the match data can be obtained from regular expression matching on a modified version of `x` with the same numbers of characters.

The replacement function can be used for replacing the matched or non-matched substrings. For vector match data, if `invert` is `TRUE`, `value` should be a character vector with length the number of matched elements in `m`. Otherwise, it should be a list of character vectors with the same length as `m`, each as long as the number of replacements needed. Replacement coerces values to character or list and generously recycles values as needed. Missing replacement values are not allowed.

Value

For `regmatches`, a character vector with the matched substrings if `m` is a vector and `invert` is `FALSE`. Otherwise, a list with the matched or non-matched substrings.

For `regmatches<-`, the updated character vector.

Examples

\[
x \leftarrow \text{c}("A and B", "A, B and C", "A, B, C and D", "foo bar") \\
\text{pattern} \leftarrow "^[[:space:]]+([[:space:]]\|,)\|([[:space:]]\|,) stunning\$"
\]

## Match data from `regexp()`
\[
m \leftarrow \text{regexp(pattern, x)} \\
\text{regmatches}(x, m) \\
\text{regmatches}(x, m, \text{invert} = \text{TRUE})
\]
## Match data from gregexpr()

```r
m <- gregexpr(pattern, x)
regmatches(x, m)
regmatches(x, m, invert = TRUE)
```

## Consider

```r
x <- "John (fishing, hunting), Paul (hiking, biking)"
```

## Suppose we want to split at the comma (plus spaces) between the persons, but not at the commas in the parenthesized hobby lists.

## One idea is to "blank out" the parenthesized parts to match the parts to be used for splitting, and extract the persons as the non-matched parts.

## First, match the parenthesized hobby lists.

```r
m <- gregexpr("\([a-zA-Z, ]\)\", x)
```

## Write a little utility for creating blank strings with given numbers of characters.

```r
blanks <- function(n) {
  vapply(Map(rep.int, rep.int(" ", length(n)), n, USE.NAMES = FALSE),
         paste, "", collapse = "")
}
```

## Create a copy of x with the parenthesized parts blanked out.

```r
s <- x
regmatches(s, m) <- Map(blanks, sapply(regmatches(s, m), nchar))
```

## Compute the positions of the split matches (note that we cannot call `strsplit()` on x with match data from s).

```r
m <- gregexpr("\", s)
```

## And finally extract the non-matched parts.

```r
regmatches(x, m, invert = TRUE)
```

---

### remove

**Remove Objects from a Specified Environment**

### Description

`remove` and `rm` can be used to remove objects. These can be specified successively as character strings, or in the character vector `list`, or through a combination of both. All objects thus specified will be removed.

If `envir` is `NULL` then the currently active environment is searched first.

If `inherits` is `TRUE` then parents of the supplied directory are searched until a variable with the given name is encountered. A warning is printed for each variable that is not found.

### Usage

```r
remove(..., list = character(), pos = -1,
       envir = as.environment(pos), inherits = FALSE)
```

```r
rm (... , list = character(), pos = -1,
     envir = as.environment(pos), inherits = FALSE)
```
Arguments

... the objects to be removed, as names (unquoted) or character strings (quoted).
list a character vector naming objects to be removed.
pos where to do the removal. By default, uses the current environment. See ‘details’
for other possibilities.
envir the environment to use. See ‘details’.
inherits should the enclosing frames of the environment be inspected?

Details

The pos argument can specify the environment from which to remove the objects in any of several
ways: as an integer (the position in the search list); as the character string name of an element
in the search list; or as an environment (including using sys.frame to access the currently active
function calls). The envir argument is an alternative way to specify an environment, but is primarily
there for back compatibility.

It is not allowed to remove variables from the base environment and base namespace, nor from any
environment which is locked (see lockEnvironment).

Earlier versions of R incorrectly claimed that supplying a character vector in ... removed the
objects named in the character vector, but it removed the character vector. Use the list argument
to specify objects via a character vector.

See Also

ls, objects

Examples

tmp <- 1:4
## work with tmp and cleanup
rm(tmp)

## Not run:
## remove (almost) everything in the working environment.
## You will get no warning, so don’t do this unless you are really sure.
rm(list = ls())

## End(Not run)
Description

`rep` replicates the values in `x`. It is a generic function, and the (internal) default method is described here.

`rep.int` and `rep.len` are faster simplified versions for two common cases. They are not generic.

Usage

```r
rep(x, ...)  # generic
rep.int(x, times)
rep.len(x, length.out)
```

Arguments

- `x` a vector (of any mode including a list) or a factor (for `rep` only) or a POSIXct or POSIXlt or Date object; or an S4 object containing such an object.
- `...` further arguments to be passed to or from other methods. For the internal default method these can include:
  - `times` A integer vector giving the (non-negative) number of times to repeat each element if of length `length(x)`, or to repeat the whole vector if of length 1. Negative or NA values are an error.
  - `length.out` non-negative integer. The desired length of the output vector. Other inputs will be coerced to an integer vector and the first element taken. Ignored if NA or invalid.
  - `each` non-negative integer. Each element of `x` is repeated each times. Other inputs will be coerced to an integer vector and the first element taken. Treated as 1 if NA or invalid.

- `times` see `...`
- `length.out` non-negative integer: the desired length of the output vector.

Details

The default behaviour is as if the call was

```r
rep(x, times = 1, length.out = NA, each = 1)
```

Normally just one of the additional arguments is specified, but if `each` is specified with either of the other two, its replication is performed first, and then that implied by `times` or `length.out`.

If `times` consists of a single integer, the result consists of the whole input repeated this many times. If `times` is a vector of the same length as `x` (after replication by `each`), the result consists of `x[1]` repeated `times[1]` times, `x[2]` repeated `times[2]` times and so on.

`length.out` may be given in place of `times`, in which case `x` is repeated as many times as is necessary to create a vector of this length. If both are given, `length.out` takes priority and `times` is ignored.
Non-integer values of `times` will be truncated towards zero. If `times` is a computed quantity it is prudent to add a small fuzz.

If `x` has length zero and `length.out` is supplied and is positive, the values are filled in using the extraction rules, that is by an NA of the appropriate class for an atomic vector (0 for raw vectors) and NULL for a list.

**Value**

An object of the same type as `x`.

`rep.int` and `rep_len` return no attributes (except the class if returning a factor).

The default method of `rep` gives the result names (which will almost always contain duplicates) if `x` had names, but retains no other attributes.

**Note**

Function `rep.int` is a simple case handled by internal code, and provided as a separate function partly for S compatibility and partly for speed (especially when names can be dropped).

Function `rep` is a primitive, but (partial) matching of argument names is performed as for normal functions. You can no longer pass a missing argument to e.g. `length.out`.

For historical reasons `rep` works on NULL: the result is always NULL even when `length.out` is positive.

Although it has never been documented, these functions have always worked on expression vectors. R 2.x.y accepted pairlists and some other objects (although the results were rarely what their users intended).

**References**

**See Also**

`seq`, `sequence`, `replicate`.

**Examples**

```r
rep(1:4, 2)
rep(1:4, each = 2)  # not the same.
rep(1:4, c(2,2,2,2))  # same as second.
rep(1:4, c(2,1,2,1))
rep(1:4, each = 2, len = 4)  # first 4 only.
rep(1:4, each = 2, len = 10)  # 8 integers plus two recycled 1's.
rep(1:4, each = 2, times = 3)  # length 24, 3 complete replications

rep(1, 40*1:10)  # length 7 on most platforms
rep(1, 40*1:10+1e-7)  # better

## replicate a list
fred <- list(happy = 1:10, name = "squash")
rep(fred, 5)

# date-time objects
x <- .leap.seconds[1:3]
```
```
rep(x, 2)
rep(as.POSIXlt(x), rep(2, 3))

## named factor
x <- factor(LETTERS[1:4]); names(x) <- letters[1:4]
x
rep(x, 2)
rep(x, each = 2)
rep.int(x, 2)  # no names
rep_len(x, 10)
```

---

**replace**

*Replace Values in a Vector*

**Description**

`replace` replaces the values in `x` with indices given in `list` by those given in `values`. If necessary, the values in `values` are recycled.

**Usage**

```r
replace(x, list, values)
```

**Arguments**

- `x` vector
- `list` an index vector
- `values` replacement values

**Value**

A vector with the values replaced.

**Note**

`x` is unchanged: remember to assign the result.

**References**

Reserved Words in R

Description
The reserved words in R’s parser are

```r
if else repeat while function for in next break
TRUE FALSE NULL Inf NaN NA_integer_ NA_real_ NA_complex_ NA_character_
... and .1, .2 etc, which are used to refer to arguments passed down from a calling function. See the ‘Introduction to R’ manual for usage of these syntactic elements, and dotsMethods for their use in formal methods.
```

Details
Reserved words outside quotes are always parsed to be references to the objects linked to in the ‘Description’, and hence they are not allowed as syntactic names (see make.names). They are allowed as non-syntactic names, e.g. inside backtick quotes.

rev
Reverse Elements

Description

`rev` provides a reversed version of its argument. It is a generic function with a default method for vectors and one for dendrograms.

Note that this is no longer needed (nor efficient) for obtaining vectors sorted into descending order, since that is now rather more directly achievable by `sort(x, decreasing = TRUE)`.

Usage

```r
rev(x)
```

Arguments

`x` a vector or another object for which reversal is defined.

References

See Also

`seq`, `sort`.

Examples

```r
x <- c(1:5, 5:3)
# sort into descending order; first more efficiently:
stopifnot(sort(x, decreasing = TRUE) == rev(sort(x)))
stopifnot(rev(1:7) == 7:1)  # don’t need ‘rev’ here
```
**Rhome**

Return the R Home Directory

**Description**

Return the R home directory.

**Usage**

```r
R.home(component = "home")
```

**Arguments**

- `component`
  - As well as "home" which gives the R home directory, other known values are "bin", "doc", "etc", "modules" and "share" giving the paths to the corresponding parts of an R installation.

**Details**

The R home directory is the top-level directory of the R installation being run.

The R home directory is often referred to as 
*R_HOME*, and is the value of an environment variable of that name in an R session. It can be found outside an R session by `R_HOME`.

**Value**

A character string giving the R home directory or path to a particular component. Normally the components are all subdirectories of the R home directory, but this may not be the case in a Unix-like installation.

The return value for "modules" and on Windows "bin" is to a sub-architecture-specific location.

The function `R.home()` bases the constructed paths on the current value of the environment variable `R_HOME` which is normally set on startup.

On Windows the values of `R.home()` and `R_HOME` are guaranteed not to contain spaces, switching to the 8.3 short form of path elements if required. From R 2.13.0 the value of `R_HOME` is set on startup to use forward slashes (since many package maintainers pass it unquoted to shells, for example in Makefiles).

---

**rle**

Run Length Encoding

**Description**

Compute the lengths and values of runs of equal values in a vector – or the reverse operation.

**Usage**

```r
rle(x)
inverse.rle(x, ...)
```

```r
## S3 method for class 'rle'
print(x, digits = getOption("digits"), prefix = "", ...)```

Arguments

x an atomic vector for rle(): an object of class "rle" for inverse.rle().
...
进一步的参数；此处忽略。
digits 数字为显著位数用于打印。参见 print.default.
prefix 字符串，前缀到每个打印行。

Details

没有值被视为与前一个值不等，即使那个值也是缺失的。
inverse.rle() 是 rle() 的逆函数，从运行重建 x。

Value

rle() 返回一个类为 "rle" 的对象，该对象是一个包含组件的列表：
lengths 一个整数向量，包含每个运行的长度。
values 一个与 lengths 相同长度的向量，包含相应的值。
inverse.rle() 返回一个原子向量。

Examples

x <- rev(rep(6:10, 1:5))
rle(x)
## lengths [1:5] 5 4 3 2 1
## values [1:5] 10 9 8 7 6

z <- c(TRUE, TRUE, FALSE, FALSE, TRUE, FALSE, TRUE, TRUE, TRUE)
　rle(z)
　rle(as.character(z))
　print(rle(z), prefix = "..|")

N <- integer(9)
stopifnot(x == inverse.rle(rle(x)),
　identical(N, inverse.rle(rle(N))),
　z == inverse.rle(rle(z)))

Round  Rounding of Numbers

Description

ceiling 带一个单个数值参数 x 并返回一个数值向量，其值是 x 中最小的整数，不小于其中的相应元素。
floor 带一个单个数值参数 x 并返回一个整数向量，其值是 x 中最大数值，不大于其中的相应元素。
trunc 带一个单个数值参数 x 并返回一个整数向量，其值由 x 中的整数部分组成。
round 圆整数值为指定的小数位数（缺省为 0）。
signif 圆整数值为指定的显著位数。
Round

Usage
ceiling(x)
floor(x)
trunc(x, ...)
round(x, digits = 0)
signif(x, digits = 6)

Arguments
x
a numeric vector. Or, for round and signif, a complex vector.
digits
integer indicating the number of decimal places (round) or significant digits (signif) to be used. Negative values are allowed (see ‘Details’).
...
arguments to be passed to methods.

Details
These are generic functions: methods can be defined for them individually or via the Math group generic.

Note that for rounding off a 5, the IEC 60559 standard is expected to be used, ‘go to the even digit’. Therefore round(0.5) is 0 and round(-1.5) is -2. However, this is dependent on OS services and on representation error (since e.g. 0.15 is not represented exactly, the rounding rule applies to the represented number and not to the printed number, and so round(0.15, 1) could be either 0.1 or 0.2).

Rounding to a negative number of digits means rounding to a power of ten, so for example round(x, digits = -2) rounds to the nearest hundred.

For signif the recognized values of digits are 1...22, and non-missing values are rounded to the nearest integer in that range. Complex numbers are rounded to retain the specified number of digits in the larger of the components. Each element of the vector is rounded individually, unlike printing.

These are all primitive functions.

S4 methods
These are all (internally) S4 generic.

ceiling, floor and trunc are members of the Math group generic. As an S4 generic, trunc has only one argument.

round and signif are members of the Math2 group generic.

References

as.integer.
Examples

```r
round(.5 + -2:4) # IEEE rounding: -2 0 0 2 2 4 4
(x1 <- seq(-2, 4, by = .5))
round(x1) #-- IEEE rounding!
x1[trunc(x1) != floor(x1)]
x1[(round(x1) != floor(x1 + .5))]
(non.int <- ceiling(x1) != floor(x1))

x2 <- pi * 100^(-1:3)
round(x2, 3)
signif(x2, 3)
```

round.POSIXt

Round / Truncate Data-Time Objects

Description

Round or truncate date-time objects.

Usage

```r
## S3 method for class 'POSIXt'
round(x, units = c("secs", "mins", "hours", "days"))
## S3 method for class 'POSIXt'
trunc(x, units = c("secs", "mins", "hours", "days"), ...)
## S3 method for class 'Date'
round(x, ...)
## S3 method for class 'Date'
trunc(x, ...)
```

Arguments

- `x`: an object inheriting from "POSIXt" or "Date".
- `units`: one of the units listed. Can be abbreviated.
- `...`: arguments to be passed to or from other methods, notably digits for `round`.

Details

The time is rounded or truncated to the second, minute, hour or day. Timezones are only relevant to days, when midnight in the current timezone is used.

The methods for class "Date" are of little use except to remove fractional days.

Value

An object of class "POSIXt" or "Date".

See Also

- `round` for the generic function and default methods.
- `DateTimeClasses`, `Date`
Examples

```r
cround(leap.seconds + 1000, "hour")
trunc(Sys.time(), "day")
```

---

### Description

Returns a matrix of integers indicating their row number in a matrix-like object, or a factor indicating the row labels.

### Usage

```r
row(x, as.factor = FALSE)
```

### Arguments

- `x`: a matrix-like object, that is one with a two-dimensional `dim`.
- `as.factor`: a logical value indicating whether the value should be returned as a factor of row labels (created if necessary) rather than as numbers.

### Value

An integer (or factor) matrix with the same dimensions as `x` and whose `i,j`-th element is equal to `i` (or the `i`-th row label).

### References

### See Also

- `col` to get columns.

### Examples

```r
x <- matrix(1:12, 3, 4)
# extract the diagonal of a matrix
dx <- x[row(x) == col(x)]
dx

# create an identity 5-by-5 matrix
x <- matrix(0, nrow = 5, ncol = 5)
x[row(x) == col(x)] <- 1
x
```
**Row and Column Names**

**Description**

Retrieve or set the row or column names of a matrix-like object.

**Usage**

```r
rownames(x, do.NULL = TRUE, prefix = "row")
rownames(x) <- value
```

```r
colnames(x, do.NULL = TRUE, prefix = "col")
colnames(x) <- value
```

**Arguments**

- `x`: a matrix-like R object, with at least two dimensions for `colnames`.
- `do.NULL`: logical. If `FALSE` and names are `NULL`, names are created.
- `prefix`: for created names.
- `value`: a valid value for that component of `dimnames(x)`. For a matrix or array this is either `NULL` or a character vector of non-zero length equal to the appropriate dimension.

**Details**

The extractor functions try to do something sensible for any matrix-like object `x`. If the object has `dimnames` the first component is used as the row names, and the second component (if any) is used for the column names. For a data frame, `rownames` and `colnames` eventually call `rownames` and `names` respectively, but the latter are preferred.

If `do.NULL` is `FALSE`, a character vector (of length `NROW(x)` or `NCOL(x)`) is returned in any case, prepending `prefix` to simple numbers, if there are no dimnames or the corresponding component of the dimnames is `NULL`.

The replacement methods for arrays/matrices coerce vector and factor values of `value` to character, but do not dispatch methods for `as.character`.

For a data frame, `value` for `rownames` should be a character vector of non-duplicated and non-missing names (this is enforced), and for `colnames` a character vector of (preferably) unique syntactically-valid names. In both cases, `value` will be coerced by `as.character`, and setting `colnames` will convert the row names to character.

**Note**

If the replacement versions are called on a matrix without any existing dimnames, they will add suitable dimnames. But constructions such as

```r
rownames(x)[3] <- "c"
```

may not work unless `x` already has dimnames, since this will create a length-3 `value` from the `NULL` value of `rownames(x)`. 
See Also

dimnames, case.names, variable.names.

Examples

```r
m0 <- matrix(NA, 4, 0)
row.names(m0)

m2 <- cbind(1, 1:4)
colnames(m2, do.NULL = FALSE)
colnames(m2) <- c("x", "y")
rownames(m2) <- rownames(m2, do.NULL = FALSE, prefix = "Obs.")
m2
```

Value

`row.names` returns a character vector.
`row.names<-` returns a data frame with the row names changed.
Note

row.names is similar to rownames for arrays, and it has a method that calls rownames for an array argument.

Row names of the form 1:n for n > 2 are stored internally in a compact form, which might be seen from C code or by deparsing but never via row.names or attr(x, "row.names"). Additionally, some names of this sort are marked as 'automatic' and handled differently by as.matrix and data.matrix (and potentially other functions). (All zero-row data frames are regarded as having automatic row.names.)

References

See Also
data.frame, rownames, names.
.row_names_info for the internal representations.

Description

Compute column sums across rows of a numeric matrix-like object for each level of a grouping variable. rowsum is generic, with a method for data frames and a default method for vectors and matrices.

Usage

rowsum(x, group, reorder = TRUE, ...)

## S3 method for class 'data.frame'
rowsum(x, group, reorder = TRUE, na.rm = FALSE, ...)

## Default S3 method:
rowsum(x, group, reorder = TRUE, na.rm = FALSE, ...)

Arguments

x a matrix, data frame or vector of numeric data. Missing values are allowed. A numeric vector will be treated as a column vector.

group a vector or factor giving the grouping, with one element per row of x. Missing values will be treated as another group and a warning will be given.

reorder if TRUE, then the result will be in order of sort(unique(group)), if FALSE, it will be in the order that groups were encountered.

na.rm logical (TRUE or FALSE). Should NA (including NaN) values be discarded?

... other arguments to be passed to or from methods
Details

The default is to reorder the rows to agree with `tapply` as in the example below. Reordering should not add noticeably to the time except when there are very many distinct values of `group` and `x` has few columns.

The original function was written by Terry Therneau, but this is a new implementation using hashing that is much faster for large matrices.

To sum over all the rows of a matrix (i.e., a single `group`) use `colSums`, which should be even faster.

For integer arguments, over/underflow in forming the sum results in `NA`.

Value

A matrix or data frame containing the sums. There will be one row per unique value of `group`.

See Also

`tapply, aggregate, rowSums`

Examples

```r
require(stats)

x <- matrix(runif(100), ncol = 5)
group <- sample(1:8, 20, TRUE)
(xsum <- rowsum(x, group))
## Slower versions
tapply(x, list(group[rownames(x)], col(x)), sum)
t(sapply(split(as.data.frame(x), group), colSums))
aggregate(x, list(group), sum)[-1]
```

Description

`sample` takes a sample of the specified size from the elements of `x` using either with or without replacement.

Usage

```r
sample(x, size, replace = FALSE, prob = NULL)
sample.int(n, size = n, replace = FALSE, prob = NULL)
```

Arguments

- `x` Either a vector of one or more elements from which to choose, or a positive integer. See ‘Details.’
- `n` a positive number, the number of items to choose from. See ‘Details.’
- `size` a non-negative integer giving the number of items to choose.
- `replace` Should sampling be with replacement?
- `prob` A vector of probability weights for obtaining the elements of the vector being sampled.
Details

If \(x\) has length 1, is numeric (in the sense of is.numeric) and \(x \geq 1\), sampling via sample takes place from \(1:x\). Note that this convenience feature may lead to undesired behaviour when \(x\) is of varying length in calls such as sample(x). See the examples.

Otherwise \(x\) can be any R object for which length and subsetting by integers make sense: S3 or S4 methods for these operations will be dispatched as appropriate.

For sample the default for size is the number of items inferred from the first argument, so that sample(x) generates a random permutation of the elements of \(x\) (or \(1:x\)). It is allowed to ask for size = 0 samples with \(n = 0\) or a length-zero \(x\), but otherwise \(n > 0\) or positive length(x) is required.

Non-integer positive numerical values of \(n\) or \(x\) will be truncated to the next smallest integer, which has to be no larger than .Machine$integer.max.

The optional prob argument can be used to give a vector of weights for obtaining the elements of the vector being sampled. They need not sum to one, but they should be non-negative and not all zero. If replace is true, Walker’s alias method (Ripley, 1987) is used when there are more than 250 reasonably probable values: this gives results incompatible with those from R < 2.2.0, and there will be a warning the first time this happens in a session.

If replace is false, these probabilities are applied sequentially, that is the probability of choosing the next item is proportional to the weights amongst the remaining items. The number of nonzero weights must be at least size in this case.

sample.int is a bare interface in which both \(n\) and size must be supplied as integers.

As from R 3.0.0, \(n\) can be larger than the largest integer of type integer, up to the largest representable integer in type double. Only uniform sampling is supported. Two random numbers are used to ensure uniform sampling of large integers.

Value

For sample a vector of length size with elements drawn from either \(x\) or from the integers \(1:x\).

For sample.int, an integer vector of length size with elements from \(1:n\), or a double vector if \(n \geq \mathbb{2}^{31}\).

References

See Also

RNG about random number generation.

CRAN package sampling for other methods of weighted sampling without replacement.

Examples

```r
x <- 1:12
# a random permutation
sample(x)
# bootstrap resampling -- only if length(x) > 1!
sample(x, replace = TRUE)
```
# 100 Bernoulli trials
sample(c(0,1), 100, replace = TRUE)

## More careful bootstrapping -- Consider this when using sample()  
## programmatically (i.e., in your function or simulation)!

# sample()'s surprise -- example
x <- 1:10  
sample(x[x > 9]) # length 3  
sample(x[x > 9]) # oops -- length 10!  
sample(x[x > 10]) # length 0  

resample <- function(x, ...) x[sample.int(length(x), ...)]  
resample(x[x > 8]) # length 2  
resample(x[x > 9]) # length 1  
resample(x[x > 10]) # length 0  

## R 3.x.y only
sample.int(1e10, 12, replace = TRUE)  
sample.int(1e10, 12) # not that there is much chance of duplicates

---

**save**  
**Save R Objects**

**Description**

`save` writes an external representation of R objects to the specified file. The objects can be read back from the file at a later date by using the function `load` (or `data` in some cases).

`save.image()` is just a short-cut for ‘save my current workspace’, i.e., `save(list = ls(all = TRUE), file = "RData")`. It is also what happens with `q("yes")`.

**Usage**

```r
save(..., list = character(),  
      file = stop("'file' must be specified"),  
      ascii = FALSE, version = NULL, envir = parent.frame(),  
      compress = !ascii, compression_level,  
      eval.promises = TRUE, precheck = TRUE)

save.image(file = ".RData", version = NULL, ascii = FALSE,  
           compress = !ascii, safe = TRUE)
```

**Arguments**

- **...** the names of the objects to be saved (as symbols or character strings).
- **list** A character vector containing the names of objects to be saved.
- **file** a (writable binary-mode) connection or the name of the file where the data will be saved (when tilde expansion is done). Must be a file name for `save.image` or `version = 1`.
- **ascii** if TRUE, an ASCII representation of the data is written. The default value of `ascii` is FALSE which leads to a binary file being written.
**version**

the workspace format version to use. NULL specifies the current default format. The version used from R 0.99.0 to R 1.3.1 was version 1. The default format as from R 1.4.0 is version 2.

**envir**

environment to search for objects to be saved.

**compress**

logical or character string specifying whether saving to a named file is to use compression. TRUE corresponds to gzip compression, and character strings "gzip", "bzip2" or "xz" specify the type of compression. Ignored when file is a connection and for workspace format version 1.

**compression_level**

integer: the level of compression to be used. Defaults to 6 for gzip compression and to 9 for bzip2 or xz compression.

**eval.promises**

logical: should objects which are promises be forced before saving?

**precheck**

logical: should the existence of the objects be checked before starting to save (and in particular before opening the file/connection)? Does not apply to version 1 saves.

**safe**

logical. If TRUE, a temporary file is used for creating the saved workspace. The temporary file is renamed to file if the save succeeds. This preserves an existing workspace file if the save fails, but at the cost of using extra disk space during the save.

**Details**

The names of the objects specified either as symbols (or character strings) in ... or as a character vector in list are used to look up the objects from environment envir. By default promises are evaluated, but if eval.promises = FALSE promises are saved (together with their evaluation environments). (Promises embedded in objects are always saved unevaluated.)

All R platforms use the XDR (bigendian) representation of C ints and doubles in binary save-d files, and these are portable across all R platforms. (ASCII saves used to be useful for moving data between platforms but are now mainly of historical interest. They can be more compact than binary saves where compression is not used, but are almost always slower to both read and write: binary saves compress much better than ASCII ones.)

Default values for the ascii, compress, safe and version arguments can be modified with the "save.defaults" option (used both by save and save.image), see also the 'Examples' section. If a "save.image.defaults" option is set it is used in preference to "save.defaults" for function save.image (which allows this to have different defaults).

A connection that is not already open will be opened in mode "wb".

**Compression**

Large files can be reduced considerably in size by compression. A particular 46MB object was saved as 35MB without compression in 2 seconds, 22MB with gzip compression in 8 secs, 19MB with bzip2 compression in 13 secs and 9.4MB with xz compression in 40 secs. The load times were 1.3, 2.8, 5.5 and 5.7 seconds respectively. These results are indicative, but the relative performances do depend on the actual file: xz compressed unusually well here.

It is possible to compress later (with gzip, bzip2 or xz) a file saved with compress = FALSE: the effect is the same as saving with compression. Also, a saved file can be uncompressed and re-compressed under a different compression scheme (and see resaveRdaFiles for a way to do so from within R).
Warnings

The ... arguments only give the names of the objects to be saved: they are searched for in the environment given by the envir argument, and the actual objects given as arguments need not be those found.

Saved R objects are binary files, even those saved with ascii = TRUE, so ensure that they are transferred without conversion of end of line markers and of 8-bit characters. The lines are delimited by LF on all platforms.

Although the default version has not changed since R 1.4.0, this does not mean that saved files are necessarily backwards compatible. You will be able to load a saved image into an earlier version of R unless use is made of later additions (for example, raw vectors or external pointers).

Note

The most common reason for failure is lack of write permission in the current directory. For save.image and for saving at the end of a session this will shown by messages like

```r
Error in gzfile(file, "wb") : unable to open connection
In addition: Warning message:
  In gzfile(file, "wb") :
    cannot open compressed file '.RDataTmp',
    probable reason 'Permission denied'
```

See Also

dput, dump, load, data.

For other interfaces to the underlying serialization format, see serialize and saveRDS.

Examples

```r
x <- stats::runif(20)
y <- list(a = 1, b = TRUE, c = "oops")
save(x, y, file = "xy.RData")
save.image()
unlink("xy.RData")
unlink(".RData")

# set save defaults using option:
options(save.defaults = list(ascii = TRUE, safe = FALSE))
save.image()
unlink(".RData")
```

scale

Scaling and Centering of Matrix-like Objects

Description

scale is generic function whose default method centers and/or scales the columns of a numeric matrix.

Usage

scale(x, center = TRUE, scale = TRUE)
scale

Arguments

- **x**: a numeric matrix (like object).
- **center**: either a logical value or a numeric vector of length equal to the number of columns of x.
- **scale**: either a logical value or a numeric vector of length equal to the number of columns of x.

Details

The value of `center` determines how column centering is performed. If `center` is a numeric vector with length equal to the number of columns of x, then each column of x has the corresponding value from center subtracted from it. If `center` is `TRUE` then centering is done by subtracting the column means (omitting NAs) of x from their corresponding columns, and if `center` is `FALSE`, no centering is done.

The value of `scale` determines how column scaling is performed (after centering). If `scale` is a numeric vector with length equal to the number of columns of x, then each column of x is divided by the corresponding value from `scale`. If `scale` is `TRUE` then scaling is done by dividing the (centered) columns of x by their standard deviations if `center` is `TRUE`, and the root mean square otherwise. If `scale` is `FALSE`, no scaling is done.

The root-mean-square for a (possibly centered) column is defined as \( \sqrt{\sum(x^2)/(n-1)} \), where \( x \) is a vector of the non-missing values and \( n \) is the number of non-missing values. In the case `center = TRUE`, this is the same as the standard deviation, but in general it is not. (To scale by the standard deviations without centering, use `scale(x, center = FALSE, scale = apply(x, 2, sd, na.rm = TRUE)).`)

Value

For `scale.default`, the centered, scaled matrix. The numeric centering and scalings used (if any) are returned as attributes "scaled:center" and "scaled:scale".

References

See Also

- `sweep` which allows centering (and scaling) with arbitrary statistics.

For working with the scale of a plot, see `par`.

Examples

```r
require(stats)
x <- matrix(1:10, ncol = 2)
(centered.x <- scale(x, scale = FALSE))
cov(centered.scaled.x <- scale(x)) # all 1
```
Description

Read data into a vector or list from the console or file.

Usage

\[
\text{scan}(\text{file} = "", \text{what} = \text{double()}, \text{nmax} = -1, \text{n} = -1, \text{sep} = "", \\
\text{quote} = \text{if}(\text{identical}(\text{sep}, "\n")) "" \text{else} "'\n'", \text{dec} = ":.", \\
\text{skip} = 0, \text{nlines} = 0, \text{na.strings} = "\text{NA}", \\
\text{flush} = \text{FALSE}, \text{fill} = \text{FALSE}, \text{strip.white} = \text{FALSE}, \\
\text{quiet} = \text{FALSE}, \text{blank.lines.skp} = \text{TRUE}, \text{multi.line} = \text{TRUE}, \\
\text{comment.char} = "", \text{allowEscapes} = \text{FALSE}, \\
\text{fileEncoding} = "", \text{encoding} = "\text{unknown}", \text{text})
\]

Arguments

- **file**: the name of a file to read data values from. If the specified file is "", then input is taken from the keyboard (or whatever stdin() reads if input is redirected or R is embedded). (In this case input can be terminated by a blank line or an EOF signal, ‘Ctrl-D’ on Unix and ‘Ctrl-Z’ on Windows.)
  - Otherwise, the file name is interpreted relative to the current working directory (given by getwd()), unless it specifies an absolute path. Tilde-expansion is performed where supported. When running R from a script, file = "stdin" can be used to refer to the process’s stdin file stream.
  - This can be a compressed file (see file).
  - Alternatively, file can be a connection, which will be opened if necessary, and if so closed at the end of the function call. Whatever mode the connection is opened in, any of LF, CRLF or CR will be accepted as the EOL marker for a line and so will match sep = "\n".
  - file can also be a complete URL. (For the supported URL schemes, see the ‘URLs’ section of the help for url.)
  - To read a data file not in the current encoding (for example a Latin-1 file in a UTF-8 locale or conversely) use a file connection setting its encoding argument (or scan’s fileEncoding argument).

- **what**: the type of what gives the type of data to be read. The supported types are logical, integer, numeric, complex, character, raw and list. If what is a list, it is assumed that the lines of the data file are records each containing length(what) items (‘fields’) and the list components should have elements which are one of the first six types listed or NULL, see section ‘Details’ below.

- **nmax**: integer: the maximum number of data values to be read, or if what is a list, the maximum number of records to be read. If omitted or not positive or an invalid value for an integer (and nlines is not set to a positive value), scan will read to the end of file.

- **n**: integer: the maximum number of data values to be read, defaulting to no limit. Invalid values will be ignored.
sep
by default, scan expects to read ‘white-space’ delimited input fields. Alternatively, sep can be used to specify a character which delimits fields. A field is always delimited by an end-of-line marker unless it is quoted. If specified this should be the empty character string (the default) or NULL or a character string containing just one single-byte character.

quote
the set of quoting characters as a single character string or NULL. In a multibyte locale the quoting characters must be ASCII (single-byte).

dec
decimal point character. This should be a character string containing just one single-byte character. (NULL and a zero-length character vector are also accepted, and taken as the default.)

skip
the number of lines of the input file to skip before beginning to read data values.
nlines
if positive, the maximum number of lines of data to be read.

na.strings
character vector. Elements of this vector are to be interpreted as missing (NA) values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields.

flush
logical: if TRUE, scan will flush to the end of the line after reading the last of the fields requested. This allows putting comments after the last field, but precludes putting more that one record on a line.

fill
logical: if TRUE, scan will implicitly add empty fields to any lines with fewer fields than implied by what.

strip.white
vector of logical value(s) corresponding to items in the what argument. It is used only when sep has been specified, and allows the stripping of leading and trailing ‘white space’ from character fields (numeric fields are always stripped). Note: white space inside quoted strings is not stripped.
If strip.white is of length 1, it applies to all fields; otherwise, if strip.white[i] is TRUE and the i-th field is of mode character (because what[i] is) then the leading and trailing unquoted white space from field i is stripped.

quiet
logical: if FALSE (default), scan() will print a line, saying how many items have been read.

blank.lines.skip
logical: if TRUE blank lines in the input are ignored, except when counting skip and nlines.

multi.line
logical. Only used if what is a list. If FALSE, all of a record must appear on one line (but more than one record can appear on a single line). Note that using fill = TRUE implies that a record will be terminated at the end of a line.

comment.char
character: a character vector of length one containing a single character or an empty string. Use ‘”’ to turn off the interpretation of comments altogether (the default).

allowEscapes
logical. Should C-style escapes such as ‘\n’ be processed (the default) or read verbatim? Note that if not within quotes these could be interpreted as a delimiter (but not as a comment character).
The escapes which are interpreted are the control characters ‘\a, \b, \f, \n, \r, \t, \v’ and octal and hexadecimal representations like ‘\040’ and ‘\x2A’. Any other escaped character is treated as itself, including backslash. Note that Unicode escapes (starting ‘\u’ or ‘\U’: see Quotes) are never processed.
fileEncoding  character string: if non-empty declares the encoding used on a file (not a connection nor the keyboard) so the character data can be re-encoded. See the ‘Encoding’ section of the help for file, and the ‘R Data Import/Export Manual’.

encoding  encoding to be assumed for input strings. If the value is "latin1" or "UTF-8" it is used to mark character strings as known to be in Latin-1 or UTF-8: it is not used to re-encode the input (see fileEncoding. See also ‘Details’.

text  character string: if file is not supplied and this is, then data are read from the value of text via a text connection.

Details

The value of what can be a list of types, in which case scan returns a list of vectors with the types given by the types of the elements in what. This provides a way of reading columnar data. If any of the types is NULL, the corresponding field is skipped (but a NULL component appears in the result).

The type of what or its components can be one of the six atomic vector types or NULL (see is.atomic).

‘White space’ is defined for the purposes of this function as one or more contiguous characters from the set space, horizontal tab, carriage return and line feed. It does not include form feed or vertical tab, but in Latin-1 and Windows 8-bit locales ‘space’ includes non-breaking space.

Empty numeric fields are always regarded as missing values. Empty character fields are scanned as empty character vectors, unless na.strings contains "" when they are regarded as missing values.

The allowed input for a numeric field is optional whitespace followed either NA or an optional sign followed by a decimal or hexadecimal constant (see NumericConstants), or NaN, Inf or infinity (ignoring case). Out-of-range values are recorded as Inf, -Inf or 0.

For an integer field the allowed input is optional whitespace, followed by either NA or an optional sign and one or more digits ('0–9'): all out-of-range values are converted to NA_integer_.

If sep is the default (""), the character ‘\' in a quoted string escapes the following character, so quotes may be included in the string by escaping them.

If sep is non-default, the fields may be quoted in the style of ‘.csv’ files where separators inside quotes (’’ or ‘”’) are ignored and quotes may be put inside strings by doubling them. However, if sep = "\n" it is assumed by default that one wants to read entire lines verbatim.

Quoting is only interpreted in character fields and in NULL fields (which might be skipping character fields).

Note that since sep is a separator and not a terminator, reading a file by scan("foo", sep = "\n", blank.lines.skip = FALSE) will give an empty final line if the file ends in a linefeed and not if it does not. This might not be what you expected; see also readLines.

If comment.char occurs (except inside a quoted character field), it signals that the rest of the line should be regarded as a comment and be discarded. Lines beginning with a comment character (possibly after white space with the default separator) are treated as blank lines.

There is a line-length limit of 4095 bytes when reading from the console (which may impose a lower limit: see ‘An Introduction to R’).

There is a check for a user interrupt every 1000 lines if what is a list, otherwise every 10000 items.

If file is a character string and fileEncoding is non-default, or it is a not-already-open connection with a non-default encoding argument, the text is converted to UTF-8 and declared as such (and the encoding argument to scan is ignored). See the examples of readLines.
Value

if what is a list, a list of the same length and same names (as any) as what.

Otherwise, a vector of the type of what.

Character strings in the result will have a declared encoding if encoding is "latin1" or "UTF-8".

Note

The default for multi.line differs from S. To read one record per line, use flush = TRUE and multi.line = FALSE. (Note that quoted character strings can still include embedded newlines.)

If number of items is not specified, the internal mechanism re-allocates memory in powers of two and so could use up to three times as much memory as needed. (It needs both old and new copies.) If you can, specify either n or nmax whenever inputting a large vector, and nmax or nlines when inputting a large list.

Using scan on an open connection to read partial lines can lose chars: use an explicit separator to avoid this.

Having nul bytes in fields (including ‘\0’ if allowEscapes = TRUE) may lead to interpretation of the field being terminated at the nul. They not normally present in text files – see readBin.

References

See Also

read.table for more user-friendly reading of data matrices; readLines to read a file a line at a time. write.

Quotes for the details of C-style escape sequences.

readChar and readBin to read fixed or variable length character strings or binary representations of numbers a few at a time from a connection.

Examples

cat("TITLE extra line", "2 3 5 7", "11 13 17", file = "ex.data", sep = "\n")
pp <- scan("ex.data", skip = 1, quiet = TRUE)
scan("ex.data", skip = 1)
scan("ex.data", skip = 1, nlines = 1) # only 1 line after the skipped one
scan("ex.data", what = list("","","")) # flush is F -> read "7"
scan("ex.data", what = list("","",""), flush = TRUE)
unlink("ex.data") # tidy up

## "inline" usage
scan(text = "1 2 3")
search  

Give Search Path for R Objects

Description

Gives a list of attached packages (see library), and R objects, usually data.frames.

Usage

search()
searchpaths()

Value

A character vector, starting with ".GlobalEnv", and ending with "package:base" which is R's base package required always.

searchpaths gives a similar character vector, with the entries for packages being the path to the package used to load the code.

References

See Also

.packages to list just the packages on search path.
loadedNamespaces to list loaded namespaces.
attach and detach to change the search path, objects to find R objects in there.

Examples

search()
searchpaths()
Usage

seek(con, ...)  
## S3 method for class 'connection'
seek(con, where = NA, origin = "start", rw = ",", ...)  
isSeekable(con)  
truncate(con, ...)

Arguments

con       a connection.
where     numeric. A file position (relative to the origin specified by origin), or NA.
rw       character. Empty or "read" or "write", partial matches allowed.
origin    character. One of "start", "current", "end": see 'Details'.
...       further arguments passed to or from other methods.

Details

seek with where = NA returns the current byte offset of a connection (from the beginning), and with a non-missing where argument the connection is re-positioned (if possible) to the specified position. isSeekable returns whether the connection in principle supports seek: currently only (possibly gz-compressed) file connections do.

where is stored as a real but should represent an integer: non-integer values are likely to be truncated. Note that the possible values can exceed the largest representable number in an R integer on 64-bit builds, and on some 32-bit builds.

File connections can be open for both writing/appending, in which case R keeps separate positions for reading and writing. Which seek refers to can be set by its rw argument: the default is the last mode (reading or writing) which was used. Most files are only opened for reading or writing and so default to that state. If a file is open for both reading and writing but has not been used, the default is to give the reading position (0).

The initial file position for reading is always at the beginning. The initial position for writing is at the beginning of the file for modes "r+" and "r+b", otherwise at the end of the file. Some platforms only allow writing at the end of the file in the append modes. (The reported write position for a file opened in an append mode will typically be unreliable until the file has been written to.)

gzfile connections support seek with a number of limitations, using the file position of the uncompressed file. They do not support origin = "end". When writing, seeking is only possible forwards: when reading seeking backwards is supported by rewinding the file and re-reading from its start.

If seek is called with a non-NA value of where, any pushback on a text-mode connection is discarded.

truncate truncates a file opened for writing at its current position. It works only for file connections, and is not implemented on all platforms: on others (including Windows) it will not work for large (> 2Gb) files.

None of these should be expected to work on text-mode connections with re-encoding selected.
Value

seek returns the current position (before any move), as a (numeric) byte offset from the origin, if relevant, or 0 if not. Note that the position can exceed the largest representable number in an \( \mathbb{R} \) integer on 64-bit builds, and on some 32-bit builds.

truncate returns NULL; it stops with an error if it fails (or is not implemented).

isSeekable returns a logical value, whether the connection supports seek.

Warning

Use of seek on Windows is discouraged. We have found so many errors in the Windows implementation of file positioning that users are advised to use it only at their own risk, and asked not to waste the \( \mathbb{R} \) developers’ time with bug reports on Windows’ deficiencies.

---

seq

Sequence Generation

Description

Generate regular sequences. seq is a standard generic with a default method. seq.int is a primitive which can be much faster but has a few restrictions. seq_along and seq_len are very fast primitives for two common cases.

Usage

seq(...)

## Default S3 method:
seq(from = 1, to = 1, by = ((to - from)/(length.out - 1)),
   length.out = NULL, along.with = NULL, ...)

seq.int(from, to, by, length.out, along.with, ...)

seq_along(along.with)
seq_len(length.out)

Arguments

... arguments passed to or from methods.
from, to the starting and (maximal) end values of the sequence. Of length 1 unless just from is supplied as an unnamed argument.
by number: increment of the sequence.
length.out desired length of the sequence. A non-negative number, which for seq and seq.int will be rounded up if fractional.
along.with take the length from the length of this argument.
Details

Numerical inputs should all be finite (that is, not infinite, NaN or NA).

The interpretation of the unnamed arguments of `seq` and `seq.int` is not standard, and it is recommended always to name the arguments when programming.

`seq` is generic, and only the default method is described here. Note that it dispatches on the class of the first argument irrespective of argument names. This can have unintended consequences if it is called with just one argument intending this to be taken as along.with: it is much better to use `seq_along` in that case.

`seq.int` is an internal generic which dispatches on methods for "seq" based on the class of the first supplied argument (before argument matching).

Typical usages are

```r
seq(from, to)
seq(from, to, by= )
seq(from, to, length.out= )
seq(along.with = )
seq(from)
seq(length.out= )
```

The first form generates the sequence from, from+/-1, ..., to (identical to from:to).

The second form generates from, from+by, ..., up to the sequence value less than or equal to to. Specifying to - from and by of opposite signs is an error. Note that the computed final value can go just beyond to to allow for rounding error, but is truncated to to. (‘Just beyond’ is by up to 10^{-10} times abs(from - to).)

The third generates a sequence of length.out equally spaced values from from to to. (length.out is usually abbreviated to length or len, and seq_len is much faster.)

The fourth form generates the integer sequence 1, 2, ..., length(along.with). (along.with is usually abbreviated to along, and seq_along is much faster.)

The fifth form generates the sequence 1, 2, ..., length(from) (as if argument along.with had been specified), unless the argument is numeric of length 1 when it is interpreted as 1:from (even for seq(0) for compatibility with S). Using either seq_along or seq_len is much preferred (unless strict S compatibility is essential).

The final form generates the integer sequence 1, 2, ..., length.out unless length.out = 0, when it generates integer(0).

Very small sequences (with from - to of the order of 10^{-14} times the larger of the ends) will return from.

For seq (only), up to two of from, to and by can be supplied as complex values provided length.out or along.with is specified. More generally, the default method of seq will handle classed objects with methods for the Math, Ops and Summary group generics.

`seq.int`, `seq_along` and `seq_len` are primitive.

Value

`seq.int` and the default method of seq for numeric arguments return a vector of type "integer" or "double": programmers should not rely on which.

`seq_along` and `seq_len` return an integer vector, unless it is a long vector when it will be double.
seq.Date

Generate Regular Sequences of Dates

Description

The method for seq for objects of class "Date" representing calendar dates.

Usage

## S3 method for class 'Date'
seq(from, to, by, length.out = NULL, along.with = NULL, ...)

Arguments

- **from**: starting date. Required
- **to**: end date. Optional.
- **by**: increment of the sequence. Optional. See ‘Details’.
- **length.out**: integer, optional. Desired length of the sequence.
- **along.with**: take the length from the length of this argument.
- **...**: arguments passed to or from other methods.

Details

by can be specified in several ways.

- A number, taken to be in days.
- A object of class difftime
- A character string, containing one of "day", "week", "month" or "year". This can optionally be preceded by a (positive or negative) integer and a space, or followed by "s".
  See seq.POSIXt for the details of "month".

Examples

seq(0, 1, length.out = 11)
seq(stats::rnorm(20)) # effectively 'along'
seq(1, 9, by = 2)   # matches 'end'
seq(1, 9, by = pi)  # stays below 'end'
seq(1, 6, by = 3)
seq(1.575, 5.125, by = 0.05)
seq(17) # same as 1:17, or even better seq_len(17)

References

See Also

The methods seq.Date and seq.POSIXt.

rep, sequence, row, col.
Value

A vector of class "Date".

See Also

Date

Examples

## first days of years
seq(as.Date("1910/1/1"), as.Date("1999/1/1"), "years")

## by month
seq(as.Date("2000/1/1"), by = "month", length.out = 12)

## quarters
seq(as.Date("2000/1/1"), as.Date("2003/1/1"), by = "3 months")

## find all 7th of the month between two dates, the last being a 7th.
st <- as.Date("1998-12-17")
en <- as.Date("2000-1-7")
ll <- seq(en, st, by = "-1 month")
rev(ll[ll > st & ll < en])
• A character string, containing one of "sec", "min", "hour", "day", "DSTday", "week", "month" or "year". This can optionally be preceded by a (positive or negative) integer and a space, or followed by "s".

The difference between "day" and "DSTday" is that the former ignores changes to/from daylight savings time and the latter takes the same clock time each day. ("week" ignores DST (it is a period of 144 hours), but "7 DSTdays") can be used as an alternative. "month" and "year" allow for DST.)

The timezone of the result is taken from \texttt{from}: remember that GMT means UTC (and not the timezone of Greenwich, England) and so does not have daylight savings time.

Using "month" first advances the month without changing the day: if this results in an invalid day of the month, it is counted forward into the next month: see the examples.

Value

A vector of class "\POSIXct".

See Also

\texttt{DateTimeClasses}

Examples

\begin{verbatim}
## first days of years
seq(ISoDate(1910,1,1), ISoDate(1999,1,1), "years")
## by month
seq(ISoDate(2000,1,1), by = "month", length.out = 12)
seq(ISoDate(2000,1,31), by = "month", length.out = 4)
## quarters
seq(ISoDate(1990,1,1), ISoDate(2000,1,1), by = "3 months")
## days vs DSTdays: use c() to lose the timezone.
seq(c(ISoDate(2000,3,29)), by = "day", length.out = 10)
seq(c(ISoDate(2000,3,29)), by = "DSTday", length.out = 10)
seq(c(ISoDate(2000,3,29)), by = "7 DSTdays", length.out = 4)
\end{verbatim}
**Details**

Earlier versions of sequence used to work for 0 or negative inputs as seq(x) == 1:x.

Note that sequence <- function(nvec) unlist(lapply(nvec, seq_len)) and it mainly exists in reverence to the very early history of R.

**See Also**

gl, seq, rep.

**Examples**

```r
sequence(c(3, 2)) # the concatenated sequences 1:3 and 1:2.
#> [1] 1 2 3 1 2
```

---

**serialize**

**Simple Serialization Interface**

**Description**

A simple low-level interface for serializing to connections.

**Usage**

```r
serialize(object, connection, ascii = TRUE, xdr = TRUE, version = NULL, refhook = NULL)

unserialize(connection, refhook = NULL)
```

**Arguments**

- **object** \( \text{R} \) object to serialize.
- **connection** an open connection or (for serialize) NULL or (for unserialize) a raw vector (see ‘Details’).
- **ascii** a logical. If TRUE, an ASCII representation is written; otherwise binary one. The default is TRUE for a text-mode connection and FALSE otherwise. See also the comments in the help for `save`.
- **xdr** a logical: if a binary representation is used, should a big-endian one (XDR) be used?
- **version** the workspace format version to use. NULL specifies the current default version (2). Versions prior to 2 are not supported, so this will only be relevant when there are later versions.
- **refhook** a hook function for handling reference objects.
Details

The function `serialize` serializes object to the specified connection. If `connection` is `NULL` then object is serialized to a raw vector, which is returned as the result of `serialize`.

Sharing of reference objects is preserved within the object but not across separate calls to `serialize`.

`unserialize` reads an object (as written by `serialize`) from `connection` or a raw vector.

The `refhook` functions can be used to customize handling of non-system reference objects (all external pointers and weak references, and all environments other than namespace and package environments and `.GlobalEnv`). The hook function for `serialize` should return a character vector for references it wants to handle; otherwise it should return `NULL`. The hook for `unserialize` will be called with character vectors supplied to `serialize` and should return an appropriate object.

For a text-mode connection, the default value of `ascii` is set to `TRUE`: only ASCII representations can be written to text-mode connections and attempting to use `ascii = FALSE` will throw an error.

The format consists of a single line followed by the data: the first line contains a single character: `X` for binary serialization and `A` for ASCII serialization, followed by a new line. (The format used is identical to that used by `readRDS`.)

The option of `xdr = FALSE` was introduced in R 2.15.0. As almost all systems in current use are little-endian, this can be used to avoid byte-shuffling at both ends when transferring data from one little-endian machine to another. Depending on the system, this can speed up serialization and unserialization by a factor of up to 3x.

Value

For `serialize`, `NULL` unless `connection = NULL`, when the result is returned in a raw vector.

For `unserialize` an R object.

Warning

These functions have provided a stable interface since R 2.4.0 (when the storage of serialized objects was changed from character to raw vectors). However, the serialization format may change in future versions of R, so this interface should not be used for long-term storage of R objects.

On 32-bit platforms a raw vector is limited to $2^{31} - 1$ bytes, but R objects can exceed this and their serializations will normally be larger than the objects.

See Also

`saveRDS` for a more convenient interface to serialize an object to a file or connection.

`save` and `load` to serialize and restore one or more named objects.

The ‘R Internals’ manual for details of the format used.

Examples

```r
x <- serialize(list(1,2,3), NULL)
unserialize(x)

## see also the examples for saveRDS
```
Description

Performs set union, intersection, (asymmetric!) difference, equality and membership on two vectors.

Usage

\[
\begin{align*}
\text{union}(x, y) \\
\text{intersect}(x, y) \\
\text{setdiff}(x, y) \\
\text{setequal}(x, y) \\
is.\text{element}(el, set)
\end{align*}
\]

Arguments

\(x, y, el, set\) vectors (of the same mode) containing a sequence of items (conceptually) with no duplicated values.

Details

Each of union, intersect, setdiff and setequal will discard any duplicated values in the arguments, and they apply \texttt{as.vector} to their arguments (and so in particular coerce factors to character vectors).

\(\text{is.element}(x, y)\) is identical to \(x \%in\% y\).

Value

A vector of the same mode as \(x\) or \(y\) for setdiff and intersect, respectively, and of a common mode for union.

A logical scalar for setequal and a logical of the same length as \(x\) for \texttt{is.element}.

See Also

\%in% 

‘plotmath’ for the use of union and intersect in plot annotation.

Examples

\[
\begin{align*}
(x & \leftarrow \text{c(sort(sample(1:20, 9)), NA)}) \\
(y & \leftarrow \text{c(sort(sample(3:23, 7)), NA)}) \\
\text{union}(x, y) \\
\text{intersect}(x, y) \\
\text{setdiff}(x, y) \\
\text{setdiff}(y, x) \\
\text{setequal}(x, y)
\end{align*}
\]

## True for all possible \(x\) & \(y\):
\(\text{setequal}(\text{union}(x, y),\)
c(setdiff(x, y), intersect(x, y), setdiff(y, x))

is.element(x, y) # length 10
is.element(y, x) # length 8

**setTimeLimit**

*Set CPU and/or Elapsed Time Limits*

**Description**

Functions to set CPU and/or elapsed time limits for top-level computations or the current session.

**Usage**

```r
setTimeLimit(cpu = Inf, elapsed = Inf, transient = FALSE)
```

```r
setSessionTimeLimit(cpu = Inf, elapsed = Inf)
```

**Arguments**

- **cpu**
  - double. Limit on total cpu time.

- **elapsed**
  - double. Limit on elapsed time.

- **transient**
  - logical. If TRUE, the limits apply only to the rest of the current computation.

**Details**

**setTimeLimit** sets limits which apply to each top-level computation, that is a command line (including any continuation lines) entered at the console or from a file. If it is called from within a computation the limits apply to the rest of the computation and (unless transient = TRUE) to subsequent top-level computations.

**setSessionTimeLimit** sets limits for the rest of the session. Once a session limit is reached it is reset to Inf.

Setting any limit has a small overhead – well under 1% on the systems measured.

Time limits are checked whenever a user interrupt could occur. This will happen frequently in R code and during `Sys.sleep`, but only at points in compiled C and Fortran code identified by the code author.

‘Total cpu time’ includes that used by child processes where the latter is reported.

**showConnections**  

*Display Connections*

**Description**  

Display aspects of connections.

**Usage**

```
showConnections(all = FALSE)  
getConnection(what)  
closeAllConnections()
```

```
stdin()  
stdout()  
stderr()  
isatty(con)
```

**Arguments**

- **all** logical: if true all connections, including closed ones and the standard ones are displayed. If false only open user-created connections are included.
- **what** integer: a row number of the table given by `showConnections`.
- **con** a connection.

**Details**

`stdin()`, `stdout()` and `stderr()` are standard connections corresponding to input, output and error on the console respectively (and not necessarily to file streams). They are text-mode connections of class "terminal" which cannot be opened or closed, and are read-only, write-only and write-only respectively. The `stdout()` and `stderr()` connections can be re-directed by `sink` (and in some circumstances the output from `stdout()` can be split: see the help page).

The encoding for `stdin()` when redirected can be set by the command-line flag ‘--encoding’.

`showConnections` returns a matrix of information. If a connection object has been lost or forgotten, `getConnection` will take a row number from the table and return a connection object for that connection, which can be used to close the connection, for example. However, if there is no R level object referring to the connection it will be closed automatically at the next garbage collection (except for `gzcon` connections).

`closeAllConnections` closes (and destroys) all user connections, restoring all `sink` diversions as it does so.

`isatty` returns true if the connection is one of the class "terminal" connections and it is apparently connected to a terminal, otherwise false. This may not be reliable in embedded applications, including GUI consoles.
Value

stdin(), stdout() and stderr() return connection objects.
showConnections returns a character matrix of information with a row for each connection, by default only for open non-standard connections.
getConnection returns a connection object, or NULL.

Note

stdin() refers to the ‘console’ and not to the C-level ‘stdin’ of the process. The distinction matters in GUI consoles (which may not have an active ‘stdin’, and if they do it may not be connected to console input), and also in embedded applications. If you want access to the C-level file stream ‘stdin’, use file("stdin").
When R is reading a script from a file, the file is the ‘console’: this is traditional usage to allow in-line data (see ‘An Introduction to R’ for an example).

Examples

showConnections(all = TRUE)
## Not run:
textConnection(letters)
# oops, I forgot to record that one
showConnections()
# class description mode text isOpen can read can write
# "letters" "textConnection" "r" "text" "opened" "yes" "no"
mycon <- getConnection(3)
## End(Not run)
c(isatty(stdin()), isatty(stdout()), isatty(stderr()))

shQuote

Quote Strings for Use in OS Shells

Description

Quote a string to be passed to an operating system shell.

Usage

shQuote(string, type = c("sh", "csh", "cmd"))

Arguments

string

a character vector, usually of length one.

type

character: the type of shell. Partial matching is supported. "cmd" refers to the Windows NT shell, and is the default under Windows.
Details

The default type of quoting supported under Unix-alikes is that for the Bourne shell sh. If the string does not contain single quotes, we can just surround it with single quotes. Otherwise, the string is surrounded in double quotes, which suppresses all special meanings of metacharacters except dollar, backquote and backslash, so these (and of course double quote) are preceded by backslash. This type of quoting is also appropriate for bash, ksh and zsh.

The other type of quoting is for the C-shell (csh and tcsh). Once again, if the string does not contain single quotes, we can just surround it with single quotes. If it does contain single quotes, we can use double quotes provided it does not contain dollar or backquote (and we need to escape backslash, exclamation mark and double quote). As a last resort, we need to split the string into pieces not containing single quotes and surround each with single quotes, and the single quotes with double quotes.

References

http://www.mhuffman.com/notes/dos/bash_cmd.htm

See Also

Quotes for quoting R code.

sQuote for quoting English text.

Examples

test <- "abc$def'gh'\i\j"
cat(shQuote(test), "\n")
## Not run: system(paste("echo", shQuote(test)))
test <- "don't do it!"
cat(shQuote(test), "\n")

tryit <- paste("use the", sQuote("-c"), "switch\nlike this")
cat(shQuote(tryit), "\n")
## Not run: system(paste("echo", shQuote(tryit)))
cat(shQuote(tryit, type = "csh"), "\n")

## Windows-only example.
perlcmd <- 'print "Hello World\n";'
## Not run: shell(paste("perl -e", shQuote(perlcmd, type = "cmd")))

---

sign

**Sign Function**

sign returns a vector with the signs of the corresponding elements of x (the sign of a real number is 1, 0, or −1 if the number is positive, zero, or negative, respectively).

Note that sign does not operate on complex vectors.

Usage

sign(x)
Arguments

\( x \) a numeric vector

Details

This is an internal generic primitive function: methods can be defined for it directly or via the Math group generic.

See Also

abs

Examples

\[
\begin{align*}
\text{sign(pi)} & \quad \# == 1 \\
\text{sign(-2:3)} & \quad \# -1 -1 0 1 1 1
\end{align*}
\]

Signals

Interrupting Execution of R

Description

On receiving SIGUSR1 R will save the workspace and quit. SIGUSR2 has the same result except that the .Last function and on.exit expressions will not be called.

Usage

\[
\begin{align*}
\text{kill} -\text{USR1} \text{ pid} \\
\text{kill} -\text{USR2} \text{ pid}
\end{align*}
\]

Arguments

\( \text{pid} \) The process ID of the R process.

Details

The commands history will also be saved if would be at normal termination.

This is not available on Windows, and possibly on other OSes which do not support these signals.

Warning

It is possible that one or more R objects will be undergoing modification at the time the signal is sent. These objects could be saved in a corrupted form.

See Also

Sys.getpid to report the process ID for future use.
sink

Send R Output to a File

Description

sink diverts R output to a connection.
sink.number() reports how many diversions are in use.
sink.number(type = "message") reports the number of the connection currently being used for error messages.

Usage

sink(file = NULL, append = FALSE, type = c("output", "message"),
     split = FALSE)

sink.number(type = c("output", "message"))

Arguments

file a writable connection or a character string naming the file to write to, or NULL to stop sink-ing.
append logical. If TRUE, output will be appended to file; otherwise, it will overwrite the contents of file.
type character. Either the output stream or the messages stream.
split logical: if TRUE, output will be sent to the new sink and to the current output stream, like the Unix program tee.

Details

sink diverts R output to a connection. If file is a character string, a file connection with that name will be established for the duration of the diversion.

Normal R output (to connection stdout) is diverted by the default type = "output". Only prompts and (most) messages continue to appear on the console. Messages sent to stderr() (including those from message, warning and stop) can be diverted by sink(type = "message") (see below).

sink() or sink(file = NULL) ends the last diversion (of the specified type). There is a stack of diversions for normal output, so output reverts to the previous diversion (if there was one). The stack is of up to 21 connections (20 diversions).

If file is a connection it will be opened if necessary (in "wt" mode) and closed once it is removed from the stack of diversions.

split = TRUE only splits R output (via Rprintf) and the default output from writelines: it does not split all output that might be sent to stdout().

Sink-ing the messages stream should be done only with great care. For that stream file must be an already open connection, and there is no stack of connections.

If file is a character string, the file will be opened using the current encoding. If you want a different encoding (e.g. to represent strings which have been stored in UTF-8), use a file connection — but some ways to produce R output will already have converted such strings to the current encoding.
Value

sink returns NULL.

For sink.number() the number (0, 1, 2, ...) of diversions of output in place.

For sink.number("message") the connection number used for messages, 2 if no diversion has been used.

Warning

Do not use a connection that is open for sink for any other purpose. The software will stop you closing one such inadvertently.

Do not sink the messages stream unless you understand the source code implementing it and hence the pitfalls.

capture.output

Examples

```r
sink("sink-examp.txt")
i <- 1:10
outer(i, i, "+")
sink()
unlink("sink-examp.txt")
# Not run:
# capture all the output to a file.
zz <- file("all.Rout", open = "wt")
sink(zz)
sink(zz, type = "message")
try(log("a"))
# back to the console
sink(type = "message")
sink()
try(log("a"))

# End(Not run)
```

slice.index

Slice Indexes in an Array

Description

Returns a matrix of integers indicating the number of their slice in a given array.
Usage

slice.index(x, MARGIN)

Arguments

x                  an array. If x has no dimension attribute, it is considered a one-dimensional array.
MARGIN             an integer giving the dimension number to slice by.

Value

An integer array y with dimensions corresponding to those of x such that all elements of slice number i with respect to dimension MARGIN have value i.

See Also

row and col for determining row and column indexes; in fact, these are special cases of slice.index corresponding to MARGIN equal to 1 and 2, respectively when x is a matrix.

Examples

x <- array(1:24, c(2, 3, 4))
slice.index(x, 2)

---

**Extract or Replace A Slot**

Description

Extract or replace the contents of a slot in a object with a formal (S4) class structure.

Usage

object@name
object@name <- value

Arguments

object                  An object from a formally defined (S4) class.
name                    The character-string name of the slot, quoted or not. Must be the name of a slot in the definition of the class of object.
value                   A replacement value for the slot, which must be from a class compatible with the class defined for this slot in the definition of the class of object.
Details

These operators support the formal classes of package methods, and are enabled only when package methods is loaded (as per default). See slot for further details, in particular for the differences between slot() and the @ operator.

It is checked that object is an S4 object (see isS4), and it is an error to attempt to use @ on any other object. (There is an exception for name .data for internal use only.) The replacement operator checks that the slot already exists on the object (which it should if the object is really from the class it claims to be).

Prior to R 3.0.0 the replacement operator was in package methods and had a different test for validity of name.

These are internal generic operators: see InternalMethods.

Value

The current contents of the slot.

See Also

extract, slot

socketSelect Wait on Socket Connections

Description

Waits for the first of several socket connections to become available.

Usage

socketSelect(socklist, write = FALSE, timeout = NULL)

Arguments

socklist list of open socket connections
write logical. If TRUE wait for corresponding socket to become available for writing; otherwise wait for it to become available for reading.
timeout numeric or NULL. Time in seconds to wait for a socket to become available; NULL means wait indefinitely.

Details

The values in write are recycled if necessary to make up a logical vector the same length as socklist. Socket connections can appear more than once in socklist; this can be useful if you want to determine whether a socket is available for reading or writing.

Value

Logical the same length as socklist indicating whether the corresponding socket connection is available for output or input, depending on the corresponding value of write.
solve

Examples

## Not run:
## test whether socket connection s is available for writing or reading
socketSelect(list(s, s), c(TRUE, FALSE), timeout = 0)

## End(Not run)

solve

Solve a System of Equations

Description

This generic function solves the equation \( a \cdot x = b \) for \( x \), where \( b \) can be either a vector or a matrix.

Usage

solve(a, b, ...)

## Default S3 method:
solve(a, b, tol, LINPACK = FALSE, ...)

Arguments

- **a**: a square numeric or complex matrix containing the coefficients of the linear system. Logical matrices are coerced to numeric.
- **b**: a numeric or complex vector or matrix giving the right-hand side(s) of the linear system. If missing, \( b \) is taken to be an identity matrix and \( \text{solve} \) will return the inverse of \( a \).
- **tol**: the tolerance for detecting linear dependencies in the columns of \( a \). The default is \( \text{.Machine}\$\text{double.eps} \). Not currently used with complex matrices \( a \).
- **LINPACK**: logical. Defunct and ignored (with a warning for a true value).
- **...**: further arguments passed to or from other methods

Details

- \( a \) or \( b \) can be complex, but this uses double complex arithmetic which might not be available on all platforms and LAPACK will always be used.
- The row and column names of the result are taken from the column names of \( a \) and of \( b \) respectively. If \( b \) is missing the column names of the result are the row names of \( a \). No check is made that the column names of \( a \) and the row names of \( b \) are equal.
- For back-compatibility \( a \) can be a (real) QR decomposition, although \( \text{qr.solve} \) should be called in that case. \( \text{qr.solve} \) can handle non-square systems.

Source

The default method is an interface to the LAPACK routines DGESV and ZGESV.

LAPACK is from [http://www.netlib.org/lapack](http://www.netlib.org/lapack).
sort

Sorting or Ordering Vectors

Description

Sort (or order) a vector or factor (partially) into ascending or descending order. For ordering along more than one variable, e.g., for sorting data frames, see order.

Usage

sort(x, decreasing = FALSE, ...)

## Default S3 method:
sort(x, decreasing = FALSE, na.last = NA, ...)

sort.int(x, partial = NULL, na.last = NA, decreasing = FALSE,
          method = c("shell", "quick"), index.return = FALSE)

Arguments

x

decreasing

...
for controlling the treatment of NAs. If TRUE, missing values in the data are put last; if FALSE, they are put first; if NA, they are removed.

NULL or a vector of indices for partial sorting.

character string specifying the algorithm used. Not available for partial sorting.

logical indicating if the ordering index vector should be returned as well; this is only available for a few cases, the default na.last = NA and full sorting of non-factors.

sort is a generic function for which methods can be written, and sort.int is the internal method which is compatible with S if only the first three arguments are used.

The default sort method makes use of order for classed objects, which in turn makes use of the generic function xtfrm (and can be slow unless a xtfrm method has been defined or is.numeric(x) is true).

Complex values are sorted first by the real part, then the imaginary part.

The sort order for character vectors will depend on the collating sequence of the locale in use: see Comparison. The sort order for factors is the order of their levels (which is particularly appropriate for ordered factors).

If partial is not NULL, it is taken to contain indices of elements of the result which are to be placed in their correct positions in the sorted array by partial sorting. For each of the result values in a specified position, any values smaller than that one are guaranteed to have a smaller index in the sorted array and any values which are greater are guaranteed to have a bigger index in the sorted array. (This is included for efficiency, and many of the options are not available for partial sorting. It is only substantially more efficient if partial has a handful of elements, and a full sort is done (a Quicksort if possible) if there are more than 10.) Names are discarded for partial sorting.

Method "shell" uses Shellsort (an $O(n^{4/3})$ variant from Sedgewick (1986)). If x has names a stable modification is used, so ties are not reordered. (This only matters if names are present.)

Method "quick" uses Singleton (1969)'s implementation of Hoare's Quicksort method and is only available when x is numeric (double or integer) and partial is NULL. (For other types of x Shellsort is used, silently.) It is normally somewhat faster than Shellsort (perhaps 50% faster on vectors of length a million and twice as fast at a billion) but has poor performance in the rare worst case. (Peto's modification using a pseudo-random midpoint is used to make the worst case rarer.) This is not a stable sort, and ties may be reordered.

Factors with less than 100,000 levels are sorted by radix sorting when method is not supplied: see sort.list.

For sort, the result depends on the S3 method which is dispatched. If x does not have a class sort.int is used and it description applies. For classed objects which do not have a specific method the default method will be used and is equivalent to x[order(x, ...)]: this depends on the class having a suitable method for order (and also that order will work, which is not the case for a class based on a list).

For sort.int the value is the sorted vector unless index.return is true, when the result is a list with components named x and ix containing the sorted numbers and the ordering index vector. In the latter case, if method == "quick" ties may be reversed in the ordering (unlike sort.list) as quicksort is not stable. NB: the index vector refers to element numbers after removal of NAs: see order if you want the original element numbers.
All attributes are removed from the return value (see Becker et al, 1988, p.146) except names, which are sorted. (If partial is specified even the names are removed.) Note that this means that the returned value has no class, except for factors and ordered factors (which are treated specially and whose result is transformed back to the original class).

### Read R Code from a File or a Connection

**Description**

`source` causes R to accept its input from the named file or URL or connection. Input is read and **parsed** from that file until the end of the file is reached, then the parsed expressions are evaluated sequentially in the chosen environment.

**Usage**

```r
source(file, local = FALSE, echo = verbose, print.eval = echo,
verbose = getOption("verbose"),
prompt.echo = getOption("prompt"),
max.deparse.length = 150, chdir = FALSE,
encoding = getOption("encoding"),
continue.echo = getOption("continue"),
skip.echo = 0, keep.source = getOption("keep.source"))
```

**Arguments**

- `file`: a connection or a character string giving the pathname of the file or URL to read from. "" indicates the connection `stdin()`.
- `local`: TRUE, FALSE or an environment, determining where the parsed expressions are evaluated. FALSE (the default) corresponds to the user’s workspace (the global environment) and TRUE to the environment from which `source` is called.
- `echo`: logical; if TRUE, each expression is printed after parsing, before evaluation.
- `print.eval`: logical; if TRUE, the result of `eval(i)` is printed for each expression `i`; defaults to the value of `echo`.
- `verbose`: if TRUE, more diagnostics (than just `echo = TRUE`) are printed during parsing and evaluation of input, including extra info for `each` expression.
- `prompt.echo`: character; gives the prompt to be used if `echo = TRUE`.
- `max.deparse.length`: integer; is used only if `echo` is TRUE and gives the maximal number of characters output for the deparse of a single expression.
- `chdir`: logical; if TRUE and `file` is a pathname, the R working directory is temporarily changed to the directory containing `file` for evaluating.
- `encoding`: character vector. The encoding(s) to be assumed when `file` is a character string: see `file`. A possible value is "unknown" when the encoding is guessed: see the ‘Encodings’ section.
- `continue.echo`: character; gives the prompt to use on continuation lines if `echo = TRUE`. 
skip.echo  integer; how many comment lines at the start of the file to skip if echo = TRUE.
keep.source logical: should the source formatting be retained when echoing expressions, if possible?

Details

Note that running code via source differs in a few respects from entering it at the R command line. Since expressions are not executed at the top level, auto-printing is not done. So you will need to include explicit print calls for things you want to be printed (and remember that this includes plotting by lattice, FAQ Q7.22). Since the complete file is parsed before any of it is run, syntax errors result in none of the code being run. If an error occurs in running a syntactically correct script, anything assigned into the workspace by code that has been run will be kept (just as from the command line), but diagnostic information such as traceback() will contain additional calls to withVisible.

All versions of R accept input from a connection with end of line marked by LF (as used on Unix), CRLF (as used on DOS/Windows) or CR (as used on classic Mac OS) and map this to newline. The final line can be incomplete, that is missing the final end-of-line marker.

If keep.source is true (the default in interactive use), the source of functions is kept so they can be listed exactly as input.

Unlike input from a console, lines in the file or on a connection can contain an unlimited number of characters.

When skip.echo > 0, that many comment lines at the start of the file will not be echoed. This does not affect the execution of the code at all. If there are executable lines within the first skip.echo lines, echoing will start with the first of them.

If echo is true and a deparsed expression exceeds max.deparse.length, that many characters are output followed by .... [TRUNCATED].

Encodings

By default the input is read and parsed in the current encoding of the R session. This is usually what it required, but occasionally re-encoding is needed, e.g. if a file from a UTF-8-using system is to be read on Windows (or vice versa).

The rest of this paragraph applies if file is an actual filename or URL (and not "") nor a connection. If encoding = "unknown", an attempt is made to guess the encoding: the result of localeToCharSet() is used as a guide. If encoding has two or more elements, they are tried in turn until the file/URL can be read without error in the trial encoding. If an actual encoding is specified (rather than the default or "unknown") in a Latin-1 or UTF-8 locale then character strings in the result will be translated to the current encoding and marked as such (see Encoding).

If file is a connection (including one specified by ""); it is not possible to re-encode the input inside source, and so the encoding argument is just used to mark character strings in the parsed input in Latin-1 and UTF-8 locales: see parse.

‘The R Language Definition’ for a discussion of source directives.

**Examples**

```r
### If you want to source() a bunch of files, something like
### the following may be useful:
sourceDir <- function(path, trace = TRUE, ...) {
  for (mm in list.files(path, pattern = "[.]\([\w\s\$]*\)\)"") {
    if (trace) cat(mm,":")
    source(file.path(path, mm), ...)
  }
  if (trace) cat("\n")
}
```

---

**Special Functions of Mathematics**

**Description**

Special mathematical functions related to the beta and gamma functions.

**Usage**

- `beta(a, b)`
- `lbeta(a, b)`
- `gamma(x)`
- `lgamma(x)`
- `psigamma(x, deriv = 0)`
- `digamma(x)`
- `trigamma(x)`
- `choose(n, k)`
- `lchoose(n, k)`
- `factorial(x)`
- `lfactorial(x)`

**Arguments**

- `a, b` non-negative numeric vectors.
- `x, n` numeric vectors.
- `k, deriv` integer vectors.

**Details**

The functions `beta` and `lbeta` return the beta function and the natural logarithm of the beta function,

\[
B(a, b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a + b)}.
\]

The formal definition is

\[
B(a, b) = \int_0^1 t^{a-1}(1 - t)^{b-1} dt
\]
Special

(Abramowitz and Stegun section 6.2.1, page 258). Note that it is only defined in \( \mathbb{R} \) for non-negative \( a \) and \( b \), and is infinite if either is zero.

The functions `gamma` and `lgamma` return the gamma function \( \Gamma(x) \) and the natural logarithm of the absolute value of the gamma function. The gamma function is defined by (Abramowitz and Stegun section 6.1.1, page 255)

\[
\Gamma(x) = \int_0^\infty t^{x-1}e^{-t}dt
\]

for all real \( x \) except zero and negative integers (when NaN is returned). There will be a warning on possible loss of precision for values which are too close (within about \( 10^{-8} \)) to a negative integer less than \(-10^\text{MQP}\).

`factorial(x)` \((x!\text{ for non-negative integer } x)\) is defined to be \( \gamma(x+1) \) and `ifactorial` to be \( \Gamma(x+1) \).

The functions `digamma` and `trigamma` return the first and second derivatives of the logarithm of the gamma function. \( \psi(x) \) \( = \frac{d}{dx} \ln \Gamma(x) = \frac{\Gamma'(x)}{\Gamma(x)} \)

This is often called the ‘polygamma’ function, e.g. in Abramowitz and Stegun (section 6.4.1, page 260); and higher derivatives \( (\text{deriv} = 2:4) \) have occasionally been called ‘tetragamma’, ‘pentagamma’, and ‘hexagamma’.

The functions `choose` and `lchoose` return binomial coefficients and the logarithms of their absolute values. Note that `choose(n, k)` is defined for all real numbers \( n \) and integer \( k \). For \( k \geq 1 \) it is defined as \( n(n-1)\cdots(n-k+1)/k! \), as 1 for \( k = 0 \) and as 0 for negative \( k \). Non-integer values of \( k \) are rounded to an integer, with a warning.

`choose(n, k)` uses direct arithmetic (instead of \([1]\gamma\) calls) for small \( k \), for speed and accuracy reasons. Note the function `combn` (package `utils`) for enumeration of all possible combinations.

The gamma, lgamma, digamma and trigamma functions are internal generic primitive functions: methods can be defined for them individually or via the `Math` group generic.

Source

`gamma`, `lgamma`, `beta` and `lbeta` are based on C translations of Fortran subroutines by W. Fullerton of Los Alamos Scientific Laboratory (now available as part of SLATEC).

`digamma`, `trigamma` and `psigamma` are based on

    dy <- diff(y) / dx # finite difference
    der <- which(ch == c("di", "tri", "tetra", "penta")) - 1
    mm2 <- paste0("psigamma(*, deriv = ", der, ")")
    y <- if(der == 2) nm2 else paste(nm, mm2, sep = " ==\n")
    y <- psigamma(x, deriv = der)
  } else {
    y <- get(nm)(x)
  }
  plot(x, y, type = "l", main = nm, col = "red")
  abline(h = 0, col = "lightgray")
  if (is.deriv) lines(x[-1], dy, col = "blue", lty = 2)
}
par(mfrow = c(1, 1))

## "Extended" Pascal triangle:
fn <- function(n) formatC(n, width=2)
for (n in -4:10) {
  cat(fn(n), ":", fn(choose(n, k = -2:max(3, n+2))))
  cat("\n")
}

## R code version of choose() [simplistic; warning for k < 0]:
mychoose <- function(r, k)
  ifelse(k <= 0, (k == 0),
    sapply(k, function(k) prod(r:(r-k+1))) / factorial(k))
k <- -1:6
ccbind(k = k, choose(1/2, k), mychoose(1/2, k))

## Binomial theorem for n = 1/2:
## sqrt((1+x)^{1/2}) = sum_{k=0}^{\infty} choose(1/2, k) \times x^k
k <- 0:10 # 10 is sufficient for ~ 9 digit precision:
```
\[ \text{split} \quad \sqrt{1.25} \quad \text{sum(choose(1/2, k) \times 25^k)} \]

**split**

**Divide into Groups and Reassemble**

**Description**

`split` divides the data in the vector `x` into the groups defined by `f`. The replacement forms replace values corresponding to such a division. `unsplit` reverses the effect of `split`.

**Usage**

```r
split(x, f, drop = FALSE, ...)  
split(x, f, drop = FALSE, ...) <- value  
unsplit(value, f, drop = FALSE)
```

**Arguments**

- `x` vector or data frame containing values to be divided into groups.
- `f` a `factor` in the sense that `as.factor(f)` defines the grouping, or a list of such factors in which case their interaction is used for the grouping.
- `drop` logical indicating if levels that do not occur should be dropped (if `f` is a `factor` or a list).
- `value` a list of vectors or data frames compatible with a splitting of `x`. Recycling applies if the lengths do not match.
- `...` further potential arguments passed to methods.

**Details**

`split` and `split<-` are generic functions with default and `data.frame` methods. The data frame method can also be used to split a matrix into a list of matrices, and the replacement form likewise, provided they are invoked explicitly.

`unsplit` works with lists of vectors or data frames (assumed to have compatible structure, as if created by `split`). It puts elements or rows back in the positions given by `f`. In the data frame case, row names are obtained by unsplitting the row name vectors from the elements of `value`.

`f` is recycled as necessary and if the length of `x` is not a multiple of the length of `f` a warning is printed.

Any missing values in `f` are dropped together with the corresponding values of `x`.

The default method calls `interaction`. If the levels of the factors contain `.` they may not be split as expected, so the method has argument `sep` which is used to join the levels.

**Value**

The value returned from `split` is a list of vectors containing the values for the groups. The components of the list are named by the levels of `f` (after converting to a factor, or if already a factor and `drop = TRUE`, dropping unused levels).

The replacement forms return their right hand side. `unsplit` returns a vector or data frame for which `split(x, f)` equals `value`.

split(zz, g) <- lapply(split(x, g), scale)

# and check that the within-group std dev is indeed one
tapply(z, g, sd)
tapply(zz, g, sd)

### data frame variation

## Notice that assignment form is not used since a variable is being added

g <- airquality$Month
l <- split(airquality, g)
l <- lapply(l, transform, OZ.Z = scale(Ozone))
aq2 <- unsplit(l, g)
head(aq2)
with(aq2, tapply(OZ.Z, Month, sd, na.rm = TRUE))

### Split a matrix into a list by columns

ma <- cbind(x = 1:10, y = (-4:5)^2)
split(ma, col(ma))

split(1:10, 1:2)
```
**sprintf**

*Use C-style String Formatting Commands*

**Description**

A wrapper for the C function `sprintf`, that returns a character vector containing a formatted combination of text and variable values.

**Usage**

```r
sprintf(fmt, ...)  
gettextf(fmt, ..., domain = NULL)
```

**Arguments**

- `fmt` a character vector of format strings, each of up to 8192 bytes.
- `...` values to be passed into `fmt`. Only logical, integer, real and character vectors are supported, but some coercion will be done: see the 'Details' section.
- `domain` see `gettext`.

**Details**

`sprintf` is a wrapper for the system `sprintf` C-library function. Attempts are made to check that the mode of the values passed match the format supplied, and R’s special values (NA, Inf, -Inf and NaN) are handled correctly.

`gettextf` is a convenience function which provides C-style string formatting with possible translation of the format string.

The arguments (including `fmt`) are recycled if possible a whole number of times to the length of the longest, and then the formatting is done in parallel. Zero-length arguments are allowed and will give a zero-length result. All arguments are evaluated even if unused, and hence some types (e.g., "symbol" or "language", see `typeof`) are not allowed.

The following is abstracted from Kernighan and Ritchie (see References): however the actual implementation will follow the C99 standard and fine details (especially the behaviour under user error) may depend on the platform.

The string `fmt` contains normal characters, which are passed through to the output string, and also conversion specifications which operate on the arguments provided through `...`. The allowed conversion specifications start with a `E` and end with one of the letters in the set `aAdifeGeGosxX`. These letters denote the following types:

- `d`, `i`, `o`, `x`, `X` Integer value, `o` being octal, `x` and `X` being hexadecimal (using the same case for `a`-`f` as the code). Numeric variables with exactly integer values will be coerced to integer. Formats `d` and `i` can also be used for logical variables, which will be converted to 0, 1 or NA.
- `f` Double precision value, in “fixed point” decimal notation of the form "[-]mm.mmm.ddd”. The number of decimal places ("d") is specified by the precision: the default is 6; a precision of 0 suppresses the decimal point. Non-finite values are converted to NA, NaN or (perhaps a sign followed by) Inf.
- `e`, `E` Double precision value, in “exponential” decimal notation of the form `[-]m.ddde[+-]xx` or `[-]m.dde[+-]xx`.  

g, G Double precision value, in %e or %E format if the exponent is less than -4 or greater than or equal to the precision, and %f format otherwise. (The precision (default 6) specifies the number of significant digits here, whereas in %f, %e, it is the number of digits after the decimal point.)

a, A Double precision value, in binary notation of the form [-]0xh.hhhhp[+-]d. This is a binary fraction expressed in hex multiplied by a (decimal) power of 2. The number of hex digits after the decimal point is specified by the precision: the default is enough digits to represent exactly the internal binary representation. Non-finite values are converted to NA, NaN or (perhaps a sign followed by) Inf. Format %a uses lower-case for x, p and the hex values: format %A uses upper-case.

This should be supported on all platforms as it is a feature of C99. The format is not uniquely defined: although it would be possible to make the leading h always zero or one, this is not always done. Most systems will suppress trailing zeros, but a few do not. On a well-written platform, for normal numbers there will be a leading one before the decimal point plus (by default) 13 hexadecimal digits, hence 53 bits. The treatment of denormalized (aka ‘subnormal’) numbers is very platform-dependent.

s Character string. Character NAs are converted to "NA".

% Literal % (none of the extra formatting characters given below are permitted in this case).

Conversion by as.character is used for non-character arguments with %s and by as.double for non-double arguments with %f, %e, %E, %g, %G. NB: the length is determined before conversion, so do not rely on the internal coercion if this would change the length. The coercion is done only once, so if length(fmt) > 1 then all elements must expect the same types of arguments.

In addition, between the initial % and the terminating conversion character there may be, in any order:

m.n Two numbers separated by a period, denoting the field width (m) and the precision (n).

- Left adjustment of converted argument in its field.

+ Always print number with sign: by default only negative numbers are printed with a sign.

a space Prefix a space if the first character is not a sign.

0 For numbers, pad to the field width with leading zeros.

# specifies “alternate output” for numbers, its action depending on the type: For x or X, 0x or 0X will be prefixed to a non-zero result. For e, e, f, g and G, the output will always have a decimal point; for g and G, trailing zeros will not be removed.

Further, immediately after % may come 1 $ to 99$ to refer to numbered argument: this allows arguments to be referenced out of order and is mainly intended for translators of error messages. If this is done it is best if all formats are numbered: if not the unnumbered ones process the arguments in order. See the examples. This notation allows arguments to be used more than once, in which case they must be used as the same type (integer, double or character).

A field width or precision (but not both) may be indicated by an asterisk *: in this case an argument specifies the desired number. A negative field width is taken as a `-' flag followed by a positive field width. A negative precision is treated as if the precision were omitted. The argument should be integer, but a double argument will be coerced to integer.

There is a limit of 8192 bytes on elements of fmt, and on strings included from a single %letter conversion specification.

Field widths and precisions of %s conversions are interpreted as bytes, not characters, as described in the C standard.
The `sprintf` function is used to format character vectors. It takes a string of format codes and a list of values to format, and returns a character vector of formatted values.

**Value**

A character vector of length that of the longest input. If any element of `fmt` or any character argument is declared as UTF-8, the element of the result will be in UTF-8 and have the encoding declared as UTF-8. Otherwise it will be in the current locale’s encoding.

**Warning**

The format string is passed down the OS’s `sprintf` function, and incorrect formats can cause the latter to crash the R process. R does perform sanity checks on the format, and since R 2.10.0, we have not seen crashes anymore. But not all possible user errors on all platforms have been tested, and some might be terminal.

The behaviour on inputs not documented here is ‘undefined’, which means it is allowed to differ by platform.

**Author(s)**

Original code by Jonathan Rougier.

**See Also**

`formatC` for a way of formatting vectors of numbers in a similar fashion.

`paste` for another way of creating a vector combining text and values.

`gettext` for the mechanisms for the automated translation of text.

**Examples**

```r
## be careful with the format: most things in R are floats
## only integer-valued reals get coerced to integer.

sprintf("%s is %f feet tall\n", "Sven", 7.1)  # OK
try(sprintf("%s is %i feet tall\n", "Sven", 7.1)) # not OK
 sprintf("%s is %i feet tall\n", "Sven", 7  ) # OK

## use a literal %:

sprintf("%.0f%%% said yes (out of a sample of size %.0f)", 66.666, 3)

## various formats of pi :

sprintf("%f", pi)
 sprintf("%.3f", pi)
 sprintf("%.1f", pi)
 sprintf("%5.1f", pi)
 sprintf("%05.1f", pi)
 sprintf("%+f", pi)
```
sQuote

description

Single or double quote text by combining with appropriate single or double left and right quotation marks.

Usage

sQuote(x)
dQuote(x)
sQuote

Arguments

x an R object, to be coerced to a character vector.

Details

The purpose of the functions is to provide a simple means of markup for quoting text to be used in the R output, e.g., in warnings or error messages.

The choice of the appropriate quotation marks depends on both the locale and the available character sets. Older Unix/X11 fonts displayed the grave accent (ASCII code 0x60) and the apostrophe (0x27) in a way that they could also be used as matching open and close single quotation marks. Using modern fonts, or non-Unix systems, these characters no longer produce matching glyphs. Unicode provides left and right single quotation mark characters (U+2018 and U+2019); if Unicode markup cannot be assumed to be available, it seems good practice to use the apostrophe as a non-directional single quotation mark.

Similarly, Unicode has left and right double quotation mark characters (U+201C and U+201D); if only ASCII’s typewriter characteristics can be employed, than the ASCII quotation mark (0x22) should be used as both the left and right double quotation mark.

Some other locales also have the directional quotation marks, notably on Windows. TeX uses grave and apostrophe for the directional single quotation marks, and doubled grave and doubled apostrophe for the directional double quotation marks.

What rendering is used depend on the options setting for useFancyQuotes. If this is FALSE then the undirectional ASCII quotation style is used. If this is TRUE (the default), Unicode directional quotes are used and are used where available (currently, UTF-8 locales on Unix-alikes and all Windows locales except C): if set to "UTF-8" UTF-8 markup is used (whatever the current locale). If set to "TeX", TeX-style markup is used. Finally, if this is set to a character vector of length four, the first two entries are used for beginning and ending single quotes and the second two for beginning and ending double quotes: this can be used to implement non-English quoting conventions such as the use of guillemets.

Where fancy quotes are used, you should be aware that they may not be rendered correctly as not all fonts include the requisite glyphs: for example some have directional single quotes but not directional double quotes.

Value

A character vector of the same length as x (after any coercion) in the current locale’s encoding.

Quotes for quoting R code.

shQuote for quoting OS commands.

Examples

op <- options("useFancyQuotes")
paste("argument", sQuote("x"), "must be non-zero")
options(useFancyQuotes = FALSE)
References to source files

Description

These functions are for working with source files.

Usage

srcfile(filename, encoding = getOption("encoding"), Enc = "unknown")
srcfilecopy(filename, lines, timestamp = Sys.time(), isFile = FALSE)
srcrealias(filename, srcfile)
getSrclines(srcfile, first, last)
srcref(srcfile, lloc)
## S3 method for class 'srcfile'
print(x, ...)
## S3 method for class 'srcfile'
summary(object, ...)
## S3 method for class 'srcfile'
open(con, line, ...)  
## S3 method for class 'srcfile'
close(con, ...)
## S3 method for class 'srcref'
print(x, useSource = TRUE, ...)
## S3 method for class 'srcref'
summary(object, useSource = FALSE, ...)
## S3 method for class 'srcref'
as.character(x, useSource = TRUE, ...)
.isopen(srcfile)

Arguments

filename  The name of a file.
encoding

Enc

lines

timestamp

isfile

srcfile

first, last, line

llloc

x, object, con

useSource

...
Lists of \texttt{srcref} objects may be attached to expressions as the "srcref" attribute. (The list of \texttt{srcref} objects should be the same length as the expression.) By default, expressions are printed by \texttt{print.default} using the associated \texttt{srcref}. To see deparsed code instead, call \texttt{print} with argument \texttt{useSource = FALSE}. If a \texttt{srcref} object is printed with \texttt{useSource = FALSE}, the $<$\texttt{srcref}: ...$>$ record will be printed.

\texttt{.isOpen} is intended for internal use: it checks whether the connection associated with a \texttt{srcfile} object is open.

**Value**

- \texttt{srcfile} returns a \texttt{srcfile} object.
- \texttt{srcfilecopy} returns a \texttt{srcfilecopy} object.
- \texttt{getSrcLines} returns a character vector of source code lines.
- \texttt{srcref} returns a \texttt{srcref} object.

**Author(s)**

Duncan Murdoch

**See Also**

- \texttt{getSrcFilename} for extracting information from a source reference.

**Examples**

```r
# has timestamp
src <- srcfile(system.file("DESCRIPTION", package = "base"))
summary(src)
getSrcLines(src, 1, 4)
ref <- srcref(src, c(1, 1, 2, 1000))
ref
print(ref, useSource = FALSE)
```

---

**Description**

In \textit{R}, the startup mechanism is as follows.

Unless ‘--no-environ’ was given on the command line, \textit{R} searches for site and user files to process for setting environment variables. The name of the site file is the one pointed to by the environment variable \texttt{R_ENVIRON}; if this is unset, ‘\texttt{R_HOME/etc/Renviron.site}’ is used (if it exists, which it does not in a ‘factory-fresh’ installation). The name of the user file can be specified by the \texttt{R_ENVIRON_USER} environment variable; if this is unset, the files searched for are ‘.Renviron’ in the current or in the user's home directory (in that order). See ‘Details’ for how the files are read.

Then \textit{R} searches for the site-wide startup profile file of \textit{R} code unless the command line option ‘--no-site-file’ was given. The path of this file is taken from the value of the \texttt{R_PROFILE} environment variable (after tilde expansion). If this variable is unset, the default is ‘\texttt{R_HOME/etc/Rprofile.site}’, which is used if it exists (which it does not in a ‘factory-fresh’
startup. This code is sourced into the **base** package. Users need to be careful not to unintentionally overwrite objects in **base**, and it is normally advisable to use `local` if code needs to be executed: see the examples.

Then, unless `--no-init-file` was given, R searches for a user profile, a file of `R` code. The path of this file can be specified by the `R_PROFILE_USER` environment variable (and tilde expansion will be performed). If this is unset, a file called `.`Rprofile` is searched for in the current directory or in the user’s home directory (in that order). The user profile file is sourced into the workspace.

Note that when the site and user profile files are sourced only the **base** package is loaded, so objects in other packages need to be referred to by e.g. `utils::dump.frames` or after explicitly loading the package concerned.

R then loads a saved image of the user workspace from `.RData` in the current directory if there is one (unless `--no-restore-data` or `--no-restore` was specified on the command line).

Next, if a function `.First` is found on the search path, it is executed as `.First()`. Finally, function `.First.sys()` in the **base** package is run. This calls `require` to attach the default packages specified by `options("defaultPackages")`. If the `methods` package is included, this will have been attached earlier (by function `.OptRequireMethods()`) so that namespace initializations such as those from the user workspace will proceed correctly.

A function `.First` (and `.Last`) can be defined in appropriate `.`Rprofile` or `Rprofile.site` files or have been saved in `.RData`. If you want a different set of packages than the default ones when you start, insert a call to `options` in the `.`Rprofile` or `Rprofile.site` file. For example, `options(defaultPackages = character())` will attach no extra packages on startup (only the **base** package) or (set `R_DEFAULT_PACKAGES=NULL` as an environment variable before running R). Using `options(defaultPackages = "")` or `R_DEFAULT_PACKAGES=""` enforces the R _system_ default.

On front-ends which support it, the commands history is read from the file specified by the environment variable `R_HISTFILE` (default `.Rhistory` in the current directory) unless `--no-restore-history` or `--no-restore` was specified.

The command-line option `--vanilla` implies `--no-site-file`, `--no-init-file`, `--no-environ` and (except for R CMD) `--no-restore`

### Details

Note that there are two sorts of files used in startup: _environment files_ which contain lists of environment variables to be set, and _profile files_ which contain R code.

Lines in a site or user environment file should be either comment lines starting with `#`, or lines of the form `name=value`. The latter sets the environmental variable `name` to `value`, overriding an existing value. If `value` contains an expression of the form `$\{foo-bar\}`, the value is that of the environmental variable `foo` if that exists and is set to a non-empty value, otherwise `bar`. (If it is of the form `$\{foo\}`, the default is "") This construction can be nested, so `bar` can be of the same form (as in `$\{foo-$\{bar-blah\}\}`). Note that the braces are essential: for example `$HOME` will not be interpreted.

Leading and trailing white space in value are stripped. value is then processed in a similar way to a Unix shell: in particular the outermost level of (single or double) quotes is stripped, and backslashes are removed except inside quotes.

On systems with sub-architectures (mainly Windows), the files `Renvir.on.site` and `Rprofile.site` are looked for first in architecture-specific directories, e.g. `R_HOME/etc/i386/Renvir.on.site`. And e.g. `.`Renvir.i386` will be used in preference to `.`Renvir`. 
Note

It is not intended that there be interaction with the user during startup code. Attempting to do so can crash the R process, especially so prior to R 3.0.2.

On Unix versions of R here is also a file `$R_HOME/etc/Renviron` which is read very early in the start-up processing. It contains environment variables set by R in the configure process. Values in that file can be overridden in site or user environment files: do not change `$R_HOME/etc/Renviron` itself. Note that this is distinct from `$R_HOME/etc/Renviron.site`.

Command-line options may well not apply to alternative front-ends: they do not apply to `R.app` on OS X.

`R CMD` `check` and `R CMD` `build` do not always read the standard startup files, but they do always read specific ‘Renviron’ files. The location of these can be controlled by the environment variables `R_CHECK_ENVIRON` and `R_BUILD_ENVIRON`. If these are set their value is used as the path for the ‘Renviron’ file; otherwise, files ‘~/.R/check.Renviron’ or ‘~/.R/build.Renviron’ or sub-architecture-specific versions are employed.

If you want ‘~/.Renviron’ or ‘~/.Rprofile’ to be ignored by child R processes (such as those run by `R CMD` `check` and `R CMD` `build`), set the appropriate environment variable `R_ENVIRONMENT_USER` or `R_PROFILE_USER` to (if possible, which it is not on Windows) "" or to the name of a non-existent file.

`readRenviron` to read ‘.Renviron’ files.

For profiling code, see `Rprof`.

Examples

```r
## Not run:
## Example `~/.Renviron` on Unix
R_LIBS="/R/library"
PAGER="/usr/local/bin/less"

## Example `.Renviron` on Windows
R_LIBS=C:/R/library
MY_TCLTK="c:/Program Files/Tcl/bin"

## Example of setting `R_DEFAULT_PACKAGES` (from `R CMD` `check`)
R_DEFAULT_PACKAGES='utils,grDevices,graphics,stats'
# this loads the packages in the order given, so they appear on
# the search path in reverse order.

## Example of `.Rprofile`
options(width=65, digits=5)
```
options(show.signif.stars=FALSE)
setHook(packageEvent("grDevices", "onLoad"),
  function(...) grDevices::ps.options(horizontal=FALSE))
set.seed(1234)
.First <- function() cat("\n Welcome to R!\n\n")
.Last <- function() cat("\n Goodbye!\n\n")

## Example of Rprofile.site
local()
  # add MASS to the default packages, set a CRAN mirror
  old <-getOption("defaultPackages"); r <-getOption("repos")
  r["CRAN"] <- "http://my.local.cran"
  options(defaultPackages = c(old, "MASS"), repos = r)
  ## (for Unix terminal users) set the width from COLMUNS if set
  cols <- Sys.getenv("COLUMNS")
  if(nzchar(cols)) options(width = as.integer(cols))
  # interactive sessions get a fortune cookie (needs fortunes package)
  if (interactive())
    fortunes::fortune()
)

## if .Renviron contains
FOOBAR="coo\bar"doh\ex"abc\"def"

## then we get
# > cat(Sys.getenv("FOOBAR"), "\n")
# coo\bardoh\exabc"def"

## End(Not run)

---

**stop**

**Stop Function Execution**

**Description**

`stop` stops execution of the current expression and executes an error action.

`geterrmessage` gives the last error message.

**Usage**

```r
stop(..., call. = TRUE, domain = NULL)
geterrmessage()
```

**Arguments**

- `...` zero or more objects which can be coerced to character (and which are pasted together with no separator) or a single condition object.
- `call.` logical, indicating if the call should become part of the error message.
- `domain` see `gettext`. If NA, messages will not be translated.
Details

The error action is controlled by error handlers established within the executing code and by the current default error handler set by options(error=). The error is first signaled as if using signalCondition(). If there are no handlers or if all handlers return, then the error message is printed (if options("show.error.message") is true) and the default error handler is used. The default behaviour (the NULL error-handler) in interactive use is to return to the top level prompt or the top level browser, and in non-interactive use to (effectively) call q("no", status = 1, runLast = FALSE). The default handler stores the error message in a buffer; it can be retrieved by gettextmessage(). It also stores a trace of the call stack that can be retrieved by traceback()

Errors will be truncated to getOption("warning.length") characters, default 1000.

If a condition object is supplied it should be the only argument, and further arguments will be ignored, with a warning.

Value

getextmessage gives the last error message, as a character string ending in "\n".

Note

Use domain = NA whenever ... contain a result from gettext() as that is translated already.

References

See Also

warning, try to catch errors and retry, and options for setting error handlers. stopifnot for validity testing. tryCatch and withCallingHandlers can be used to establish custom handlers while executing an expression.

gettext for the mechanisms for the automated translation of messages.

Examples

options(error = expression(NULL))
# don't stop on stop(.) << Use with CARE! >>

iter <- 12
if(iter > 10) stop("too many iterations")

tst1 <- function(...) stop("dummy error")
tst1(1:10, long, calling, expression)

tst2 <- function(...) stop("dummy error", call. = FALSE)
tst2(1:10, longcalling, expression, but.not.seen.in.Error)

options(error = NULL) # restore to default
stopifnot

Ensure the Truth of R Expressions

Description

If any of the expressions in ... are not all TRUE, stop is called, producing an error message indicating the first of the elements of ... which were not true.

Usage

stopifnot(...)

Arguments

... any number of (logical) R expressions, which should evaluate to TRUE.

Details

This function is intended for use in regression tests or also argument checking of functions, in particular to make them easier to read.

stopifnot(A, B) is conceptually equivalent to

{ if(any(is.na(A)) || !all(A)) stop(...) ;
  if(any(is.na(B)) || !all(B)) stop(...) }

Value

(NULL if all statements in ... are TRUE.)

See Also

stop, warning.

Examples

stopifnot(1 == 1, all.equal(pi, 3.14159265), 1 < 2) # all TRUE
m <- matrix(c(1,3,3,1), 2, 2)
stopifnot(m == t(m), diag(m) == rep(1, 2)) # all(.) |=> TRUE
op <- options(error = expression(NULL))
# "disable stop(.)"  << Use with CARE! >>
stopifnot(all.equal(pi, 3.141593), 2 < 2, all(1:10 < 12), "a" < "b")
stopifnot(all.equal(pi, 3.1415927), 2 < 2, all(1:10 < 12), "a" < "b")
options(op) # revert to previous error handler
strptime

Date-time Conversion Functions to and from Character

Description

Functions to convert between character representations and objects of classes "POSIXlt" and "POSIXct" representing calendar dates and times.

Usage

```r
## S3 method for class 'POSIXct'
format(x, format = "", tz = "", usetz = FALSE, ...)
## S3 method for class 'POSIXlt'
format(x, format = "", usetz = FALSE, ...)

## S3 method for class 'POSIXt'
as.character(x, ...)

strftime(x, format = "", tz = "", usetz = FALSE, ...)
strptime(x, format, tz = "")
```

Arguments

- `x` An object to be converted.
- `tz` A character string specifying the timezone to be used for the conversion. System-specific (see `as.POSIXct`), but "" is the current time zone, and "GMT" is UTC.
- `format` A character string. The default for the format methods is "%Y-%m-%d %H:%M:%S" if any component has a time component which is not midnight, and "%Y-%m-%d" otherwise. If `options(digits.secs)` is set, up to the specified number of digits will be printed for seconds.
- `...` Further arguments to be passed from or to other methods.
- `usez` logical. Should the timezone be appended to the output? This is used in printing times, and as a workaround for problems with using "%Z" on some Linux systems.

Details

The `format` and `as.character` methods and `strftime` convert objects from the classes "POSIXlt" and "POSIXct" (not `strptime`) to character vectors.

`strptime` converts character vectors to class "POSIXlt": its input `x` is first converted by `as.character`. Each input string is processed as far as necessary for the format specified: any trailing characters are ignored.

`strptime` is a wrapper for `format.POSIXlt`, and it and `format.POSIXct` first convert to class "POSIXlt" by calling `as.POSIXt`. Note that only that conversion depends on the time zone.

The usual vector recycling rules are applied to `x` and `format` so the answer will be of length that of the longer of the vectors.
Locale-specific conversions to and from character strings are used where appropriate and available. This affects the names of the days and months, the AM/PM indicator (if used) and the separators in formats such as `%s` and `%x` (via the setting of the `LC_TIME` locale category).

The details of the formats are system-specific, but the following are defined by the ISO C99 / POSIX standard for `strftime` and are likely to be widely available. A *conversion specification* is introduced by `%`, usually followed by a single letter or `0` or `E` and then a single letter. Any character in the format string not part of a conversion specification is interpreted literally (and `%` gives `%`). Widely implemented conversion specifications include

- `%a` Abbreviated weekday name in the current locale. (Also matches full name on input.)
- `%A` Full weekday name in the current locale. (Also matches abbreviated name on input.)
- `%b` Abbreviated month name in the current locale. (Also matches full name on input.)
- `%B` Full month name in the current locale. (Also matches abbreviated name on input.)
- `%c` Date and time. Locale-specific on output, "%a %b %e %H:%M:%S %Y" on input.
- `%d` Day of the month as decimal number (01–31).
- `%H` Hours as decimal number (00–23). As a special exception times such as ‘24:00:00’ are accepted for input, since ISO 8601 allows these.
- `%I` Hours as decimal number (01–12).
- `%j` Day of year as decimal number (001–366).
- `%m` Month as decimal number (00–12).
- `%M` Minute as decimal number (00–59).
- `%p` AM/PM indicator in the locale. Used in conjunction with `%I` and not with `%h`. An empty string in some locales.
- `%S` Second as decimal number (00–61), allowing for up to two leap-seconds (but POSIX-compliant implementations will ignore leap seconds).
- `%u` Week of the year as decimal number (00–53) using Sunday as the first day 1 of the week (and typically with the first Sunday of the year as day 1 of week 1). The US convention.
- `%w` Week of the year as decimal number (00–53) using Monday as the first day of week (and typically with the first Monday of the year as day 1 of week 1). The UK convention.
- `%x` Date. Locale-specific on output, "%y/%m/%d" on input.
- `%X` Time. Locale-specific on output, "%H:%M:%S" on input.
- `%Y` Year without century (00–99). On input, values 00 to 68 are prefixed by 20 and 69 to 99 by 19 – that is the behaviour specified by the 2004 and 2008 POSIX standards, but they do also say ‘it is expected that in a future version the default century inferred from a 2-digit year will change’.
- `%z` Signed offset in hours and minutes from UTC, so ‘–0800’ is 8 hours behind UTC. `%Z` (output only.) Time zone as a character string (empty if not available).

Where leading zeros are shown they will be used on output but are optional on input.

Note that when `%z` or `%Z` is used for output with an object with an assigned timezone an attempt is made to use the values for that timezone — but it is not guaranteed to succeed.

Also defined in the current standards but less widely implemented (e.g. not for output on Windows) are
strptime

%C Century (00–99): the integer part of the year divided by 100.

%D Date format such as %m/%d/%y: ISO C99 says it should be that exact format.

%e Day of the month as decimal number (1–31), with a leading space for a single-digit number.

%F Equivalent to %Y-%m-%d (the ISO 8601 date format).

%g The last two digits of the week-based year (see %V). (Accepted but ignored on input.)

%G The week-based year (see %V) as a decimal number. (Accepted but ignored on input.)

%h Equivalent to %b.

%k The 24-hour clock time with single digits preceded by a blank.

%l The 12-hour clock time with single digits preceded by a blank.

%n Newline on output, arbitrary whitespace on input.

%r The 12-hour clock time (using the locale’s AM or PM).

%R Equivalent to %H:%M.

%t Tab on output, arbitrary whitespace on input.

%T Equivalent to %H:%M:%S.

%w Weekday as a decimal number (1–7, Monday is 1).

%w Week of the year as decimal number (00–53) as defined in ISO 8601. If the week (starting on Monday) containing 1 January has four or more days in the new year, then it is considered week 1. Otherwise, it is the last week of the previous year, and the next week is week 1. (Accepted but ignored on input.)

For output there are also %O[%dhImmJuWwWw] which may emit numbers in an alternative locale-dependent format (e.g. roman numerals), and %E[cCyYxx] which can use an alternative ‘era’ (e.g. a different religious calendar). Which of these are supported is OS-dependent. These are accepted for input, but with the standard interpretation.

Specific to R is %OSn, which for output gives the seconds truncated to \( 0 \leq n \leq 6 \) decimal places (and if %OS is not followed by a digit, it uses the setting of getOption("digits.secs"), or if that is unset, \( n = 3 \)). Further, for strptime %OS will input seconds including fractional seconds. Note that %S ignores (and not rounds) fractional parts on output.

Even when conversion specifications are implemented they may not be implemented correctly: %z seems particularly unreliable.

The behaviour of other conversion specifications (and even if other character sequences commencing with % are conversion specifications) is system-specific.

Value

The format methods and strftime return character vectors representing the time. NA times are returned as NA_character_.

strftime turns character representations into an object of class "POSIXt". The timezone is used to set the isdst component and to set the “tzone” attribute if tz != "". If the specified time is invalid (for example "2010-02-30 08:00") all the components of the result are NA. (NB: this does mean exactly what it says – if it is an invalid time, not just a time that does not exist in some timezone.)
Note
The default formats follow the rules of the ISO 8601 international standard which expresses a day as "2001-02-28" and a time as "14:01:02" using leading zeroes as here. The ISO form uses no space to separate dates and times.
For strptime the input string need not specify the date completely: it is assumed that unspecified seconds, minutes or hours are zero, and an unspecified year, month or day is the current one.
If the timezone specified is invalid on your system, what happens is system-specific but it will probably be ignored.
OS facilities will probably not print years before 1 CE (aka 1 AD) correctly.
Remember that in most timezones some times do not occur and some occur twice because of transitions to/from 'daylight saving' (also known a 'summer') time. strptime does not validate such times (it does not assume a specific timezone), but conversion by as.POSIXct) will do so. Conversion by strftime and formattingprinting uses OS facilities and may (and does on Windows) return nonsensical results for non-existent times at DST transitions.

References
The POSIX 1003.1 standard, which is in some respects stricter than ISO 8601.

See Also
DateTimeClasses for details of the date-time classes; locales to query or set a locale.
Your system's help pages on strftime and strptime to see how to specify their formats.
(On some Unix-like systems strptime is replaced by corrected code from 'glibc', when all the conversion specifications described here are supported, but with no alternative number representation nor era available in any locale.)
Windows users will find no help page for strptime: code based on 'glibc' is used (with corrections), so all the conversion specifications described here are supported, but with no alternative number representation nor era available in any locale.

Examples
## locale-specific version of date()
format(Sys.time(), "%a %b %d %X %Y %z")

## time to sub-second accuracy (if supported by the OS)
format(Sys.time(), "%H:%M:%OS3")

## read in date info in format 'ddmmyyyy'
## This will give NA(s) in some locales; setting the C locale
## as in the commented lines will overcome this on most systems.
## lcT <- Sys.getlocale("LC_TIME"); Sys.setlocale("LC_TIME", "C")
x <- c("1jan1960", "2jan1960", "3mar1960", "3jul1960")
z <- strftime(x, "%d%b%Y")
## Sys.setlocale("LC_TIME", lct)
strsplit

Split the Elements of a Character Vector

Description

Split the elements of a character vector `x` into substrings according to the matches to substring `split` within them.

Usage

```r
strsplit(x, split, fixed = FALSE, perl = FALSE, useBytes = FALSE)
```

Arguments

- `x` character vector, each element of which is to be split. Other inputs, including a factor, will give an error.
- `split` character vector (or object which can be coerced to such) containing regular expression(s) (unless `fixed = TRUE`) to use for splitting. If empty matches occur, in particular if `split` has length 0, `x` is split into single characters. If `split` has length greater than 1, it is re-cycled along `x`.
- `fixed` logical. If `TRUE` match `split` exactly, otherwise use regular expressions. Has priority over `perl`.
- `perl` logical. Should perl-compatible regexps be used?
- `useBytes` logical. If `TRUE` the matching is done byte-by-byte rather than character-by-character, and inputs with marked encodings are not converted. This is forced (with a warning) if any input is found which is marked as "bytes".
Details

Argument split will be coerced to character, so you will see uses with split = NULL to mean split = character(0), including in the examples below.

Note that splitting into single characters can be done via split = character(0) or split = ""; the two are equivalent. The definition of ‘character’ here depends on the locale: in a single-byte locale it is a byte, and in a multi-byte locale it is the unit represented by a ‘wide character’ (almost always a Unicode point).

A missing value of split does not split the corresponding element(s) of x at all.

The algorithm applied to each input string is

```
repeat {
    if the string is empty
        break.
    if there is a match
        add the string to the left of the match to the output.
        remove the match and all to the left of it.
    else
        add the string to the output.
        break.
}
```

Note that this means that if there is a match at the beginning of a (non-empty) string, the first element of the output is "", but if there is a match at the end of the string, the output is the same as with the match removed.

Value

A list of the same length as x, the i-th element of which contains the vector of splits of x[i].

If any element of x or split is declared to be in UTF-8 (see Encoding), all non-ASCII character strings in the result will be in UTF-8 and have their encoding declared as UTF-8. As from R 2.10.0, for perl = TRUE, useBytes = FALSE all non-ASCII strings in a multibyte locale are translated to UTF-8.

Note

Prior to R 2.11.0 there was an argument extended which could be used to select ‘basic’ regular expressions: this was often used when fixed = TRUE would be preferable. In the actual implementation (as distinct from the POSIX standard) the only difference was that ‘?’ , ‘*‘ , ‘[‘ , ‘]‘ , ‘(‘ , and ‘)‘ were not interpreted as metacharacters.

See Also

`paste` for the reverse, `grep` and `sub` for string search and manipulation; also `nchar`, `substr`.

‘regular expression’ for the details of the pattern specification.

Examples

```
noquote(strsplit("A text I want to display with spaces", NULL)[[1]])
```

```
x <- c(as = "asf", qu = "qwerty", "yuiop", "b", "stuff.blah.yech")
# split x on the letter e
strsplit(x, "e")
```
unlist(strsplit("a.b.c", "."))
## [1] "a" "b" "c"
## Note that 'split' is a regexp!
## If you really want to split on '.', use
unlist(strsplit("a.b.c", "."))
## [1] "a" "b" "c"
## or
unlist(strsplit("a.b.c", ".", fixed = TRUE))

## a useful function: rev() for strings
strReverse <- function(x)
  sapply(lapply(strsplit(x, NULL), rev), paste, collapse = "")
strReverse(c("abc", "Statistics"))

## get the first names of the members of R-core
a <- readlines(file.path(R.home("doc"),"AUTHORS"))[-(1:8)]
a <- a[0:2]-length(a)]
(a <- sub(" \.*","", a))
# and reverse them
strReverse(a)

## Note that final empty strings are not produced:
strsplit(paste(c("\", "a", ""), collapse=""), split=""))[1]
# [1] "a"
## and also an empty string is only produced before a definite match:
strsplit("", "")[1]  # character(0)
strsplit("", "")[1]  # [1] ""

---

**strtoi**

Convert Strings to Integers

**Description**

Convert strings to integers according to the given base using the C function `strtol`, or choose a suitable base following the C rules.

**Usage**

`strtoi(x, base = 0L)`

**Arguments**

- `x` a character vector, or something coercible to this by `as.character`.
- `base` an integer which is between 2 and 36 inclusive, or zero (default).

**Details**

Conversion is based on the C library function `strtol`. For the default base = 0L, the base chosen from the string representation of that element of x, so different elements can have different bases (see the first example). The standard C rules for choosing the base are that octal constants (prefix 0 not followed by x or X) and hexadecimal constants (prefix 0x or 0X) are interpreted as base 8 and 16; all other strings are interpreted as base 10. For a base greater than 10, letters a to z (or A to Z) are used to represent 10 to 35.
strtrim

Trim Character Strings to Specified Display Widths

Description
Trim character strings to specified display widths.

Usage
strtrim(x, width)

Arguments
x
a character vector, or an object which can be coerced to a character vector by as.character.
width
Positive integer values: recycled to the length of x.

Details
‘Width’ is interpreted as the display width in a monospaced font. What happens with non-printable characters (such as backspace, tab) is implementation-dependent and may depend on the locale (e.g. they may be included in the count or they may be omitted).
Using this function rather than substr is important when there might be double-width (e.g. Chinese/Japanese/Korean) characters in the character vector.

Value
A character vector of the same length and with the same attributes as x (after possible coercion).
Elements of the result will have the encoding declared as that of the current locale (see Encoding) if the corresponding input had a declared encoding and the current locale is either Latin-1 or UTF-8.

Examples
strtrim(c("abcdef", "abcdef", "abcdef"), c(1,5,10))
**structure**

---

**Attribute Specification**

**Description**

structure returns the given object with further attributes set.

**Usage**

structure(.Data, ...)

**Arguments**

- **.Data** an object which will have various attributes attached to it.
- **...** attributes, specified in tag = value form, which will be attached to data.

**Details**

Adding a class "factor" will ensure that numeric codes are given integer storage mode.

For historical reasons (these names are used when decompiling), attributes ".Dim", ".Dimnames", ".Names", ".Tsp" and ".Label" are renamed to "dim", "dimnames", "names", "tsp" and "levels".

It is possible to give the same tag more than once, in which case the last value assigned wins. As with other ways of assigning attributes, using tag = NULL removes attribute tag from .Data if it is present.

**References**

**See Also**

attributes, attr.

**Examples**

structure(1:6, dim = 2:3)
strwrap

Wrap Character Strings to Format Paragraphs

Description

Each character string in the input is first split into paragraphs (or lines containing whitespace only). The paragraphs are then formatted by breaking lines at word boundaries. The target columns for wrapping lines and the indentation of the first and all subsequent lines of a paragraph can be controlled independently.

Usage

strwrap(x, width = 0.9 * getOption("width"), indent = 0,
       exdent = 0, prefix = "", simplify = TRUE, initial = prefix)

Arguments

  x  
  width  
  indent  
  exdent  
  prefix, initial  
  simplify

- x: a character vector, or an object which can be converted to a character vector by as.character.
- width: a positive integer giving the target column for wrapping lines in the output.
- indent: a non-negative integer giving the indentation of the first line in a paragraph.
- exdent: a non-negative integer specifying the indentation of subsequent lines in paragraphs.
- prefix, initial: a character string to be used as prefix for each line except the first, for which initial is used.
- simplify: a logical. If TRUE, the result is a single character vector of line text; otherwise, it is a list of the same length as x the elements of which are character vectors of line text obtained from the corresponding element of x. (Hence, the result in the former case is obtained by unlisting that of the latter.)

Details

Whitespace (space, tab or newline characters) in the input is destroyed. Double spaces after periods, question and explanation marks (thought as representing sentence ends) are preserved. Currently, possible sentence ends at line breaks are not considered specially.

Indentation is relative to the number of characters in the prefix string.

Value

A character vector in the current locale’s encoding (if simplify is TRUE), or a list of such character vectors.

Examples

```r
## Read in file 'THANKS'.
x <- paste(readLines(file.path(R.home("doc"), "THANKS")), collapse = "\n")
## Split into paragraphs and remove the first three ones
x <- unlist(strsplit(x, "\n\[ \t\n\]*\n")[-c(1:3)]
## Join the rest
```
x <- paste(x, collapse = "\n\n")
## Now for some fun:
writeLines(strwrap(x, width = 60))
writeLines(strwrap(x, width = 60, indent = 5))
writeLines(strwrap(x, width = 60, exdent = 5))
writeLines(strwrap(x, prefix = "THANKS> "))

## Note that messages are wrapped AT the target column indicated by
## 'width' (and not beyond it).
## From an R-devel posting by J. Hosking <jh910@juno.com>.
x <- paste(sapply(sample(10, 100, replace = TRUE),
    function(x) substring("aaaaaaaaaaa", 1, x)), collapse = " ")
sapply(10:40,
    function(m)
    c(target = m, actual = max(nchar(strwrap(x, m)))))

---

subset  | Subsetting Vectors, Matrices and Data Frames

**Description**

Return subsets of vectors, matrices or data frames which meet conditions.

**Usage**

subset(x, ...)

## Default S3 method:
subset(x, subset, ...)

## S3 method for class 'matrix'
subset(x, subset, select, drop = FALSE, ...)

## S3 method for class 'data.frame'
subset(x, subset, select, drop = FALSE, ...)

**Arguments**

- **x**: object to be subsetted.
- **subset**: logical expression indicating elements or rows to keep: missing values are taken as false.
- **select**: expression, indicating columns to select from a data frame.
- **drop**: passed on to [ indexing operator.
- **...**: further arguments to be passed to or from other methods.

**Details**

This is a generic function, with methods supplied for matrices, data frames and vectors (including lists). Packages and users can add further methods.

For ordinary vectors, the result is simply x[subset & !is.na(subset)].
For data frames, the subset argument works on the rows. Note that subset will be evaluated in the data frame, so columns can be referred to (by name) as variables in the expression (see the examples).

The select argument exists only for the methods for data frames and matrices. It works by first replacing column names in the selection expression with the corresponding column numbers in the data frame and then using the resulting integer vector to index the columns. This allows the use of the standard indexing conventions so that for example ranges of columns can be specified easily, or single columns can be dropped (see the examples).

The drop argument is passed on to the indexing method for matrices and data frames: note that the default for matrices is different from that for indexing.

Factors may have empty levels after subsetting; unused levels are not automatically removed. See drop.levels for a way to drop all unused levels from a data frame.

Value

An object similar to x contain just the selected elements (for a vector), rows and columns (for a matrix or data frame), and so on.

Warning

This is a convenience function intended for use interactively. For programming it is better to use the standard subsetting functions like [], and in particular the non-standard evaluation of argument subset can have unanticipated consequences.

Examples

subset(airquality, Temp > 80, select = c(Ozone, Temp))
subset(airquality, Day == 1, select = ~Temp)
subset(airquality, select = Ozone:Wind)

with(airquality, subset(Ozone, Temp > 80))

## sometimes requiring a logical 'subset' argument is a nuisance
nm <- rownames(state.x77)
start_with_M <- nm %in% grep("M", nm, value = TRUE)
subset(state.x77, start_with_M, Illiteracy:Murder)
# but in recent versions of R this can simply be
subset(state.x77, grepl("M", nm), Illiteracy:Murder)
Substitute returns the parse tree for the (unevaluated) expression `expr`, substituting any variables bound in `env`.

Quote simply returns its argument. The argument is not evaluated and can be any R expression.

Enquote is a simple one-line utility which transforms a call of the form `foo(....)` into the call `quote(foo(....))`. This is typically used to protect a call from early evaluation.

**Usage**

```r
substitute(expr, env)
quote(expr)
enquote(cl)
```

**Arguments**

- `expr` any syntactically valid R expression
- `cl` a call, i.e., an R object of class (and mode) "call".
- `env` an environment or a list object. Defaults to the current evaluation environment.

**Details**

The typical use of `substitute` is to create informative labels for data sets and plots. The `myplot` example below shows a simple use of this facility. It uses the functions `deparse` and `substitute` to create labels for a plot which are character string versions of the actual arguments to the function `myplot`.

Substitution takes place by examining each component of the parse tree as follows: If it is not a bound symbol in `env`, it is unchanged. If it is a promise object, i.e., a formal argument to a function or explicitly created using `delayedAssign()`, the expression slot of the promise replaces the symbol. If it is an ordinary variable, its value is substituted, unless `env` is `.GlobalEnv` in which case the symbol is left unchanged.

Both `quote` and `substitute` are ‘special’ primitive functions which do not evaluate their arguments.

**Value**

The mode of the result is generally “call” but may in principle be any type. In particular, single-variable expressions have mode “name” and constants have the appropriate base mode.

**Note**

`substitute` works on a purely lexical basis. There is no guarantee that the resulting expression makes any sense.

Substituting and quoting often cause confusion when the argument is `expression(...)`. The result is a call to the `expression` constructor function and needs to be evaluated with `eval` to give the actual expression object.

missing for argument ‘missingness’, bquote for partial substitution, sQuote and dquote for adding quotation marks to strings,
all.names to retrieve the symbol names from an expression or call.

Examples

require(graphics)
(s.e <- substitute(expression(a + b), list(a = 1))) #> expression(1 + b)
(s.s <- substitute(a + b, list(a = 1))) #> 1 + b
c(mode(s.e), typeof(s.e)) # "call", "language"
c(mode(s.s), typeof(s.s)) # (the same)
# but:
(e.s.e <- eval(s.e)) #> expression(1 + b)
c(mode(e.s.e), typeof(e.s.e)) # "expression", "expression"

substring(x <- x + 1, list(x = 1)) # nonsense

myplot <- function(x, y)
  plot(x, y, xlab = deparse(substitute(x)),
       ylab = deparse(substitute(y)))

## Simple examples about lazy evaluation, etc:

f1 <- function(x, y = x) { x <- x + 1; y }
s1 <- function(x, y = substitute(x)) { x <- x + 1; y }
s2 <- function(x, y) { if(missing(y)) y <- substitute(x); x <- x + 1; y }
a <- 10
f1(a) # 11
s1(a) # 11
s2(a) # a
typeof(s2(a)) # "symbol"

substr

Substrings of a Character Vector

Description

Extract or replace substrings in a character vector.

Usage

substr(x, start, stop)
substring(text, first, last = 1000000L)
substr(x, start, stop) <- value
substring(text, first, last = 1000000L) <- value
**subsr**

Arguments

- **x, text** a character vector.
- **start, first** integer. The first element to be replaced.
- **stop, last** integer. The last element to be replaced.
- **value** a character vector, recycled if necessary.

Details

substring is compatible with S, with first and last instead of start and stop. For vector arguments, it expands the arguments cyclically to the length of the longest *provided* none are of zero length.

When extracting, if start is larger than the string length then "" is returned.

For the extraction functions, x or text will be converted to a character vector by `as.character` if it is not already one.

For the replacement functions, if start is larger than the string length then no replacement is done.

If the portion to be replaced is longer than the replacement string, then only the portion the length of the string is replaced.

If any argument is an NA element, the corresponding element of the answer is NA.

Elements of the result will be have the encoding declared as that of the current locale (see `Encoding` if the corresponding input had a declared Latin-1 or UTF-8 encoding and the current locale is either Latin-1 or UTF-8).

If an input element has declared "bytes" encoding, the subsetting is done in units of bytes not characters.

Value

For substr, a character vector of the same length and with the same attributes as x (after possible coercion).

For substring, a character vector of length the longest of the arguments. This will have names taken from x (if it has any after coercion, repeated as needed), and other attributes copied from x if it is the longest of the arguments).

Elements of x with a declared encoding (see `Encoding`) will be returned with the same encoding.

Note

The S4 version of substrings<- ignores last; this version does not.

These functions are often used with `nchar` to truncate a display. That does not really work (you want to limit the width, not the number of characters, so it would be better to use `strtrim`), but at least make sure you use the default nchar(type = "c").

References

See Also

`strsplit, paste, nchar`. 
sum

Examples

```r
substr("abcdef", 2, 4)
substring("abcdef", 1:6, 1:6)
## strsplit is more efficient ...

substr(rep("abcdef", 4), 1:4, 4:5)
x <- c("asfef", "qwerty", "yuiop", "b", "stuff.blah.yech")
substr(x, 2, 5)
substring(x, 2, 4:6)

substring(x, 2) <- c("..", "+++")
x
```

sum

Sum of Vector Elements

Description

sum returns the sum of all the values present in its arguments.

Usage

```r
sum(..., na.rm = FALSE)
```

Arguments

... numeric or complex or logical vectors.

na.rm logical. Should missing values (including NaN) be removed?

Details

This is a generic function: methods can be defined for it directly or via the `summary` group generic. For this to work properly, the arguments ... should be unnamed, and dispatch is on the first argument.

If na.rm is FALSE an NA or NaN value in any of the arguments will cause a value of NA or NaN to be returned, otherwise NA and NaN values are ignored.

Logical true values are regarded as one, false values as zero. For historical reasons, NULL is accepted and treated as if it were integer(0).

Loss of accuracy can occur when summing values of different signs: this can even occur for sufficiently long integer inputs if the partial sums would cause integer overflow. Where possible extended-precision accumulators are used, but this is platform-dependent.

Value

The sum. If all of ... are of type integer or logical, then the sum is integer, and in that case the result will be NA (with a warning) if integer overflow occurs. Otherwise it is a length-one numeric or complex vector.

NB: the sum of an empty set is zero, by definition.
S4 methods

This is part of the S4 `summary` group generic. Methods for it must use the signature `x, ..., na.rm`.

‘plotmath’ for the use of `sum` in plot annotation.

References

See Also

`colSums` for row and column sums.

summary

Object Summaries

Description

`summary` is a generic function used to produce result summaries of the results of various model fitting functions. The function invokes particular methods which depend on the `class` of the first argument.

Usage

```r
summary(object, ...)  
## Default S3 method:  
summary(object, ..., digits = max(3, getOption("digits")-3))  
## S3 method for class 'data.frame'  
summary(object, maxsum = 7,  
digits = max(3, getOption("digits")-3), ...)  
## S3 method for class 'factor'  
summary(object, maxsum = 100, ...)  
## S3 method for class 'matrix'  
summary(object, ...)  
```

Arguments

- `object` an object for which a summary is desired.
- `maxsum` integer, indicating how many levels should be shown for factors.
- `digits` integer, used for number formatting with `signif()` (for `summary.default`) or `format()` (for `summary.data.frame`).
- `...` additional arguments affecting the summary produced.
svd

Singular Value Decomposition of a Matrix

Description

Compute the singular-value decomposition of a rectangular matrix.

Usage

svd(x, nu = min(n, p), nv = min(n, p), LINPACK = FALSE)

La.svd(x, nu = min(n, p), nv = min(n, p))
svd

Arguments

- **x**: A numeric or complex matrix whose SVD decomposition is to be computed. Logical matrices are coerced to numeric.
- **nu**: The number of left singular vectors to be computed. This must be between 0 and \( n = \text{ncol}(x) \).
- **nv**: The number of right singular vectors to be computed. This must be between 0 and \( p = \text{ncol}(x) \).
- **LINPACK**: Logical. Defunct and ignored (with a warning for true values).

Details

The singular value decomposition plays an important role in many statistical techniques. svd and \texttt{la.svd} provide two slightly different interfaces.

Computing the singular vectors is the slow part for large matrices. The computation will be more efficient if \( nu \leq \min(n, p) \) and \( nv \leq \min(n, p) \), and even more efficient if one or both are zero.

Unsuccessful results from the underlying LAPACK code will result in an error giving a positive error code (most often 1); these can only be interpreted by detailed study of the FORTRAN code but mean that the algorithm failed to converge.

Value

The SVD decomposition of the matrix as computed by LAPACK,

\[
X = UDV',
\]

where \( U \) and \( V \) are orthogonal, \( V' \) means \( V \) transposed, and \( D \) is a diagonal matrix with the singular values \( D_{ii} \). Equivalently, \( D = U'XV \), which is verified in the examples, below.

The returned value is a list with components

- **d**: A vector containing the singular values of \( x \), of length \( \min(n, p) \).
- **u**: A matrix whose columns contain the left singular vectors of \( x \), present if \( nu > 0 \). Dimension \( c(n, nu) \).
- **v**: A matrix whose columns contain the right singular vectors of \( x \), present if \( nv > 0 \). Dimension \( c(p, nv) \).

For \texttt{la.svd} the return value replaces \( v \) by \( v^t \), the (conjugated if complex) transpose of \( v \).

Source

The main functions used are the LAPACK routines \texttt{DGESDD} and \texttt{ZGESVD}.

LAPACK is from \url{http://www.netlib.org/lapack} and its guide is listed in the references.

References

Available on-line at \url{http://www.netlib.org/lapack/lug/lapack_lug.html}.

Sweep out Array Summaries

Description

Return an array obtained from an input array by sweeping out a summary statistic.

Usage

sweep(x, MARGIN, STATS, FUN = "-", check.margin = TRUE, ...)

Arguments

x  
an array.

MARGIN  
a vector of indices giving the extent(s) of x which correspond to STATS.

STATS  
the summary statistic which is to be swept out.

FUN  
the function to be used to carry out the sweep.

check.margin  
logical. If TRUE (the default), warn if the length or dimensions of STATS do not match the specified dimensions of x. Set to FALSE for a small speed gain when you know that dimensions match.

...

optional arguments to FUN.

Details

FUN is found by a call to match.fun. As in the default, binary operators can be supplied if quoted or backquoted.

FUN should be a function of two arguments: it will be called with arguments x and an array of the same dimensions generated from STATS by aperm.

The consistency check among STATS, MARGIN and x is stricter if STATS is an array than if it is a vector. In the vector case, some kinds of recycling are allowed without a warning. Use sweep(x, MARGIN, as.array(STATS)) if STATS is a vector and you want to be warned if any recycling occurs.

Value

An array with the same shape as x, but with the summary statistics swept out.
switch

Select One of a List of Alternatives

Description

switch evaluates EXPR and accordingly chooses one of the further arguments (in ...).

Usage

switch(EXPR, ...)

Arguments

EXPR  an expression evaluating to a number or a character string.

...  the list of alternatives. If it is intended that EXPR has a character-string value these will be named, perhaps except for one alternative to be used as a 'default' value.
Details

switch works in two distinct ways depending whether the first argument evaluates to a character string or a number.

If the value of EXPR is not a character string it is coerced to integer. If this is between 1 and nargs()-1 then the corresponding element of ... is evaluated and the result returned: thus if the first argument is 3 then the fourth argument is evaluated and returned.

If EXPR evaluates to a character string then that string is matched (exactly) to the names of the elements in ... If there is a match then that element is evaluated unless it is missing, in which case the next non-missing element is evaluated, so for example switch("cc", a = 1, cc =, cd =, d = 2) evaluates to 2. If there is more than one match, the first matching element is used. In the case of no match, if there is an unnamed element of ... its value is returned. (If there is more than one such argument an error is returned. Before R 2.13.0 the first one would have been used.)

The first argument is always taken to be EXPR: if it is named its name must (partially) match.

This is implemented as a primitive function that only evaluates its first argument and one other if one is selected.

Value

The value of one of the elements of ... or NULL, invisibly (whenever no element is selected).

The result has the visibility (see invisible) of the element evaluated.

Warning

Before R 2.11.0 it was necessary to avoid partial matching: an alternative f = foo matched the first argument EXPR unless that was named.

It is possible to write calls to switch that can be confusing and may not work in the same way in earlier versions of R. For compatibility (and clarity), always have EXPR as the first argument, naming it if partial matching is a possibility. For the character-string form, have a single unnamed argument as the default after the named values.

References

Examples

```
require(stats)
centre <- function(x, type) {
  switch(type,
    mean = mean(x),
    median = median(x),
    trimmed = mean(x, trim = .1))
}
x <- rcauchy(10)
centre(x, "mean")
centre(x, "median")
centre(x, "trimmed")

ccc <- c("b","Q","a","A","bb")
# note: cat() produces no output for NULL
do(ch in ccc)
```
```r
for(ch in ccc)
cat(ch,"::), switch(EXPR = ch, a = 1, b = 2:3), "\n")

## Numeric EXPR does not allow a default value to be specified
## it is always NULL
for(i in c(-1:3, 9)) print(switch(i, 1, 2, 3, 4))

## visibility
switch(1, invisible(pi), pi)
switch(2, invisible(pi), pi)
```
Note

There are substantial precedence differences between R and S. In particular, in S ? has the same precedence as (binary) + - and & & | | have equal precedence.

---

**Sys.getenv**

*Get Environment Variables*

**Description**

Sys.getenv obtains the values of the environment variables.

**Usage**

Sys.getenv(x = NULL, unset = "", names = NA)

**Arguments**

- `x`: a character vector, or NULL.
- `unset`: a character string.
- `names`: logical: should the result be named? If NA (the default) single-element results are not named whereas multi-element results are.

**Details**

Both arguments will be coerced to character if necessary.

Setting `unset = NA` will enable unset variables and those set to the value "" to be distinguished, if the OS does. POSIX requires the OS to distinguish, and all known current R platforms do.

**Value**

A vector of the same length as `x`, with (if `names` == TRUE) the variable names as its names attribute. Each element holds the value of the environment variable named by the corresponding component of `x` (or the value of `unset` if no environment variable with that name was found).

On most platforms `Sys.getenv()` will return a named vector giving the values of all the environment variables, sorted in the current locale. It may be confused by names containing = which some platforms allow but POSIX does not. (Windows is such a platform: there names including = are truncated just before the first =.)

Argument names was introduced in R 2.13.0 to avoid needing the common use of `as.vector(Sys.getenv())`. 
Sys.getpid

Get the Process ID of the R Session

Description

Get the process ID of the R Session. It is guaranteed by the operating system that two R sessions running simultaneously will have different IDs, but it is possible that R sessions running at different times will have the same ID.

Usage

Sys.getpid()

Value

An integer, often between 1 and 32767 under Unix-alikes (but for example FreeBSD and Mac OS >= 10.5 uses IDs up to 99999) and a positive integer up to 32767) under Windows.

Examples

Sys.getpid()

Sys.glob

Wildcard Expansion on File Paths

Description

Function to do wildcard expansion (also known as 'globbing') on file paths.

Usage

Sys.glob(paths, dirmark = FALSE)
Arguments

paths
character vector of patterns for relative or absolute filepaths. Missing values will
be ignored.

dirmark
logical: should matches to directories from patterns that do not already end in /
have a slash appended? May not be supported on all platforms.

Details

This expands wildcards in file paths. For precise details, see your system’s documentation on
the \texttt{glob} system call. There is a POSIX 1003.2 standard (see \url{http://pubs.opengroup.org/onlinepubs/9699919799/functions/glob.html}) but some OSes will go beyond this. The \texttt{R}
implementation will always do tilde expansion.

All systems should interpret \texttt{*} (match zero or more characters), \texttt{?} (match a single character) and
(probably) \texttt{[} (begin a character class or range). The handling of paths ending with a separator is
system-dependent. On a POSIX-2008 compliant OS they will match directories (only), but as they
are not valid filepaths on Windows, they match nothing there. (Earlier POSIX standards allowed
them to match files.)

The rest of these details are indicative (and based on the POSIX standard).

If a filename starts with \texttt{.}, this may need to be matched explicitly: for example
\texttt{Sys.glob(".*.RData")} may or may not match \texttt{.RData’} but will not usually match \texttt{.aa.Rdata’}.

Note that this is platform-dependent: e.g. on Solaris \texttt{Sys.glob("*.x")} matches \texttt{.’} and \texttt{..’}.

\texttt{[} begins a character class. If the first character in \texttt{[...]} is not \texttt{!}, this is a character class which
matches a single character against any of the characters specified. The class cannot be empty, so \texttt{[}
can be included provided it is first. If the first character is \texttt{!}, the character class matches a single
character which is \texttt{none} of the specified characters. Whether \texttt{.} in a character class matches a leading
\texttt{.} in the filename is OS-dependent.

Character classes can include ranges such as \texttt{[A-Z]}: include \texttt{~} as a character by having it first or last
in a class. (The interpretation of ranges should be locale-specific, so the example is not a good idea
in an Estonian locale.)

One can remove the special meaning of \texttt{?, \* and [} by preceding them by a backslash (except within
a character class).

Value

A character vector of matched file paths. The order is system-specific (but in the order of the
elements of \texttt{paths}): it is normally collated in either the current locale or in byte (ASCII) order;
however, on Windows collation is in the order of Unicode points.

Directory errors are normally ignored, so the matches are to accessible file paths (but not necessarily
accessible files).

See Also

\texttt{path.expand}.

Quotes for handling backslashes in character strings.

Examples

```r
## Not run:
Sys.glob(file.path(R.home(), "library", \"*\", \"R\", \".*.rdx\"))

## End(Not run)
```
Description

Reports system and user information.

Usage

Sys.info()

Details

This function is not implemented on all R platforms, and returns NULL when not available. Where possible it is based on POSIX system calls. (Under Windows, it is obtained by Windows system calls and the last three values are the same.)

Sys.info() returns details of the platform R is running on, whereas R.version gives details of the platform R was built on: they may well be different.

Value

A character vector with fields

- sysname: The operating system.
- release: The OS release.
- version: The OS version.
- nodename: A name by which the machine is known on the network (if any).
- machine: A concise description of the hardware.
- login: The user's login name, or "unknown" if it cannot be ascertained.
- user: The name of the real user ID, or "unknown" if it cannot be ascertained.
- effective_user: The name of the effective user ID, or "unknown" if it cannot be ascertained. This may differ from the real user in 'set-user-ID' processes.

The first five fields come from the uname() system call. The login name comes from getlogin(), and the user names from getpwuid(getuid()) and getpwnam(geteuid())

Note

The meaning of OS 'release' and 'version' is system-dependent and there is no guarantee that the node or login or user names will be what you might reasonably expect. (In particular on some Linux distributions the login name is unknown from sessions with re-directed inputs.)

The use of alternatives such as system("whoami") is not portable: the POSIX command system("id") is much more portable on Unix-alikes, provided only the POSIX options are used (and not the many GNU extensions).

See Also

.Platform, and R.version. sessionInfo() gives a synopsis of both your system and the R session.
Description

Get details of the numerical and monetary representations in the current locale.

Usage

Sys.localeconv()

Details

Normally \texttt{R} is run without looking at the value of \texttt{LC\_NUMERIC}, so the decimal point remains \texttt{.}. So the first three of these components will only be useful if you have set the locale category \texttt{LC\_NUMERIC} using \texttt{Sys.setlocale} in the current \texttt{R} session (when \texttt{R} may not work correctly).

The monetary components will only be set to non-default values (see the ‘Examples’ section if the \texttt{LC\_MONETARY} category is set. It often is not set: set the examples for how to trigger setting it.

Value

A character vector with 18 named components. See your ISO C documentation for details of the meaning.

It is possible to compile \texttt{R} without support for locales, in which case the value will be \texttt{NULL}.

See Also

\texttt{Sys.setlocale} for ways to set locales.

Examples

Sys.localeconv()

```R
## The results in the C locale are
##   decimal_point thousands_sep grouping int_curr_symbol
##   "." "" "" ""       
##   currency_symbol mon_decimal_point mon_thousands_sep mon_grouping
##   "" "" "" ""       
##   positive_sign negative_sign int_frac_digits frac_digits
##   "" "" "" ""       
##   p_cs_precedes p_sep_by_space n_cs_precedes n_sep_by_space
##   "127" "127" "127" "127"       
##   p_sign_posn n_sign_posn
##   "127" "127"       

## Now try your default locale (which might be "C").
## Not run: old <- Sys.getlocale()
```
Functions to Access the Function Call Stack

Description

These functions provide access to environments (‘frames’ in S terminology) associated with functions further up the calling stack.

Usage

sys.call(which = 0)
sys.frame(which = 0)
sys.nframe()
sys.function(which = 0)
sys.parent(n = 1)

sys.calls()
sys.frames()
sys.parents()
sys.on.exit()
sys.status()
parent.frame(n = 1)

Arguments

which the frame number if non-negative, the number of frames to go back if negative.
n the number of generations to go back. (See the ‘Details’ section.)

Details

.GlobalEnv is given number 0 in the list of frames. Each subsequent function evaluation increases the frame stack by 1 and the call, function definition and the environment for evaluation of that function are returned by sys.call, sys.function and sys.frame with the appropriate index.
sys.call, sys.frame and sys.function accept integer values for the argument which. Non-negative values of which are frame numbers whereas negative values are counted back from the frame number of the current evaluation.

The parent frame of a function evaluation is the environment in which the function was called. It is not necessarily numbered one less than the frame number of the current evaluation, nor is it the environment within which the function was defined. sys.parent returns the number of the parent frame if n is 1 (the default), the grandparent if n is 2, and so on. See also the ‘Note’.
sys.nframe returns an integer, the number of the current frame as described in the first paragraph. sys.calls and sys.frames give a pairlist of all the active calls and frames, respectively, and sys.parents returns an integer vector of indices of the parent frames of each of those frames.

Notice that even though the sys.xxx functions (except sys.status) are interpreted, their contexts are not counted nor are they reported. There is no access to them.

sys.status() returns a list with components sys.calls, sys.parents and sys.frames, the results of calls to those three functions (which this will include the call to sys.status: see the first example).

sys.on.exit() returns the expression stored for use by on.exit in the function currently being evaluated. (Note that this differs from S, which returns a list of expressions for the current frame and its parents.)

parent.frame(n) is a convenient shorthand for sys.frame(sys.parent(n)) (implemented slightly more efficiently).

Value

sys.call returns a call, sys.function a function definition, and sys.frame and parent.frame return an environment.

For the other functions, see the ‘Details’ section.

Note

Strictly, sys.parent and parent.frame refer to the context of the parent interpreted function. So internal functions (which may or may not set contexts and so may or may not appear on the call stack) may not be counted, and S3 methods can also do surprising things.

Beware of the effect of lazy evaluation: these two functions look at the call stack at the time they are evaluated, not at the time they are called. Passing calls to them as function arguments is unlikely to be a good idea.

References

See Also
evau for a usage of sys.frame and parent.frame.

Examples

require(utils)

## Note: the first two examples will give different results
## if run by example().
ff <- function(x) gg(x)
gg <- function(y) sys.status()
str(ff())

gg <- function(y) {
  ggg <- function() {
    cat("current frame is", sys.nframe(), "\n")
    cat("parents are", sys.parents(), "\n")
  }
}
Sys.readlink

Read File Symbolic Links

Description

Find out if a file path is a symbolic link, and if so what it is linked to, via the system call `readlink`.

Symbolic links are a POSIX concept, not implemented on Windows but for most filesystems on Unix-alikes.
Sys.setenv

Usage

Sys.readlink(paths)

Arguments

paths character vector of file paths. Tilde expansion is done: see path.expand.

Value

A character vector of the same length as paths. The entries are the path of the file linked to, "" if the path is not a symbolic link, and NA if there is an error (e.g., the path does not exist).

On platforms without the readlink system call, all elements are "".

See Also

file.symlink for the creation of symbolic links (and their Windows analogues), file.info

Sys.setenv

Set or Unset Environment Variables

Description

Sys.setenv sets environment variables (for other processes called from within R or future calls to Sys.getenv from this R process).

Sys.unsetenv removes environment variables.

Usage

Sys.setenv(...) Sys.unsetenv(x)

Arguments

... named arguments with values coercible to a character string.

x a character vector, or an object coercible to character.

Details

Non-standard R names must be quoted in Sys.setenv: see the examples. Most platforms (and POSIX) do not allow names containing "=". Windows does, but the facilities provided by R may not handle these correctly so they should be avoided. Most platforms allow setting an environment variable to "", but Windows does not, and there Sys.setenv(FOO = "") unsets FOO.

There may be system-specific limits on the maximum length of the values of individual environment variables or of all environment variables.

Value

A logical vector, with elements being true if (un)setting the corresponding variable succeeded. (For Sys.unsetenv this includes attempting to remove a non-existent variable.)
Note

If `Sys.unsetenv` is not supported, it will at least try to set the value of the environment variable to "", with a warning.

See Also

`Sys.getenv`, `Startup` for ways to set environment variables for the R session.

`setwd` for the working directory.

The help for ‘environment variables’ lists many of the environment variables used by R.

Examples

```r
print(Sys.setenv(R_TEST = "testit", "A+C" = 123))  # `A+C` could also be used
Sys.getenv("R_TEST")
Sys.unsetenv("R_TEST")  # may warn and not succeed
Sys.getenv("R_TEST", unset = NA)
```

Description

Uses system calls to set the times on a file or directory.

Usage

```r
Sys.setFileTime(path, time)
```

Arguments

- `path`: A length-one character vector specifying the path to a file or directory.
- `time`: A date-time of class "POSIXct" or an object which can be coerced to one. Fractions of a second are ignored.

Details

This attempts sets the file time to the value specified.

On a Unix-alike it uses the system call `utimes` if that is available, otherwise `utimes`. On a POSIX file system it sets both the last-access and modification times.

On Windows it uses the system call `SetFileTime` to set the ‘last write time’. Some Windows file systems only record the time at a resolution of two seconds.

Value

Logical, invisibly. An indication if the operation succeeded.
Sys.sleep  

Suspend Execution for a Time Interval

Description

Suspend execution of \( R \) expressions for a given number of seconds

Usage

\[
\text{Sys.sleep(time)}
\]

Arguments

time  
The time interval to suspend execution for, in seconds.

Details

Using this function allows \( R \) to be given very low priority and hence not to interfere with more important foreground tasks. A typical use is to allow a process launched from \( R \) to set itself up and read its input files before \( R \) execution is resumed.

The intention is that this function suspends execution of \( R \) expressions but wakes the process up often enough to respond to GUI events, typically every 0.5 seconds.

There is no guarantee that the process will sleep for the whole of the specified interval, and it may well take slightly longer in real time to resume execution. The resolution of the time interval is system-dependent, but will normally be down to 0.02 secs or better. (On modern Unix-alikes it will be better than 1ms.)

Value

Invisible NULL.

Note

This function may not be implemented on all systems. Where it is not implemented calling it given an error.

Examples

\[
\text{testit <- function(x)}
\{
  \text{p1 <- proc.time()}
  \text{Sys.sleep(x)}
  \text{proc.time()} - p1 \text{ # The cpu usage should be negligible}
}\]

\text{testit(3.7)}
Parse and Evaluate Expressions from a File

Description

Parses expressions in the given file, and then successively evaluates them in the specified environment.

Usage

```r
sys.source(file, envir = baseenv(), chdir = FALSE,
       keep.source = getOption("keep.source.pkgs"))
```

Arguments

- `file` a character string naming the file to be read from
- `envir` an R object specifying the environment in which the expressions are to be evaluated. May also be a list or an integer. The default value `NULL` corresponds to evaluation in the base environment. This is probably not what you want; you should typically supply an explicit `envir` argument.
- `chdir` logical; if `TRUE`, the R working directory is changed to the directory containing file for evaluating.
- `keep.source` logical. If `TRUE`, functions keep their source including comments, see `options(keep.source = *)` for more details.

Details

For large files, `keep.source = FALSE` may save quite a bit of memory.

In order for the code being evaluated to use the correct environment (for example, in global assignments), source code in packages should call `topenv()`, which will return the namespace, if any, the environment set up by `sys.source`, or the global environment if a saved image is being used.

See Also

`source`, and `library` which uses `sys.source`.

Examples

```r
## a simple way to put some objects in an environment
## high on the search path
tmp <- tempfile()
writeLines("aaa <- pi", tmp)
env <- attach(NULL, name = "myenv")
sys.source(tmp, env)
unlink(tmp)
search()
aaa
detach("myenv")
```
Sys.time  Get Current Date and Time

Description
Sys.time and Sys.Date returns the system’s idea of the current date with and without time.

Usage
Sys.time()
Sys.Date()

Details
Sys.time returns an absolute date-time value which can be converted to various time zones and may return different days.
Sys.Date returns the current day in the current timezone.

Value
Sys.time returns an object of class "POSIXct" (see DateTimeClasses). On almost all systems it will have sub-second accuracy, possibly microseconds or better. On Windows it increments in clock ticks (usually 1/60 of a second) reported to millisecond accuracy.
Sys.Date returns an object of class "Date" (see Date).

Note
Sys.time may return fractional seconds, but they are ignored by the default conversions (e.g. printing) for class "POSIXct". See the examples and format.POSIXct for ways to reveal them.

See Also
date for the system time in a fixed-format character string.
Sys.timezone.
system.time for measuring elapsed/CPU time of expressions.

Examples
Sys.time()
## print with possibly greater accuracy:
op <- options(digits.secs = 6)
Sys.time()
options(op)

## locale-specific version of date()
format(Sys.time(), "%a %b %d %X %Y")

Sys.Date()
Sys.which

Find Full Paths to Executables

Description
This is an interface to the system command *which*, or to an emulation on Windows.

Usage
```r
Sys.which(names)
```

Arguments
- `names` Character vector of names or paths of possible executables.

Details
The system command *which* reports on the full path names of an executable (including an executable script) as would be executed by a shell, accepting either absolute paths or looking on the path.

On Windows an 'executable' is a file with extension '.exe', '.com', '.cmd' or '.bat'. Such files need not actually be executable, but they are what *system* tries.

On a Unix-alike the full path to *which* (usually '/usr/bin/which') is found when *R* is installed.

Value
A character vector of the same length as `names`, named by `names`. The elements are either the full path to the executable or some indication that no executable of that name was found. Typically the indication is "", but this does depend on the OS (and the known exceptions are changed to ":"). Missing values in `names` have missing return values (as from *R* 3.0.0).

On Windows the paths will be short paths (8+3 components, no spaces) with `\` as the path delimiter.

Note
Except on Windows this calls the system command *which*: since that is not part of e.g. the POSIX standards, exactly what it does is OS-dependent. It will usually do tilde-expansion and it may make use of *csh* aliases.

In *R* 2.x.y, arguments containing spaces or other metacharacters needed to be escaped as they would be for a shell: for example Windows paths containing spaces needed to be enclosed in double quotes.

Examples
```r
## the first two are likely to exist everywhere
## texi2dvi exists on most Unix-alikes and under MiKTeX
Sys.which(c("ftp", "ping", "texi2dvi", "this-does-not-exist"))
```
**system**  
Invoke a System Command

**Description**

system invokes the OS command specified by command.

**Usage**

system(command, intern = FALSE,  
ignore.stdout = FALSE, ignore.stderr = FALSE,  
wait = TRUE, input = NULL, show.output.on.console = TRUE,  
minimized = FALSE, invisible = TRUE)

**Arguments**

command  
the system command to be invoked, as a character string.

intern  
a logical (not NA) which indicates whether to capture the output of the command  
as an R character vector.

ignore.stdout, ignore.stderr  
a logical (not NA) indicating whether messages written to 'stdout' or 'stderr'  
should be ignored.

wait  
a logical (not NA) indicating whether the R interpreter should wait for the command  
to finish, or run it asynchronously. This will be ignored (and the interpreter  
will always wait) if intern = TRUE.

input  
if a character vector is supplied, this is copied one string per line to a temporary  
file, and the standard input of command is redirected to the file.

show.output.on.console, minimized, invisible  
arguments that are accepted on Windows but ignored on this platform, with a  
warning.

**Details**

command is parsed as a command plus arguments separated by spaces. So if the path to the command  
(or an argument) contains spaces, it must be quoted e.g. by shQuote. Unix-alikes pass the command  
line to a shell (normally '/bin/sh', and POSIX requires that shell), so command can be anything the  
shell regards as executable, including shell scripts, and it can contain multiple commands separated  
by ;.

On Windows, system does not use a shell and there is a separate function shell which passes  
command lines to a shell.

If intern is TRUE then popen is used to invoke the command and the output collected, line by line,  
into an R character vector. If intern is FALSE then the C function system is used to invoke the command.

wait is implemented by appending & to the command: this is in principle shell-dependent, but  
required by POSIX and so widely supported.

The ordering of arguments after the first two has changed from time to time: it is recommended to  
name all arguments after the first.

There are many pitfalls in using system to ascertain if a command can be run — Sys.which is more  
suitable.
system

Value

If `intern` = TRUE, a character vector giving the output of the command, one line per character string. (Output lines of more than 8095 bytes will be split.) If the command could not be run an R error is generated. If command runs but gives a non-zero exit status this will be reported with a warning and in the attribute "status" of the result: an attribute "errmsg" may also be available.

If `intern` = FALSE, the return value is an error code (0 for success), given the invisible attribute (so needs to be printed explicitly). If the command could not be run for any reason, the value is 127. Otherwise if `wait` = TRUE the value is the exit status returned by the command, and if `wait` = FALSE it is 0 (the conventional success value).

Stdout and stderr

For command-line R, error messages written to `stderr` will be sent to the terminal unless `ignore.stderr` = TRUE. They can be captured (in the most likely shells) by

```r
system("some command 2>&1", intern = TRUE)
```

For GUIs, what happens to output sent to `stdout` or `stderr` if `intern` = FALSE is interface-specific, and it is unsafe to assume that such messages will appear on a GUI console (they do on the Mac OS X console, but not on some others).

Differences between Unix and Windows

How processes are launched differs fundamentally between Windows and Unix-alike operating systems, as do the higher-level OS functions on which this R function is built. So it should not be surprising that there are many differences between OSes in how `system` behaves. For the benefit of programmers, the more important ones are summarized in this section.

- The most important difference is that on a Unix-alike system launches a shell which then runs `command`. On Windows the command is run directly – use `shell` for an interface which runs `command` via a shell (by default the Windows shell `cmd.exe`, which has many differences from a POSIX shell).
  
  This means that it cannot be assumed that redirection or piping will work in `system` (redirection sometimes does, but we have seen cases where it stopped working after a Windows security patch), and `system2` (or `shell`) must be used on Windows.

- What happens to stdout and stderr when not captured depends on how R is running: Windows batch commands behave like a Unix-alike, but from the Windows GUI they are generally lost. `system(intern = TRUE)` captures `stderr` when run from the Windows GUI console unless `ignore.stderr` = TRUE.

- The behaviour on error is different in subtle ways (and has differed between R versions).

- The quoting conventions for command differ, but `shQuote` is a portable interface.

- Arguments `show.output.on.console, minimized, invisible` only do something on Windows (and are most relevant to `Rgui` there).

See Also

`system2`, `man system` and `man sh` for how this is implemented on the OS in use.

`Platform` for platform-specific variables.

`pipe` to set up a pipe connection.
Examples

# list all files in the current directory using the -F flag
## Not run: system("ls -F")

# tl is a character vector, each element giving a line of output from who
# (if the platform has who)
tl <- try(system("who", intern = TRUE))

try(system("ls fzzlippuzzli", intern = TRUE, ignore.stderr = TRUE))
# zero-length result since file does not exist, and will give warning.

system.file Find Names of R System Files

Description

Finds the full file names of files in packages etc.

Usage

system.file(..., package = "base", lib.loc = NULL,
            mustWork = FALSE)

Arguments

... character vectors, specifying subdirectory and file(s) within some package. The
default, none, returns the root of the package. Wildcards are not supported.
package a character string with the name of a single package. An error occurs if more
than one package name is given.
lib.loc a character vector with path names of R libraries. See ‘Details’ for the meaning
of the default value of NULL.
mustWork logical. If TRUE, an error is given if there are no matching files.

Details

This checks the existence of the specified files with file.exists. So file paths are only returned if
there are sufficient permissions to establish their existence.

The unnamed arguments in ... are usually character strings, but if character vectors they are
recycled to the same length.

This uses find.package to find the package, and hence with the default lib.loc = NULL looks
first for attached packages then in each library listed in .libPaths(). Note that if a namespace is
loaded but the package is not attached, this will look only on .libPaths().

Value

A character vector of positive length, containing the file paths that matched ..., or the empty string,
"", if none matched (unless mustWork = TRUE).
If matching the root of a package, there is no trailing separator.

system.file() with no arguments gives the root of the base package.
system.time

See Also

R.home for the root directory of the R installation, list.files.
Sys.glob to find paths via wildcards.

Examples

system.file() # The root of the 'base' package
system.file(package = "stats") # The root of package 'stats'
system.file("INDEX")
system.file("help", "AnIndex", package = "splines")

system.time

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Return CPU (and other) times that expr used.</td>
</tr>
</tbody>
</table>

Usage

system.time(expr, gcFirst = TRUE)
unix.time(expr, gcFirst = TRUE)

Arguments

- `expr` Valid R expression to be timed.
- `gcFirst` Logical - should a garbage collection be performed immediately before the timing? Default is TRUE.

Details

system.time calls the function proc.time, evaluates expr, and then calls proc.time once more, returning the difference between the two proc.time calls.
unix.time is an alias of system.time, for compatibility with S.

Timings of evaluations of the same expression can vary considerably depending on whether the evaluation triggers a garbage collection. When gcFirst is TRUE a garbage collection (gc) will be performed immediately before the evaluation of expr. This will usually produce more consistent timings.

Value

A object of class "proc_time": see proc.time for details.

See Also

proc.time, time which is for time series.
Sys.time to get the current date & time.
Examples

require(stats)
system.time(for(i in 1:100) mad(runif(1000)))
## Not run:
exT <- function(n = 10000) {
  # Purpose: Test if system.time works ok; n: loop size
  system.time(for(i in 1:n) x <- mean(rt(1000, df = 4)))
}
#-- Try to interrupt one of the following (using Ctrl-C / Escape):
exT()    # about 4 secs on a 2.5GHz Xeon
system.time(exT())    # +/- same
## End(Not run)

---

system2  
Invoke a System Command

Description

system2 invokes the OS command specified by command.

Usage

system2(command, args = character(),
  stdout = "", stderr = "", stdin = "", input = NULL,
  env = character(),
  wait = TRUE, minimized = FALSE, invisible = TRUE)

Arguments

command    the system command to be invoked, as a character string.
args       a character vector of arguments to command.
stdout, stderr where output to 'stdout' or 'stderr' should be sent. Possible values are "", to the R console (the default), NULL or FALSE (discard output), TRUE (capture the output in a character vector) or a character string naming a file.
stdin       should input be diverted? "" means the default, alternatively a character string naming a file. Ignored if input is supplied.
input       if a character vector is supplied, this is copied one string per line to a temporary file, and the standard input of command is redirected to the file.
env         character vector of name=value strings to set environment variables.
wait         a logical (not NA) indicating whether the R interpreter should wait for the command to finish, or run it asynchronously. This will be ignored (and the interpreter will always wait) if stdout = TRUE.
minimized, invisible arguments that are accepted on Windows but ignored on this platform, with a warning.
Details

Unlike `system`, command is always quoted by `shQuote`, so it must be a single command without arguments.

For details of how command is found see `system`.

On Windows, `env` is currently only supported for commands such as `R` and `make` which accept environment variables on their command line.

Some Unix commands (such as `ls`) change their output depending on whether they think it is redirected: `stdout = TRUE` uses a pipe whereas `stdout = "$some_file_name"` uses redirection.

Because of the way it is implemented, on a Unix-alike `stderr = TRUE` implies `stdout = TRUE`: a warning is given if this is not what was specified.

Value

If `stdout = TRUE` or `stderr = TRUE`, a character vector giving the output of the command, one line per character string. (Output lines of more than 8095 bytes will be split.) If the command could not be run an `R` error is generated. If command runs but gives a non-zero exit status this will be reported with a warning and in the attribute "status" of the result: an attribute "errmsg" may also be available.

In other cases, the return value is an error code (0 for success), given the invisible attribute (so needs to be printed explicitly). If the command could not be run for any reason, the value is 127. Otherwise if `wait = TRUE` the value is the exit status returned by the command, and if `wait = FALSE` it is 0 (the conventional success value).

Note

`system2` is a more portable and flexible interface than `system`, introduced in R 2.12.0. It allows redirection of output without needing to invoke a shell on Windows, a portable way to set environment variables for the execution of command, and finer control over the redirection of `stdout` and `stderr`. Conversely, `system` (and `shell` on Windows) allows the invocation of arbitrary command lines.

There is no guarantee that if `stdout` and `stderr` are both `TRUE` or the same file that the two streams will be interleaved in order. This depends on both the buffering used by the command and the OS.

See Also

`system`.

### t

**Matrix Transpose**

**Description**

Given a matrix or `data.frame` `x`, `t` returns the transpose of `x`.

**Usage**

\[ t(x) \]
Arguments

- `x`: a matrix or data frame, typically.

Details

This is a generic function for which methods can be written. The description here applies to the default and “data.frame” methods.

A data frame is first coerced to a matrix: see `as.matrix`. When `x` is a vector, it is treated as a column, i.e., the result is a 1-row matrix.

Value

A matrix, with `dim` and `dimnames` constructed appropriately from those of `x`, and other attributes except names copied across.

Note

The conjugate transpose of a complex matrix `A`, denoted `A^H` or `A^*`, is computed as `Conj(t(A))`.

References

See Also

- `aperm` for permuting the dimensions of arrays.

Examples

```r
a <- matrix(1:30, 5, 6)
ta <- t(a)  # i.e., a[i, j] == ta[j, i] for all i, j:
for(j in seq(ncol(a)))
  if(! all(a[, j] == ta[j, ])) stop("wrong transpose")
```

**Description**

*table* uses the cross-classifying factors to build a contingency table of the counts at each combination of factor levels.

**Usage**

- `table(..., exclude = if (useNA == "no") c(NA, NaN), useNA = c("no", "ifany", "always"), dnn = list.names(...), deparse.level = 1)`
  
  `as.table(x, ...)`
  
  `is.table(x)`

  `## S3 method for class 'table'`
as.data.frame(x, row.names = NULL, ..., 
  responseName = "Freq", stringsAsFactors = TRUE)

Arguments

... one or more objects which can be interpreted as factors (including character strings), or a list (or data frame) whose components can be so interpreted. (For as.table and as.data.frame, arguments passed to specific methods.)

exclude levels to remove for all factors in .... If set to NULL, it implies useNA = "always". See ‘Details’ for its interpretation for non-factor arguments.

useNA whether to include NA values in the table. See ‘Details’.

dnn the names to be given to the dimensions in the result (the dimnames names).

deparse.level controls how the default dnn is constructed. See ‘Details’.

x an arbitrary R object, or an object inheriting from class "table" for the as.data.frame method.

row.names a character vector giving the row names for the data frame.

responseName The name to be used for the column of table entries, usually counts.

stringsAsFactors logical: should the classifying factors be returned as factors (the default) or character vectors?

Details

If the argument dnn is not supplied, the internal function list.names is called to compute the ‘dimname names’. If the arguments in ... are named, those names are used. For the remaining arguments, deparse.level = 0 gives an empty name, deparse.level = 1 uses the supplied argument if it is a symbol, and deparse.level = 2 will deparse the argument.

Only when exclude is specified and non-NULL (i.e., not by default), will table potentially drop levels of factor arguments.

useNA controls if the table includes counts of NA values: the allowed values correspond to never, only if the count is positive and even for zero counts. This is overridden by specifying exclude = NULL. Note that levels specified in exclude are mapped to NA and so included in NA counts.

Both exclude and useNA operate on an "all or none" basis. If you want to control the dimensions of a multiway table separately, modify each argument using factor or addNA.

It is best to supply factors rather than rely on coercion. In particular, exclude will be used in coercion to a factor, and so values (not levels) which appear in exclude before coercion will be mapped to NA rather than be discarded.

The summary method for class "table" (used for objects created by table or xtabs) which gives basic information and performs a chi-squared test for independence of factors (note that the function chisq.test currently only handles 2-d tables).

Value

table() returns a contingency table, an object of class "table", an array of integer values. Note that unlike S the result is always an array, a 1D array if one factor is given.

as.table and is.table coerce to and test for contingency table, respectively.

The as.data.frame method for objects inheriting from class "table" can be used to convert the array-based representation of a contingency table to a data frame containing the classifying factors
and the corresponding entries (the latter as component named by `responseName`). This is the inverse of `xtabs`.

References

See Also

`tabulate` is the underlying function and allows finer control.

Use `ftable` for printing (and more) of multidimensional tables. `margin.table`, `prop.table`, `addmargins`.

Examples

```r
require(stats) # for rpois and xtabs
## Simple frequency distribution
table(rpois(100, 5))
## Check the design:
with(warpbreaks, table(wool, tension))
table(state.division, state.region)

# simple two-way contingency table
with(airquality, table(cut(Temp, quantile(Temp)), Month))

a <- letters[1:3]
table(a, sample(a)) # dnn is c("a", ")
table(a, sample(a), deparse.level = 0) # dnn is c("", ")
table(a, sample(a), deparse.level = 2) # dnn is c("a", "sample(a)"

## xtabs() <- as.data.frame.table() :
UCBAdmisions # already a contingency table
DF <- as.data.frame(UCBAdmisions)
class(tab <- xtabs(Freq ~ ., DF)) # xtabs & table
## tab *is* "the same" as the original table:
all(tab == UCBAdmisions)
all.equal(dimnames(tab), dimnames(UCBAdmisions))

a <- rep(c(NA, 1/0:3), 10)
table(a)
table(a, exclude = NULL)
b <- factor(rep(c("A","B","C"), 10))
table(b)
table(b, exclude = "B")
d <- factor(rep(c("A","B","C"), 10), levels = c("A","B","C","D","E"))
table(d, exclude = "B")
print(table(b, d), zero.print = ".")

## NA counting:
is.na(d) <- 3:4
d. <- addNA(d)
d.[1:7]
table(d.) # ", exclude = NULL" is not needed
## i.e., if you want to count the NA's of 'd', use
table(d, useNA = "ifany")
```
## Tabulation for Vectors

### Description

`tabulate` takes the integer-valued vector `bin` and counts the number of times each integer occurs in it.

### Usage

```r
tabulate(bin, nbins = max(1, bin, na.rm = TRUE))
```

### Arguments

- `bin`: a numeric vector (of positive integers), or a factor. Long vectors are supported.
- `nbins`: the number of bins to be used.

### Details

`tabulate` is the workhorse for the `table` function.

- If `bin` is a factor, its internal integer representation is tabulated.
- If the elements of `bin` are numeric but not integers, they are truncated by `as.integer`.

### Value

An integer vector (without names). There is a bin for each of the values 1, ..., `nbins`; values outside that range and NAs are (silently) ignored.

On 64-bit platforms `bin` can have $2^{31}$ or more elements and hence a count could exceed the maximum integer: this is currently an error.

### See Also

- `table`, `factor`.

### Examples

```r
tabulate(c(2,3,5))
tabulate(c(2,3,5), nbins = 10)
tabulate(c(-2,0,2,3,5))  # -2 and 0 are ignored
tabulate(c(-2,0,2,3,5), nbins = 3)
tabulate(factor(letters[1:10]))
```
**tapply**

*Apply a Function Over a Ragged Array*

**Description**

Apply a function to each cell of a ragged array, that is to each (non-empty) group of values given by a unique combination of the levels of certain factors.

**Usage**

`tapply(X, INDEX, FUN = NULL, ..., simplify = TRUE)`

**Arguments**

- **X**: an atomic object, typically a vector.
- **INDEX**: list of one or more factors, each of same length as X. The elements are coerced to factors by `as.factor`.
- **FUN**: the function to be applied, or NULL. In the case of functions like +, **%, etc., the function name must be backquoted or quoted. If FUN is NULL, `tapply` returns a vector which can be used to subscript the multi-way array `tapply` normally produces.
- **...**: optional arguments to FUN: the Note section.
- **simplify**: If FALSE, `tapply` always returns an array of mode "list". If TRUE (the default), then if FUN always returns a scalar, `tapply` returns an array with the mode of the scalar.

**Value**

If FUN is not NULL, it is passed to `match.fun`, and hence it can be a function or a symbol or character string naming a function.

When FUN is present, `tapply` calls FUN for each cell that has any data in it. If FUN returns a single atomic value for each such cell (e.g., functions `mean` or `var`) and when simplify is TRUE, `tapply` returns a multi-way array containing the values, and NA for the empty cells. The array has the same number of dimensions as INDEX has components; the number of levels in a dimension is the number of levels (nlevels()) in the corresponding component of INDEX. Note that if the return value has a class (e.g. an object of class "Date") the class is discarded.

Note that contrary to S, simplify = TRUE always returns an array, possibly 1-dimensional.

If FUN does not return a single atomic value, `tapply` returns an array of mode list whose components are the values of the individual calls to FUN, i.e., the result is a list with a dim attribute.

When there is an array answer, its dimnames are named by the names of INDEX and are based on the levels of the grouping factors (possibly after coercion).

For a list result, the elements corresponding to empty cells are NULL.

**Note**

Optional arguments to FUN supplied by the ... argument are not divided into cells. It is therefore inappropriate for FUN to expect additional arguments with the same length as X.
References

See Also

the convenience functions `by` and `aggregate` (using `tapply`); `apply`, `lapply` with its versions `sapply` and `mapply`.

Examples

```r
require(stats)
groups <- as.factor(rbinom(32, n = 5, prob = 0.4))
tapply(groups, groups, length) # is almost the same as
table(groups)

# contingency table from data.frame : array with named dimnames
tapply(warpbreaks$breaks, warpbreaks[,1], sum)
tapply(warpbreaks$breaks, warpbreaks[, 3, drop = FALSE], sum)

n <- 17; fac <- factor(rep(1:3, length = n), levels = 1:5)
table(fac)
tapply(1:n, fac, sum)
tapply(1:n, fac, sum, simplify = FALSE)
tapply(1:n, fac, range)
tapply(1:n, fac, quantile)

# example of ... argument: find quarterly means
tapply(presidents, cycle(presidents), mean, na.rm = TRUE)

ind <- list(c(1, 2, 2), c("A", "A", "B"))
table(ind)
tapply(1:3, ind) #-> the split vector
tapply(1:3, ind, sum)
```

---

taskCallback

*Add or Remove a Top-Level Task Callback*

Description

`addTaskCallback` registers an R function that is to be called each time a top-level task is completed.

`removeTaskCallback` un-registers a function that was registered earlier via `addTaskCallback`.

These provide low-level access to the internal/native mechanism for managing task-completion actions. One can use `taskCallbackManager` at the S-language level to manage S functions that are called at the completion of each task. This is easier and more direct.

Usage

```r
addTaskCallback(f, data = NULL, name = character())
removeTaskCallback(id)
```
Arguments

- \( f \) the function that is to be invoked each time a top-level task is successfully completed. This is called with 5 or 4 arguments depending on whether \( \text{data} \) is specified or not, respectively. The return value should be a logical value indicating whether to keep the callback in the list of active callbacks or discard it.
- \( \text{data} \) if specified, this is the 5-th argument in the call to the callback function \( f \).
- \( \text{id} \) a string or an integer identifying the element in the internal callback list to be removed. Integer indices are 1-based, i.e. the first element is 1. The names of currently registered handlers is available using \texttt{getTaskCallbackNames} and is also returned in a call to \texttt{addTaskCallback}.
- \( \text{name} \) character: names to be used.

Details

Top-level tasks are individual expressions rather than entire lines of input. Thus an input line of the form \texttt{expression1 ; expression2} will give rise to 2 top-level tasks.

A top-level task callback is called with the expression for the top-level task, the result of the top-level task, a logical value indicating whether it was successfully completed or not (always \texttt{TRUE} at present), and a logical value indicating whether the result was printed or not. If the \( \text{data} \) argument was specified in the call to \texttt{addTaskCallback}, that value is given as the fifth argument.

The callback function should return a logical value. If the value is \texttt{FALSE}, the callback is removed from the task list and will not be called again by this mechanism. If the function returns \texttt{TRUE}, it is kept in the list and will be called on the completion of the next top-level task.

Value

- \texttt{addTaskCallback} returns an integer value giving the position in the list of task callbacks that this new callback occupies. This is only the current position of the callback. It can be used to remove the entry as long as no other values are removed from earlier positions in the list first.
- \texttt{removeTaskCallback} returns a logical value indicating whether the specified element was removed. This can fail (i.e., return \texttt{FALSE}) if an incorrect name or index is given that does not correspond to the name or position of an element in the list.

Note

- There is also C-level access to top-level task callbacks to allow C routines rather than R functions to be used.

See Also

- \texttt{getTaskCallbackNames}
- \texttt{taskCallbackManager}
- \texttt{http://developer.r-project.org/TaskHandlers.pdf}

Examples

```r
times <- function(total = 3, \texttt{str} = "Task a") {
  \texttt{ctr} <- 0

  function(\texttt{expr}, \texttt{value}, \texttt{ok}, \texttt{visible}) {
    \texttt{ctr} <- \texttt{ctr} + 1
    \texttt{cat}(\texttt{str}, \texttt{ctr}, \"\n")
    \texttt{if}(\texttt{ctr} == \texttt{total}) {
```
taskCallbackManager

Create an R-level Task Callback Manager

Description

This provides an entirely S-language mechanism for managing callbacks or actions that are invoked at the conclusion of each top-level task. Essentially, we register a single R function from this manager with the underlying, native task-callback mechanism and this function handles invoking the other R callbacks under the control of the manager. The manager consists of a collection of functions that access shared variables to manage the list of user-level callbacks.

Usage

```r
taskCallbackManager(handlers = list(), registered = FALSE, verbose = FALSE)
```

Arguments

- **handlers**: this can be a list of callbacks in which each element is a list with an element named "f" which is a callback function, and an optional element named "data" which is the 5-th argument to be supplied to the callback when it is invoked. Typically this argument is not specified, and one uses add to register callbacks after the manager is created.

- **registered**: a logical value indicating whether the evaluate function has already been registered with the internal task callback mechanism. This is usually FALSE and the first time a callback is added via the add function, the evaluate function is automatically registered. One can control when the function is registered by specifying TRUE for this argument and calling addTaskCallback manually.
**taskCallbackManager**

**verbose**
a logical value, which if TRUE, causes information to be printed to the console about certain activities this dispatch manager performs. This is useful for debugging callbacks and the handler itself.

**Value**
A list containing 6 functions:

- **add**
  register a callback with this manager, giving the function, an optional 5-th argument, an optional name by which the callback is stored in the list, and a register argument which controls whether the evaluate function is registered with the internal C-level dispatch mechanism if necessary.

- **remove**
  remove an element from the manager’s collection of callbacks, either by name or position/index.

- **evaluate**
  the ‘real’ callback function that is registered with the C-level dispatch mechanism and which invokes each of the R-level callbacks within this manager’s control.

- **suspend**
  a function to set the suspend state of the manager. If it is suspended, none of the callbacks will be invoked when a task is completed. One sets the state by specifying a logical value for the status argument.

- **register**
  a function to register the evaluate function with the internal C-level dispatch mechanism. This is done automatically by the add function, but can be called manually.

- **callbacks**
  returns the list of callbacks being maintained by this manager.

**See Also**

- `addTaskCallback`
- `removeTaskCallback`
- `getTaskCallbackNames`

**Examples**

```r
# create the manager
h <- taskCallbackManager()

# add a callback
h$add(function(expr, value, ok, visible) {
  cat("In handler\n")
  return(TRUE)
}, name = "simpleHandler")

# look at the internal callbacks.
getTaskCallbackNames()

# look at the R-level callbacks
names(h$callbacks())

getTaskCallbackNames()
removeTaskCallback("R-taskCallbackManager")
```
**taskCallbackNames**

*Query the Names of the Current Internal Top-Level Task Callbacks*

**Description**

This provides a way to get the names (or identifiers) for the currently registered task callbacks that are invoked at the conclusion of each top-level task. These identifiers can be used to remove a callback.

**Usage**

```r
getTaskCallbackNames()
```

**Value**

A character vector giving the name for each of the registered callbacks which are invoked when a top-level task is completed successfully. Each name is the one used when registering the callbacks and returned as the in the call to `addTaskCallback`.

**Note**

One can use `taskCallbackManager` to manage user-level task callbacks, i.e., S-language functions, entirely within the S language and access the names more directly.

**See Also**

`addTaskCallback`, `removeTaskCallback`, `taskCallbackManager`

**Examples**

```r
n <- addTaskCallback(function(expr, value, ok, visible) {
  cat("In handler\n")
  return(TRUE)
}, name = "simpleHandler")

getTaskCallbackNames()

# now remove it by name
removeTaskCallback("simpleHandler")

h <- taskCallbackManager()
h$add(function(expr, value, ok, visible) {
  cat("In handler\n")
  return(TRUE)
}, name = "simpleHandler")

getTaskCallbackNames()
removeTaskCallback("R-taskCallbackManager")
```
tempfile

Create Names for Temporary Files

description
tempfile returns a vector of character strings which can be used as names for temporary files.

Usage
tempfile(pattern = "file", tmpdir = tempdir(), fileext = "")
tempdir()

Arguments
- pattern: a non-empty character vector giving the initial part of the name.
- tmpdir: a non-empty character vector giving the directory name
- fileext: a non-empty character vector giving the file extension

Details
The length of the result is the maximum of the lengths of the three arguments; values of shorter arguments are recycled.
The names are very likely to be unique among calls to tempfile in an R session and across simultaneous R sessions (unless tmpdir is specified). The filenames are guaranteed not to be currently in use.
The file name is made by concatenating the path given by tmpdir, the pattern string, a random string in hex and a suffix of fileext.
By default, tmpdir will be the directory given by tempdir(). This will be a subdirectory of the per-session temporary directory found by the following rule when the R session is started. The environment variables TMPDIR, TMP and TEMP are checked in turn and the first found which points to a writable directory is used: if none succeeds ‘/tmp’ is used. The path should not contain spaces.
Note that setting any of these environment variables in the R session has no effect on tempdir(): the per-session temporary directory is created before the interpreter is started.

Value
For tempfile a character vector giving the names of possible (temporary) files. Note that no files are generated by tempfile.
For tempdir, the path of the per-session temporary directory.

Note on parallel
R processes forked by functions such as mclapply in package parallel (or multicore) share a per-session temporary directory. Further, the ‘guaranteed not to be currently in use’ applies only at the time of asking, and two children could ask simultaneously. This is circumvented by ensuring that tempfile calls in different children try different names.

References
textConnection

See Also

unlink for deleting files.

Examples

tempfile(c("ab", "a b c"))  # give file name with spaces in!
tempfile("plot", fileext = c(".ps", ".pdf"))
tempdir()  # works on all platforms with a platform-dependent result

textConnection

Description

Input and output text connections.

Usage

textConnection(object, open = "r", local = FALSE,
       encoding = c("", "bytes", "UTF-8"))
textConnectionValue(con)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object</td>
<td>character. A description of the connection. For an input this is an R character vector object, and for an output connection the name for the R character vector to receive the output, or NULL (for none).</td>
</tr>
<tr>
<td>open</td>
<td>character. Either &quot;r&quot; (or equivalently &quot;&quot;&quot;) for an input connection or &quot;w&quot; or &quot;a&quot; for an output connection.</td>
</tr>
<tr>
<td>local</td>
<td>logical. Used only for output connections. If TRUE, output is assigned to a variable in the calling environment. Otherwise the global environment is used.</td>
</tr>
<tr>
<td>encoding</td>
<td>character. Used only for input connections. How marked strings in object should be handled: converted to the current locale, used byte-by-byte or translated to UTF-8.</td>
</tr>
<tr>
<td>con</td>
<td>An output text connection.</td>
</tr>
</tbody>
</table>

Details

An input text connection is opened and the character vector is copied at time the connection object is created, and close destroys the copy. object should be the name of a character vector: however, short expressions will be accepted provided they deparse to less than 60 bytes.

An output text connection is opened and creates an R character vector of the given name in the user’s workspace or in the calling environment, depending on the value of the local argument. This object will at all times hold the completed lines of output to the connection, and isIncomplete will indicate if there is an incomplete final line. Closing the connection will output the final line, complete or not. (A line is complete once it has been terminated by end-of-line, represented by "\n" in R.) The output character vector has locked bindings (see lockBinding) until close is called on
the connection. The character vector can also be retrieved via `textConnectionValue`, which is the only way to do so if `object = NULL`. If the current locale is detected as Latin-1 or UTF-8, non-ASCII elements of the character vector will be marked accordingly (see Encoding).

Opening a text connection with `mode = "a"` will attempt to append to an existing character vector with the given name in the user’s workspace or the calling environment. If none is found (even if an object exists of the right name but the wrong type) a new character vector will be created, with a warning.

You cannot seek on a text connection, and `seek` will always return zero as the position.

Text connections have slightly unusual semantics: they are always open, and throwing away an input text connection without closing it (so it get garbage-collected) does not give a warning.

**Value**

For `textConnection`, a connection object of class "textConnection" which inherits from class "connection".

For `textConnectionValue`, a character vector.

**Note**

As output text connections keep the character vector up to date line-by-line, they are relatively expensive to use, and it is often better to use an anonymous `file()` connection to collect output.

On (rare) platforms where `vsnprintf` does not return the needed length of output there is a 100,000 character limit on the length of line for output connections: longer lines will be truncated with a warning.

**References**

[S has input text connections only.]

**See Also**

`connections`, `showConnections`, `pushBack`, `capture.output`.

**Examples**

```r
zz <- textConnection(LETTERS)
readlines(zz, 2)
scan(zz, "", 4)
pushBack(c("aa", "bb"), zz)
scan(zz, "", 4)
close(zz)

zz <- textConnection("foo", "w")
writeLines(c("testit1", "testit2"), zz)
cat("testit3", file = zz)
isIncomplete(zz)
cat("testit4\n", file = zz)
isIncomplete(zz)
close(zz)
foo
```

## Not run: # capture R output: use part of example from help(lm)
tilde

Description
Tilde is used to separate the left- and right-hand sides in a model formula.

Usage
y ~ model

Arguments
y, model symbolic expressions.

Details
The left-hand side is optional, and one-sided formulae are used in some contexts.

A formula has mode call. It can be subsetted by [[: the components are ~, the left-hand side (if present) and the right-hand side in that order.

Description

Information about time zones in R. Sys.timezone returns the current time zone.

Usage

Sys.timezone()

Details

Time zones are a system-specific topic, but these days almost all R platforms use the same underlying code, used by Linux, OS X, Solaris, AIX, FreeBSD, Sun Java >= 1.4 and Tcl >= 8.5, and installed with R on Windows.

It is not in general possible to retrieve the system's own name(s) for the current timezone, but Sys.timezone will retrieve the name it uses for the current time (and the name may differ depending on whether daylight saving time is in effect).

On most platforms it is possible to set the time zone via the environment variable TZ: see the section on ‘Time zone names’ for suitable values.

Note that the principal difficulty with time zones is their individual history: over the last 100 years places have changed their affiliation between major time zones, have opted out of (or in to) DST in various years or adopted rule changes late or not at all. This often involves tiny administrative units in the US/Canada: Iowa had 23 different implementations of DST in the 1960’s!

Time zones did not come into use until the second half of the nineteenth century, and DST was first introduced in the early twentieth century, most widely during the First World War (in 1916). The most common implementation of POSIXct is as signed 32-bit integers and so only goes back to the end of 1901: on such systems R assumes that dates prior to that are in the same time zone as they were in 1902.

Value

Sys.timezone returns an OS-specific character string, possibly an empty string. Typically this is an abbreviation such as “EST”.

Time zone names

Where OSes describe their valid time zones can be obscure. The help for the C function tzset can be helpful, but it can also be inaccurate. There is a cumbersome POSIX specification (listed under environment variable TZ at http://pubs.opengroup.org/onlinepubs/9699913799/basedefs/V1_chap08.html#tag_08), which is often at least partially supported, but there usually are other more user-friendly ways to specify timezones.

Many systems make use of a timezone database compiled by Arthur Olson, in which the preferred way to refer to a time zone by a location (typically of a city) e.g. Europe/London, America/Los_Angeles, Pacific/Easter. Some traditional designations are also allowed such as EST5EDT or GB. (Beware that some of these designations may not be what you think: in particular EST is a time zone used in Canada without daylight savings time, and not EST5EDT nor (Australian) Eastern Standard Time.) The designation can also be an optional colon prepended to the path to a file giving complied zone information (and the examples above are all files in a system-specific
location). See http://www.twinsun.com/tz/tz-link.htm for more details and references. By convention, regions with a unique timezone history since 1970 have specific names, but those with different earlier histories may not.

For most Unix-alikes use the Olson database. The system-specific default location in the file system varies, e.g. ‘/usr/share/zoneinfo’ (Linux, OS X, FreeBSD), ‘/usr/share/lib/zoneinfo’ (Solaris, AIX), ‘/usr/etc/zoneinfo’. It is likely that there is a file ‘zone.tab’ in that directory listing the locations known as time-zone names (but not for example EST5EDT). See also http://en.wikipedia.org/wiki/Zone.tab.

Many systems support timezones of the form ‘GMT+n’ and ‘GMT-n’, which are at a fixed offset from UTC (hence no DST). Contrary to some usage (but consistent with names such as ‘PST8PDT’), negative offsets are times ahead of (east of) UTC, positive offsets are times behind (west of) UTC.

Note

There is currently (since 2007) considerable disruption over changes to the timings of the DST transitions, aimed at energy conservation. These often have short notice and timezone databases may not be up to date (even if the OS has been updated recently).

Note that except on Windows, the operation of time zones is an OS service, and even on Windows a third-party database is used and can be updated (see the section on ‘Time zone names’). Incorrect results will never be an R issue, so please ensure that you have the courtesy not to blame R for them.

  as.is = TRUE, fill = TRUE, comment.char = "+")
str(tzones$name)

## End(Not run)

---

**toString**

Convert an R Object to a Character String

**Description**

This is a helper function for `format` to produce a single character string describing an R object.
Usage

toString(x, ...)

## Default S3 method:
toString(x, width = NULL, ...)

Arguments

- **x**: The object to be converted.
- **width**: Suggestion for the maximum field width. Values of NULL or 0 indicate no maximum. The minimum value accepted is 6 and smaller values are taken as 6.

... Optional arguments passed to or from methods.

Details

This is a generic function for which methods can be written: only the default method is described here. Most methods should honor the width argument to specify the maximum display width (as measured by `nchar(type = "width")` of the result.

The default method first converts x to character and then concatenates the elements separated by ",", ". If width is supplied and is not NULL, the default method returns the first width - 4 characters of the result with . . . appended, if the full result would use more than width characters.

Value

A character vector of length 1 is returned.

```r
x <- c("a", "b", "aaaaaaaaaaa")
toString(x)
toString(x, width = 8)
```

---

trace

*Interactive Tracing and Debugging of Calls to a Function or Method*

Description

A call to `trace` allows you to insert debugging code (e.g., a call to `browser` or `recover`) at chosen places in any function. A call to `untrace` cancels the tracing. Specified methods can be traced the same way, without tracing all calls to the function. Trace code can be any R expression. Tracing can be temporarily turned on or off globally by calling `tracingState`. 
Usage

trace(what, tracer, exit, at, print, signature,
     where = topenv(parent.frame()), edit = FALSE)
untrace(what, signature = NULL, where = topenv(parent.frame()))

tracingState(on = NULL)
doTrace(expr, msg)

Arguments

what  The name (quoted or not) of a function to be traced or untraced. For untrace
     or for trace with more than one argument, more than one name can be given in
     the quoted form, and the same action will be applied to each one.
tracer Either a function or an unevaluated expression. The function will be called or
the expression will be evaluated either at the beginning of the call, or before
those steps in the call specified by the argument at. See the details section.
exit   Either a function or an unevaluated expression. The function will be called or
the expression will be evaluated on exiting the function. See the details section.
at    optional numeric vector or list. If supplied, tracer will be called just before the
     corresponding step in the body of the function. See the details section.
print If TRUE (as per default), a descriptive line is printed before any trace expression
     is evaluated.
signature If this argument is supplied, it should be a signature for a method for function
     what. In this case, the method, and not the function itself, is traced.
edit   For complicated tracing, such as tracing within a loop inside the function, you
     will need to insert the desired calls by editing the body of the function. If so,
supply the edit argument either as TRUE, or as the name of the editor you want
     to use. Then trace() will call edit and use the version of the function after
     you edit it. See the details section for additional information.
where  where to look for the function to be traced; by default, the top-level environment
     of the call to trace.
     An important use of this argument is to trace a function when it is called from
     a package with a namespace. The current namespace mechanism imports the
     functions to be called (with the exception of functions in the base package). The
functions being called are not the same objects seen from the top-level (in gen-
     eral, the imported packages may not even be attached). Therefore, you must
     ensure that the correct versions are being traced. The way to do this is to set
     argument where to a function in the namespace. The tracing computations will
     then start looking in the environment of that function (which will be the names-
     space of the corresponding package). (Yes, it’s subtle, but the semantics here are
     central to how namespaces work in R.)
on    logical; a call to the support function tracingState returns TRUE if tracing is
     globally turned on, FALSE otherwise. An argument of one or the other of those
     values sets the state. If the tracing state is FALSE, none of the trace actions will
     actually occur (used, for example, by debugging functions to shut off tracing
     during debugging).
expr, msg arguments to the support function .doTrace, calls to which are inserted into
the modified function or method: expr is the tracing action (such as a call to
     browser()), and msg is a string identifying the place where the trace action oc-
     curs.
Details

The `trace` function operates by constructing a revised version of the function (or of the method, if signature is supplied), and assigning the new object back where the original was found. If only the what argument is given, a line of trace printing is produced for each call to the function (back compatible with the earlier version of `trace`).

The object constructed by `trace` is from a class that extends "function" and which contains the original, untraced version. A call to `untrace` re-assigns this version.

If the argument tracer or exit is the name of a function, the tracing expression will be a call to that function, with no arguments. This is the easiest and most common case, with the functions `browser` and `recover` the likeliest candidates; the former browses in the frame of the function being traced, and the latter allows browsing in any of the currently active calls.

The tracer or exit argument can also be an unevaluated expression (such as returned by a call to `quote` or `substitute`). This expression itself is inserted in the traced function, so it will typically involve arguments or local objects in the traced function. An expression of this form is useful if you only want to interact when certain conditions apply (and in this case you probably want to supply `print = FALSE` in the call to `trace` also).

When the at argument is supplied, it can be a vector of integers referring to the substeps of the body of the function (this only works if the body of the function is enclosed in `{ ...`). In this case `tracer` is not called on entry, but instead just before evaluating each of the steps listed in at. (Hint: you don’t want to try to count the steps in the printed version of a function; instead, look at `as.list(body(f))` to get the numbers associated with the steps in function `f`.)

The at argument can also be a list of integer vectors. In this case, each vector refers to a step nested within another step of the function. For example, `at = list(c(3,4))` will call the tracer just before the fourth step of the third step of the function. See the example below.

Using `setBreakpoint` (from package `utils`) may be an alternative, calling `trace(..., at, ...)`. An intrinsic limitation in the exit argument is that it won’t work if the function itself uses `@exit`, since the existing calls will override the one supplied by `trace`.

Tracing does not nest. Any call to `trace` replaces previously traced versions of that function or method (except for edited versions as discussed below), and `untrace` always restores an untraced version. (Allowing nested tracing has too many potentials for confusion and for accidentally leaving traced versions behind.)

When the edit argument is used repeatedly with no call to `untrace` on the same function or method in between, the previously edited version is retained. If you want to throw away all the previous tracing and then edit, call `untrace` before the next call to `trace`. Editing may be combined with automatic tracing; just supply the other arguments such as tracer, and the edit argument as well. The `edit = TRUE` argument uses the default editor (see `edit`).

Tracing primitive functions (builtins and specials) from the base package works, but only by a special mechanism and not very informatively. Tracing a primitive causes the primitive to be replaced by a function with argument ...(only). You can get a bit of information out, but not much. A warning message is issued when `trace` is used on a primitive.

The practice of saving the traced version of the function back where the function came from means that tracing carries over from one session to another, if the traced function is saved in the session image. (In the next session, `untrace` will remove the tracing.) On the other hand, functions that were in a package, not in the global environment, are not saved in the image, so tracing expires with the session for such functions.

Tracing a method is basically just like tracing a function, with the exception that the traced version is stored by a call to `setMethod` rather than by direct assignment, and so is the untraced version after a call to `untrace`. 
The version of trace described here is largely compatible with the version in S-Plus, although the two work by entirely different mechanisms. The S-Plus trace uses the session frame, with the result that tracing never carries over from one session to another (R does not have a session frame). Another relevant distinction has nothing directly to do with trace: The browser in S-Plus allows changes to be made to the frame being browsed, and the changes will persist after exiting the browser. The R browser allows changes, but they disappear when the browser exits. This may be relevant in that the S-Plus version allows you to experiment with code changes interactively, but the R version does not. (A future revision may include a ‘destructive’ browser for R.)

**Value**

In the simple version (just the first argument), invisible NULL. Otherwise, the traced function(s) name(s). The relevant consequence is the assignment that takes place.

**Note**

The version of function tracing that includes any of the arguments except for the function name requires the methods package (because it uses special classes of objects to store and restore versions of the traced functions).

If methods dispatch is not currently on, trace will load the methods namespace, but will not put the methods package on the search list.

**References**

**See Also**

`browser` and `recover`, the likeliest tracing functions; also, `quote` and `substitute` for constructing general expressions.

**Examples**

```r
require(graphics)

## Very simple use
trace(sum)
hist(stats::rnorm(100)) # shows about 3-4 calls to sum()
untrace(sum)

if(!.isMethodsDispatchOn()) { # non-simple use needs 'methods' package
  f <- function(x, y) {
    y <- pmax(y, 0.001)
    if (x > 0) x ^ y else stop("x must be positive")
  }

  ## arrange to call the browser on entering and exiting
  ## function f
  trace("f", quote(browser(skipCalls = 4)),
        exit = quote(browser(skipCalls = 4)))

  ## instead, conditionally assign some data, and then browse
  ## on exit, but only then. Don't bother me otherwise
```
trace("f", quote(if(any(y < 0)) yOrig <- y),
   exit = quote(if(exists("yOrig")) browser(skipCalls = 4)),
   print = FALSE)

## Enter the browser just before stop() is called. First, find
## the step numbers

as.list(body(f))
as.list(body(f)[[3]])

## Now call the browser there

trace("f", quote(browser(skipCalls = 4)), at = list(c(3,4)))

## trace a utility function, with recover so we
## can browse in the calling functions as well.

trace("as.matrix", recover)

## turn off the tracing

untrace(c("f", "as.matrix"))

## Not run:
## trace calls to the function lm() that come from
## the nlme package.
## (The function nlme is in that package, and the package
## has a namespace, so the where= argument must be used
## to get the right version of lm)

trace(lm, exit = recover, where = nlme)

## End(Not run)

---

**Print Call Stacks**

**Description**

By default `traceback()` prints the call stack of the last uncaught error, i.e., the sequence of calls that lead to the error. This is useful when an error occurs with an unidentifiable error message. It can also be used to print the current stack or arbitrary lists of deparsed calls.

**Usage**

```r
traceback(x = NULL, max.lines =getOption("deparse.max.lines"))
```

**Arguments**

- `x` : `NULL` (default, meaning `.Traceback`), or an integer count of calls to skip in the current stack, or a list or pairlist of deparsed calls. See the details.
- `max.lines` : The maximum number of lines to be printed *per call*. The default is unlimited.
Details

The default display is of the stack of the last uncaught error as stored as a list of deparsed calls in .Traceback, which traceback prints in a user-friendly format. The stack of deparsed calls always contains all function calls and all foreign function calls (such as .Call): if profiling is in progress it will include calls to some primitive functions. (Calls to builtins are included, but not to specials.) Errors which are caught via try or tryCatch do not generate a traceback, so what is printed is the call sequence for the last uncaught error, and not necessarily for the last error.

If x is numeric, then the current stack is printed, skipping x entries at the top of the stack. For example, options(error = function() traceback(2)) will print the stack at the time of the error, skipping the call to traceback() and the error function that called it.

Otherwise, x is assumed to be a list or pairlist of deparsed calls and will be displayed in the same way.

Value

traceback() prints the deparsed call stack deepest call first, and returns it invisibly. The calls may print on more than one line, and the first line for each call is labelled by the frame number. The number of lines printed per call can be limited via max.lines.

Warning

It is undocumented where .Traceback is stored nor that it is visible, and this is subject to change.

References

Examples

```r
foo <- function(x) { print(1); bar(2) }
bar <- function(x) { x + a.variable.which.does.not.exist }
## Not run:
foo(2) # gives a strange error
traceback()
## End(Not run)
## 2: bar(2)
## 1: foo(2)
bar
## Ah, this is the culprit ...

## This will print the stack trace at the time of the error.
options(error = function() traceback(2))
```

Description

This function marks an object so that a message is printed whenever the internal code copies the object. It is a major cause of hard-to-predict memory use in R.
tracemem

Usage

tracemem(x)
untracemem(x)
retracemem(x, previous = NULL)

Arguments

x  An R object, not a function or environment or NULL.
previous  A value as returned by tracemem or retracemem.

Details

This functionality is optional, determined at compilation, because it makes R run a little more slowly even when no objects are being traced. tracemem and untracemem give errors when R is not compiled with memory profiling; retracemem does not (so it can be left in code during development).

It is enabled in the CRAN OS X and Windows builds of R.

When an object is traced any copying of the object by the C function duplicate produces a message to standard output, as does type coercion and copying when passing arguments to .C or .Fortran.

The message consists of the string tracemem, the identifying strings for the object being copied and the new object being created, and a stack trace showing where the duplication occurred. retracemem() is used to indicate that a variable should be considered a copy of a previous variable (e.g. after subscripting).

The messages can be turned off with tracingState.

It is not possible to trace functions, as this would conflict with trace and it is not useful to trace NULL, environments, promises, weak references, or external pointer objects, as these are not duplicated.

These functions are primitive.

Value

A character string for identifying the object in the trace output (an address in hex enclosed in angle brackets), or NULL (invisibly).

See Also

capabilities("profmem") to see if this was enabled for this build of R.
trace, Rprofmem
http://developer.r-project.org/memory-profiling.html

Examples

## Not run:
a <- 1:10
tracemem(a)
## b and a share memory
b <- a
b[1] <- 1
untracemem(a)

## copying in 1m: less than R <= 2.15.0
**transform**  

Transform an Object, for Example a Data Frame

**Description**

transform is a generic function, which—at least currently—only does anything useful with data frames. transform.default converts its first argument to a data frame if possible and calls transform.data.frame.

**Usage**

```r
transform(`_data`, ...)
```

**Arguments**

- `_data` The object to be transformed
- `...` Further arguments of the form `tag=value`

**Details**

The `...` arguments to `transform.data.frame` are tagged vector expressions, which are evaluated in the data frame `_data`. The tags are matched against `names(_data)`, and for those that match, the value replace the corresponding variable in `_data`, and the others are appended to `_data`.

**Value**

The modified value of `_data`.

**Warning**

This is a convenience function intended for use interactively. For programming it is better to use the standard subsetting arithmetic functions, and in particular the non-standard evaluation of argument `transform` can have unanticipated consequences.

**Note**

If some of the values are not vectors of the appropriate length, you deserve whatever you get!

```r
d <- stats::rnorm(10)
tracemem(d)
lm(d ~ a+log(b))

## f is not a copy and is not traced
f <- d[-1]
f+1
## indicate that f should be traced as a copy of d
retracemem(f, retracemem(d))
f+1

## End(Not run)
```
Trig

transform(Ozone, logOzone = log(Ozone)) # marginally interesting ...
detach(airquality)

Trigonometric Functions

Description

These functions give the obvious trigonometric functions. They respectively compute the cosine, sine, tangent, arc-cosine, arc-sine, arc-tangent, and the two-argument arc-tangent.

Usage

cos(x)
sin(x)
tan(x)
acos(x)
asin(x)
atan(x)
atan2(y, x)

Arguments

x, y numeric or complex vectors.

Details

The arc-tangent of two arguments atan2(y, x) returns the angle between the x-axis and the vector from the origin to (x, y), i.e., for positive arguments atan2(y, x) == atan(y/x).

Angles are in radians, not degrees (i.e., a right angle is π/2).

All except atan2 are internal generic primitive functions: methods can be defined for them individually or via the Math group generic.
Complex values

For the inverse trigonometric functions, branch cuts are defined as in Abramowitz and Stegun, figure 4.4, page 79.

For asin and acos, there are two cuts, both along the real axis: \((-\infty, -1]\) and \([1, \infty)\).

For atan there are two cuts, both along the pure imaginary axis: \((-\infty i, -1i]\) and \([1i, \infty i)\).

The behaviour actually on the cuts follows the C99 standard which requires continuity coming round the endpoint in a counter-clockwise direction.

S4 methods

All except atan2 are S4 generic functions: methods can be defined for them individually or via the Math group generic.

---

try

Try an Expression Allowing Error Recovery

Description

try is a wrapper to run an expression that might fail and allow the user’s code to handle error-recovery.

Usage

try(expr, silent = FALSE)

Arguments

expr an R expression to try.
silent logical: should the report of error messages be suppressed?

Details

try evaluates an expression and traps any errors that occur during the evaluation. If an error occurs then the error message is printed to the stderr connection unless options("show.error.messages") is false or the call includes silent = TRUE. The error message is also stored in a buffer where it can be retrieved by geterrmessage. (This should not be needed as the value returned in case of an error contains the error message.)

try is implemented using tryCatch; for programming, instead of try(expr, silent = TRUE), something like tryCatch(expr, error = function(e) e) (or other simple error handler functions) may be more efficient and flexible.
Value

The value of the expression if `expr` is evaluated without error, but an invisible object of class "try-error" containing the error message, and the error condition as the "condition" attribute, if it fails.

See Also

`options` for setting error handlers and suppressing the printing of error messages; `geterrmessage` for retrieving the last error message. `tryCatch` provides another means of catching and handling errors.

Examples

```r
## this example will not work correctly in example(try), but
## it does work correctly if pasted in
options(show.error.messages = FALSE)
try(log("a"))
print(.Last.value)
options(show.error.messages = TRUE)

## alternatively,
print(try(log("a"), TRUE))

## run a simulation, keep only the results that worked.
set.seed(123)
x <- stats::rnorm(50)
doit <- function(x)
{
  x <- sample(x, replace = TRUE)
  if(length(unique(x)) > 30) mean(x)
  else stop("too few unique points")
}
## alternative 1
res <- lapply(1:100, function(i) try(doit(x), TRUE))
## alternative 2
## Not run: res <- vector("list", 100)
for(i in 1:100) res[[i]] <- try(doit(x), TRUE)
## End(Not run)
unlist(res[sapply(res, function(x) !inherits(x, "try-error"))])
```

`typeof`  

The Type of an Object

typeof determines the (R internal) type or storage mode of any object

Usage

`typeof(x)`

Arguments

- `x`  
  any R object.
**Value**

A character string. The possible values are listed in the structure `TypeTable` in `src/main/util.c`. Current values are the vector types "logical", "integer", "double", "complex", "character", "raw" and "list", "NULL", "closure" (function), "special" and "builtin" (basic functions and operators), "environment", "S4" (some S4 objects) and others that are unlikely to be seen at user level ("symbol", "pairlist", "promise", "language", "char", ",", "any", "expression", "externalptr", "bytecode" and "weakref").

**See Also**

`mode`, `storage.mode`. `isS4` to determine if an object has an S4 class.

**Examples**

```r
typeof(2)
mode(2)
```

---

**unique**  
*Extract Unique Elements*

**Description**

`unique` returns a vector, data frame or array like `x` but with duplicate elements/rows removed.

**Usage**

```r
unique(x, incomparables = FALSE, ...)
```

### Default S3 method:

```r
unique(x, incomparables = FALSE, fromLast = FALSE,
       nmax = NA, ...)
```

### S3 method for class 'matrix'

```r
unique(x, incomparables = FALSE, MARGIN = 1,
       fromLast = FALSE, ...)
```

### S3 method for class 'array'

```r
unique(x, incomparables = FALSE, MARGIN = 1,
       fromLast = FALSE, ...)
```

**Arguments**

- **x**: a vector or a data frame or an array or `NULL`.
- **incomparables**: a vector of values that cannot be compared. `FALSE` is a special value, meaning that all values can be compared, and may be the only value accepted for methods other than the default. It will be coerced internally to the same type as `x`.
- **fromLast**: logical indicating if duplication should be considered from the last, i.e., the last (or rightmost) of identical elements will be kept. This only matters for names or dimnames.
unique

nmax the maximum number of unique items expected. See duplicated.

... arguments for particular methods.

MARGIN the array margin to be held fixed: a single integer.

Details

This is a generic function with methods for vectors, data frames and arrays (including matrices).
The array method calculates for each element of the dimension specified by MARGIN if the remaining
dimensions are identical to those for an earlier element (in row-major order). This would most
commonly be used for matrices to find unique rows (the default) or columns (with MARGIN = 2).

Note that unlike the Unix command uniq this omits duplicated and not just repeated elements/rows.
That is, an element is omitted if it is equal to any previous element and not just if it is equal the
immediately previous one. (For the latter, see rle).

Missing values are regarded as equal, but NaN is not equal to NA_real_. Character strings are
regarded as equal if they are in different encodings but would agree when translated to UTF-8.

Values in incomparables will never be marked as duplicated. This is intended to be used for a
fairly small set of values and will not be efficient for a very large set.

When used on a data frame with more than one column, or an array or matrix when comparing
dimensions of length greater than one, this tests for identity of character representations. This will
catch people who unwisely rely on exact equality of floating-point numbers!

Character strings will be compared as byte sequences if any input is marked as "bytes".

Value

For a vector, an object of the same type of x, but with only one copy of each duplicated element.
No attributes are copied (so the result has no names).

For a data frame, a data frame is returned with the same columns but possibly fewer rows (and with
row names from the first occurrences of the unique rows).

A matrix or array is subsetted by [, drop = FALSE], so dimensions and dimnames are copied
appropriately, and the result always has the same number of dimensions as x.

Warning

Using this for lists is potentially slow, especially if the elements are not atomic vectors (see vector)
or differ only in their attributes. In the worst case it is $O(n^2)$.

Examples

x <- c(3:5, 11:8, 8 + 0:5)
ux <- unique(x))
(u2 <- unique(x, fromLast = TRUE)) # different order
stopifnot(identical(sort(ux), sort(u2))

length(unique(sample(100, 100, replace = TRUE)))
## approximately 100(1 - 1/e) = 63.21
unique(iris)

unlink

Delete Files and Directories

Description

unlink deletes the file(s) or directories specified by x.

Usage

unlink(x, recursive = FALSE, force = FALSE)

Arguments

x a character vector with the names of the file(s) or directories to be deleted. Wildcards (normally ‘*’ and ‘?’) are allowed.

recursive logical. Should directories be deleted recursively?

force logical. Should permissions be changed (if possible) to allow the file or directory to be removed?

Details

Tilde-expansion (see path.expand) is done on x.

If recursive = FALSE directories are not deleted, not even empty ones.

On most platforms ‘file’ includes symbolic links, fifos and sockets. Prior to R 2.15.0 unlink(x, recursive = TRUE) would delete the contents of a directory target of a symbolic link: it now only deletes the symbolic link (as unlink(x, recursive = FALSE) always has).

Wildcard expansion is done by the internal code of Sys.glob. Wildcards never match a leading ‘.’ in the filename, and files ‘.’ and ‘..’ will never be considered for deletion. Wildcards will only be expanded if the system supports it. Most systems will support not only ‘*’ and ‘?’ but also character classes such as ‘[a-z]’ (see the man pages for the system call glob on your OS). The metacharacters * ? [ can occur in Unix filenames, and this makes it difficult to use unlink to delete such files (see file.remove), although escaping the metacharacters by backslashes usually works. If a metacharacter matches nothing it is considered as a literal character.

recursive = TRUE might not be supported on all platforms, when it will be ignored, with a warning: however there are no known current examples.
Value

0 for success, 1 for failure, invisibly. Not deleting a non-existent file is not a failure, nor is being unable to delete a directory if `recursive = FALSE`. However, missing values in \( x \) are regarded as failures.

**unlist**

**Flatten Lists**

Description

Given a list structure \( x \), `unlist` simplifies it to produce a vector which contains all the atomic components which occur in \( x \).

Usage

`unlist(x, recursive = TRUE, use.names = TRUE)`

Arguments

- \( x \): an \( R \) object, typically a list or vector.
- `recursive`: logical. Should unlisting be applied to list components of \( x \)?
- `use.names`: logical. Should names be preserved?

Details

`unlist` is generic: you can write methods to handle specific classes of objects, see `InternalMethods`, and note, e.g., `relist` with the `unlist` method for `relistable` objects.

If `recursive = FALSE`, the function will not recurse beyond the first level items in \( x \).

Factors are treated specially. If all non-list elements of \( x \) are factors (or ordered factors) then the result will be a factor with levels the union of the level sets of the elements, in the order the levels occur in the level sets of the elements (which means that if all the elements have the same level set, that is the level set of the result).

\( x \) can be an atomic vector, but then `unlist` does nothing useful, not even drop names.

By default, `unlist` tries to retain the naming information present in \( x \). If `use.names = FALSE` all naming information is dropped.

Where possible the list elements are coerced to a common mode during the unlisting, and so the result often ends up as a character vector. Vectors will be coerced to the highest type of the components in the hierarchy `NULL < raw < logical < integer < double < complex < character < list < expression`: pairlists are treated as lists.
A list is a (generic) vector, and the simplified vector might still be a list (and might be unchanged). Non-vector elements of the list (for example language elements such as names, formulas and calls) are not coerced, and so a list containing one or more of these remains a list. (The effect of unlisting an \texttt{lm} fit is a list which has individual residuals as components.) Note that \texttt{unlist(x)} now returns \texttt{x} unchanged also for non-vector \texttt{x}, instead of signalling an error in that case.

**Value**

NULL or an expression or a vector of an appropriate mode to hold the list components. The output type is determined from the highest type of the components in the hierarchy NULL < raw < logical < integer < double < complex < character < list < expression, after coercion of pairlists to lists.

**Examples**

\begin{verbatim}
unlist(options())
unlist(options(), use.names = FALSE)

1.ex <- list(a = list(1:5, LETTERS[1:5]), b = "Z", c = NA)
unlist(1.ex, recursive = FALSE)
unlist(1.ex, recursive = TRUE)

l1 <- list(a = "a", b = 2, c = pi+2i)
unlist(l1) # a character vector
l2 <- list(a = "a", b = as.name("b"), c = pi+2i)
unlist(l2) # remains a list

l1 <- list(as.name("sinc"), quote( a + b ), 1:10, letters, expression(1+x))
utils::str(l1)
for(x in l1)
  stopifnot(identical(x, unlist(x))
\end{verbatim}

**Description**

Remove the \texttt{names} or \texttt{dimnames} attribute of an \texttt{R} object.

**Usage**

\begin{verbatim}
unname(obj, force = FALSE)
\end{verbatim}
UseMethod

Arguments

attachment

UseMethod

Arguments

obj an R object.
force logical; if true, the dimnames (names and row names) are removed even from data.frames.

Value

Object as obj but without names or dimnames.

Examples

require(graphics); require(stats)

## Answering a question on R-help (14 Oct 1999):
col3 <- 750+ 100*rt(1500, df = 3)
breaks <- factor(cut(col3, breaks = 300+5*(0:155))
z <- table(breaks)
z[1:5] # The names are larger than the data ...
barplot(unname(z), axes = FALSE)

UseMethod

Class Methods

Description

R possesses a simple generic function mechanism which can be used for an object-oriented style of programming. Method dispatch takes place based on the class(es) of the first argument to the generic function or of the object supplied as an argument to UseMethod or NextMethod.

Usage

UseMethod(generic, object)

NextMethod(generic = NULL, object = NULL, ...)

Arguments

generic a character string naming a function (and not a built-in operator). Required for UseMethod.
object for UseMethod: an object whose class will determine the method to be dispatched. Defaults to the first argument of the enclosing function.
... further arguments to be passed to the next method.

Details

An R object is a data object which has a class attribute (and this can be tested by is.object). A class attribute is a character vector giving the names of the classes from which the object inherits. If the object does not have a class attribute, it has an implicit class. Matrices and arrays have class "matrix" or "array" followed by the class of the underlying vector. Most vectors have class the result of mode(x), except that integer vectors have class c("integer", "numeric") and real vectors have class c("double", "numeric").
When a function calling `UseMethod("fun")` is applied to an object with class attribute `c("first", "second")`, the system searches for a function called `fun.first` and, if it finds it, applies it to the object. If no such function is found a function called `fun.second` is tried. If no class name produces a suitable function, the function `fun.default` is used, if it exists, or an error results.

Function `methods` can be used to find out about the methods for a particular generic function or class.

`UseMethod` is a primitive function but (as from R 2.11.0) uses standard argument matching. It is not the only means of dispatch of methods, for there are internal generic and group generic functions. `UseMethod` currently dispatches on the implicit class even for arguments that are not objects, but the other means of dispatch do not.

`NextMethod` invokes the next method (determined by the class vector, either of the object supplied to the generic, or of the first argument to the function containing `NextMethod` if a method was invoked directly). Normally `NextMethod` is used with only one argument, `generic`, but if further arguments are supplied these modify the call to the next method.

`NextMethod` should not be called except in methods called by `UseMethod` or from internal generics (see `InternalGenerics`). In particular it will not work inside anonymous calling functions (e.g. `get("print.ts")(AirPassengers)`).

Namespaces can register methods for generic functions. To support this, `UseMethod` and `NextMethod` search for methods in two places: first in the environment in which the generic function is called, and then in the registration data base for the environment in which the generic is defined (typically a namespace). So methods for a generic function need to be available in the environment of the call to the generic, or they must be registered. (It does not matter whether they are visible in the environment in which the generic is defined.)

**Technical Details**

Now for some obscure details that need to appear somewhere. These comments will be slightly different than those in Chambers(1992). (See also the draft ‘R Language Definition’.) `UseMethod` creates a new function call with arguments matched as they came in to the generic. Any local variables defined before the call to `UseMethod` are retained (unlike S). Any statements after the call to `UseMethod` will not be evaluated as `UseMethod` does not return. `UseMethod` can be called with more than two arguments: a warning will be given and additional arguments ignored. (They are not completely ignored in S.) If it is called with just one argument, the class of the first argument of the enclosing function is used as object: unlike S this is the first actual argument passed and not the current value of the object of that name.

`NextMethod` works by creating a special call frame for the next method. If no new arguments are supplied, the arguments will be the same in number, order and name as those to the current method but their values will be promises to evaluate their name in the current method and environment. Any named arguments matched to ... are handled specially: they either replace existing arguments of the same name or are appended to the argument list. They are passed on as the promise that was supplied as an argument to the current environment. (S does this differently!) If they have been evaluated in the current (or a previous environment) they remain evaluated. (This is a complex area, and subject to change: see the draft ‘R Language Definition’.)

The search for methods for `NextMethod` is slightly different from that for `UseMethod`. Finding no `fun.default` is not necessarily an error, as the search continues to the generic itself. This is to pick up an internal generic like `[]` which has no separate default method, and succeeds only if the generic is a primitive function or a wrapper for a .Internal function of the same name. (When a primitive is called as the default method, argument matching may not work as described above due to the different semantics of primitives.)
You will see objects such as `.Generic`, `.Method`, and `.Class` used in methods. These are set in the environment within which the method is evaluated by the dispatch mechanism, which is as follows:

1. Find the context for the calling function (the generic): this gives us the unevaluated arguments for the original call.
2. Evaluate the object (usually an argument) to be used for dispatch, and find a method (possibly the default method) or throw an error.
3. Create an environment for evaluating the method and insert special variables (see below) into that environment. Also copy any variables in the environment of the generic that are not formal (or actual) arguments.
4. Fix up the argument list to be the arguments of the call matched to the formals of the method.

`.Generic` is a length-one character vector naming the generic function.

`.Method` is a character vector (normally of length one) naming the method function. (For functions in the group generic `Ops` it is of length two.)

`.Class` is a character vector of classes used to find the next method. `NextMethod` adds an attribute "previous" to `.Class` giving the `.Class` last used for dispatch, and shifts `.Class` along to that used for dispatch.

`.GenericCallEnv` and `.GenericDefEnv` are the environments of the call to be generic and defining the generic respectively. (The latter is used to find methods registered for the generic.)

Note that `.Class` is set when the generic is called, and is unchanged if the class of the dispatching argument is changed in a method. It is possible to change the method that `NextMethod` would dispatch by manipulating `.Class`, but ‘this is not recommended unless you understand the inheritance mechanism thoroughly’ (Chambers & Hastie, 1992, p. 469).

Note

This scheme is called S3 (S version 3). For new projects, it is recommended to use the more flexible and robust S4 scheme provided in the `methods` package.

---

**Description**

These functions allow users to set actions to be taken before packages are attached/detached and namespaces are (un)loaded.
Usage

```r
getHook(hookName)
setHook(hookName, value,
       action = c("append", "prepend", "replace"))
```

```r
event = c("onLoad", "attach", "detach", "onUnload")
```

Arguments

- **hookName**: character string: the hook name
- **pkgname**: character string: the package/namespace name
- **event**: character string: an event for the package
- **value**: A function or a list of functions, or for `action = "replace", NULL`
- **action**: The action to be taken. The names can be abbreviated.

Details

setHook provides a general mechanism for users to register hooks, a list of functions to be called from system (or user) functions. The initial set of hooks was associated with events on packages/namespaces: these hooks are named via calls to packageEvent.

To remove a hook completely, call `setHook(hookName, NULL, "replace")`.

When an R package is attached by `library` or loaded by other means, it can call initialization code. See .onLoad for a description of the package hook functions called during initialization. Users can add their own initialization code via the hooks provided by `setHook()`, functions which will be called as `funname(pkgname, pkgpath)` inside a `try` call.

The sequence of events depends on which hooks are defined, and whether a package is attached or just loaded. In the case where all hooks are defined and a package is attached, the order of initialization events is as follows:

1. The package namespace is loaded.
2. The package’s `.onLoad` function is run.
3. The namespace is sealed.
4. The user’s “onLoad” hook is run.
5. The package is added to the search path.
6. The package’s `.onAttach` function is run.
7. The package environment is sealed.
8. The user’s “attach” hook is run.

A similar sequence (but in reverse) is run when a package is detached and its namespace unloaded:

1. The user’s “detach” hook is run.
2. The package’s `.Last.lib` function is run.
3. The package is removed from the search path.
4. The user’s “onUnload” hook is run.
5. The package’s `.onUnload` function is run.
6. The package namespace is unloaded.
Note that when an R session is finished, packages are not detached and namespaces are not unloaded, so the corresponding hooks will not be run.

Also note that some of the user hooks are run without the package being on the search path, so in those hooks objects in the package need to be referred to using the double (or triple) colon operator, as in the example.

If multiple hooks are added, they are normally run in the order shown by getHook, but the "detach" and "onUnload" hooks are run in reverse order so the default for package events is to add hooks ‘inside’ existing ones.

The hooks are stored in the environment .userHooksEnv in the base package, with ‘mangled’ names.

Value

For getHook function, a list of functions (possibly empty). For setHook function, no return value. For packageEvent, the derived hook name (a character string).

See Also

library, detach, loadNamespace.

See :: for a discussion of the double and triple colon operators.

Other hooks may be added later: functions plot.new and persp already have them.

Examples

setHook(packageEvent("grDevices", "onLoad"),
       function(...) grDevices::ps.options(horizontal = FALSE))

utf8Conversion

Convert to or from UTF-8-encoded Character Vectors

Description

Conversion of UTF-8 encoded character vectors to and from integer vectors.

Usage

utf8ToInt(x)
intToUtf8(x, multiple = FALSE)

Arguments

x

object to be converted.

multiple

logical: should the conversion be to a single character string or multiple individual characters?

Details

These will work in any locale, including on machines that do not otherwise support multi-byte character sets.
Value

utf8ToInt converts a length-one character string encoded in UTF-8 to an integer vector of (numeric) UTF-8 code points.

intToUtf8 converts a vector of (numeric) UTF-8 code points either to a single character string or a character vector of single characters. (For a single character string \( \emptyset \) is silently omitted; otherwise \( \emptyset \) is mapped to "". Non-integral numeric values are truncated to integers.) The Encoding is declared as "UTF-8".

NA inputs are mapped to NA output.

Examples

```r
## Not run:
## will only display in some locales and fonts
intToUtf8(0x03B2L) # Greek beta

## End(Not run)
```

vector

Vectors

Description

vector produces a vector of the given length and mode.

as.vector, a generic, attempts to coerce its argument into a vector of mode mode (the default is to coerce to whichever vector mode is most convenient): if the result is atomic all attributes are removed.

is.vector returns TRUE if x is a vector of the specified mode having no attributes other than names. It returns FALSE otherwise.

Usage

```r
vector(mode = "logical", length = 0)
as.vector(x, mode = "any")
is.vector(x, mode = "any")
```

Arguments

- **mode** character string naming an atomic mode or "list" or "expression" or (except for vector) "any".
- **length** a non-negative integer specifying the desired length. For a long vector, i.e., length > .Machine$integer.max, it has to be of type "double". Supplying an argument of length other than one is an error.
- **x** an R object.
Details

The atomic modes are "logical", "integer", "numeric" (synonym "double"), "complex", "character" and "raw".

If mode = "any", is.vector may return TRUE for the atomic modes, list and expression. For any mode, it will return FALSE if x has any attributes except names. (This is incompatible with S.) On the other hand, as.vector removes all attributes including names for results of atomic mode (but not those of mode "list" nor "expression").

Note that factors are not vectors; is.vector returns FALSE and as.vector converts a factor to a character vector for mode = "any".

Value

For vector, a vector of the given length and mode. Logical vector elements are initialized to FALSE, numeric vector elements to 0, character vector elements to "", raw vector elements to null bytes and list/expression elements to NULL.

For as.vector, a vector (atomic or of type list or expression). All attributes are removed from the result if it is of an atomic mode, but not in general for a list result. The default method handles 24 input types and 12 values of type: the details of most coercions are undocumented and subject to change.

For is.vector, TRUE or FALSE. is.vector(x, mode = "numeric") can be true for vectors of types "integer" or "double" whereas is.vector(x, mode = "double") can only be true for those of type "double".

Methods for as.vector()

Writers of methods for as.vector need to take care to follow the conventions of the default method. In particular

• Argument mode can be "any", any of the atomic modes, "list", "expression", "symbol", "pairlist" or one of the aliases "double" and "name".
• The return value should be of the appropriate mode. For mode = "any" this means an atomic vector or list.
• Attributes should be treated appropriately: in particular when the result is an atomic vector there should be no attributes, not even names.
• is.vector(as.vector(x, m), m) should be true for any mode m, including the default "any".

Note

as.vector and is.vector are quite distinct from the meaning of the formal class "vector" in the methods package, and hence as(x, "vector") and is(x, "vector").

Note that as.vector(x) is not necessarily a null operation if is.vector(x) is true: any names will be removed from an atomic vector.

Non-vector modes "symbol" (synonym "name") and "pairlist" are accepted but have long been undocumented: they are used to implement as.name and as.pairlist, and those functions should preferably be used directly. None of the description here applies to those modes: see the help for the preferred forms.

! is.vector(df)
! is.vector(df, mode = "list")

is.vector(list(), mode = "list")

---

Vectorize Vectorize a Scalar Function

Description

Vectorize creates a function wrapper that vectorizes the action of its argument FUN.

Usage

Vectorize(FUN, vectorize.args = arg.names, SIMPLIFY = TRUE,
           USE.NAMES = TRUE)

Arguments

FUN function to apply, found via match.fun.
vectorize.args a character vector of arguments which should be vectorized. Defaults to all arguments of FUN.
SIMPLIFY logical or character string: attempt to reduce the result to a vector, matrix or higher dimensional array; see the simplify argument of sapply.
USE.NAMES logical; use names if the first...argument has names, or if it is a character vector, use that character vector as the names.
Details

The arguments named in the `vectorize.args` argument to `Vectorize` are the arguments passed in the `...` list to `mapply`. Only those that are actually passed will be vectorized; default values will not. See the examples.

`Vectorize` cannot be used with primitive functions as they do not have a value for `formals`.

Value

A function with the same arguments as `FUN`, wrapping a call to `mapply`.

Examples

```r
# We use rep.int as rep is primitive
vrep <- Vectorize(rep.int)
vrep(1:4, 4:1)
vrep(times = 1:4, x = 4:1)

vrep <- Vectorize(rep.int, "times")
vrep(times = 1:4, x = 42)

f <- function(x = 1:3, y) c(x, y)
vf <- Vectorize(f, SIMPLIFY = FALSE)
f(1:3, 1:3)
vf(1:3, 1:3)
vf(y = 1:3) # Only vectorizes y, not x

# Nonlinear regression contour plot, based on nls() example
require(graphics)
SS <- function(Vm, K, resp, conc) {
  pred <- (Vm * conc)/(K + conc)
  sum((resp - pred)^2 / pred)
}
vSS <- Vectorize(SS, c("Vm", "K"))
Treated <- subset(Puromycin, state == "treated")

Vm <- seq(140, 310, length.out = 50)
K <- seq(0.15, length.out = 40)
SSvals <- outer(Vm, K, vSS, Treated$d<rate, Treated$d<conc)
contour(Vm, K, SSvals, levels = (1:10)^2, xlab = "Vm", ylab = "K")
```

---

### warning

**Warning Messages**

Generates a warning message that corresponds to its argument(s) and (optionally) the expression or function from which it was called.

**Usage**

`warning(..., call. = TRUE, immediate. = FALSE, domain = NULL)`

`suppressWarnings(expr)`
warning

Arguments

... zero or more objects which can be coerced to character (and which are pasted together with no separator) or a single condition object.

call. logical, indicating if the call should become part of the warning message.

immediate. logical, indicating if the call should be output immediately, even if `getOption("warn")` <= 0.

expr expression to evaluate.

domain see `gettext`. If NA, messages will not be translated, see also the note in `stop`.

Details

The result depends on the value of `options("warn")` and on handlers established in the executing code.

If a condition object is supplied it should be the only argument, and further arguments will be ignored, with a message.

`warning` signals a warning condition by (effectively) calling `signalCondition`. If there are no handlers or if all handlers return, then the value of `warn = getOption("warn")` is used to determine the appropriate action. If `warn` is negative warnings are ignored; if it is zero they are stored and printed after the top-level function has completed; if it is one they are printed as they occur and if it is 2 (or larger) warnings are turned into errors. Calling `warning(immediate = TRUE)` turns `warn <= 0` into `warn = 1` for this call only.

If `warn` is zero (the default), a read-only variable `last.warning` is created. It contains the warnings which can be printed via a call to `warnings`.

Warnings will be truncated to `getOption("warning.length")` characters, default 1000, indicated by `[
od truncated]`.

While the warning is being processed, a `muffleWarning` restart is available. If this restart is invoked with `invokeRestart`, then `warning` returns immediately.

An attempt is made to coerce other types of inputs to `warning` to character vectors.

`suppressWarnings` evaluates its expression in a context that ignores all warnings.

Value

The warning message as `character` string, invisibly.

References

See Also

`stop` for fatal errors, `message` for diagnostic messages, `warnings`, and `options` with argument `warn`.

`gettext` for the mechanisms for the automated translation of messages.
Examples

testit <- function() warning("testit")
testit() # shows call
testit <- function() warning("problem in testit", call. = FALSE)
testit() ## no call
suppressWarnings(warning("testit"))

Description

warnings and its print method print the variable last.warning in a pleasing form.

Usage

warnings(...)

Arguments

... arguments to be passed to cat.

Details

See the description of options("warn") for the circumstances under which there is a last.warning object and warnings() is used. In essence this is if options(warn = 0) and warning has been called at least once.

It is possible that last.warning refers to the last recorded warning and not to the last warning, for example if options(warn) has been changed or if a catastrophic error occurred.

Warning

It is undocumented where last.warning is stored nor that it is visible, and this is subject to change. Prior to R 2.4.0 it was stored in the workspace, but no longer.

References

See Also

warning.
**Examples**

```r
## NB this example is intended to be pasted in,
## rather than run by example()
ow <- options("warn")
for(w in 1:1) {
  options(warn = w); cat("\n warn =", w, "\n")
  for(i in 1:3) { cat(i,"..\n"); m <- matrix(1:7, 3,4) }
}
warnings()
options(ow) # reset
tail(warnings(), 2) # see the last two warnings only (via '[' method)
```

---

**Description**

Extract the weekday, month or quarter, or the Julian time (days since some origin). These are generic functions: the methods for the internal date-time classes are documented here.

**Usage**

```r
weekdays(x, abbreviate)
## S3 method for class 'POSIXt'
weekdays(x, abbreviate = FALSE)
## S3 method for class 'Date'
weekdays(x, abbreviate = FALSE)

months(x, abbreviate)
## S3 method for class 'POSIXt'
months(x, abbreviate = FALSE)
## S3 method for class 'Date'
months(x, abbreviate = FALSE)

quarters(x, abbreviate)
## S3 method for class 'POSIXt'
quarters(x, ...)
## S3 method for class 'Date'
quar ters(x, ...)

j ulian(x, ...)
## S3 method for class 'POSIXt'
j ulian(x, origin = as.POSIXct("1970-01-01", tz = "GMT"), ...)
## S3 method for class 'Date'
j ulian(x, origin = as.Date("1970-01-01"), ...)
```

**Arguments**

- `x` an object inheriting from class "POSIXt" or "Date".
- `abbreviate` logical. Should the names be abbreviated?
- `origin` an length-one object inheriting from class "POSIXt" or "Date".
- `...` arguments for other methods.
Value

weekdays and months return a character vector of names in the locale in use.
quarters returns a character vector of "Q1" to "Q4".
julian returns the number of days (possibly fractional) since the origin, with the origin as a "origin" attribute. All time calculations in R are done ignoring leap-seconds.

Note

Other components such as the day of the month or the year are very easy to compute: just use as.POSIXlt and extract the relevant component. Alternatively (especially if the components are desired as character strings), use strftime.

See Also

DateTimeClasses, Date

Examples

weekdays(.leap.seconds)
months(.leap.seconds)
quarters(.leap.seconds)

## is the number of days since noon UTC on the first day of 4317 BC.
## in the proleptic Julian calendar. To more recently, in
## 'Terrestrial Time' which differs from UTC by a few seconds
## See http://en.wikipedia.org/wiki/Terrestrial_Time
julian(Sys.Date(), -2440588) # from a day
floor(as.numeric(julian(Sys.time())) + 2440587.5) # from a date-time

which 

Which indices are TRUE?

Description

Give the TRUE indices of a logical object, allowing for array indices.

Usage

which(x, arr.ind = FALSE, useNames = TRUE)
arrayInd(ind, .dim, .dimnames = NULL, useNames = FALSE)

Arguments

x a logical vector or array. NAs are allowed and omitted (treated as if FALSE).
arr.ind logical; should array indices be returned when x is an array?
ind integer-valued index vector, as resulting from which(x).
.dim dim(.) integer vector
.dimnames optional list of character dimnames(.), of which only .dimnames[[1]] is used.
useNames logical indicating if the value of arrayInd() should have (non-null) dimnames at all.
Value

If `arr.ind == FALSE` (the default), an integer vector with length equal to `sum(x)`, i.e., to the number of `TRUE`es in `x`. Basically, the result is `(1:length(x))[x]`.

If `arr.ind == TRUE` and `x` is an `array` (has a `dim` attribute), the result is `arrayInd(which(x), dim(x), dimnames(x))`, namely a matrix whose rows each are the indices of one element of `x`; see Examples below.

Author(s)

Werner Stahel and Peter Holzer (ETH Zurich) proposed the `arr.ind` option.

See Also

`Logic`, `which.min` for the index of the minimum or maximum, and `match` for the first index of an element in a vector, i.e., for a scalar `a`, `match(a, x)` is equivalent to `min(which(x == a))` but much more efficient.

Examples

```r
which(LETTERS == "R")
which(ll <- c(TRUE, FALSE, TRUE, NA, FALSE, FALSE, TRUE)) #> 1 3 7
names(ll) <- letters[seq(ll)]
which(ll)
which((1:12)%2 == 0) # which are even?
which(1:10 > 3, arr.ind = TRUE)

(m <- matrix(1:12, 3, 4))
div.3 <- m %%% 3 == 0
which(div.3)
which(div.3, arr.ind = TRUE)
rownames(m) <- paste("Case", 1:3, sep = ",")
which(m %% 3 == 0, arr.ind = TRUE)

dim(m) <- c(2, 2, 3); m
which(div.3, arr.ind = FALSE)
which(div.3, arr.ind = TRUE)

vm <- c(m)
dim(vm) <- length(vm) #-- funny thing with length(dim(...)) == 1
which(vm %%% 3 == 0, arr.ind = TRUE)
```

Description

Determines the location, i.e., index of the (first) minimum or maximum of a numeric (or logical) vector.

For a logical vector `x`, `which.min(x)` and `which.max(x)` return the index of the first `FALSE` or `TRUE`, respectively.
which.min

Usage

which.min(x)
which.max(x)

Arguments

x numeric (integer or double) vector, whose min or max is searched for.

Value

Missing and NaN values are discarded.

an integer of length 1 or 0 (iff x has no non-NAs), giving the index of the first minimum or maximum respectively of x.

If this extremum is unique (or empty), the results are the same as (but more efficient than) which(x == min(x)) or which(x == max(x)) respectively.

Author(s)

Martin Maechler

See Also

which, max.col, max, etc.

Use arrayInd(), if you need array/matrix indices instead of 1D vector ones.

which.is.max in package nnet differs in breaking ties at random (and having a ‘fuzz’ in the definition of ties).

Examples

x <- c(1:4, 0.5, 11)
which.min(x)
which.max(x)

## it *does* work with NA's present, by discarding them:
presidents[1:30]
range(presidents, na.rm = TRUE)
which.min(presidents) # 28
which.max(presidents) # 2

## Find the first occurrence, i.e. the first TRUE:
x <- rpois(10000, lambda = 10); x[sample.int(50, 20)] <- NA
## where is the first value >= 20 ?
which.max(x >= 20)
**Evaluate an Expression in a Data Environment**

**Description**
Evaluate an R expression in an environment constructed from data, possibly modifying the original data.

**Usage**
```r
with(data, expr, ...)  
within(data, expr, ...)
```

**Arguments**
- `data` data to use for constructing an environment. For the default `with` method this may be an environment, a list, a data frame, or an integer as in `sys.call`. For `within`, it can be a list or a data frame.
- `expr` expression to evaluate.
- `...` arguments to be passed to future methods.

**Details**
`with` is a generic function that evaluates `expr` in a local environment constructed from data. The environment has the caller’s environment as its parent. This is useful for simplifying calls to modeling functions. (Note: if `data` is already an environment then this is used with its existing parent.) Note that assignments within `expr` take place in the constructed environment and not in the user’s workspace.

`within` is similar, except that it examines the environment after the evaluation of `expr` and makes the corresponding modifications to `data` (this may fail in the data frame case if objects are created which cannot be stored in a data frame), and returns it. `within` can be used as an alternative to `transform`.

**Value**
For `with`, the value of the evaluated `expr`. For `within`, the modified object.

**See Also**
- `evalq`, `attach`, `assign`, `transform`.

**Examples**
```r
require(stats); require(graphics)
#examples from glm:
## Not run:
library(MASS)
with(anorexia, {
  anorex.1 <- glm(Postwt ~ Prewt + Treat + offset(Prewt),
                  family = gaussian)
  summary(anorex.1)
})
```
### withVisible

Return both a value and its visibility

#### Description

This function evaluates an expression, returning it in a two element list containing its value and a flag showing whether it would automatically print.

#### Usage

```r
withVisible(x)
```
Arguments

x
An expression to be evaluated.

Details
The argument is evaluated in the caller's context.
This is a primitive function.

Value

value
The value of x after evaluation.
visible
logical; whether the value would auto-print.

See Also

 invisible, eval

Examples

x <- 1
withVisible(x <- 1)
x
withVisible(x)

# Wrap the call in evalq() for special handling
df <- data.frame(a = 1:5, b = 1:5)
evalq(withVisible(a + b), envir = df)

Description
The data (usually a matrix) x are written to file file. If x is a two-dimensional matrix you need to transpose it to get the columns in file the same as those in the internal representation.

Usage

write(x, file = "data",
     ncolumns = if(is.character(x)) 1 else 5,
     append = FALSE, sep = " ")

Arguments

x
the data to be written out, usually an atomic vector.
file
A connection, or a character string naming the file to write to. If ",", print to the standard output connection. If it is ":\cmd", the output is piped to the command given by `cmd`.
ncolumns
the number of columns to write the data in.
append
if TRUE the data x are appended to the connection.
sep
a string used to separate columns. Using sep = "\t" gives tab delimited output; default is " ".
writeLines

Write Lines to a Connection

Description

Write text lines to a connection.

Usage

writeLines(text, con = stdout(), sep = "\n", useBytes = FALSE)

Arguments

- **text**: A character vector
- **con**: A connection object or a character string.
- **sep**: character. A string to be written to the connection after each line of text.
- **useBytes**: logical. See ‘Details’.

Details

If the `con` is a character string, the function calls `file` to obtain a file connection which is opened for the duration of the function call.

If the connection is open it is written from its current position. If it is not open, it is opened for the duration of the call in "wt" mode and then closed again.

Normally `writeLines` is used with a text-mode connection, and the default separator is converted to the normal separator for that platform (LF on Unix/Linux, CRLF on Windows). For more control, open a binary connection and specify the precise value you want written to the file in `sep`. For even more control, use `writeChar` on a binary connection.
useBytes is for expert use. Normally (when false) character strings with marked encodings are converted to the current encoding before being passed to the connection (which might do further re-encoding). useBytes = TRUE suppresses the re-encoding of marked strings so they are passed byte-by-byte to the connection: this can be useful when strings have already been re-encoded by e.g. iconv. (It is invoked automatically for strings with marked encoding “bytes”.)

See Also

connections, writeChar, writeBin, readLines, cat

xtfrm

Auxiliary Function for Sorting and Ranking

Description

A generic auxiliary function that produces a numeric vector which will sort in the same order as x.

Usage

xtfrm(x)

Arguments

x

an R object.

Details

This is a special case of ranking, but as a less general function than rank is more suitable to be made generic. The default method is similar to rank(x, ties.method = "min", na.last = "keep"), so NA values are given rank NA and all tied values are given equal integer rank.

The factor method extracts the codes. The Surv method sorts first on times and then on status code(s).

The default method will unclass the object if is.numeric(x) is true but otherwise make use of == and > methods for the class of x[i] (for integers i), and the is.na method for the class of x, but might be rather slow when doing so.

This is an internal generic primitive, so S3 or S4 methods can be written for it.

Value

A numeric (usually integer) vector of the same length as x.

See Also

rank, sort, order.
zapsmall

**Rounding of Numbers**

**Description**

zapsmall determines a digits argument \( dr \) for calling \( \text{round}(x, \text{digits} = dr) \) such that values close to zero (compared with the maximal absolute value) are ‘zapped’, i.e., treated as 0.

**Usage**

\[
\text{zapsmall}(x, \text{digits} = \text{getOption("digits")})
\]

**Arguments**

- \( x \) a numeric or complex vector.
- \( \text{digits} \) integer indicating the precision to be used.

**References**

**Examples**

\[
x2 \leftarrow \text{pi} \times 100^{(-1:3)}
\]

\[
\text{print}(x2 / 1000, \text{digits} = 4)
\]

\[
\text{zapsmall}(x2 / 1000, \text{digits} = 4)
\]

\[
\text{zapsmall}(\exp(1i*0:4*pi/2))
\]

zpackages

**Listing of Packages**

**Description**

`.packages` returns information about package availability.

**Usage**

`.packages(all.available = FALSE, lib.loc = NULL)`

**Arguments**

- `all.available` logical; if TRUE return a character vector of all available packages in `lib.loc`.
- `lib.loc` a character vector describing the location of \( R \) library trees to search through, or NULL. The default value of NULL corresponds to `.libPaths()`.
Details
.packages() returns the names of the currently attached packages *invisibly* whereas .packages(all.available = TRUE) gives (visibly) all packages available in the library location path lib.loc.

For a package to be regarded as being ‘available’ it must have valid metadata (and hence be an installed package). However, this will report a package as available if the metadata does not match the directory name: use `find.package` to confirm that the metadata match or `installed.packages` for a much slower but more comprehensive check of ‘available’ packages.

Value
A character vector of package base names, invisible unless all.available = TRUE.

Note
.packages(all.available = TRUE) is not a way to find out if a small number of packages are available for use: not only is it expensive when thousands of packages are installed, it is an incomplete test. See the help for `find.package` for why `require` should be used.

Author(s)
R core; Guido Masarotto for the all.available = TRUE part of .packages.

See Also
library, .libPaths, installed.packages.

Examples

```r
.packages()
# maybe just "base"
.packages(all.available = TRUE) # return all available as character vector
require(splines)
.packages()
# "splines", too
detach("package:splines")
```

---

**zutils**

**Miscellaneous Internal/Programming Utilities**

Description

Miscellaneous internal/programming utilities.

Usage

`.standard_regexps()`

Details

`.standard_regexps` returns a list of ‘standard’ regexps, including elements named `valid_package_name` and `valid_package_version` with the obvious meanings. The regexps are not anchored.
Chapter 2

The compiler package

| compile | Byte Code Compiler |

Description

These functions provide an interface to a byte code compiler for R.

Usage

```r
cmpfun(f, options = NULL)
cmpfile(infile, outfile, ascii = FALSE, env = .GlobalEnv,
        verbose = FALSE, options = NULL)
loadcmp(file, envir = .GlobalEnv, chdir = FALSE)
disassemble(code)
enableJIT(level)
compilePKGS(enable)
getCompilerOption(name, options)
setCompilerOptions(...)```

Arguments

- `f`: a closure.
- `options`: list of named compiler options
- `env`: the top level environment for the compiling.
- `file, infile, outfile`: pathnames; outfile defaults to infile with a .Rc extension in place of any existing extension.
- `ascii`: logical; should the compiled file be saved in ascii format?
- `verbose`: logical; should the compiler show what is being compiled
- `envir`: environment to evaluate loaded expressions in.
- `chdir`: logical; change directory before evaluation?
- `code`: byte code expression or compiled closure
e expression to compile
level integer; the JIT level to use
enable logical; enable compiling packages if TRUE
name character string; name of option to return

Details

The function cmpfun compiles the body of a closure and returns a new closure with the same formals and the body replaced by the compiled body expression.

compile compiles an expression into a byte code object; the object can then be evaluated with eval.

cmpfile parses the expression in infile, compiles them, and writes the compiled expressions to outfile. If outfile is not provided, it is formed from infile by replacing or appending a .Rc suffix.

loadcmp is used to load compiled files. It is similar to sys.source, except that its default loading environment is the global environment rather than the base environment.

disassemble produces a printed representation of the code that may be useful to give a hint of what is going on.

enableJIT enables or disables just-in-time (JIT) compilation. JIT is disabled if the argument is 0. If enable is 1 then closures are compiled before their first use. If enable is 2, then in addition closures are also compiled before they are duplicated (useful for some packages, like lattice, that store closures in lists). If enable is 3 then in addition all loops are compiled before they are executed. JIT can also be enabled by starting R with the environment variable R_ENABLE_JIT set to one of these values.

compilePKGS enables or disables compiling packages when they are installed. This requires that the package use lazy loading as compilation occurs as functions are written to the lazy loading data base. This can also be enabled by starting R with the environment variable R_COMPILE_PKGS set to a positive integer value.

Currently the compiler warns about a variety of things. It does this by using cat to print messages. Eventually this should use the condition handling mechanism.

The options argument can be used to control compiler operation. There are currently three options: optimize, suppressAll, and suppressUndefined. optimize specifies the optimization level, which can be an integer form 0 to 3. suppressAll should be a scalar logical; if TRUE no messages will be shown. suppressUndefined can be TRUE to suppress all messages about undefined variables, or it can be a character vector of the names of variables for which messages should not be shown.

compilerOption returns the value of the specified option. The default value is returned unless a value is supplied in the options argument; the options argument is primarily for internal use.

setCompilerOption sets the default option values. It returns a named list of the previous values.

Calling the compiler a byte code compiler is actually a bit of a misnomer: the external representation of code objects currently uses Int operands, and when compiled with gcc the internal representation is actually threaded code rather than byte code.

require(graphics)
plot(airmiles, main = "airmiles data",
    xlab = "Passenger-miles flown by U.S. commercial airlines", col = 4)
```

---

**AirPassengers**

*Monthly Airline Passenger Numbers 1949-1960*

Description

The classic Box & Jenkins airline data. Monthly totals of international airline passengers, 1949 to 1960.

Usage

AirPassengers

Format

A monthly time series, in thousands.

Source

Examples

```r
## Not run:
## These are quite slow and so not run by example(AirPassengers)

## The classic 'airline model', by full ML
(fit <- arima(log10(AirPassengers), c(0, 1, 1),
    seasonal = list(order = c(0, 1, 1), period = 12)))
update(fit, method = "CSS")
update(fit, x = window(log10(AirPassengers), start = 1954))
pred <- predict(fit, n.ahead = 24)
t1 <- pred$pred - 1.96 * pred$se
tu <- pred$pred + 1.96 * pred$se
ts.plot(AirPassengers, 10^t1, 10^tu, log = "y", lty = c(1, 2, 2))

## full ML fit is the same if the series is reversed, CSS fit is not
ap0 <- rev(log10(AirPassengers))
attributes(ap0) <- attributes(AirPassengers)
arima(ap0, c(0, 1, 1), seasonal = list(order = c(0, 1, 1), period = 12))
```
airquality

**New York Air Quality Measurements**

**Description**

**Usage**

airquality

**Format**

A data frame with 154 observations on 6 variables.

```
[,1]  Ozone    numeric  Ozone (ppb)
[,3]    Wind    numeric  Wind (mph)
[,4]   Temp    numeric  Temperature (degrees F)
[,5]   Month    numeric  Month (1–12)
```

**Details**

Daily readings of the following air quality values for May 1, 1973 (a Tuesday) to September 30, 1973.

- **Ozone**: Mean ozone in parts per billion from 1300 to 1500 hours at Roosevelt Island
- **Solar.R**: Solar radiation in Langley's in the frequency band 4000–7700 Angstroms from 0800 to 1200 hours at Central Park
- **Wind**: Average wind speed in miles per hour at 0700 and 1000 hours at LaGuardia Airport
- **Temp**: Maximum daily temperature in degrees Fahrenheit at LaGuardia Airport.

**Source**

The data were obtained from the New York State Department of Conservation (ozone data) and the National Weather Service (meteorological data).

anscombe

Anscombe’s Quartet of ‘Identical’ Simple Linear Regressions

Description
Four x-y datasets which have the same traditional statistical properties (mean, variance, correlation, regression line, etc.), yet are quite different.

Usage

```r
anscombe
```

Format
A data frame with 11 observations on 8 variables.

- `x1 == x2 == x3` the integers 4:14, specially arranged
- `x4` values 8 and 19
- `y1, y2, y3, y4` numbers in (3, 12.5) with mean 7.5 and sdev 2.03

Source

References

Examples

```r
require(stats); require(graphics)
summary(anscombe)
```

```r
###-- now some "magic" to do the 4 regressions in a loop:
ff <- y ~ x
mods <- setNames(as.list(1:4), paste("lm", 1:4))
for(i in 1:4) {
  ff[2:3] <- lapply(paste0(c("y","x"), i), as.name)
  ## or  ff[[2]] <- as.name(paste0("y", i))
  ## ff[[3]] <- as.name(paste0("x", i))
  mods[[i]] <- lmi <- lm(ff, data = anscombe)
  print(anova(lmi))
}
```
## The Joyner–Boore Attenuation Data

This data gives peak accelerations measured at various observation stations for 23 earthquakes in California. The data have been used by various workers to estimate the attenuating affect of distance on ground acceleration.

### Usage

```r
attenu
```

### Format

A data frame with 182 observations on 5 variables.

### austres

*Quarterly Time Series of the Number of Australian Residents*

**Description**

Numbers (in thousands) of Australian residents measured quarterly from March 1971 to March 1994. The object is of class "ts".

**Usage**

```r
austres
```

**Source**

---

### beavers

*Body Temperature Series of Two Beavers*

**Description**

Reynolds (1994) describes a small part of a study of the long-term temperature dynamics of beaver *Castor canadensis* in north-central Wisconsin. Body temperature was measured by telemetry every 10 minutes for four females, but data from a one period of less than a day for each of two animals is used there.

**Usage**

```r
beaver1
beaver2
```

**Format**

The `beaver1` data frame has 114 rows and 4 columns on body temperature measurements at 10 minute intervals.

The `beaver2` data frame has 100 rows and 4 columns on body temperature measurements at 10 minute intervals.

The variables are as follows:
day  Day of observation (in days since the beginning of 1990), December 12–13 (beaver1) and November 3–4 (beaver2).

time Time of observation, in the form 0330 for 3:30am

temp Measured body temperature in degrees Celsius.

activ Indicator of activity outside the retreat.

Note

The observation at 22:20 is missing in beaver1.

Source

Examples

```r
require(graphics)
(y1 <- range(beaver1$temp, beaver2$temp))

beaver.plot <- function(bdat, ...) {
  nam <- deparse(substitute(bdat))
  with(bdat, {
    # Hours since start of day:
    hours <- time %% 100 + 24*(day - day[1]) + (time %% 100)/60
    plot(hours, temp, type = "l", ..., main = paste(nam, "body temperature"))
    abline(h = 37.5, col = "gray", lty = 2)
    is.act <- activ == 1
    points(hours[is.act], temp[is.act], col = 2, cex = .8)
  })
}

op <- par(mfrow = c(2, 1), mar = c(3, 3, 4, 2), mgp = 0.9 * 2:0)
beaver.plot(beaver1, ylim = y1)
beaver.plot(beaver2, ylim = y1)
par(op)
```

BJsales  

_Sales Data with Leading Indicator_

Description

The sales time series BJsales and leading indicator BJsales.lead each contain 150 observations. The objects are of class "ts".

Usage

BJsales
BJsales.lead

BOD

Biochemical Oxygen Demand

Description

The BOD data frame has 6 rows and 2 columns giving the biochemical oxygen demand versus time in an evaluation of water quality.

Usage

BOD

Format

This data frame contains the following columns:

- **Time**: A numeric vector giving the time of the measurement (days).
- **demand**: A numeric vector giving the biochemical oxygen demand (mg/l).

Source

Examples

```r
require(stats)
# simplest form of fitting a first-order model to these data
fm1 <- nls(demand ~ A*(1-exp(-exp(lrc)*Time)), data = BOD,
       start = c(A = 20, lrc = log(.35)))
coef(fm1)
fm1
# using the plinear algorithm
fm2 <- nls(demand ~ (1-exp(-exp(lrc)*Time)), data = BOD,
       start = c(lrc = log(.35)), algorithm = "plinear", trace = TRUE)
# using a self-starting model
fm3 <- nls(demand ~ SSasympOrig(Time, A, lrc), data = BOD)
summary(fm3)
```
Speed and Stopping Distances of Cars

Description

The data give the speed of cars and the distances taken to stop. Note that the data were recorded in the 1920s.

Usage

cars

Format

A data frame with 50 observations on 2 variables.

```
  [,1] speed  numeric Speed (mph)
  [,2] dist  numeric Stopping distance (ft)
```

Source

References

Examples

```r
require(stats); require(graphics)
plot(cars, xlab = "Speed (mph)", ylab = "Stopping distance (ft)",
     las = 1)
lines(lowess(cars$speed, cars$dist, f = 2/3, iter = 3), col = "red")
title(main = "cars data")
plot(cars, xlab = "Speed (mph)", ylab = "Stopping distance (ft)",
     las = 1, log = "xy")
title(main = "cars data (logarithmic scales)"
lines(lowess(cars$speed, cars$dist, f = 2/3, iter = 3), col = "red")
summary(fm1 <- lm(log(dist) ~ log(speed), data = cars))
opar <- par(mfrow = c(2, 2), oma = c(0, 0, 1.1, 0),
       mar = c(4.1, 4.1, 2.1, 1.1))
plot(fm1)
par(opar)

## An example of polynomial regression
plot(cars, xlab = "Speed (mph)", ylab = "Stopping distance (ft)",
     las = 1, xlim = c(0, 25))
d <- seq(0, 25, length.out = 200)
for(degree in 1:4) {
  fm <- lm(dist ~ poly(speed, degree), data = cars)
  assign(paste("cars", degree, sep = "."), fm)
  lines(d, predict(fm, data.frame(speed = d)), col = degree)
}
anova(cars.1, cars.2, cars.3, cars.4)
```
ChickWeight

Weight versus age of chicks on different diets

Description
The ChickWeight data frame has 578 rows and 4 columns from an experiment on the effect of diet on early growth of chicks.

Usage
ChickWeight

Format
An object of class c("nfnGroupedData", "nfgroupedData", "groupedData", "data.frame") containing the following columns:

- **weight** a numeric vector giving the body weight of the chick (gm).
- **Time** a numeric vector giving the number of days since birth when the measurement was made.
- **Chick** an ordered factor with levels 1 < ... < 48 giving a unique identifier for the chick. The ordering of the levels groups chicks on the same diet together and orders them according to their final weight (lightest to heaviest) within diet.
- **Diet** a factor with levels 1, ..., 4 indicating which experimental diet the chick received.

Details
The body weights of the chicks were measured at birth and every second day thereafter until day 20. They were also measured on day 21. There were four groups on chicks on different protein diets.

This dataset was originally part of package nlme, and that has methods (including for [, as.data.frame, plot and print) for its grouped-data classes.

Source

See Also
- **SSlogis** for models fitted to this dataset.

Examples

```r
require(graphics)
coplot(weight ~ Time | Chick, data = ChickWeight,
       type = "b", show.given = FALSE)
```
Description

An experiment was conducted to measure and compare the effectiveness of various feed supplements on the growth rate of chickens.

Usage

chickwts

Format

A data frame with 71 observations on 2 variables.

weight  a numeric variable giving the chick weight.

feed  a factor giving the feed type.

Details

Newly hatched chicks were randomly allocated into six groups, and each group was given a different feed supplement. Their weights in grams after six weeks are given along with feed types.

Source

References

Examples

```r
require(stats); require(graphics)
boxplot(weight ~ feed, data = chickwts, col = "lightgray",
        varwidth = TRUE, notch = TRUE, main = "chickwt data",
        ylab = "Weight at six weeks (gm)")
anova(fm1 <- lm(weight ~ feed, data = chickwts))
opar <- par(mfrow = c(2, 2), oma = c(0, 0, 1.1, 0),
        mar = c(4.1, 4.1, 2.1, 1.1))
plot(fm1)
par(opar)
```
**Description**

The CO2 data frame has 84 rows and 5 columns of data from an experiment on the cold tolerance of the grass species *Echinochloa crus-galli*.

**Usage**

CO2

**Format**

An object of class c("nfnGroupedData", "nfgroupedData", "groupedData", "data.frame") containing the following columns:

- **Plant** an ordered factor with levels Qn1 < Qn2 < Qn3 < ... < Mc1 giving a unique identifier for each plant.
- **Type** a factor with levels Quebec Mississippi giving the origin of the plant
- **Treatment** a factor with levels nonchilled chilled
- **conc** a numeric vector of ambient carbon dioxide concentrations (mL/L).
- **uptake** a numeric vector of carbon dioxide uptake rates (µmol/m2 sec).

**Details**

The CO2 uptake of six plants from Quebec and six plants from Mississippi was measured at several levels of ambient CO2 concentration. Half the plants of each type were chilled overnight before the experiment was conducted.

This dataset was originally part of package nlme, and that has methods (including for [, as.data.frame, plot and print) for its grouped-data classes.

**Source**

**Examples**

```r
require(stats); require(graphics)

coplot(up uptake ~ conc | Plant, data = CO2, show.given = FALSE, type = "b")
## fit the data for the first plant
fml <- nls(up uptake ~ SSasymp(conc, Asym, lrc, c0),
  data = CO2, subset = Plant == "Qn1")
summary(fml)
## fit each plant separately
fmlist <- list()
for (pp in levels(CO2$Plant)) {
  fmlist[[pp]] <- nls(up uptake ~ SSasymp(conc, Asym, lrc, c0),
```
data = CO2, subset = Plant == pp)
)
## check the coefficients by plant
print(sapply(fmlist, coef), digits = 3)

---

**Mauna Loa Atmospheric CO2 Concentration**

**Description**

Atmospheric concentrations of CO\(_2\) are expressed in parts per million (ppm) and reported in the preliminary 1997 SIO manometric mole fraction scale.

**Usage**

co2

**Format**

A time series of 468 observations; monthly from 1959 to 1997.

**Details**

The values for February, March and April of 1964 were missing and have been obtained by interpolating linearly between the values for January and May of 1964.

**Source**

Keeling, C. D. and Whorf, T. P., Scripps Institution of Oceanography (SIO), University of California, La Jolla, California USA 92093-0220.

**References**

**Examples**

```r
require(graphics)
plot(co2, ylab = expression("Atmospheric concentration of CO"[2]),
    las = 1)
title(main = "co2 data set")
```
Description

Data of 3000 male criminals over 20 years old undergoing their sentences in the chief prisons of England and Wales.

Usage

`crimtab`

Format

A `table` object of `integer` counts, of dimension `42 x 22` with a total count, `sum(crimtab)` of `3000`. The `42` `rownames` ("9.4", "9.5", ...) correspond to midpoints of intervals of finger lengths whereas the `22` column names (`colnames`) ("142.24", "144.78", ...) correspond to (body) heights of `3000` criminals, see also below.

Details

Student is the pseudonym of William Sealy Gosset. In his 1908 paper he wrote (on page 13) at the beginning of section VI entitled `Practical Test of the foregoing Equations`:

"Before I had succeeded in solving my problem analytically, I had endeavoured to do so empirically. The material used was a correlation table containing the height and left middle finger measurements of 3000 criminals, from a paper by W. R. MacDonell (Biometrika, Vol. I., p. 219). The measurements were written out on 3000 pieces of cardboard, which were then very thoroughly shuffled and drawn at random. As each card was drawn its numbers were written down in a book, which thus contains the measurements of 3000 criminals in a random order. Finally, each consecutive set of `4` was taken as a sample—`750` in all—and the mean, standard deviation, and correlation of each sample determined. The difference between the mean of each sample and the mean of the population was then divided by the standard deviation of the sample, giving us the `z` of Section III."

The table is in fact page 216 and not page 219 in MacDonell(1902). In the MacDonell table, the middle finger lengths were given in mm and the heights in feet/inches intervals, they are both converted into cm here. The midpoints of intervals were used, e.g., where MacDonell has $4'7''9/16 - 8''9/16$, we have `142.24` which is $2.54*56 = 2.54*(4'8'')$.

MacDonell credited the source of data (page 178) as follows: The data on which the memoir is based were obtained, through the kindness of Dr Garson, from the Central Metric Office, New Scotland Yard... He pointed out on page 179 that: The forms were drawn at random from the mass on the office shelves; we are therefore dealing with a random sampling.

Source

References

Examples

```r
require(stats)
dim(crimtab)
utils::str(crimtab)
## for nicer printing:
local({
cT <- crimtab
colnames(cT) <- substring(colnames(cT), 2, 3)
print(cT, zero.print = " ")
})

## Repeat Student's experiment:

# 1) Reconstitute 3000 raw data for heights in inches and rounded to
# nearest integer as in Student's paper:

(heIn <- round(as.numeric(colnames(crimtab)) / 2.54))
d.hei <- data.frame(height = rep(heIn, colSums(crimtab)))

# 2) shuffle the data:

set.seed(1)
d.hei <- d.hei[sample(1:3000), , drop = FALSE]

# 3) Make 750 samples each of size 4:

d.hei$sample <- as.factor(rep(1:750, each = 4))

# 4) Compute the means and standard deviations (n) for the 750 samples:

h.mean <- with(d.hei, tapply(height, sample, FUN = mean))
h.sd <- with(d.hei, tapply(height, sample, FUN = sd)) * sqrt(3/4)

# 5) Compute the difference between the mean of each sample and
# the mean of the population and then divide by the
# standard deviation of the sample:

zobs <- (h.mean - mean(d.hei[, "height"]))/h.sd

# 6) Replace infinite values by +/- 6 as in Student's paper:

zobs[is.infinite(zobs)] <- 6 * sign(zobs[is.infinite(zobs)]

# 7) Plot the distribution:

require(grDevices); require(graphics)
hist(x = zobs, probability = TRUE, xlab = "Student's z",
```
discoveries  |  Yearly Numbers of Important Discoveries

**Description**

The numbers of “great” inventions and scientific discoveries in each year from 1860 to 1959.

**Usage**

discoveries

**Format**

A time series of 100 values.

**Source**

**DNase**  |  Elisa assay of DNase

**Description**

The DNase data frame has 176 rows and 3 columns of data obtained during development of an ELISA assay for the recombinant protein DNase in rat serum.

**Usage**

DNase
**esoph**

**Smoking, Alcohol and (O)esophageal Cancer**

Data from a case-control study of (o)esophageal cancer in Ille-et-Vilaine, France.

**Usage**

esoph

**Format**

A data frame with records for 88 age/alcohol/tobacco combinations.

**Description**

Data from a case-control study of (o)esophageal cancer in Ille-et-Vilaine, France.

**Examples**

```r
require(stats); require(graphics)

coplot(density ~ conc | Run, data = DNase,
       show.given = FALSE, type = "b")
coplot(density ~ log(conc) | Run, data = DNase,
       show.given = FALSE, type = "b")
## fit a representative run
fm1 <- nls(density ~ SSlogis( log(conc), Asym, xmid, scal ),
           data = DNase, subset = Run == 1)
## compare with a four-parameter logistic
fm2 <- nls(density ~ SSfpl( log(conc), A, B, xmid, scal ),
           data = DNase, subset = Run == 1)
summary(fm2)
anova(fm1, fm2)
```

**Format**

An object of class `c("nfnGroupedData", "nfgroupedData", "groupedData", "data.frame")` containing the following columns:

- **Run** an ordered factor with levels `10 < ... < 3` indicating the assay run.
- **conc** a numeric vector giving the known concentration of the protein.
- **density** a numeric vector giving the measured optical density (dimensionless) in the assay. Duplicate optical density measurements were obtained.

**Details**

This dataset was originally part of package `nlme`, and that has methods (including for `[`, `as.data.frame`, `plot` and `print`) for its grouped-data classes.

```
**euro**

*Conversion Rates of Euro Currencies*

**Description**

Conversion rates between the various Euro currencies.

**Usage**

```r
euro

euro.cross
```

**Format**

`euro` is a named vector of length 11, `euro.cross` a matrix of size 11 by 11, with dimnames.

**Details**

The data set `euro` contains the value of 1 Euro in all currencies participating in the European monetary union (Austrian Schilling ATS, Belgian Franc BEF, German Mark DEM, Spanish Peseta ESP, Finnish Markka FIM, French Franc FRF, Irish Punt IEP, Italian Lira ITL, Luxembourg Franc LUF, Dutch Guilder NLG and Portuguese Escudo PTE). These conversion rates were fixed by the European Union on December 31, 1998. To convert old prices to Euro prices, divide by the respective rate and round to 2 digits.

The data set `euro.cross` contains conversion rates between the various Euro currencies, i.e., the result of `outer(1 / euro, euro)`.

**Examples**

```r
cbind(euro)
```

## These relations hold:
`euro == signif(euro, 6)` # [6 digit precision in Euro's definition]
`all(euro.cross == outer(1/euro, euro))`

## Convert 20 Euro to Belgian Franc
`20 * euro["BEF"]`

## Convert 20 Austrian Schilling to Euro
`20 / euro["ATS"]`

## Convert 20 Spanish Pesetas to Italian Lira
`20 * euro.cross["ESP", "ITL"]`

```r
require(graphics)
dotchart(euro,
        main = "euro data: 1 Euro in currency unit")
dotchart(1/euro,
        main = "euro data: 1 currency unit in Euros")
dotchart(log(euro, 10),
        main = "euro data: log10(1 Euro in currency unit)"
)
EuStockMarkets

EuStockMarkets  
*Daily Closing Prices of Major European Stock Indices, 1991–1998*

**Description**

Contains the daily closing prices of major European stock indices: Germany DAX (Ibis), Switzerland SMI, France CAC, and UK FTSE. The data are sampled in business time, i.e., weekends and holidays are omitted.

**Usage**

EuStockMarkets

**Format**

A multivariate time series with 1860 observations on 4 variables. The object is of class "mts".

**Source**

The data were kindly provided by Erste Bank AG, Vienna, Austria.
Old Faithful Geyser Data

Description

Waiting time between eruptions and the duration of the eruption for the Old Faithful geyser in Yellowstone National Park, Wyoming, USA.

Usage

faithful

Format

A data frame with 272 observations on 2 variables.

\[
\begin{array}{ll}
[,1] & \text{eruptions numeric Eruption time in mins} \\
[,2] & \text{waiting numeric Waiting time to next eruption (in mins)}
\end{array}
\]

Details

A closer look at faithful$eruptions reveals that these are heavily rounded times originally in seconds, where multiples of 5 are more frequent than expected under non-human measurement. For a better version of the eruption times, see the example below.

There are many versions of this dataset around: Azzalini and Bowman (1990) use a more complete version.

Source

W. Härdle.

HairEyeColor

Hair and Eye Color of Statistics Students

Description

Distribution of hair and eye color and sex in 592 statistics students.

Usage

HairEyeColor

Format

A 3-dimensional array resulting from cross-tabulating 592 observations on 3 variables. The variables and their levels are as follows:

<table>
<thead>
<tr>
<th>No</th>
<th>Name</th>
<th>Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Hair</td>
<td>Black, Brown, Red, Blond</td>
</tr>
<tr>
<td>2</td>
<td>Eye</td>
<td>Brown, Blue, Hazel, Green</td>
</tr>
<tr>
<td>3</td>
<td>Sex</td>
<td>Male, Female</td>
</tr>
</tbody>
</table>

Details

The Hair × Eye table comes from a survey of students at the University of Delaware reported by Snee (1974). The split by Sex was added by Friendly (1992a) for didactic purposes.

This data set is useful for illustrating various techniques for the analysis of contingency tables, such as the standard chi-squared test or, more generally, log-linear modelling, and graphical methods such as mosaic plots, sieve diagrams or association plots.

Source

http://euclid.psych.yorku.ca/ftp/sas/vcd/catdata/haireye.sas

Snee (1974) gives the two-way table aggregated over Sex. The Sex split of the ‘Brown hair, Brown eye’ cell was changed in R 2.6.0 to agree with that used by Friendly (2000).

```

Description

The `Indometh` data frame has 66 rows and 3 columns of data on the pharmacokinetics of indometacin (or, older spelling, ‘indomethacin’).

Usage

Indometh

Format

An object of class `c("nfnGroupedData", "nfGroupedData", "groupedData", "data.frame")` containing the following columns:

- **Subject**: an ordered factor containing the subject codes. The ordering is according to increasing maximum response.
- **time**: a numeric vector of times at which blood samples were drawn (hr).
- **conc**: a numeric vector of plasma concentrations of indometacin (mcg/ml).

Details

Each of the six subjects were given an intravenous injection of indometacin.

This dataset was originally part of package `nlme`, and that has methods (including for `[`, `as.data.frame`, `plot` and `print`) for its grouped-data classes.

Infertility after Spontaneous and Induced Abortion

Description

This is a matched case-control study dating from before the availability of conditional logistic regression.

Usage

infert

Format

1. Education 0 = 0-5 years
   1 = 6-11 years
   2 = 12+ years
2. age age in years of case
3. parity count
4. number of prior induced abortions 0 = 0
   1 = 1
   2 = 2 or more
5. case status 1 = case
   0 = control
6. number of prior spontaneous abortions 0 = 0
   1 = 1
   2 = 2 or more
7. matched set number 1-83
8. stratum number 1-63

Note

One case with two prior spontaneous abortions and two prior induced abortions is omitted.

Source

Examples

```r
require(stats)
model1 <- glm(case ~ spontaneous+induced, data = infert, family = binomial())
summary(model1)
## adjusted for other potential confounders:
summary(model2 <- glm(case ~ age+parity+education+spontaneous+induced,
                        data = infert, family = binomial()))
## Really should be analysed by conditional logistic regression
## which is in the survival package
if(require(survival)){
```
Effectiveness of Insect Sprays

Description
The counts of insects in agricultural experimental units treated with different insecticides.

Usage
InsectSprays

Format
A data frame with 72 observations on 2 variables.

\[
\begin{array}{lc}
\text{[1]} & \text{count numeric Insect count} \\
\text{[2]} & \text{spray factor The type of spray}
\end{array}
\]

Source

References

Examples
```r
require(stats); require(graphics)
boxplot(count ~ spray, data = InsectSprays,
       xlab = "Type of spray", ylab = "Insect count",
       main = "InsectSprays data", varwidth = TRUE, col = "lightgray")
fml <- aov(count ~ spray, data = InsectSprays)
summary(fml)
opar <- par(mfrow = c(2, 2), oma = c(0, 0, 1.1, 0))
plot(fml)
fm2 <- aov(sqrt(count) ~ spray, data = InsectSprays)
summary(fm2)
plot(fm2)
par(opar)
```
Description

This famous (Fisher’s or Anderson’s) iris data set gives the measurements in centimeters of the variables sepal length and width and petal length and width, respectively, for 50 flowers from each of 3 species of iris. The species are *Iris setosa*, *versicolor*, and *virginica*.

Usage

```r
iris
iris3
```

Format

`iris` is a data frame with 150 cases (rows) and 5 variables (columns) named `Sepal.Length`, `Sepal.Width`, `Petal.Length`, `Petal.Width`, and `Species`.

`iris3` gives the same data arranged as a 3-dimensional array of size 50 by 4 by 3, as represented by S-PLUS. The first dimension gives the case number within the species subsample, the second the measurements with names `Sepal L`, `Sepal W`, `Petal L`, and `Petal W`, and the third the species.

Source

References

See Also

`matplot` some examples of which use `iris`.

Examples

```r
dni3 <- dimnames(iris3)
ii <- data.frame(matrix(aperm(iris3, c(1,3,2)), ncol = 4,
                           dimnames = list(NULL, sub(" L",".Length",
                           sub(" W",".Width", dni3[[2]]))),
Species = gl(3, 50, labels = sub("S", "s", sub("V", "v", dni3[[3]]))))
all.equal(ii, iris) # TRUE
```
islands  

**Areas of the World’s Major Landmasses**

**Description**

The areas in thousands of square miles of the landmasses which exceed 10,000 square miles.

**Usage**

`islands`

**Format**

A named vector of length 48.

**Source**

**References**

**Examples**

```r
require(graphics)
dotchart(log(islands, 10),
   main = "islands data: log10(area) (log10(sq. miles))")
dotchart(log(islands[order(islands)], 10),
   main = "islands data: log10(area) (log10(sq. miles))")
```

LifeCycleSavings  Intercountry Life-Cycle Savings Data

Description

Usage
LifeCycleSavings

Format
A data frame with 50 observations on 5 variables.

```
[,1] sr  numeric  aggregate personal savings
[,2] pop15 numeric  % of population under 15
[,3] pop75 numeric  % of population over 75
[,4] dpi numeric  real per-capita disposable income
[,5] ddpi numeric  % growth rate of dpi
```

Details
Under the life-cycle savings hypothesis as developed by Franco Modigliani, the savings ratio (aggregate personal saving divided by disposable income) is explained by per-capita disposable income, the percentage rate of change in per-capita disposable income, and two demographic variables: the percentage of population less than 15 years old and the percentage of the population over 75 years old. The data are averaged over the decade 1960–1970 to remove the business cycle or other short-term fluctuations.

Source
The data were obtained from Belsley, Kuh and Welsch (1980). They in turn obtained the data from Sterling (1977).

References

Examples
```
require(stats); require(graphics)
pairs(LifeCycleSavings, panel = panel.smooth, main = "LifeCycleSavings data")
fm1 <- lm(sr ~ pop15 + pop75 + dpi + ddpi, data = LifeCycleSavings)
summary(fm1)
```
Description

The Loblolly data frame has 84 rows and 3 columns of records of the growth of Loblolly pine trees.

Usage

Loblolly

Format

An object of class c("nfnGroupedData", "nfGroupedData", "groupedData", "data.frame") containing the following columns:

- **height** a numeric vector of tree heights (ft).
- **age** a numeric vector of tree ages (yr).
- **Seed** an ordered factor indicating the seed source for the tree. The ordering is according to increasing maximum height.

Details

This dataset was originally part of package nlme, and that has methods (including for [., as.data.frame, plot and print) for its grouped-data classes.

Source

Examples

```r
require(stats); require(graphics)
plot(height ~ age, data = Loblolly, subset = Seed == 329,
     xlab = "Tree age (yr)", las = 1,
     ylab = "Tree height (ft)",
     main = "Loblolly data and fitted curve (Seed 329 only)"
)
fm1 <- nls(height ~ SSasymp(age, Asym, R0, lrc),
           data = Loblolly, subset = Seed == 329)
age <- seq(0, 30, length.out = 101)
lines(age, predict(fm1, list(age = age)))
```
longley  

Longley’s Economic Regression Data

Description
A macroeconomic data set which provides a well-known example for a highly collinear regression.

Usage
longley

Format
A data frame with 7 economical variables, observed yearly from 1947 to 1962 ($n = 16$).

- **GNP.deflator**: GNP implicit price deflator (1954 = 100)
- **GNP**: Gross National Product.
- **Unemployed**: number of unemployed.
- **Armed.Forces**: number of people in the armed forces.
- **Population**: ‘noninstitutionalized’ population ≥ 14 years of age.
- **Year**: the year (time).
- **Employed**: number of people employed.

The regression $\text{lm(Employed} \sim .)$ is known to be highly collinear.

Source

References

Examples
```r
require(stats); require(graphics)
## give the data set in the form it is used in S-PLUS:
longley.x <- data.matrix(longley[, 1:6])
longley.y <- longley[, "Employed"]
pairs(longley, main = "longley data")
summary(fm1 <- lm(Employed ~ ., data = longley))
opar <- par(mfrow = c(2, 2), oma = c(0, 0, 1.1, 0),
          mar = c(4.1, 4.1, 2.1, 1.1))
plot(fm1)
par(opar)
```
**lynx**

*Annual Canadian Lynx trappings 1821–1934*

**Description**

Annual numbers of lynx trappings for 1821–1934 in Canada. Taken from Brockwell & Davis (1991), this appears to be the series considered by Campbell & Walker (1977).

**Usage**

`lynx`

**Source**

**References**

---

**morley**

*Michelson Speed of Light Data*

**Description**

A classical data of Michelson (but not this one with Morley) on measurements done in 1879 on the speed of light. The data consists of five experiments, each consisting of 20 consecutive ‘runs’. The response is the speed of light measurement, suitably coded (km/sec, with 299000 subtracted).

**Usage**

`morley`

**Format**

A data frame contains the following components:

- **Expt**  The experiment number, from 1 to 5.
- **Run** The run number within each experiment.
- **Speed** Speed-of-light measurement.
Details

The data is here viewed as a randomized block experiment with 'experiment' and 'run' as the factors. 'run' may also be considered a quantitative variate to account for linear (or polynomial) changes in the measurement over the course of a single experiment.

Note

This is the same dataset as michelson in package MASS.

Source

A. A. Michelson (1882) Experimental determination of the velocity of light made at the United States Naval Academy, Annapolis. *Astronomic Papers* **1** 135–8. U.S. Nautical Almanac Office. (See Table 24.)

Examples

```r
require(stats); require(graphics)
michelson <- transform(morley, Expt = factor(Expt), Run = factor(Run))
xtabs(~ Expt + Run, data = michelson)  # 5 x 20 balanced (two-way)
plot(Speed ~ Expt, data = michelson,
    main = "Speed of Light Data", xlab = "Experiment No.")
fm <- aov(Speed ~ Run + Expt, data = michelson)
summary(fm)
fm0 <- update(fm, . ~ . - Run)
anova(fm0, fm)
```

mtcars

*Motor Trend Car Road Tests*

Description

The data was extracted from the 1974 *Motor Trend* US magazine, and comprises fuel consumption and 10 aspects of automobile design and performance for 32 automobiles (1973–74 models).

Usage

```r
mtcars
```

Format

A data frame with 32 observations on 11 variables.

```r
[, 1] mpg  Miles/(US) gallon
[, 2] cyl Number of cylinders
[, 3] disp Displacement (cu.in.)
[, 4] hp  Gross horsepower
[, 5] drat Rear axle ratio
```
nhtemp

[. 6] wt  Weight (lb/1000)
[.7] qsec 1/4 mile time
[.8] vs V/S
[.9] am Transmission (0 = automatic, 1 = manual)
[.10] gear Number of forward gears
[.11] carb Number of carburetors

Source

Examples

```r
require(graphics)
pairs(mtcars, main = "mtcars data")
coplot(mpg ~ disp | as.factor(cyl), data = mtcars,
      panel = panel.smooth, rows = 1)
```

<table>
<thead>
<tr>

pred <-
  predict(arima(window(NileNA, 1871, 1938), c(2, 0, 0)), n.ahead = 20)
lines(pred$pred, lty = 3, col = "red")
lines(pred$pred + 2*pred$se, lty = 2, col = "blue")
```
**nottem**

Average Monthly Temperatures at Nottingham, 1920–1939

Description

A time series object containing average air temperatures at Nottingham Castle in degrees Fahrenheit for 20 years.

Usage

nottem

Source

Examples

```r
## Not run: require(stats); require(graphics)
nott <- window(nottem, end = c(1936,12))
fit <- arima(nott, order = c(1,0,0), list(order = c(2,1,0), period = 12))
nott.fore <- predict(fit, n.ahead = 36)
ts.plot(nott, nott.fore$pred, nott.fore$pred+2*nott.fore$se,
        nott.fore$pred-2*nott.fore$se, gpars = list(col = c(1,1,4,4)))
## End(Not run)
```
Classical N, P, K Factorial Experiment

Description

A classical N, P, K (nitrogen, phosphate, potassium) factorial experiment on the growth of peas conducted on 6 blocks. Each half of a fractional factorial design confounding the NPK interaction was used on 3 of the plots.

Usage

npk

Format

The npk data frame has 24 rows and 5 columns:

block which block (label 1 to 6).
N indicator (0/1) for the application of nitrogen.
P indicator (0/1) for the application of phosphate.
K indicator (0/1) for the application of potassium.
yield Yield of peas, in pounds/plot (the plots were (1/70) acre).

Source

References

Examples

options(contrasts = c("contr.sum", "contr.poly"))
npk.aov <- aov(yield ~ block + N+P+K, npk)
npk.aov
summary(npk.aov)
coef(npk.aov)

options(contrasts = c("contr.treatment", "contr.poly"))
npk.aov1 <- aov(yield ~ block + N + K, data = npk)
summary.lm(npk.aov1)
se.contrast(npk.aov1, list(N="0", N="1"), data = npk)
model.tables(npk.aov1, type = "means", se = TRUE)
occupationalStatus

Description

Cross-classification of a sample of British males according to each subject’s occupational status and his father’s occupational status.

Usage

occupationalStatus

Format

A table of counts, with classifying factors origin (father’s occupational status; levels 1:8) and destination (son’s occupational status; levels 1:8).

Source

The data set has been in package gnm and been provided by the package authors.

Examples

```r
require(stats); require(graphics)
plot(occupationalStatus)

# Fit a uniform association model separating diagonal effects
Diag <- as.factor(diag(1:8))
Rscore <- scale(as.numeric(row(occupationalStatus)), scale = FALSE)
Cscore <- scale(as.numeric(col(occupationalStatus)), scale = FALSE)
modUnif <- glm(Freq ~ origin + destination + Diag + Rscore:Cscore,
               family = poisson, data = occupationalStatus)
summary(modUnif)
plot(modUnif) # 4 plots, with warning about h_ii == 1
```

Orange

Description

The Orange data frame has 35 rows and 3 columns of records of the growth of orange trees.

Usage

Orange
An object of class c("nfnGroupedData", "nfgroupedData", "groupedData", "data.frame") containing the following columns:

**Tree** an ordered factor indicating the tree on which the measurement is made. The ordering is according to increasing maximum diameter.

**age** a numeric vector giving the age of the tree (days since 1968/12/31)

**circumference** a numeric vector of trunk circumferences (mm). This is probably “circumference at breast height”, a standard measurement in forestry.

This dataset was originally part of package nlmee, and that has methods (including for [, as.data.frame, plot and print) for its grouped-data classes.

```r
require(stats); require(graphics)
coplot(circumference ~ age | Tree, data = Orange, show.given = FALSE)
fml <- nls(circumference ~ SSlogis(age, Asym, xmid, scal),
          data = Orange, subset = Tree == 3)
plot(circumference ~ age, data = Orange, subset = Tree == 3,
     xlab = "Tree age (days since 1968/12/31)",
     ylab = "Tree circumference (mm)", las = 1,
     main = "Orange tree data and fitted model (Tree 3 only)"
age <- seq(0, 1600, length.out = 101)
lines(age, predict(fml, list(age = age)))
```

**OrchardSprays**

*Potency of Orchard Sprays*

**Description**

An experiment was conducted to assess the potency of various constituents of orchard sprays in repelling honeybees, using a Latin square design.

**Usage**

OrchardSprays

**Format**

A data frame with 64 observations on 4 variables.

- **[.1]** rowpos numeric Row of the design
- **[.2]** colpos numeric Column of the design
- **[.3]** treatment factor Treatment level
- **[.4]** decrease numeric Response
Details

Individual cells of dry comb were filled with measured amounts of lime sulphur emulsion in sucrose solution. Seven different concentrations of lime sulphur ranging from a concentration of 1/100 to 1/1,562,500 in successive factors of 1/5 were used as well as a solution containing no lime sulphur. The responses for the different solutions were obtained by releasing 100 bees into the chamber for two hours, and then measuring the decrease in volume of the solutions in the various cells. An 8 × 8 Latin square design was used and the treatments were coded as follows:

A  highest level of lime sulphur
B  next highest level of lime sulphur
. 
. 
. 
G  lowest level of lime sulphur
H  no lime sulphur

**PlantGrowth**

*Results from an Experiment on Plant Growth*

**Description**

Results from an experiment to compare yields (as measured by dried weight of plants) obtained under a control and two different treatment conditions.

**Usage**

`PlantGrowth`

**Format**

A data frame of 30 cases on 2 variables.

```
[, 1] weight   numeric
[, 2] group   factor
```

The levels of group are ‘ctrl’, ‘trt1’, and ‘trt2’.
precip

Source

Examples

```r
# One factor ANOVA example from Dobson's book, cf. Table 7.4:
require(stats); require(graphics)
boxplot(weight ~ group, data = PlantGrowth, main = "PlantGrowth data",

        notch = TRUE, varwidth = TRUE)
anova(lm(weight ~ group, data = PlantGrowth))
```

precip    Annual Precipitation in US Cities

Description

The average amount of precipitation (rainfall) in inches for each of 70 United States (and Puerto Rico) cities.

Usage

precip

Format

A named vector of length 70.

Source

References

Examples

```r
require(graphics)
dotchart(precip[order(precip)], main = "precip data")
title(sub = "Average annual precipitation (in.)")
```
presidents  Quarterly Approval Ratings of US Presidents

Description
The (approximately) quarterly approval rating for the President of the United states from the first quarter of 1945 to the last quarter of 1974.

Usage
presidents

Format
A time series of 120 values.

Details
The data are actually a fudged version of the approval ratings. See McNeil’s book for details.

Source
The Gallup Organisation.

References

Examples
require(stats); require(graphics)
plot(presidents, las = 1, ylab = "Approval rating (%)", main = "presidents data")

pressure  Vapor Pressure of Mercury as a Function of Temperature

Description
Data on the relation between temperature in degrees Celsius and vapor pressure of mercury in millimeters (of mercury).

Usage
pressure

Format
A data frame with 19 observations on 2 variables.

[1, 1] temperature numeric temperature (deg C)
[1, 2] pressure numeric pressure (mm)
Puromycin

Source

     ylab = "Pressure (mm of Hg)",
     main = "pressure data: Vapor Pressure of Mercury")
```

Puromycin

Reaction Velocity of an Enzymatic Reaction

Description

The Puromycin data frame has 23 rows and 3 columns of the reaction velocity versus substrate concentration in an enzymatic reaction involving untreated cells or cells treated with Puromycin.

Usage

Puromycin

Format

This data frame contains the following columns:

- `conc` a numeric vector of substrate concentrations (ppm)
- `rate` a numeric vector of instantaneous reaction rates (counts/min/min)
- `state` a factor with levels `treated` `untreated`

Details

Data on the velocity of an enzymatic reaction were obtained by Treloar (1974). The number of counts per minute of radioactive product from the reaction was measured as a function of substrate concentration in parts per million (ppm) and from these counts the initial rate (or velocity) of the reaction was calculated (counts/min/min). The experiment was conducted once with the enzyme treated with Puromycin, and once with the enzyme untreated.

Source

**quakes**

Locations of Earthquakes off Fiji

**Description**

The data set gives the locations of 1000 seismic events of MB > 4.0. The events occurred in a cube near Fiji since 1964.

**Usage**

`quakes`

**Format**

A data frame with 1000 observations on 5 variables.

- [1] lat numeric Latitude of event
- [2] long numeric Longitude
- [3] depth numeric Depth (km)
- [4] mag numeric Richter Magnitude
- [5] stations numeric Number of stations reporting

**See Also**

`SSmicmen` for other models fitted to this dataset.

**Examples**

```
require(stats); require(graphics)

           start = c(Vm = 100, K = 0.05))

summary(fm1)
summary(fm2)

## add fitted lines to the plot
conc <- seq(0.1, 2, length.out = 101)
lines(conc, predict(fm1, list(conc = conc)), lty = 1, col = 1)
lines(conc, predict(fm2, list(conc = conc)), lty = 2, col = 2)
legend(0.8, 120, levels(Puromycin$state),
       col = 1:2, lty = 1:2, pch = 1:2)

## using partial linearity
fm3 <- nls(rate ~ conc/(K + conc), data = Puromycin,
           subset = state == "treated", start = c(K = 0.05),
           algorithm = "plinear")
```
There are two clear planes of seismic activity. One is a major plate junction; the other is the Tonga trench off New Zealand. These data constitute a subsample from a larger dataset containing 5000 observations.

This is one of the Harvard PRIM-H project data sets. They in turn obtained it from Dr. John Woodhouse, Dept. of Geophysics, Harvard University.

400 triples of successive random numbers were taken from the VAX FORTRAN function RANDU running under VMS 1.5.

A data frame with 400 observations on 3 variables named x, y and z which give the first, second and third random number in the triple.

In three dimensional displays it is evident that the triples fall on 15 parallel planes in 3-space. This can be shown theoretically to be true for all triples from the RANDU generator.

These particular 400 triples start 5 apart in the sequence, that is they are ((U[5i+1], U[5i+2], U[5i+3]), i= 0, ..., 399), and they are rounded to 6 decimal places.

Under VMS versions 2.0 and higher, this problem has been fixed.

David Donoho
Examples

```r
## Not run: ## We could re-generate the dataset by the following R code
seed <- as.double(1)
RANDU <- function()
  seed <<- ((2^16 + 3) * seed) %% (2^31)
  seed/(2^31)
}
for(i in 1:400) {
  U <- c(RANDU(), RANDU(), RANDU(), RANDU(), RANDU())
  print(round(U[1:3], 6))
}
## End(Not run)
```

---

**rivers**

*Lengths of Major North American Rivers*

Description

This data set gives the lengths (in miles) of 141 “major” rivers in North America, as compiled by the US Geological Survey.

Usage

```r
rivers
```

Format

A vector containing 141 observations.

**rock**

*Measurements on Petroleum Rock Samples*

Description

Measurements on 48 rock samples from a petroleum reservoir.

Usage

```r
rock
```

Format

A data frame with 48 rows and 4 numeric columns.
Twelve core samples from petroleum reservoirs were sampled by 4 cross-sections. Each core sample was measured for permeability, and each cross-section has total area of pores, total perimeter of pores, and shape.

Source

Data from BP Research, image analysis by Ronit Katz, U. Oxford.

### sleep

#### Student’s Sleep Data

**Description**

Data which show the effect of two soporific drugs (increase in hours of sleep compared to control) on 10 patients.

**Usage**

sleep

**Format**

A data frame with 20 observations on 3 variables.

| [, 1] extra numeric increase in hours of sleep |
| [, 2] group factor drug given               |
| [, 3] ID factor patient ID                 |

**Source**

**References**

Examples

```r
require(stats)
## Student's paired t-test
with(sleep, 
  t.test(extra[group == 1], 
         extra[group == 2], paired = TRUE))

## The sleep prolongations
sleep1 <- with(sleep, extra[group == 2] - extra[group == 1])
summary(sleep1)
stripchart(sleep1, method = "stack", xlab = "hours", 
           main = "Sleep prolongation (n = 10)")
boxplot(sleep1, horizontal = TRUE, add = TRUE, 
        at = .6, pars = list(boxwex = 0.5, staplewex = 0.25))
```

stackloss

Brownlee's Stack Loss Plant Data

Description

Operational data of a plant for the oxidation of ammonia to nitric acid.

Usage

stackloss

stack.x

stack.loss

Format

stackloss is a data frame with 21 observations on 4 variables.

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>.1</td>
<td>Air Flow</td>
</tr>
<tr>
<td>.2</td>
<td>Water Temp</td>
</tr>
<tr>
<td>.3</td>
<td>Acid Conc.</td>
</tr>
<tr>
<td>.4</td>
<td>stack.loss</td>
</tr>
</tbody>
</table>

For compatibility with S-PLUS, the data sets stack.x, a matrix with the first three (independent) variables of the data frame, and stack.loss, the numeric vector giving the fourth (dependent) variable, are provided as well.

Details

“Obtained from 21 days of operation of a plant for the oxidation of ammonia (NH\textsubscript{3}) to nitric acid (HNO\textsubscript{3}). The nitric oxides produced are absorbed in a countercurrent absorption tower”. (Brownlee, cited by Dodge, slightly reformatted by MM.)

Air Flow represents the rate of operation of the plant. Water Temp is the temperature of cooling water circulated through coils in the absorption tower. Acid Conc. is the concentration of the acid circulating, minus 50, times 10: that is, 89 corresponds to 58.9 per cent acid. stack.loss (the
dependent variable) is 10 times the percentage of the ingoing ammonia to the plant that escapes from the absorption column unabsorbed; that is, an (inverse) measure of the over-all efficiency of the plant.

Source

References

Examples

```r
require(stats)
summary(lm(stack <- lm(stack.loss ~ stack.x))
```

<table>
<thead>
<tr>
<th>state</th>
<th>US State Facts and Figures</th>
</tr>
</thead>
</table>

Description

Data sets related to the 50 states of the United States of America.

Usage

- `state.abb`
- `state.area`
- `state.center`
- `state.division`
- `state.name`
- `state.region`
- `state.x77`

Details

R currently contains the following “state” data sets. Note that all data are arranged according to alphabetical order of the state names.

- `state.abb`: character vector of 2-letter abbreviations for the state names.
- `state.area`: numeric vector of state areas (in square miles).
- `state.center`: list with components named `x` and `y` giving the approximate geographic center of each state in negative longitude and latitude. Alaska and Hawaii are placed just off the West Coast.
- `state.division`: factor giving state divisions (New England, Middle Atlantic, South Atlantic, East South Central, West South Central, East North Central, West North Central, Mountain, and Pacific).
state.name: character vector giving the full state names.
state.region: factor giving the region (Northeast, South, North Central, West) that each state belongs to.

state.x77: matrix with 50 rows and 8 columns giving the following statistics in the respective columns.
- Population: population estimate as of July 1, 1975
- Illiteracy: illiteracy (1970, percent of population)
- Life Exp: life expectancy in years (1969–71)
- Murder: murder and non-negligent manslaughter rate per 100,000 population (1976)
- HS Grad: percent high-school graduates (1970)
- Frost: mean number of days with minimum temperature below freezing (1931–1960) in capital or large city
- Area: land area in square miles

sunspot.month

Monthly Sunspot Data, 1749–1997

Description

Monthly numbers of sunspots.

Usage

sunspot.month

Format

The univariate time series sunspot.year and sunspot.month contain 289 and 2988 observations, respectively. The objects are of class "ts".

Source

World Data Center-C1 For Sunspot Index Royal Observatory of Belgium, Av. Circulaire, 3, B-1180 BRUSSELS http://www.oma.be/KSB-ORB/SIDC/sidc_txt.html

See Also

sunspot.month is a longer version of sunspots that runs until 1988 rather than 1983.
Examples

```r
require(stats); require(graphics)
## Compare the monthly series
plot(sunspot.month, main = 
"sunspot.month [stats]", col = 2)
lines(sunspots) # "very barely" see something

## Now look at the difference :
all(tsp(sunspots)[c(1,3)] ==
tsp(sunspot.month)[c(1,3)]) # Start & Periodicity are the same
n1 <- length(sunspots)
table(eq <- sunspots == sunspot.month[1:n1]) #> 132 are different !
i <- which(!eq)
 rug(time(eq)[i])
s1 <- sunspots[i] ; s2 <- sunspot.month[i]
cbind(i = i, sunspots = s1, ss.month = s2,
     perc.diff = round(100*2*abs(s1-s2)/(s1+s2), 1))
```

sunspot.year  

**Yearly Sunspot Data, 1700–1988**

**Description**

Yearly numbers of sunspots.

**Usage**

sunspot.year

**Format**

The univariate time series sunspot.year contains 289 observations, and is of class "ts".

**Source**

sunspots  

**Monthly Sunspot Numbers, 1749–1983**

**Description**

Monthly mean relative sunspot numbers from 1749 to 1983. Collected at Swiss Federal Observatory, Zurich until 1960, then Tokyo Astronomical Observatory.

**Usage**

sunspots

**Format**

A time series of monthly data from 1749 to 1983.
Source

See Also

sunspot.month has a longer (and a bit different) series.

Examples

```r
require(graphics)
plot(sunspots, main = "sunspots data", xlab = "Year",
     ylab = "Monthly sunspot numbers")
```

---

### swiss

**Swiss Fertility and Socioeconomic Indicators (1888) Data**

**Description**

Standardized fertility measure and socio-economic indicators for each of 47 French-speaking provinces of Switzerland at about 1888.

**Usage**

```r
swiss
```

**Format**

A data frame with 47 observations on 6 variables, each of which is in percent, i.e., in \([0, 100]\).

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>[.1]</td>
<td>Fertility</td>
<td>(I_9), ‘common standardized fertility measure’</td>
</tr>
<tr>
<td>[.2]</td>
<td>Agriculture</td>
<td>% of males involved in agriculture as occupation</td>
</tr>
<tr>
<td>[.3]</td>
<td>Examination</td>
<td>% draftees receiving highest mark on army examination</td>
</tr>
<tr>
<td>[.4]</td>
<td>Education</td>
<td>% education beyond primary school for draftees.</td>
</tr>
<tr>
<td>[.5]</td>
<td>Catholic</td>
<td>% ‘catholic’ (as opposed to ‘protestant’).</td>
</tr>
</tbody>
</table>

All variables but ‘Fertility’ give proportions of the population.

**Details**

(paraphrasing Mosteller and Tukey):

Switzerland, in 1888, was entering a period known as the *demographic transition*; i.e., its fertility was beginning to fall from the high level typical of underdeveloped countries.

The data collected are for 47 French-speaking “provinces” at about 1888.

Here, all variables are scaled to \([0, 100]\), where in the original, all but "Catholic" were scaled to \([0, 1]\).
Files for all 182 districts in 1888 and other years have been available at http://opr.princeton.edu/archive/eufert/switz.html or http://opr.princeton.edu/archive/pefp/switz.asp. They state that variables Examination and Education are averages for 1887, 1888 and 1889.

Source

Project “16P5”, pages 549–551 in

References

Examples

```r
require(stats); require(graphics)
pairs(swiss, panel = panel.smooth, main = "swiss data",
col = 3 + (swiss$Catholic > 50))
summary(lm(Fertility ~ . , data = swiss))
```

---

**Pharmacokinetics of Theophylline**

**Description**

The Theoph data frame has 132 rows and 5 columns of data from an experiment on the pharmacokinetics of theophylline.

**Usage**

Theoph

**Format**

An object of class `c("nfnGroupedData", "nfgroupedData", "groupedData", "data.frame")` containing the following columns:

- **Subject** an ordered factor with levels 1, ..., 12 identifying the subject on whom the observation was made. The ordering is by increasing maximum concentration of theophylline observed.
- **Wt** weight of the subject (kg).
- **Dose** dose of theophylline administered orally to the subject (mg/kg).
- **Time** time since drug administration when the sample was drawn (hr).
- **conc** theophylline concentration in the sample (mg/L).
Details

Boeckmann, Sheiner and Beal (1994) report data from a study by Dr. Robert Upton of the kinetics of the anti-asthmatic drug theophylline. Twelve subjects were given oral doses of theophylline then serum concentrations were measured at 11 time points over the next 25 hours.

These data are analyzed in Davidian and Giltinan (1995) and Pinheiro and Bates (2000) using a two-compartment open pharmacokinetic model, for which a self-starting model function, SSfol, is available.

This dataset was originally part of package nlme, and that has methods (including for [ as.data.frame plot and print) for its grouped-data classes.

Source

SSfol

Examples

require(stats); require(graphics)

coplot(conc ~ Time | Subject, data = Theoph, show.given = FALSE)
Theoph.4 <- subset(Theoph, Subject == 4)
fm1 <- nls(conc ~ SSfol(Dose, Time, 1Ke, 1Ka, 1Cl),
  data = Theoph.4)
summary(fm1)
plot(conc ~ Time, data = Theoph.4,
  xlab = "Time since drug administration (hr)",
  ylab = "Theophylline concentration (mg/L)",
  main = "Observed concentrations and fitted model",
  sub = "Theophylline data - Subject 4 only",
  las = 1, col = 4)
xvals <- seq(0, par("usr")[2], length.out = 55)
lines(xvals, predict(fm1, newdata = list(Time = xvals)),
  col = 4)

Titanic

Survival of passengers on the Titanic

Description

This data set provides information on the fate of passengers on the fatal maiden voyage of the ocean liner 'Titanic', summarized according to economic status (class), sex, age and survival.
Usage

Titanic

Format

A 4-dimensional array resulting from cross-tabulating 2201 observations on 4 variables. The variables and their levels are as follows:

<table>
<thead>
<tr>
<th>No</th>
<th>Name</th>
<th>Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Class</td>
<td>1st, 2nd, 3rd, Crew</td>
</tr>
<tr>
<td>2</td>
<td>Sex</td>
<td>Male, Female</td>
</tr>
<tr>
<td>3</td>
<td>Age</td>
<td>Child, Adult</td>
</tr>
<tr>
<td>4</td>
<td>Survived</td>
<td>No, Yes</td>
</tr>
</tbody>
</table>

Details

The sinking of the Titanic is a famous event, and new books are still being published about it. Many well-known facts—from the proportions of first-class passengers to the ‘women and children first’ policy, and the fact that that policy was not entirely successful in saving the women and children in the third class—are reflected in the survival rates for various classes of passenger.

These data were originally collected by the British Board of Trade in their investigation of the sinking. Note that there is not complete agreement among primary sources as to the exact numbers on board, rescued, or lost.

Due in particular to the very successful film ‘Titanic’, the last years saw a rise in public interest in the Titanic. Very detailed data about the passengers is now available on the Internet, at sites such as Encyclopedia Titanica (http://www.rmlc.co.uk/eduweb/sites/phind).

Source

The source provides a data set recording class, sex, age, and survival status for each person on board of the Titanic, and is based on data originally collected by the British Board of Trade and reprinted in:

Examples

```r
require(graphics)
mosaicplot(Titanic, main = "Survival on the Titanic")
## Higher survival rates in children?
apply(Titanic, c(3, 4), sum)
## Higher survival rates in females?
apply(Titanic, c(2, 4), sum)
## Use loglm() in package 'MASS' for further analysis ...
```
ToothGrowth  

*The Effect of Vitamin C on Tooth Growth in Guinea Pigs*

**Description**

The response is the length of odontoblasts (teeth) in each of 10 guinea pigs at each of three dose levels of Vitamin C (0.5, 1, and 2 mg) with each of two delivery methods (orange juice or ascorbic acid).

**Usage**

ToothGrowth

**Format**

A data frame with 60 observations on 3 variables.

<table>
<thead>
<tr>
<th>.1</th>
<th>.2</th>
<th>.3</th>
</tr>
</thead>
<tbody>
<tr>
<td>len</td>
<td>supp</td>
<td>dose</td>
</tr>
<tr>
<td>numeric</td>
<td>factor</td>
<td>numeric</td>
</tr>
<tr>
<td>Tooth length</td>

<td>Dose in milligrams</td>
</tr>
</tbody>
</table>

**Source**

**References**

**Examples**

```r
require(graphics)
coplot(len ~ dose | supp, data = ToothGrowth, panel = panel.smooth,
xlab = "ToothGrowth data: length vs dose, given type of supplement")
```

---

treering  

*Yearly Treering Data, -6000–1979*

**Description**

Contains normalized tree-ring widths in dimensionless units.

**Usage**

treering

**Format**

A univariate time series with 7981 observations. The object is of class "ts". Each tree ring corresponds to one year.
Details
The data were recorded by Donald A. Graybill, 1980, from Gt Basin Bristlecone Pine 2805M, 3726-11810 in Methuselah Walk, California.

Source

References
For background on Bristlecone pines and Methuselah Walk, see http://www.sonic.net/bristlecone/; for some photos see http://www.ltrr.arizona.edu/~hallman/sitephotos/meth.html

```r
# Description
This data set provides measurements of the girth, height and volume of timber in 31 felled black cherry trees. Note that girth is the diameter of the tree (in inches) measured at 4 ft 6 in above the ground.

# Usage
trees

# Format
A data frame with 31 observations on 3 variables.

<table>
<thead>
<tr>

## i.e., Volume ~ c * Height * Girth^2 seems reasonable

---

UCBAAdmissions | Student Admissions at UC Berkeley

**Description**

Aggregate data on applicants to graduate school at Berkeley for the six largest departments in 1973 classified by admission and sex.

**Usage**

UCBAAdmissions

**Format**

A 3-dimensional array resulting from cross-tabulating 4526 observations on 3 variables. The variables and their levels are as follows:

<table>
<thead>
<tr>
<th>No</th>
<th>Name</th>
<th>Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Admit</td>
<td>Admitted, Rejected</td>
</tr>
<tr>
<td>2</td>
<td>Gender</td>
<td>Male, Female</td>
</tr>
<tr>
<td>3</td>
<td>Dept</td>
<td>A, B, C, D, E, F</td>
</tr>
</tbody>
</table>

**Details**

This data set is frequently used for illustrating Simpson’s paradox, see Bickel et al. (1975). At issue is whether the data show evidence of sex bias in admission practices. There were 2691 male applicants, of whom 1198 (44.5%) were admitted, compared with 1835 female applicants of whom 557 (30.4%) were admitted. This gives a sample odds ratio of 1.83, indicating that males were almost twice as likely to be admitted. In fact, graphical methods (as in the example below) or log-linear modelling show that the apparent association between admission and sex stems from differences in the tendency of males and females to apply to the individual departments (females used to apply more to departments with higher rejection rates).

This data set can also be used for illustrating methods for graphical display of categorical data, such as the general-purpose mosaic plot or the fourfold display for 2-by-2-by-k tables. See the home page of Michael Friendly (http://www.math.yorku.ca/SCS/friendly.html) for further information.

**USJudgeRatings**

**Lawyers’ Ratings of State Judges in the US Superior Court**

**Description**

Lawyers’ ratings of state judges in the US Superior Court.

**Usage**

USJudgeRatings
USPersonalExpenditure

Format

A data frame containing 43 observations on 12 numeric variables.

[.1] CONT  Number of contacts of lawyer with judge.
[.2] INTG  Judicial integrity.
[.3] DMNR  Demeanor.
[.5] CFMG  Case flow managing.
[.6] DECI  Prompt decisions.
[.7] PREP  Preparation for trial.
[.8] FAMI  Familiarity with law.
[.9] ORAL  Sound oral rulings.
[.10] WRIT  Sound written rulings.
[.11] PHYS  Physical ability.
[.12] RTEN  Worthy of retention.

Source

New Haven Register, 14 January, 1977 (from John Hartigan).

Examples

```r
require(graphics)
pairs(USJudgeRatings, main = "USJudgeRatings data")
```

USPersonalExpenditure  Personal Expenditure Data

Description

This data set consists of United States personal expenditures (in billions of dollars) in the categories; food and tobacco, household operation, medical and health, personal care, and private education for the years 1940, 1945, 1950, 1955 and 1960.

Usage

USPersonalExpenditure

Format

A matrix with 5 rows and 5 columns.

Source

References

Examples

```r
require(stats) # for medpolish
USPersonalExpenditure
medpolish(log10(USPersonalExpenditure))
```

uspop

**Populations Recorded by the US Census**

**Description**

This data set gives the population of the United States (in millions) as recorded by the decennial census for the period 1790–1970.

**Usage**

uspop

**Format**

A time series of 19 values.

**Source**

Examples

```r
require(graphics)
plot(uspop, log = "y", main = "uspop data", xlab = "Year",
     ylab = "U.S. Population (millions)")
```

VADeaths

**Death Rates in Virginia (1940)**

**Description**

Death rates per 1000 in Virginia in 1940.

**Usage**

VADeaths

**Format**

A matrix with 5 rows and 4 columns.

**Details**

The death rates are measured per 1000 population per year. They are cross-classified by age group (rows) and population group (columns). The age groups are: 50–54, 55–59, 60–64, 65–69, 70–74 and the population groups are Rural/Male, Rural/Female, Urban/Male and Urban/Female.

This provides a rather nice 3-way analysis of variance example.
Source

References

Examples

```r
require(stats); require(graphics)

n <- length(dr <- c(VADeaths))
nam <- names(VADeaths)
d.VAD <- data.frame(
  Drate = dr,

**volcano**  
*Topographic Information on Auckland's Maunga Whau Volcano*

Description

Maunga Whau (Mt Eden) is one of about 50 volcanos in the Auckland volcanic field. This data set gives topographic information for Maunga Whau on a 10m by 10m grid.

Usage

`volcano`

Format

A matrix with 87 rows and 61 columns, rows corresponding to grid lines running east to west and columns to grid lines running south to north.

Source

Digitized from a topographic map by Ross Ihaka. These data should not be regarded as accurate.

See Also

`filled.contour` for a nice plot.
The Number of Breaks in Yarn during Weaving

Description
This data set gives the number of warp breaks per loom, where a loom corresponds to a fixed length of yarn.

Usage
warpbreaks

Format
A data frame with 54 observations on 3 variables.

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>breaks</td>
<td>numeric</td>
<td>The number of breaks</td>

```
women

Average Heights and Weights for American Women

Description
This data set gives the average heights and weights for American women aged 30–39.

Usage
women

Format
A data frame with 15 observations on 2 variables.

\[
\begin{array}{ll}
[,1] & \text{height} & \text{numeric} & \text{Height (in)} \\
[,2] & \text{weight} & \text{numeric} & \text{Weight (lbs)} \\
\end{array}
\]

Details
The data set appears to have been taken from the American Society of Actuaries *Build and Blood Pressure Study* for some (unknown to us) earlier year.

The World Almanac notes: “The figures represent weights in ordinary indoor clothing and shoes, and heights with shoes”.

Source

References

Examples
```r
require(graphics)
plot(women, xlab = "Height (in)", ylab = "Weight (lb)",
     main = "women data: American women aged 30-39")
```

WorldPhones

The World’s Telephones

Description
The number of telephones in various regions of the world (in thousands).

Usage
WorldPhones
WWWusage

Format

A matrix with 7 rows and 8 columns. The columns of the matrix give the figures for a given region, and the rows the figures for a year.

The regions are: North America, Europe, Asia, South America, Oceania, Africa, Central America.

Source

References

Examples

```r
require(graphics)
matplot(rownames(WorldPhones), WorldPhones, type = "b", log = "y",
xlab = "Year", ylab = "Number of telephones (1000’s)"
legend(1951.5, 80000, colnames(WorldPhones), col = 1:6, lty = 1:5,
pch = rep(21, 7))
title(main = "World phones data: log scale for response")
```

WWWusage

Internet Usage per Minute

Description

A time series of the numbers of users connected to the Internet through a server every minute.

Usage

WWWusage

Format

A time series of length 100.

Source

References

Examples

```r
require(graphics)
work <- diff(WWWusage)
par(mfrow = c(2, 1)); plot(WWWusage); plot(work)
## Not run:
require(stats)
aics <- matrix(, 6, 6, dimnames = list(p = 0:5, q = 0:5))
for(q in 1:5) aics[, 1+q] <- arima(WWWusage, c(0, 1, q),
   optim.control = list(maxit = 500))$aic
for(p in 1:5)
   for(q in 0:5) aics[1+p, 1+q] <- arima(WWWusage, c(p, 1, q),
      optim.control = list(maxit = 500))$aic
round(aics - min(aics, na.rm = TRUE), 2)
## End(Not run)
```
Chapter 4

The grDevices package

Description

Graphics devices and support for base and grid graphics

Details

This package contains functions which support both base and grid graphics.
For a complete list of functions, use `library(help = "grDevices")`.

Author(s)

R Core Team and contributors worldwide
Maintainer: R Core Team <R-core@r-project.org>

adjustcolor

Adjust Colors in One or More Directions Conveniently.

Description

Adjust or modify a vector of colors by “turning knobs” on one or more coordinates in \((r, g, b, \alpha)\) space, typically by up or down scaling them.

Usage

```r
adjustcolor(col, alpha.f = 1, red.f = 1, green.f = 1, blue.f = 1,
offset = c(0, 0, 0, 0),
transform = diag(c(red.f, green.f, blue.f, alpha.f)))
```
Arguments

- `col`: vector of colors, in any format that `col2rgb()` accepts
- `alpha.f`: factor modifying the opacity alpha; typically in [0,1]
- `red.f`, `green.f`, `blue.f`: factors modifying the "red-", "green-" or "blue-"ness of the colors, respectively.
- `offset`
- `transform`

Value

a color vector of the same length as `col`, effectively the result of `rgb()`.

See Also

`rgb, col2rgb`. For more sophisticated color constructions: `convertColor`

Examples

```r
## Illustrative examples:
opal <- palette("default")
stopifnot(identical(adjustcolor(1:8, 0.75),
                     adjustcolor(palette(), 0.75)))
cbind(palette(), adjustcolor(1:8, 0.75))

## alpha = 1/2 * previous alpha --> opaque colors
x <- palette(adjustcolor(palette(), 0.5))
sines <- outer(1:20, 1:4, function(x, y) sin(x / 20 * pi * y))
matplot(sines, type = "b", pch = 21:23, col = 2:5, bg = 2:5,
       main = "Using an 'opaque ('translucent') color palette")

x. <- adjustcolor(x, offset = c(0.5, 0.5, 0.5, 0.5), # <= "more white"
                  transform = diag(c(.7, .7, .7, .6)))
cbind(x, x.)

op <- par(bg = adjustcolor("goldenrod", offset = -rep(.4, 4)), xpd = NA)
plot(0:9, 0:9, type = "n", axes = FALSE, xlab = "", ylab = "",
     main = "adjustcolor() -> translucent")
text(1:8, labels = paste0("++", c(0, 0, 0, 0)), col = x., cex = 8)
par(op)

## and

(M <- cbind( rbind( matrix(1/3, 3, 3), 0), c(0, 0, 0, 1)))
adjustcolor(x, transform = M)

## revert to previous palette: active
palette(opal)
```
as.graphicsAnnot Coerce an Object for Graphics Annotation

Description
Coerce an \( R \) object into a form suitable for graphics annotation.

Usage
as.graphicsAnnot(x)

Arguments
x an \( R \) object

Details
Expressions, calls and names (as used by \texttt{plotmath}) are passed through unchanged. All other objects
with an explicit class (as determined by \texttt{is.object}) are coerced by \texttt{as.character} to character
vectors.
All the \texttt{graphics} and \texttt{grid} functions which use this coerce calls and names to expressions internally.

Value
A language object or a character vector.

as.raster Create a Raster Object

Description
Functions to create a raster object (representing a bitmap image) and coerce other objects to a raster
object.

Usage
is.raster(x)
as.raster(x, ...)

## S3 method for class 'logical'
as.raster(x, max = 1, ...)
## S3 method for class 'numeric'
as.raster(x, max = 1, ...)
## S3 method for class 'character'
as.raster(x, max = 1, ...)
## S3 method for class 'matrix'
as.raster(x, max = 1, ...)
## S3 method for class 'array'
as.raster(x, max = 1, ...)
Arguments

\[
x \quad \text{Any R object.}
\]
\[
\text{max} \quad \text{number giving the maximum of the color values range.}
\]
\[
\text{...} \quad \text{further arguments passed to or from other methods.}
\]

Details

An object of class "raster" is a matrix of colour values as given by \texttt{rgb} representing a bitmap image.

It is not expected that the user will need to call these functions directly; functions to render bitmap images in graphics packages will make use of the \texttt{as.raster()} function to generate a raster object from their input.

The \texttt{as.raster()} function is generic so methods can be written to convert other R objects to a raster object.

The default implementation for numeric matrices interprets scalar values on black-to-white scale.

Raster objects can be subsetted like a matrix and it is possible to assign to a subset of a raster object.

There is a method for converting a raster object to a matrix (of colour strings).

Raster objects can be compared for equality or inequality (with each other or with a colour string).

There is a \texttt{is.na} method which returns a logical matrix of the same dimensions as the raster object. Note that \texttt{NA} values are interpreted as the fully transparent colour by some (but not all) graphics devices.

Value

For \texttt{as.raster()}, a raster object.

For \texttt{is.raster()}, a logical indicating whether \texttt{x} is a raster object.

Examples

\begin{verbatim}
# A red gradient
as.raster(matrix(hcl(0, 80, seq(50, 80, 10)),
               nrow = 4, ncol = 5))

# Vectors are 1-column matrices ...
# character vectors are color names ...
as.raster(hcl(0, 80, seq(50, 80, 10)))
# numeric vectors are greyscale ...
as.raster(1:5, max = 5)
# logical vectors are black and white ...
as.raster(1:10 %% 2 == 0)

# ... unless nrow/ncol are supplied ...
as.raster(1:10 %% 2 == 0, nrow = 1)

# Matrix can also be logical or numeric ...
as.raster(matrix(c(TRUE, FALSE), nrow = 3, ncol = 2))
as.raster(matrix(1:3/4, nrow = 3, ncol = 4))

# An array can be 3-plane numeric (R, G, B planes) ...
as.raster(array(c(0:1, rep(0.5, 4)), c(2, 1, 3)))
\end{verbatim}
axisTicks

Compute Pretty Axis Tick Scales

Description

Compute pretty axis scales and tick mark locations, the same way as traditional R graphics do it. This is interesting particularly for log scale axes.

Usage

axisTicks(usr, log, axp = NULL, nint = 5)
.axisPars(usr, log = FALSE, nintLog = 5)

Arguments

usr numeric vector of length 2, with c(min, max) axis extents.
log logical indicating if a log scale is (thought to be) in use.
axp numeric vector of length 3, c(mi, ma, n.), with identical meaning to par("?axp") (where ? is x or y), namely “pretty” axis extents, and an integer code n..
nint, nintLog positive integer value indicating (approximately) the desired number of intervals. nintLog is used only for the case log = TRUE.

Details

axisTicks(usr, *) calls .axisPars(usr, ..) when axp is missing (or NULL).

Value

axisTicks() returns a numeric vector of potential axis tick locations, of length approximately nint+1.
.axisPars() returns a list with components

axp numeric vector of length 2, c(min., max.), of pretty axis extents.
n integer (code), with the same meaning as par("?axp")[3].
See Also

axTicks; axis, and par (from the graphics package).

Examples

###--- Demonstrating correspondence between graphics'
###--- axis() and the graphics-engine agnostic axisTicks():

```r
require("graphics")
plot(1:10*0.1:10); (pu <- par("usr"))
aX <- function(side, at, ...)
    axis(side, at = at, labels = FALSE, lwd.ticks = 2, col.ticks = 2,
        tck = 0.05, ...)
aX(1, print(xa <- axisTicks(pu[1:2], log = FALSE))) # x axis
aX(2, print(ya <- axisTicks(pu[3:4], log = FALSE))) # y axis
axisTicks(pu[3:4], log = FALSE, n = 10)

plot(10*(0:10), log = "y"); (pu <- par("usr"))
aX(2, print(ya <- axisTicks(pu[3:4], log = TRUE))) # y axis

plot(2*(0:9), log = "y"); (pu <- par("usr"))
aX(2, print(ya <- axisTicks(pu[3:4], log = TRUE))) # y axis
```

---

**boxplot.stats**  
*Box Plot Statistics*

**Description**

This function is typically called by another function to gather the statistics necessary for producing box plots, but may be invoked separately.

**Usage**

```
boxplot.stats(x, coef = 1.5, do.conf = TRUE, do.out = TRUE)
```

**Arguments**

- `x` a numeric vector for which the boxplot will be constructed (NA's and NaN's are allowed and omitted).
- `coef` this determines how far the plot ‘whiskers’ extend out from the box. If coef is positive, the whiskers extend to the most extreme data point which is no more than coef times the length of the box away from the box. A value of zero causes the whiskers to extend to the data extremes (and no outliers be returned).
- `do.conf`, `do.out` logicals; if FALSE, the conf or out component respectively will be empty in the result.
boxplot.stats

Details

The two ‘hinges’ are versions of the first and third quartile, i.e., close to quantile(x, c(1, 3)/4). The hinges equal the quartiles for odd \( n \) (where \( n \leftarrow \text{length}(x) \)) and differ for even \( n \). Whereas the quartiles only equal observations for \( n \%\% 4 = 1 (n \equiv 1 \text{ mod } 4) \), the hinges do so additionally for \( n \%\% 4 = 2 (n \equiv 2 \text{ mod } 4) \), and are in the middle of two observations otherwise.

The notches (if requested) extend to \( \pm 1.58 IQR/\sqrt{n} \). This seems to be based on the same calculations as the formula with 1.57 in Chambers et al. (1983, p. 62), given in McGill et al. (1978, p. 16). They are based on asymptotic normality of the median and roughly equal sample sizes for the two medians being compared, and are said to be rather insensitive to the underlying distributions of the samples. The idea appears to be to give roughly a 95% confidence interval for the difference in two medians.

Value

List with named components as follows:

- stats: a vector of length 5, containing the extreme of the lower whisker, the lower ‘hinge’, the median, the upper ‘hinge’ and the extreme of the upper whisker.
- n: the number of non-NA observations in the sample.
- conf: the lower and upper extremes of the ‘notch’ (if do.conf). See the details.
- out: the values of any data points which lie beyond the extremes of the whiskers (if do.out).

Note that $stats$ and $conf$ are sorted in increasing order, unlike $S$, and that $n$ and $out$ include any \( \pm \Inf \) values.

References

See Also

fivenum, boxplot, bxp.

Examples

```r
require(stats)
x <- c(1:100, 1000)
(b1 <- boxplot.stats(x))
(b2 <- boxplot.stats(x, do.conf = FALSE, do.out = FALSE))
stopifnot(b1 $ stats == b2 $ stats) # do.out = FALSE is still robust
boxplot.stats(x, coef = 3, do.conf = FALSE)
## no outlier treatment:
boxplot.stats(x, coef = 0)
```
cairo

Cairo-based SVG, PDF and PostScript Graphics Devices

Description

Graphics devices for SVG, PDF and PostScript graphics files.

Usage

svg(filename = if(onefile) "Rplots.svg" else "Rplot%03d.svg",
     width = 7, height = 7, pointsize = 12,
     onefile = FALSE, family = "sans", bg = "white",
     antialias = c("default", "none", "gray", "subpixel"))

cairo_pdf(filename = if(onefile) "Rplots.pdf" else "Rplot%03d.pdf",
          width = 7, height = 7, pointsize = 12,
          onefile = FALSE, family = "sans", bg = "white",
          antialias = c("default", "none", "gray", "subpixel"))

cairo_ps(filename = if(onefile) "Rplots.ps" else "Rplot%03d.ps",
         width = 7, height = 7, pointsize = 12,
         onefile = FALSE, family = "sans", bg = "white",
         antialias = c("default", "none", "gray", "subpixel"))

Arguments

filename  the name of the output file. The page number is substituted if a C integer format is included in the character string, as in the default. (The result must be less than PATH_MAX characters long, and may be truncated if not. See postscript for further details.) Tilde expansion is performed where supported by the platform.

width  the width of the device in inches.

height  the height of the device in inches.

pointsize  the default pointsize of plotted text (in big points).

onefile  should all plots appear in one file or in separate files?

cfamily  one of the device-independent font families, "sans", "serif" and "mono", or a character string specify a font family to be searched for in a system-dependent way. See, the 'Cairo fonts' section in the help for x11.

bg  the initial background colour: can be overridden by setting par("bg").

antialias  string, the type of anti-aliasing (if any) to be used; defaults to "default".

boxplot.stats(c(x, NA)) # slight change : n is 101
(r <- boxplot.stats(c(x, -1:1/0)))
stopifnot(r$out == c(1e000, -Inf, Inf))
Details

SVG (Scalar Vector Graphics) is a W3C standard for vector graphics. See http://www.w3.org/Graphics/SVG/. The output is SVG version 1.1 for onefile = FALSE (the default), otherwise SVG 1.2. (Very few SVG viewers are capable of displaying multi-page SVG files.) Although this only requires cairo >= 1.2, the output produced by cairo 1.2.4 (in Centos/RHEL 5) is incorrect.

Note that unlike postscript and pdf, cairo_pdf and cairo_ps sometimes record bitmaps and not vector graphics: a resolution of 72dpi is used. On the other hand, they can (on suitable platforms) include a much wider range of UTF-8 glyphs, and embed the fonts used.

The output produced by cairo_ps(onefile = FALSE) will be encapsulated postscript on a platform with cairo >= 1.6.

R can be compiled without support for any of these devices: this will be reported if you attempt to use them on a system where they are not supported. They all require cairo version 1.2 or later.

If you plot more than one page on one of these devices and do not include something like \texttt{Ed} for the sequence number in file (or set onefile = TRUE) the file will contain the last page plotted.

There is full support of transparency, but using this is one of the things liable to trigger bitmap output (and will always do so for cairo_ps).

Value

A plot device is opened: nothing is returned to the R interpreter.

Anti-aliasing

Anti-aliasing is applied to both graphics and fonts. It is generally preferable for lines and text, but can lead to undesirable effects for fills, e.g. for image plots, and so is never used for fills.

antialias = "default" is in principle platform-dependent, but seems most often equivalent to antialias = "gray".

Conventions

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”.

• The default device size is in pixels (svg) or inches.
• Font sizes are in big points.
• The default font family is Helvetica.
• Line widths are multiples of 1/96 inch.
• Circle radii have a minimum of 1/72 inch.
• Colours are interpreted by the viewing application.

See Also

Devices, dev.print, pdf, postscript
capabilities to see if cairo is supported.
check.options Set Options with Consistency Checks

Description
Utility function for setting options with some consistency checks. The \texttt{attributes} of the new settings in \texttt{new} are checked for consistency with the \texttt{model} (often default) list in \texttt{name.opt}.

Usage
\begin{verbatim}
check.options(new, name.opt, reset = FALSE, assign.opt = FALSE,
            envir = .GlobalEnv,
            check.attributes = c("mode", "length"),
            override.check = FALSE)
\end{verbatim}

Arguments
\begin{itemize}
\setlength\itemsep{0pt}
\item new a \texttt{named} list
\item name.opt character with the name of \texttt{R} object containing the default list.
\item reset logical; if \texttt{TRUE}, reset the options from \texttt{name.opt}. If there is more than one \texttt{R} object with name \texttt{name.opt}, remove the first one in the \texttt{search()} path.
\item assign.opt logical; if \texttt{TRUE}, assign the ...
\item envir the \texttt{environment} used for \texttt{get} and \texttt{assign}.
\item check.attributes character containing the attributes which \texttt{check.options} should check.
\item override.check logical vector of length \texttt{length(new)} (or 1 which entails recycling). For those \texttt{new[i]} where \texttt{override.check[i] == TRUE}, the checks are overridden and the changes made anyway.
\end{itemize}

Value
A list of components with the same names as the one called \texttt{name.opt}. The values of the components are changed from the new list, as long as these pass the checks (when these are not overridden according to \texttt{override.check}).

Note
Option "names" is exempt from all the checks or warnings, as in the application it can be \texttt{NULL} or a variable-length character vector.

Author(s)
Martin Maechler

See Also
\texttt{ps.options} and \texttt{pdf.options}, which use \texttt{check.options}.  
### Examples

```r
(L1 <- list(a = 1:3, b = pi, ch = "CH"))
check.options(list(a = 0:2), name.opt = "L1")
check.options(NULL, reset = TRUE, name.opt = "L1")
```

### Description

Computes the subset of points which lie on the convex hull of the set of points specified.

### Usage

```r
chull(x, y = NULL)
```

### Arguments

- `x, y`: coordinate vectors of points. This can be specified as two vectors `x` and `y`, a 2-column matrix `x`, a list `x` with two components, etc, see `xy.coords`.

### Details

`xy.coords` is used to interpret the specification of the points. The algorithm is that given by Eddy (1977).

### Value

An integer vector giving the indices of the unique points lying on the convex hull, in clockwise order. (The first will be returned for duplicate points.)

### References

### See Also

- `xy.coords`, `polygon`
Examples

```r
X <- matrix(stats::rnorm(2000), ncol = 2)
chull(X)
## Not run:
# Example usage from graphics package
plot(X, cex = 0.5)
  hpts <- chull(X)
  hpts <- c(hpts, hpts[1])
  lines(X[hpts, ])
```

## End(Not run)

---

**cm**

*Unit Transformation*

Description

Translates from inches to cm (centimeters).

Usage

```r
cm(x)
```

Arguments

- **x**
  numeric vector

Examples

```r
cm(1)  # = 2.54
```

```r
## Translate *from* cm *to* inches:
10 / cm(1) # -> 10cm are 3.937 inches
```

---

**col2rgb**

*Color to RGB Conversion*

Description

R color to RGB (red/green/blue) conversion.

Usage

```r
col2rgb(col, alpha = FALSE)
```

Arguments

- **col**
  vector of any of the three kinds of R color specifications, i.e., either a color name (as listed by `colors()`), a hexadecimal string of the form "#rrggbb" or "#rrggbbaa" (see `rgb`), or a positive integer i meaning `palette()`[i].
- **alpha**
  logical value indicating whether the alpha channel (opacity) values should be returned.
Details

NA (as integer or character) and "NA" mean transparent.

Values of col not of one of these types are coerced: real vectors are coerced to integer and other types to character. (Prior to R 3.0.2 factors were coerced to their integer codes: in all other cases the class is still ignored when doing the coercion.)

Prior to R 3.0.0, col = 0 could be used to refer to the background color of the current device in base graphics: this is now an error.

Before R 3.0.0 negative integer values were accepted and wrapped around to colors in the palette: this was not how either the base or grid graphics systems usually resolved such values. They are now always an error.

Value

An integer matrix with three or four (for alpha = TRUE) rows and number of columns the length of col. If col has names these are used as the column names of the return value.

Author(s)

Martin Maechler and the R core team.

Examples

col2rgb("peachpuff")
col2rgb(c(blu = "royalblue", reddish = "tomato"))  # note: colnames

col2rgb(1:8)  # the ones from the palette() (if the default)

col2rgb(paste0("gold", 1:4))

col2rgb("#08a0ff")
## all three kinds of color specifications:
col2rgb(c(red = "red", hex = "#abdef"))
col2rgb(c(palette = 1:3))

##-- NON-INTRODUCTORY examples --

gC <- col2rgb(paste0("gray", 0:100))
table(print(diff(grC["red",])))  # '2' or '3': almost equidistant
## The 'named' grays are in between {"slate gray" is not gray, strictly}
col2rgb(c(g66 = "gray66", dark = "dark gray", g67 = "gray67",
g74 = "gray74", gray = "gray", g75 = "gray75",
g82 = "gray82", light = "light gray", g83 = "gray83"))

crgb <- col2rgb(cc <- colors())
colnames(crgb) <- cc
t(t(crgb))  # The whole table

ccodes <- c(256*(2:0) %*% crgb)  # = internal codes
## How many names are 'aliases' of each other:
colorRamp

Description

These functions return functions that interpolate a set of given colors to create new color palettes (like `topo.colors`) and color ramps, functions that map the interval $[0, 1]$ to colors (like `grey`).

Usage

```r
colorRamp(colors, bias = 1, space = c("rgb", "Lab"),
           interpolate = c("linear", "spline"))
colorRampPalette(colors, ...)
```

Arguments

- **colors** colors to interpolate; must be a valid argument to `col2rgb()`.
- **bias** a positive number. Higher values give more widely spaced colors at the high end.
- **space** a character string; interpolation in RGB or CIE Lab color spaces.
- **interpolate** use spline or linear interpolation.
- **...** arguments to pass to `colorRamp`.

Details

The CIE Lab color space is approximately perceptually uniform, and so gives smoother and more uniform color ramps. On the other hand, palettes that vary from one hue to another via white may have a more symmetrical appearance in RGB space.

The conversion formulas in this function do not appear to be completely accurate and the color ramp may not reach the extreme values in Lab space. Future changes in the R color model may change the colors produced with `space = "Lab"`.
**colorRamp**

**Value**

colorRamp returns a function with argument a vector of values between 0 and 1 that are mapped to a numeric matrix of RGB color values with one row per color and 3 columns.
colorRampPalette returns a function that takes an integer argument (the required number of colors) and returns a character vector of colors (see rgb) interpolating the given sequence (similar to heat.colors or terrain.colors).

**See Also**

Good starting points for interpolation are the “sequential” and “diverging” ColorBrewer palettes in the RColorBrewer package.
splinefun or approxfun are used for interpolation.

**Examples**

```r
## Both return a *function*:
colorRamp(c("red", "green")( (0:4)/4 ) ## (x), x in [0,1]
colorRampPalette(c("blue", "red")( 4 ) ## (n)

require(graphics)

## Here space="rgb" gives palettes that vary only in saturation,
## as intended.  
## With space="Lab" the steps are more uniform, but the hues
## are slightly purple.
filled.contour(volcano,
  color.palette =
    colorRampPalette(c("red", "white", "blue")),
    asp = 1)
filled.contour(volcano,
  color.palette =
    colorRampPalette(c("red", "white", "blue"),
                   space = "Lab"),
    asp = 1)

## Interpolating a 'sequential' ColorBrewer palette
Y1OrBr <- c("#FFFFF4",="#FED98E","#FF9929","#D95F0E","#993404")
filled.contour(volcano,
  color.palette = colorRampPalette(Y1OrBr, space = "Lab"),
  asp = 1)
filled.contour(volcano,
  color.palette = colorRampPalette(Y1OrBr, space = "Lab",
                                      bias = 0.5),
  asp = 1)

## 'jet.colors' is "as in Matlab"
## (and hurting the eyes by over-saturation)
jet.colors <-
  colorRampPalette(c("#0000F", "blue", "#007FFFF", "cyan",
                  "#7FFFFF", "yellow", "#FFFF00", "red", "#F00000"))
filled.contour(volcano, color = jet.colors, asp = 1)

## space="Lab" helps when colors don't form a natural sequence
m <- outer(1:20,1:20,function(x,y) sin(sqrt(x*y))/3)
rgb.palette <- colorRampPalette(c("red", "orange", "blue"),
```

```r
```
colors

**Description**

Returns the built-in color names which R knows about.

**Usage**

```r
colors (distinct = FALSE)
colours (distinct = FALSE)
```

**Arguments**

- `distinct` logical indicating if the colors returned should all be distinct; e.g., "snow" and "snow1" are effectively the same point in the \((0:255)^2\) RGB space.

**Details**

These color names can be used with a `col=` specification in graphics functions. An even wider variety of colors can be created with primitives `rgb`, `hsv` and `hcl`, or the derived `rainbow`, `heat.colors`, etc.

**Value**

A character vector containing all the built-in color names.

**See Also**

`palette` for setting the 'palette' of colors for `par(col=<num>)`; `rgb`, `hsv`, `hcl`, `gray`; `rainbow` for a nice example; and `heat.colors`, `topo.colors` for images.

`col2rgb` for translating to RGB numbers and extended examples.

**Examples**

```r
c1 <- colors()
length(c1); c1[1:20]

length(c1. <- colors(TRUE))
## only 502 of the 657 named ones

## ---------- Show all named colors and more:
demo("colors")
## ----------
```
contourLines

Calculate Contour Lines

Description

Calculate contour lines for a given set of data.

Usage

contourLines(x = seq(0, 1, length.out = nrow(z)),
             y = seq(0, 1, length.out = ncol(z)),
             z, nlevels = 10,
             levels = pretty(range(z, na.rm = TRUE), nlevels))

Arguments

x, y  locations of grid lines at which the values in z are measured. These must be in ascending order. By default, equally spaced values from 0 to 1 are used. If x is a list, its components x$x and x$y are used for x and y, respectively. If the list has component z this is used for z.

z  a matrix containing the values to be plotted (NAs are allowed). Note that x can be used instead of z for convenience.

nlevels  number of contour levels desired. If levels is not supplied.

levels  numeric vector of levels at which to draw contour lines.

Details

contourLines draws nothing, but returns a set of contour lines.

There is currently no documentation about the algorithm. The source code is in ‘R_HOME/src/main/plot3d.c’.

Value

A list of contours. Each contour is a list with elements:

level  The contour level.

x  The x-coordinates of the contour.

y  The y-coordinates of the contour.

See Also

options("max.contour.segments") for the maximal complexity of a single contour line.

contour.

Examples

x <- 10*1:nrow(volcano)
y <- 10*1:ncol(volcano)
contourLines(x, y, volcano)
convertColor

Convert between Colour Spaces

Description

Convert colours between their representations in standard colour spaces.

Usage

convertColor(color, from, to, from.ref.white, to.ref.white, 
scale.in = 1, scale.out = 1, clip = TRUE)

Arguments

color A matrix whose rows specify colors.
from, to Input and output color spaces. See ‘Details’ below.
from.ref.white, to.ref.white Reference whites or NULL if these are built in to the definition, as for RGB spaces. D65 is the default, see ‘Details’ for others.
scale.in, scale.out Input is divided by scale.in, output is multiplied by scale.out. Use NULL to suppress scaling when input or output is not numeric.
clip If TRUE, truncate RGB output to [0,1], FALSE return out-of-range RGB, NA set out of range colors to NaN.

Details

Color spaces are specified by objects of class colorConverter, created by colorConverter or make.rgb. Built-in color spaces may be referenced by strings: "XYZ", "sRGB", "Apple RGB", "CIE RGB", "Lab", "Luv". The converters for these colour spaces are in the object colorspace.

The "sRGB" color space is that used by standard PC monitors. "Apple RGB" is used by Apple monitors. "Lab" and "Luv" are approximately perceptually uniform spaces standardized by the Commission Internationale d’Eclairage. XYZ is a 1931 CIE standard capable of representing all visible colors (and then some), but not in a perceptually uniform way.

The Lab and Luv spaces describe colors of objects, and so require the specification of a reference ‘white light’ color. Illuminant D65 is a standard indirect daylight, Illuminant D50 is close to direct sunlight, and Illuminant A is the light from a standard incandescent bulb. Other standard CIE illuminants supported are B, C, E and D55. RGB colour spaces are defined relative to a particular reference white, and can be only approximately translated to other reference whites. The Bradford chromatic adaptation algorithm is used for this.

The RGB color spaces are specific to a particular class of display. An RGB space cannot represent all colors, and the clip option controls what is done to out-of-range colors.

For the named color spaces color must be a matrix of values in the from color space: in particular opaque colors.

Value

A 3-column matrix whose rows specify the colors.

col2rgb and colors for ways to specify colors in graphics.

make.rgb for specifying other colour spaces.

Examples

```r
## The displayable colors from four planes of Lab space
ab <- expand.grid(a = (-10:15)*10, b = (-15:15)*10)
require(graphics); require(stats) # for na.omit
par(mfrow = c(2, 2), mar = .1+c(3, 3, 3, .5), mgp = c(2, .8, 0))

Lab <- cbind(L = 20, ab)
srgb <- convertColor(Lab, from = "Lab", to = "sRGB", clip = NA)
colored <- attr(na.omit(srgb), "na.action")
srgb[clipped, ] <- 0
cols <- rgb(srgb[, 1], srgb[, 2], srgb[, 3])
image((-10:15)*10, (-15:15)*10, matrix(1:(26*26), ncol = 26), col = cols,
      xlab = "a", ylab = "b", main = "Lab: L=20")

Lab <- cbind(L = 40, ab)
srgb <- convertColor(Lab, from = "Lab", to = "sRGB", clip = NA)
colored <- attr(na.omit(srgb), "na.action")
srgb[clipped, ] <- 0
cols <- rgb(srgb[, 1], srgb[, 2], srgb[, 3])
image((-10:15)*10, (-15:15)*10, matrix(1:(26*26), ncol = 26), col = cols,
      xlab = "a", ylab = "b", main = "Lab: L=40")

Lab <- cbind(L = 60, ab)
srgb <- convertColor(Lab, from = "Lab", to = "sRGB", clip = NA)
colored <- attr(na.omit(srgb), "na.action")
srgb[clipped, ] <- 0
cols <- rgb(srgb[, 1], srgb[, 2], srgb[, 3])
image((-10:15)*10, (-15:15)*10, matrix(1:(26*26), ncol = 26), col = cols,
      xlab = "a", ylab = "b", main = "Lab: L=60")

Lab <- cbind(L = 80, ab)
srgb <- convertColor(Lab, from = "Lab", to = "sRGB", clip = NA)
colored <- attr(na.omit(srgb), "na.action")
srgb[clipped, ] <- 0
cols <- rgb(srgb[, 1], srgb[, 2], srgb[, 3])
image((-10:15)*10, (-15:15)*10, matrix(1:(26*26), ncol = 26), col = cols,
      xlab = "a", ylab = "b", main = "Lab: L=80")

cols <- t(col2rgb(palette())); rownames(cols) <- palette(); cols
zapsmall(Lab <- convertColor(cols, from = "sRGB", to = "Lab", scale.in = 255))
stoptifnot(all.equal(cols, # converting back.. getting the original:
round(convertColor(Lab, from = "Lab", to = "sRGB", scale.out = 255)),
check.attributes = FALSE))
```
densCols

Colors for Smooth Density Plots

Description
densCols produces a vector containing colors which encode the local densities at each point in a scatterplot.

Usage
densCols(x, y = NULL, nbin = 128, bandwidth,
colramp = colorRampPalette(blues9[-(1:3)]))
blues9

Arguments

x, y  the x and y arguments provide the x and y coordinates of the points. Any reasonable way of defining the coordinates is acceptable. See the function xy.coords for details. If supplied separately, they must be of the same length.
nbin  numeric vector of length one (for both directions) or two (for x and y separately) specifying the number of equally spaced grid points for the density estimation; directly used as gridsize in bkde2D().
bandwidth  numeric vector (length 1 or 2) of smoothing bandwidth(s). If missing, a more or less useful default is used. bandwidth is subsequently passed to function bkde2D.
colramp  function accepting an integer n as an argument and returning n colors.

Details
densCols computes and returns the set of colors that will be used in plotting, calling bkde2D(*, bandwidth, gridsize = nbin, ..) from package KernSmooth.
blues9 is a set of 9 color shades of blue used as the default in plotting.

Value
densCols returns a vector of length nrow(x) that contains colors to be used in a subsequent scatterplot. Each color represents the local density around the corresponding point.

Author(s)

Florian Hahne at FHCRC, originally

See Also

bkde2D from package KernSmooth; further, smoothScatter() (package graphics) which builds on the same computations as densCols.
Examples

```r
x1 <- matrix(rnorm(1e3), ncol = 2)
x2 <- matrix(rnorm(1e3, mean = 3, sd = 1.5), ncol = 2)
x <- rbind(x1, x2)
dcols <- densCols(x)
graphics::plot(x, col = dcols, pch = 20, main = "n = 1000")
```

Description

These functions provide control over multiple graphics devices.

Usage

```r
dev.cur()
dev.list()
dev.next(which = dev.cur())
dev.prev(which = dev.cur())
dev.off(which = dev.cur())
dev.set(which = dev.next())
dev.new(...)  
graphics.off()
```

Arguments

- `which`: An integer specifying a device number.
- `...`: arguments to be passed to the device selected.

Details

Only one device is the ‘active’ device: this is the device in which all graphics operations occur. There is a "null device" which is always open but is really a placeholder: any attempt to use it will open a new device specified by `getOption("device")`.

Devices are associated with a name (e.g., "X11" or "postscript") and a number in the range 1 to 63; the "null device" is always device 1. Once a device has been opened the null device is not considered as a possible active device. There is a list of open devices, and this is considered as a circular list not including the null device. `dev.next` and `dev.prev` select the next open device in the appropriate direction, unless no device is open.

`dev.off` shuts down the specified (by default the current) device. If the current device is shut down and any other devices are open, the next open device is made current. It is an error to attempt to shut down device 1. `graphics.off()` shuts down all open graphics devices. Normal termination of a session runs the internal equivalent of `graphics.off()`.

`dev.set` makes the specified device the active device. If there is no device with that number, it is equivalent to `dev.next`. If `which = 1` it opens a new device and selects that.

`dev.new` opens a new device. Normally R will open a new device automatically when needed, but this enables you to open further devices in a platform-independent way. (For which device is used see `getOption("device")`.) Note that care is needed with file-based devices such
as pdf and postscript and in that case file names such as 'Rplots.pdf', 'Rplots1.pdf', ..., 'Rplots999.pdf' are tried in turn. Only named arguments are passed to the device, and then only if they match the argument list of the device. Even so, care is needed with the interpretation of e.g. width, and for the standard bitmap devices units = "in", res = 72 is forced if neither is supplied but both width and height are.

Value

dev.cur returns a length-one named integer vector giving the number and name of the active device, or 1, the null device, if none is active.
dev.list returns the numbers of all open devices, except device 1, the null device. This is a numeric vector with a names attribute giving the device names, or NULL is there is no open device.
dev.next and dev.prev return the number and name of the next / previous device in the list of devices. This will be the null device if and only if there are no open devices.
dev.off returns the number and name of the new active device (after the specified device has been shut down).
dev.set returns the number and name of the new active device.
dev.new returns the return value of the device opened, usually invisible NULL.

layout and its links for setting up plotting regions on the current device.

Examples

## Not run: ## Unix-specific example
x11()
plot(1:10)
x11()
plot(rnorm(10))
dev.set(dev.prev())
abline(0, 1) # through the 1:10 points
dev.set(dev.next())
abline(h = 0, col = "gray") # for the residual plot
dev.set(dev.prev())
dev.off(); dev.off() # close the two X devices

## End(Not run)
dev.capture

Arguments

what

a character vector partially matching the names of the components listed in section 'Value', or NULL which lists all available capabilities.

Details

The capabilities have to be specified by the author of the graphics device, unless they can be deduced from missing hooks. Thus they will often by returned as NA, and may reflect the maximal capabilities of the underlying device where several output formats are supported by one device.

Most recent devices support semi-transparent colours provided the graphics format does (which PostScript does not). On the other hand, relatively few graphics formats support (fully or semi-) transparent backgrounds: generally the latter is found only in PDF and PNG plots.

Value

A named list with some or all of the following components, any of which may take value NA:

semiTransparency

logical: Does the device support semi-transparent colours?

transparentBackground

character: Does the device support (semi)-transparent backgrounds? Possible values are "no", "fully" (only full transparency) and "semi" (semi-transparent background colours are supported).

rasterImage

character: To what extent does the device support raster images as used by rasterImage and grid.raster? Possible values "no", "yes" and "non-missing" (support only for arrays without any missing values).

capture

logical: Does the current device support raster capture as used by grid.cap?

locator

logical: Does the current device support locator and identify?

events

character: Which events can be generated on this device? Currently this will be a subset of c("MouseDown", "MouseMove", "MouseUp", "Keybd"), but other events may be supported in the future.

See Also

See getGraphicsEvent for details on interactive events.

Examples

dev.capabilities()

dev.capture

Capture device output as a raster image

Description

dev.capture captures the current contents of a graphics device as a raster (bitmap) image.

Usage

dev.capture(native = FALSE)
Arguments

native Logical. If FALSE the result is a matrix of R color names, if TRUE the output is returned as a nativeRaster object which is more efficient for plotting, but not portable.

Details

Not all devices support capture of the output as raster bitmaps. Typically, only image-based devices do and even not all of them.

Value

NULL if the device does not support capture, otherwise a matrix of color names (for native = FALSE) or a nativeRaster object (for native = TRUE).

dev.flush

Hold or Flush Output on an On-Screen Graphics Device.

Description

This gives a way to hold/flush output on certain on-screen devices, and is ignored by other devices.

Usage

dev.hold(level = 1L)
dev.flush(level = 1L)

Arguments

level Integer >= 0. The amount by which to change the hold level. Negative values will be silently replaced by zero.

Details

Devices which implement this maintain a stack of hold levels: calling dev.hold increases the level and dev.flush decreases it. Calling dev.hold when the hold level is zero increases the hold level and inhibits graphics display. When calling dev.flush clears all pending holds the screen display is refreshed and normal operation is resumed.

This is implemented for the cairo-based X11 types with buffering. When the hold level is positive the ‘watch’ cursor is set on the device’s window.

It is available on the quartz device on OS X.

This is implemented for the windows device with buffering selected (the default). When the hold level is positive the ‘busy’ cursor is set on the device’s window.

Value

The current level after the change, invisibly. This is 0 on devices where hold levels are not supported.
**dev.interactive**  
*Is the Current Graphics Device Interactive?*

**Description**

Test if the current graphics device (or that which would be opened) is interactive.

**Usage**

```r
dev.interactive(orfNone = FALSE)
deviceIsInteractive(name = NULL)
```

**Arguments**

- `orfNone`: logical; if TRUE, the function also returns TRUE when `.Device` == "null device" and `getOption("device")` is among the known interactive devices.
- `name`: one or more device names as a character vector, or NULL to give the existing list.

**Details**

The X11 (Unix), windows (Windows) and quartz (OS X, on-screen types only) are regarded as interactive, together with JavaGD (from the package of the same name) and CairoWin and CairoX11 (from package Cairo). Packages can add their devices to the list by calling `deviceIsInteractive`.

**Value**

- `dev.interactive()` returns a logical, TRUE if and only if an interactive (screen) device is in use.
- `deviceIsInteractive` returns the updated list of known interactive devices, invisibly unless `name = NULL`.

**See Also**

- Devices for the available devices on your platform.

**Examples**

```r
dev.interactive() print(deviceIsInteractive(NULL))
```
dev.size  
*Find Size of Device Surface*

**Description**

Find the dimensions of the device surface of the current device.

**Usage**

```r
dev.size(units = c("in", "cm", "px"))
```

**Arguments**

- **units**  
  the units in which to return the value – inches, cm, or pixels (device units).

**Value**

A two-element numeric vector giving width and height of the current device; a new device is opened if there is none, similarly to `dev.new()`.

**See Also**

The size information in inches can be obtained by `par("din")`, but this provides a way to access it independent of the graphics sub-system in use. Note that `par("din")` is only updated when a new plot is started, whereas `dev.size` tracks the size as an on-screen device is resized.

**Examples**

```r
dev.size("cm")
```

dev2  
*Copy Graphics Between Multiple Devices*

**Description**

`dev.copy` copies the graphics contents of the current device to the device specified by which or to a new device which has been created by the function specified by device (it is an error to specify both which and device). (If recording is off on the current device, there are no contents to copy: this will result in no plot or an empty plot.) The device copied to becomes the current device.

`dev.print` copies the graphics contents of the current device to a new device which has been created by the function specified by device and then shuts the new device.

`dev.copy2eps` is similar to `dev.print` but produces an EPSF output file in portrait orientation (horizontal = FALSE). `dev.copy2pdf` is the analogue for PDF output.

`dev.control` allows the user to control the recording of graphics operations in a device. If displaylist is "inhibit" ("enable") then recording is turned off (on). It is only safe to change this at the beginning of a plot (just before or just after a new page). Initially recording is on for screen devices, and off for print devices.
Usage

dev.copy(device, ..., which = dev.next())
dev.print(device = postscript, ...)
dev.copy2eps(...)
dev.copy2pdf(..., out.type = "pdf")
dev.control(displaylist = c("inhibit", "enable"))

Arguments

device      A device function (e.g., x11, postscript, ...)

...          Arguments to the device function above: for dev.copy2eps arguments to postscript and for dev.copy2pdf, arguments to pdf. For dev.print, this includes which and by default any postscript arguments.

which        A device number specifying the device to copy to.

out.type     The name of the output device: can be "pdf", or "quartz" (some OS X builds) or "cairo" (Windows and some Unix-alikes, see cairo_pdf).

displaylist  A character string: the only valid values are "inhibit" and "enable".

Details

Note that these functions copy the device region and not a plot: the background colour of the device surface is part of what is copied. Most screen devices default to a transparent background, which is probably not what is needed when copying to a device such as png.

For dev.copy2eps and dev.copy2pdf, width and height are taken from the current device unless otherwise specified. If just one of width and height is specified, the other is adjusted to preserve the aspect ratio of the device being copied. The default file name is Rplot.eps or Rplot.pdf, and can be overridden by specifying a file argument.

Copying to devices such as postscript and pdf which need font families pre-specified needs extra care — R is unaware of which families were used in a plot and so they will need to manually specified by the fonts argument passed as part of .... Similarly, if the device to be copied from was opened with a family argument, a suitable family argument will need to be included in ....

The default for dev.print is to produce and print a postscript copy. This will not work unless options("printcmd") is set suitably and you have a PostScript printing system: see postscript for how to set this up. Windows users may prefer to use dev.print(win.print).

dev.print is most useful for producing a postscript print (its default) when the following applies. Unless file is specified, the plot will be printed. Unless width, height and pointsize are specified the plot dimensions will be taken from the current device, shrunk if necessary to fit on the paper. (pointsize is rescaled if the plot is shrunk.) If horizontal is not specified and the plot can be printed at full size by switching its value this is done instead of shrinking the plot region.

If dev.print is used with a specified device (even postscript) it sets the width and height in the same way as dev.copy2eps. This will not be appropriate unless the device specifies dimensions in inches, in particular not for png, jpeg, tiff and bmp unless units = "inches" is specified.

Value

dev.copy returns the name and number of the device which has been copied to.

dev.print, dev.copy2eps and dev.copy2pdf return the name and number of the device which has been copied from.
Note

Most devices (including all screen devices) have a display list which records all of the graphics operations that occur in the device. dev.copy copies graphics contents by copying the display list from one device to another device. Also, automatic redrawing of graphics contents following the resizing of a device depends on the contents of the display list.

After the command dev.control("inhibit"), graphics operations are not recorded in the display list so that dev.copy and dev.print will not copy anything and the contents of a device will not be redrawn automatically if the device is resized.

The recording of graphics operations is relatively expensive in terms of memory so the command dev.control("inhibit") can be useful if memory usage is an issue.

See Also

dev.cur and other dev.xxx functions.

Examples

```c
## Not run:
x11() # on a Unix-alike
plot(rnorm(10), main = "Plot 1")
dev.copy(device = x11)
mtext("Copy 1", 3)
dev.print(width = 6, height = 6, horizontal = FALSE) # prints it
dev.off(dev.prev())
dev.off()
## End(Not run)
```

---

dev2bitmap

**Graphics Device for Bitmap Files via Ghostscript**

Description

`bitmap` generates a graphics file. `dev2bitmap` copies the current graphics device to a file in a graphics format.

Usage

```c
bitmap(file, type = "png16m", height = 7, width = 7, res = 72,
       units = "in", pointsize, taa = NA, gaa = NA, ...)

dev2bitmap(file, type = "png16m", height = 7, width = 7, res = 72,
           units = "in", pointsize, ..., 
           method = c("postscript", "pdf"), taa = NA, gaa = NA)
```

Arguments

- `file` The output file name, with an appropriate extension.
- `type` The type of bitmap.
- `width, height` Dimensions of the display region.
dev2bitmap works by copying the current device to a postscript or pdf device, and post-processing the output file using ghostscript. bitmap works in the same way using a postscript device and post-processing the output as 'printing'.

You will need ghostscript: the full path to the executable can be set by the environment variable R_GSCMD. If this is unset, a GhostScript executable will be looked for by name on your path: on a Unix alike "gs" is used, and on Windows the setting of the environment variable GSC is used, otherwise commands "gswin32c.exe" then "gswin32c.exe" are tried.

The default type, "png16m", supports 24-bit colour and anti-aliasing. Versions of R prior to 2.7.0 defaulted to "png256", which uses a palette of 256 colours and could be a more compact representation. Monochrome graphs can use "pngmono", or "pnggray" if anti-aliasing is desired. Plots with a transparent background and varying degrees of transparency should use "pngalpha".

Note that for a colour TIFF image you probably want "tiff24nc", which is 8-bit per channel RGB (the most common TIFF format). None of the listed TIFF types support transparency. "tiff32nc" uses 8-bit per channel CMYK, which printers might require.

For formats which contain a single image, a file specification like Rplots%03d.png can be used: this is interpreted by Ghostscript.

For dev2bitmap if just one of width and height is specified, the other is chosen to preserve aspect ratio of the device being copied. The main reason to prefer method = "pdf" over the default would be to allow semi-transparent colours to be used.

For graphics parameters such as "cra" that need to work in pixels, the default resolution of 72dpi is always used.

Value

None.

Conventions

This section describes the implementation of the conventions for graphics devices set out in the "R Internals Manual". These devices follow the underlying device, so when viewed at the stated res:
• The default device size is 7 inches square.
• Font sizes are in big points.
• The default font family is (for the standard Ghostscript setup) URW Nimbus Sans.
• Line widths are as a multiple of $1/96$ inch, with no minimum.
• Circle of any radius are allowed.
• Colours are interpreted by the viewing/printing application.

Note

Although using type = "pdfwrite" will work for simple plots, it is not recommended. Either use pdf to produce PDF directly, or call ps2pdf -dAutoRotatePages=/None on the output of postscript: that command is optimized to do the conversion to PDF in ways that these functions are not.

See Also

savePlot, which for windows and X11(type = "cairo") provides a simple way to record a PNG record of the current plot.
postscript, pdf, png, jpeg, tiff and bmp. To display an array of data, see image.

devAskNewPage

Prompt before New Page

Description

This function can be used to control (for the current device) whether the user is prompted before starting a new page of output.

Usage

devAskNewPage(ask = NULL)

Arguments

ask NULL or a logical value. If TRUE, the user will in future be prompted before a new page of output is started.

Details

If the current device is the null device, this will open a graphics device.
The default argument just returns the current setting and does not change it.
The default value when a device is opened is taken from the setting of options("device.ask.default").
The precise circumstances when the user will be asked to confirm a new page depend on the graphics subsystem. Obviously this needs to be an interactive session. In addition ‘recording’ needs to be in operation, so only when the display list is enabled (see dev.control) which it usually is only on a screen device.
Value

The current prompt setting before any new setting is applied. Invisibly if ask is logical.

plot.new, grid.newpage

Devices

List of Graphical Devices

Description

The following graphics devices are currently available:

- pdf Write PDF graphics commands to a file
- postscript Writes PostScript graphics commands to a file
- xfig Device for XFIG graphics file format
- bitmap bitmap pseudo-device via Ghostscript (if available).
- pictex Writes TeX/PicTeX graphics commands to a file (of historical interest only)

The following devices will be functional if R was compiled to use them (they exist but will return with a warning on other systems):

- X11 The graphics device for the X11 windowing system
-cairo_pdf, cairo_ps PDF and PostScript devices based on Cairo graphics.
- svg SVG device based on Cairo graphics.
- png PNG bitmap device
- jpeg JPEG bitmap device
- bmp BMP bitmap device
- tiff TIFF bitmap device
- quartz The graphics device for the OS X native Quartz 2d graphics system. (This is only functional on OS X where it can be used from the R.app GUI and from the command line: but it will display on the local screen even for a remote session.)

Details

If no device is open, using a high-level graphics function will cause a device to be opened. Which device is given by options("device") which is initially set as the most appropriate for each platform: a screen device for most interactive use and pdf (or the setting of R_DEFAULT_DEVICE) otherwise. The exception is interactive use under Unix if no screen device is known to be available, when pdf() is used.

It is possible for an R package to provide further graphics devices and several packages on CRAN do so. These include other devices outputting SVG and PGF/TiKZ (TeX-based graphics, see http://pgf.sourceforge.net/).
See Also

The individual help files for further information on any of the devices listed here: \texttt{X11.options}, \texttt{quartz.options}, \texttt{ps.options} and \texttt{pdf.options} for how to customize devices.\texttt{dev.interactive}, \texttt{dev.cur}, \texttt{dev.print}, \texttt{graphics.off}, \texttt{image}, \texttt{dev2bitmap}, \texttt{capabilities} to see if \texttt{X11.png}, \texttt{tiff}, \texttt{quartz} and the cairo-based devices are available.

Examples

\begin{verbatim}
## Not run:
## open the default screen device on this platform if no device is
## open
if(dev.cur() == 1) dev.new()

## End(Not run)
\end{verbatim}

\begin{verbatim}
embedFonts
\end{verbatim}

\begin{verbatim}
Embed Fonts in PostScript and PDF
\end{verbatim}

Description

Runs Ghostscript to process a PDF or PostScript file and embed all fonts in the file.

Usage

\begin{verbatim}
embedFonts(file, format, outfile = file, fontpaths = "",
            options = "")
\end{verbatim}

Arguments

\begin{itemize}
  \item \texttt{file} a character string giving the name of the original file.
  \item \texttt{format} either \texttt{"pswrite"} or \texttt{"pdfwrite"}. If not specified, it is guessed from the suffix of file.
  \item \texttt{outfile} the name of the new file (with fonts embedded).
  \item \texttt{fontpaths} a character vector giving directories that Ghostscript will search for fonts.
  \item \texttt{options} a character string containing further options to Ghostscript.
\end{itemize}

Details

This function is not necessary if you just use the standard default fonts for PostScript and PDF output.

If you use a special font, this function is useful for embedding that font in your PostScript or PDF document so that it can be shared with others without them having to install your special font (provided the font licence allows this).

If the special font is not installed for Ghostscript, you will need to tell Ghostscript where the font is, using something like \texttt{options="-sFONTPATH=path/to/font"}.

You will need \texttt{ghostscript}: the full path to the executable can be set by the environment variable \texttt{R\_GSCMD}. If this is unset, a GhostScript executable will be looked for by name on your path: on a Unix alike \texttt{"gs"} is used, and on Windows the setting of the environment variable \texttt{GSC} is used, otherwise commands \texttt{"gswi64c.exe"} then \texttt{"gswin32c.exe"} are tried.
Note that Ghostscript may do font substitution, so the font embedded may differ from that specified in the original file.

Some other options which can be useful (see your Ghostscript documentation) are ‘-dMaxSubsetPct=100’, ‘-dSubsetFonts=true’ and ‘-dEmbedAllFonts=true’.

Value

The shell command used to invoke Ghostscript is returned invisibly. This may be useful for debugging purposes as you can run the command by hand in a shell to look for problems.

---

desc|extendrange

extendrange

Extend a Numerical Range by a Small Percentage

Description

Extends a numerical range by a small percentage, i.e., fraction, on both sides.

Usage

```
extendrange(x, r = range(x, na.rm = TRUE), f = 0.05)
```

Arguments

- `x`: numeric vector; not used if `r` is specified.
- `r`: numeric vector of length 2; defaults to the range of `x`.
- `f`: number specifying the fraction by which the range should be extended.

Value

A numeric vector of length 2, `r + c(-f,f) * diff(r)`.

See Also

grange; pretty which can be considered a sophisticated extension of extendrange.

Examples

```
x <- 1:5
(r <- range(x)) # 1 5
extendrange(x) # 0.8 5.2
extendrange(x, f= 0.01) # 0.96 5.04
## Use 'r' if you have it already:
stopifnot(identical(extendrange(r = r),
extendrange(x)))
```
getGraphicsEvent  

**Wait for a mouse or keyboard event from a graphics window**

**Description**

This function waits for input from a graphics window in the form of a mouse or keyboard event.

**Usage**

```r
getGraphicsEvent(prompt = "Waiting for input",
                  onMouseDown = NULL, onMouseMove = NULL,
                  onMouseUp = NULL, onKeybd = NULL,
                  consolePrompt = prompt)
setGraphicsEventHandlers(which = dev.cur(), ...)
getGraphicsEventEnv(which = dev.cur())
setGraphicsEventEnv(which = dev.cur(), env)
```

**Arguments**

- `prompt`  
  prompt to be displayed to the user in the graphics window
- `onMouseDown`  
  a function to respond to mouse clicks
- `onMouseMove`  
  a function to respond to mouse movement
- `onMouseUp`  
  a function to respond to mouse button releases
- `onKeybd`  
  a function to respond to key presses
- `consolePrompt`  
  prompt to be displayed to the user in the console
- `which`  
  which graphics device does the call apply to?
- `...`  
  items including handlers to be placed in the event environment
- `env`  
  an environment to be used as the event environment

**Details**

These functions allow user input from some graphics devices (currently only the `windows()` and `X11(type = "Xlib")` screen displays in base R). Event handlers may be installed to respond to events involving the mouse or keyboard.

The functions are related as follows. If any of the first five arguments to `getGraphicsEvent` are given, then it uses those in a call to `setGraphicsEventHandlers` to replace any existing handlers in the current device. This is for compatibility with pre-2.12.0 R versions. The current normal way to set up event handlers is to set them using `setGraphicsEventHandlers` or `setGraphicsEventEnv` on one or more graphics devices, and then use `getGraphicsEvent()` with no arguments to retrieve event data. `getGraphicsEventEnv()` may be used to save the event environment for use later.

The names of the arguments in `getGraphicsEvent` are special. When handling events, the graphics system will look through the event environment for functions named `onMouseDown`, `onMouseMove`, `onMouseUp` and `onKeybd` and use them as event handlers. It will use `prompt` for a label on the graphics device. Two other special names are `which`, which will identify the graphics device, and `result`, where the result of the last event handler will be stored before being returned by `getGraphicsEvent()`.
The mouse event handlers should be functions with header `functi®n(buttons, x, y)`. The coordinates `x` and `y` will be passed to mouse event handlers in device independent coordinates (i.e. the lower left corner of the window is `(0, 0)`, the upper right is `(1, 1)`). The `buttons` argument will be a vector listing the buttons that are pressed at the time of the event, with 0 for left, 1 for middle, and 2 for right.

The keyboard event handler should be a function with header `functi®n(key)`. A single element character vector will be passed to this handler, corresponding to the key press. Shift and other modifier keys will have been processed, so `shiftMa` will be passed as `B`). The following special keys may also be passed to the handler:

- Control keys, passed as “Ctrl-A”, etc.
- Navigation keys, passed as one of “Left”, “Up”, “Right”, “Down”, “PgUp”, “PgDn”, “End”, “Home”
- Edit keys, passed as one of “Ins”, “Del”
- Function keys, passed as one of “F1”, “F2”, ...

The event handlers are standard R functions, and will be executed as though called from the event environment.

In an interactive session, events will be processed until

- one of the event handlers returns a non-NULL value which will be returned as the value of `getgraphicsevent`, or
- the user interrupts the function from the console.

**Value**

When run interactively, `getgraphicsevent` returns a non-NULL value returned from one of the event handlers. In a non-interactive session, `getgraphicsevent` will return NULL immediately.

`getgraphicseventEnv` returns the current event environment for the graphics device, or NULL if none has been set.

`setgraphicseventEnv` and `setgraphicseventHand«ers` return the previous event environment for the graphics device.

**Author(s)**

Duncan Murdoch

**Examples**

```r
savepar <- par(ask = FALSE)
dragplot <- function(..., xlim = NULL, ylim = NULL, xaxs = "r", yaxs = "r") {
  plot(..., xlim = xlim, ylim = ylim, xaxs = xaxs, yaxs = yaxs)
  startx <- NULL
  starty <- NULL
  usr <- NULL

  devset <- function()
    if (dev.cur() != eventEnv$which) dev.set(eventEnv$which)

  dragmousedown <- function(buttons, x, y) {
    startx <<- x
    starty <<- y
    devset()
  }
}
```
usr <<- par("usr")
eventEnv$onMouseMove <- dragmousemove
  NULL
)
dragmousemove <- function(buttons, x, y) {
  devset()
  deltay <- diff(grconvertY(c(starty, y), "ndc", "user"))
  plot(..., xlim =usr[1:2]-deltay, xaxs = "i",
       ylim =usr[3:4]-deltay, yaxs = "i")
  NULL
}
mouseup <- function(buttons, x, y) {
  eventEnv$onMouseMove <- NULL
}
keydown <- function(key) {
  if (key == "q") return(invisible(1))
  eventEnv$onMouseMove <- NULL
  NULL
}
setGraphicsEventHandlers(prompt = "Click and drag, hit q to quit",
  onMouseDown = dragmousedown,
  onMouseUp = mouseup,
  onKeybd = keydown)
eventEnv <- getGraphicsEventEnv()
}
dragplot(rnorm(1000), rnorm(1000))
  # This currently only works on the Windows
  # and X11(type = "Xlib") screen devices...
  getGraphicsEvent()  
  par(savepar)

---

**gray**

**Gray Level Specification**

**Description**

Create a vector of colors from a vector of gray levels.

**Usage**

`gray(level, alpha = NULL)`
`grey(level, alpha = NULL)`

**Arguments**

- `level` a vector of desired gray levels between 0 and 1; zero indicates "black" and one indicates "white".
- `alpha` the opacity, if specified.
Details

The values returned by `gray` can be used with a `col=` specification in graphics functions or in `par`. `grey` is an alias for `gray`.

Value

A vector of colors of the same length as `level`.

See Also

`rainbow`, `hsv`, `hcl`, `rgb`.

Examples

```r
gray(0:8 / 8)
```

---

**gray.colors**  
*Gray Color Palette*

Description

Create a vector of n gamma-corrected gray colors.

Usage

```r
gray.colors(n, start = 0.3, end = 0.9, gamma = 2.2, alpha = NULL)
grey.colors(n, start = 0.3, end = 0.9, gamma = 2.2, alpha = NULL)
```

Arguments

- `n`: the number of gray colors (≥ 1) to be in the palette.
- `start`: starting gray level in the palette (should be between 0 and 1 where zero indicates "black" and one indicates "white").
- `end`: ending gray level in the palette.
- `gamma`: the gamma correction.
- `alpha`: the opacity, is specified.

Details

The function `gray.colors` chooses a series of n gamma-corrected gray levels between `start` and `end`: 

```
seq(start^gamma, end^gamma, length = n)^(1/gamma).
```

The returned palette contains the corresponding gray colors. This palette is used in `barplot.default`.

`grey.colors` is an alias for `gray.colors`.

Value

A vector of n gray colors.

See Also

`gray`, `rainbow`, `palette`.
Examples

```r
require(graphics)

pie(rep(1, 12), col = gray.colors(12))
barplot(1:12, col = gray.colors(12))
```

---

**hcl**

### HCL Color Specification

#### Description

Create a vector of colors from vectors specifying hue, chroma and luminance.

#### Usage

```r
hcl(h = 0, c = 35, l = 85, alpha, fixup = TRUE)
```

#### Arguments

- **h**: The hue of the color specified as an angle in the range \([0,360]\). 0 yields red, 120 yields green 240 yields blue, etc.
- **c**: The chroma of the color. The upper bound for chroma depends on hue and luminance.
- **l**: A value in the range \([0,100]\) giving the luminance of the colour. For a given combination of hue and chroma, only a subset of this range is possible.
- **alpha**: numeric vector of values in the range \([0,1]\) for alpha transparency channel (0 means transparent and 1 means opaque).
- **fixup**: a logical value which indicates whether the resulting RGB values should be corrected to ensure that a real color results. If `fixup` is `FALSE` RGB components lying outside the range \([0,1]\) will result in an NA value.

#### Details

This function corresponds to polar coordinates in the CIE-LUV color space. Steps of equal size in this space correspond to approximately equal perceptual changes in color. Thus, `hcl` can be thought of as a perceptually based version of `hsv`.

The function is primarily intended as a way of computing colors for filling areas in plots where area corresponds to a numerical value (pie charts, bar charts, mosaic plots, histograms, etc). Choosing colors which have equal chroma and luminance provides a way of minimising the irradiation illusion which would otherwise produce a misleading impression of how large the areas are.

The default values of chroma and luminance make it possible to generate a full range of hues and have a relatively pleasant pastel appearance.

The RGB values produced by this function correspond to the sRGB color space used on most PC computer displays. There are other packages which provide more general color space facilities. Semi-transparent colors \((0 < \text{alpha} < 1)\) are supported only on some devices: see `rgb`.

#### Value

A vector of character strings which can be used as color specifications by R graphics functions.
Note

At present there is no guarantee that the colours rendered by R graphics devices will correspond to their sRGB description. It is planned to adopt sRGB as the standard R color description in future.

Examples

```r
require(graphics)

# The Foley and Van Dam PhD Data.
csd <- matrix(c(4,2,4,6, 4,3,1,4, 4,7,7,1, 0,7,3,2, 4,5,3,2, 5,4,2,2, 3,1,3,0, 4,4,6,7, 1,10,8,7, 1,5,3,2, 1,5,2,1, 4,1,4,3, 0,3,0,6, 2,1,5,5), nrow = 4)

csphd <- function(colors)
  barplot(csd, col = colors, ylim = c(0,30),
  names = 72:85, xlab = "Year", ylab = "Students",
  legend = c("Winter", "Spring", "Summer", "Fall"),
  main = "Computer Science PhD Graduates", las = 1)

# The Original (Metaphorical) Colors (Ouch!)
csphd(c("blue", "green", "yellow", "orange"))

# A Color Tetrad (Maximal Color Differences)
csphd(hcl(h = c(30, 120, 210, 240)))

# Same, but lighter and less colorful
# Turn off automatic correction to make sure
# that we have defined real colors.
csphd(hcl(h = c(30, 120, 210, 240),
  c = 20, l = 90, fixup = FALSE))

# Analogous Colors
# Good for those with red/green color confusion
csphd(hcl(h = seq(60, 240, by = 60)))

# Metaphorical Colors
# csphd(hcl(h = seq(210, 60, length = 4)))

# Cool Colors
csphd(hcl(h = seq(120, 0, length = 4) + 150))
```
Hershey Vector Fonts in R

Description

If the family graphical parameter (see par) has been set to one of the Hershey fonts (see ‘Details’) Hershey vector fonts are used to render text.

When using the text and contour functions Hershey fonts may be selected via the vfont argument, which is a character vector of length 2 (see ‘Details’ for valid values). This allows Cyrillic to be selected, which is not available via the font families.

Usage

Hershey

Details

The Hershey fonts have two advantages:

1. vector fonts describe each character in terms of a set of points; R renders the character by joining up the points with straight lines. This intimate knowledge of the outline of each character means that R can arbitrarily transform the characters, which can mean that the vector fonts look better for rotated text.

2. this implementation was adapted from the GNU libplot library which provides support for non-ASCII and non-English fonts. This means that it is possible, for example, to produce weird plotting symbols and Japanese characters.

Drawback:
You cannot use mathematical expressions (plotmath) with Hershey fonts.

The Hershey characters are organised into a set of fonts. A particular font is selected by specifying one of the following font families via par(family) and specifying the desired font face (plain, bold, italic, bold-italic) via par(font).

- family          faces available
  "HersheySerif"   plain, bold, italic, bold-italic
  "HersheySans"    plain, bold, italic, bold-italic
  "HersheyScript"  plain, bold
  "HersheyGothicEnglish"     plain
  "HersheyGothicGerman"       plain
  "HersheyGothicItalian"  plain
In the `vfont` specification for the text and contour functions, the Hershey font is specified by a typeface (e.g., serif or sans serif) and a fontindex or `style` (e.g., plain or italic). The first element of `vfont` specifies the typeface and the second element specifies the fontindex. The first table produced by `demo(Hershey)` shows the character a produced by each of the different fonts.

The available typeface and fontindex values are available as list components of the variable `Hershey`. The allowed pairs for `(typeface, fontindex)` are:

- serif plain
- serif italic
- serif bold
- serif bold italic
- serif cyrillic
- serif oblique cyrillic
- serif EUC
- sans serif plain
- sans serif italic
- sans serif bold
- sans serif bold italic
- script plain
- script italic
- script bold
- gothic english plain
- gothic german plain
- gothic italian plain
- serif symbol plain
- serif symbol italic
- serif symbol bold
- serif symbol bold italic
- sans serif symbol plain
- sans serif symbol italic

and the indices of these are available as `Hershey$allowed`.

**Escape sequences:** The string to be drawn can include escape sequences, which all begin with a `\`. When R encounters a `\`, rather than drawing the `\`, it treats the subsequent character(s) as a coded description of what to draw.

One useful escape sequence (in the current context) is of the form: `\123`. The three digits following the `\` specify an octal code for a character. For example, the octal code for p is 160 so the strings "p" and "\160" are equivalent. This is useful for producing characters when there is not an appropriate key on your keyboard.

The other useful escape sequences all begin with `\`. These are described below. Remember that backslashes have to be doubled in R character strings, so they need to be entered with four backslashes.

**Symbols:** an entire string of Greek symbols can be produced by selecting the HersheySymbol or HersheySansSymbol family or the Serif Symbol or Sans Serif Symbol typeface. To allow Greek symbols to be embedded in a string which uses a non-symbol typeface, there are a set
of symbol escape sequences of the form ‘\ab’. For example, the escape sequence ‘\*a’ produces a Greek alpha. The second table in demo(Hershey) shows all of the symbol escape sequences and the symbols that they produce.

**ISO Latin-1:** further escape sequences of the form ‘\ab’ are provided for producing ISO Latin-1 characters. Another option is to use the appropriate octal code. The (non-ASCII) ISO Latin-1 characters are in the range 241...377. For example, ‘\366’ produces the character o with an umlaut. The third table in demo(Hershey) shows all of the ISO Latin-1 escape sequences. These characters can be used directly. (Characters not in Latin-1 are replaced by a dot.) Several characters are missing, c-cedilla has no cedilla and ‘sharp s’ (‘\U+00DF’, also known as ‘esszet’) is rendered as ss.

**Special Characters:** a set of characters are provided which do not fall into any standard font. These can only be accessed by escape sequence. For example, ‘\LI’ produces the zodiac sign for Libra, and ‘\JU’ produces the astronomical sign for Jupiter. The fourth table in demo(Hershey) shows all of the special character escape sequences.

**Cyrillic Characters:** cyrillic characters are implemented according to the K018-R encoding, and can be used directly in such a locale using the Serif typeface and Cyrillic (or Oblique Cyrillic) fontindex. Alternatively they can be specified via an octal code in the range 300 to 337 for lower case characters or 340 to 377 for upper case characters. The fifth table in demo(Hershey) shows the octal codes for the available Cyrillic characters.

Cyrillic has to be selected via a (“serif”, fontindex) pair rather than via a font family.

**Japanese Characters:** 83 Hiragana, 86 Katakana, and 603 Kanji characters are implemented according to the EUC-JP (Extended Unix Code) encoding. Each character is identified by a unique hexadecimal code. The Hiragana characters are in the range 0x2421 to 0x2473, Katakana are in the range 0x2521 to 0x2576, and Kanji are (scattered about) in the range 0x3021 to 0x6d55.

When using the Serif typeface and EUC fontindex, these characters can be produced by a pair of octal codes. Given the hexadecimal code (e.g., 0x2421), take the first two digits and add 0x80 and do the same to the second two digits (e.g., 0x21 and 0x24 become 0xa4 and 0xa1), then convert both to octal (e.g., 0xa4 and 0xa1 become 244 and 241). For example, the first Hiragana character is produced by ‘\244\241’.

It is also possible to use the hexadecimal code directly. This works for all non-EUC fonts by specifying an escape sequence of the form ‘\#J1234’. For example, the first Hiragana character is produced by ‘\#J1241’.

The Kanji characters may be specified in a third way, using the so-called "Nelson Index", by specifying an escape sequence of the form ‘\#N1234’. For example, the (obsolete) Kanji for ‘one’ is produced by ‘\#N0001’.

demo(Japanese) shows the available Japanese characters.

**Raw Hershey Glyphs:** all of the characters in the Hershey fonts are stored in a large array. Some characters are not accessible in any of the Hershey fonts. These characters can only be accessed via an escape sequence of the form ‘\H1234’. For example, the fleur-de-lys is produced by ‘\H0746’. The sixth and seventh tables of demo(Hershey) shows all of the available raw glyphs.

```
Japanese characters in R

Description

The implementation of Hershey vector fonts provides a large number of Japanese characters (Hiragana, Katakana, and Kanji).

Details

Without keyboard support for typing Japanese characters, the only way to produce these characters is to use special escape sequences: see Hershey.

For example, the Hiragana character for the sound “ka” is produced by ‘\J242b’ and the Katakana character for this sound is produced by ‘\J252b’. The Kanji ideograph for “one” is produced by ‘\306c’ or ‘\N0001’.

The output from demo(Japanese) shows tables of the escape sequences for the available Japanese characters.

Examples

```r
require(graphics)

plot(1:9, type = "n", axes = FALSE, frame = TRUE, ylab = "",
     main = "example(Japanese)", xlab = "using Hershey fonts")
par(cex = 3)
Vf <- c("serif", "plain")

text(4, 2, "\J244b\J245b\J2473", vfont = Vf)

```
make.rgb

Create colour spaces

Description

These functions specify colour spaces for use in convertColor.

Usage

make.rgb(red, green, blue, name = NULL, white = "D65", gamma = 2.2)

colorConverter(toXYZ, fromXYZ, name, white = NULL)

Arguments

red,green,blue Chromaticity (xy or xyY) of RGB primaries
name Name for the colour space
white Character string specifying the reference white (see ‘Details’.)
gamma Display gamma (nonlinearity). A positive number or the string "sRGB"
fromXYZ Function to convert from XYZ tristimulus coordinates to this space
toXYZ Function to convert from this space to XYZ tristimulus coordinates.

Details

An RGB colour space is defined by the chromaticities of the red, green and blue primaries. These are given as vectors of length 2 or 3 in xyY coordinates (the Y component is not used and may be omitted). The chromaticities are defined relative to a reference white, which must be one of the CIE standard illuminants: "A", "B", "C", "D50", "D55", "D60", "E" (usually "D65").

The display gamma is most commonly 2.2, though 1.8 is used for Apple RGB. The sRGB standard specifies a more complicated function that is close to a gamma of 2.2; gamma = "sRGB" uses this function.

Colour spaces other than RGB can be specified directly by giving conversions to and from XYZ tristimulus coordinates. The functions should take two arguments. The first is a vector giving the coordinates for one colour. The second argument is the reference white. If a specific reference white is included in the definition of the colour space (as for the RGB spaces) this second argument should be ignored and may be . . . .

Value

An object of class colorConverter

stopifnot(cc == cols)

n2mfrow

Compute Default mfrow From Number of Plots

Description

Easy setup for plotting multiple figures (in a rectangular layout) on one page. This computes a sensible default for par(mfrow).

Usage

n2mfrow(nr.plots)

Arguments

nr.plots integer; the number of plot figures you’ll want to draw.

Value

A length two integer vector nr, nc giving the number of rows and columns, fulfilling nr >= nc >= 1 and nr * nc >= nr.plots.

Author(s)

Martin Maechler
nclass

Compute the Number of Classes for a Histogram

Description

Compute the number of classes for a histogram.

Usage

nclass.Sturges(x)
nclass.scott(x)
nclass.FD(x)

Arguments

x

A data vector.

Details

nclass.Sturges uses Sturges’ formula, implicitly basing bin sizes on the range of the data.
nclass.scott uses Scott’s choice for a normal distribution based on the estimate of the standard error, unless that is zero where it returns 1.
nclass.FD uses the Freedman-Diaconis choice based on the inter-quartile range (IQR) unless that’s zero where it reverts to mad(x, constant = 2) and when that is 0 as well, returns 1.

Value

The suggested number of classes.

See Also

par.layout.

Examples

require(graphics)

n2mfrow(8) # 3 x 3

n <- 5 ; x <- seq(-2, 2, len = 51)
## suppose now that 'n' is not known (inside function)
op <- par(mfrow = n2mfrow(n))
for (j in 1:n)
  plot(x, x^j, main = substitute(x^ exp, list(exp = j)), type = "l",
       col = "blue")
sapply(1:10, n2mfrow)
References

hist and truehist (package MASS); dpih (package KernSmooth) for a plugin bandwidth proposed by Wand(1995).

Examples

```r
set.seed(1)
x <- stats::rnorm(1111)
class.Sturges(x)

## Compare them:
NC <- function(x) c(Sturges = nclass.Sturges(x),
                    Scott = nclass.scott(x),
                    FD = nclass.FD(x))
NC(x)
onePt <- rep(1, 11)
NC(onePt) # no longer gives NaN
```

---

palette Set or View the Graphics Palette

Description

View or manipulate the color palette which is used when a col= has a numeric index.

Usage

`palette(value)`

Arguments

- **value**: an optional character vector.

Details

The color palette and referring to colors by number (see e.g. `par`) was provided for compatibility with S: in R it is almost always better to specify colours by name.

If `value` has length 1, it is taken to be the name of a built-in color palette (only "default" is built-in currently). If `value` has length greater than 1 it is assumed to contain a description of the colors which are to make up the new palette (either by name or by RGB levels). The maximum size for a palette is 1024 entries.
If `value` is omitted, no change is made to the current palette.

There is only one palette setting for all devices in a R session. If the palette is changed, the new palette applies to all subsequent plotting.

Prior to R 3.0.0 the current palette also applies to re-plotting (for example if an on-screen device is resized or `dev.copy` or `replayPlot` is used). In current R, the palette is recorded on the displaylist at the start of each page and when it is changed.

### Value

A character vector giving the palette which was in effect. This is `invisible` unless the argument is omitted.

### See Also

- `colors` for the vector of built-in named colors; `hsv`, `gray`, `rainbow`, `terrain.colors`, ... to construct colors.
- `adjustcolor`, e.g., for tweaking existing palettes; `colorRamp` to interpolate colors, making custom palettes; `col2rgb` for translating colors to RGB 3-vectors.

### Examples

```r
require(graphics)

palette() # obtain the current palette
palette(rainbow(6)) # six color rainbow

(palette(gray(seq(0,.9,len = 25)))) # gray scales; print old palette
matplot(outer(1:100, 1:30), type = "l", lty = 1, lwd = 2, col = 1:30,
       main = "Gray Scales Palette",
       sub = "palette(gray(seq(0,.9,len=25)))")

palette("default") # reset back to the default

## on a device where alpha-transparency is supported,
## use 'alpha = 0.3' transparency with the default palette :
mycols <- adjustcolor(palette(), alpha.f = 0.3)
opal <- palette(mycols)
x <- rnorm(1000); xy <- cbind(x, 3*x + rnorm(1000))
plot(xy, lwd = 2,
     main = "Alpha-Transparency Palette\n     alpha = 0.3")
xy[1,] <- -xy[1,]
points(xy, col = 8, pch = 16, cex = 1.5)
palette("default")
```

---

### Palettes

**Color Palettes**

### Description

Create a vector of n contiguous colors.
Usage

rainbow(n, s = 1, v = 1, start = 0, end = max(1, n - 1)/n, alpha = 1)
heat.colors(n, alpha = 1)
terrain.colors(n, alpha = 1)
topo.colors(n, alpha = 1)
cm.colors(n, alpha = 1)

Arguments

- n: the number of colors (≥ 1) to be in the palette.
- s, v: the ‘saturation’ and ‘value’ to be used to complete the HSV color descriptions.
- start: the (corrected) hue in [0,1] at which the rainbow begins.
- end: the (corrected) hue in [0,1] at which the rainbow ends.
- alpha: the alpha transparency, a number in [0,1], see argument alpha in hsv.

Details

Conceptually, all of these functions actually use (parts of) a line cut out of the 3-dimensional color space, parametrized by hsv(h, s, v), and hence equispaced hues in RGB space tend to cluster at the red, green and blue primaries.

Some applications such as contouring require a palette of colors which do not wrap around to give a final color close to the starting one.

With rainbow, the parameters start and end can be used to specify particular subranges of hues. The following values can be used when generating such a subrange: red = 0, yellow = 1/6, green = 2/6, cyan = 3/6, blue = 4/6 and magenta = 5/6.

Value

A character vector, cv, of color names. This can be used either to create a user–defined color palette for subsequent graphics by palette(cv), a col = specification in graphics functions or in par.

See Also

colors, palette, hsv, hcl, rgb, gray and col2rgb for translating to RGB numbers.

Examples

```
require(graphics)
# A Color Wheel
pie(rep(1, 12), col = rainbow(12))

######## Some palettes ############
demo.pal <-
  function(n, border = if (n < 32) "light gray" else NA,
    main = paste("color palettes;  n=" , n),
    ch.col = c("rainbow(n, start=.7, end=.1)" , "heat.colors(n)",
      "terrain.colors(n)" , "topo.colors(n)",
      "cm.colors(n)"))
{
  nt <- length(ch.col)
i <- 1:n; j <- n / nt; d <- j/6; dy <- 2*d
plot(i, i+d, type = "n", xaxt = "n", ylab = "", main = main)
```
for (k in 1:nt) {
    rect(i-.5, (k-1)*j + dy, i+.4, k*j,
        col = eval(parse(text = ch.col[k])), border = border)
    text(2*j, k * j + dy/4, ch.col[k])
}

n <- if (.Device == "postscript") 64 else 16
# Since for screen, larger n may give color allocation problem
demo.pal(n)

---

**pdf**

**PDF Graphics Device**

**Description**

`pdf` starts the graphics device driver for producing PDF graphics.

**Usage**

```r
pdf(file = ifelse(onefile, "Rplots.pdf", "Rplot%03d.pdf"),
    width, height, onefile, family, title, fonts, version,
    paper, encoding, bg, fg, pointsize, pagecentre, colormodel,
    useDingbats, useKerning, fillOddEven, compress)
```

**Arguments**

- **file** a character string giving the name of the file. If it is of the form "|cmd", the output is piped to the command given by cmd. If it is NULL, then no external file is created (effectively, no drawing occurs), but the device may still be queried (e.g., for size of text).
  
  For use with onefile = FALSE give a C integer format such as "Rplot%03d.pdf" (the default in that case). (See postscript for further details.)

  Tilde expansion (see path.expand) is done.

- **width, height** the width and height of the graphics region in inches. The default values are 7.

- **onefile** logical: if true (the default) allow multiple figures in one file. If false, generate a file with name containing the page number for each page. Defaults to TRUE, and forced to true if file is a pipe.

- **family** the font family to be used, see postscript. Defaults to "Helvetica".

- **title** title string to embed as the ‘/Title’ field in the file. Defaults to "R Graphics Output".

- **fonts** a character vector specifying R graphics font family names for additional fonts which will be included in the PDF file. Defaults to NULL.

- **version** a string describing the PDF version that will be required to view the output. This is a minimum, and will be increased (with a warning) if necessary. Defaults to "1.4", but see ‘Details’.
paper

the target paper size. The choices are "a4", "letter", "legal" (or "us")
and "executive" (and these can be capitalized), or "a4r" and "usr" for ro-
tated (‘landscape’). The default is "special", which means that the width and
height specify the paper size. A further choice is "default"; if this is selected,
the papersize is taken from the option "papersize" if that is set and as "a4" if
it is unset or empty. Defaults to "special".

encoding

the name of an encoding file. See postscript for details. Defaults to
"default".

gb

the initial background color to be used. Defaults to "transparent".

fg

the initial foreground color to be used. Defaults to "black".

points size

the default point size to be used. Strictly speaking, in bp, that is 1/72 of an inch,
but approximately in points. Defaults to 12.

gmageentre

logical: should the device region be centred on the page? – is only relevant for
paper != "special". Defaults to TRUE.

color model

a character string describing the color model: currently allowed values are
"srgb", "gray" (or "grey") and "cmyk". Defaults to "srgb". See section
‘Color models’.

useDingbats

logical. Should small circles be rendered via the Dingbats font? Defaults to
TRUE, which produces smaller and better output. Setting this to FALSE can work
around font display problems in broken PDF viewers: although this font is one of the 14
guaranteed to be available in all PDF viewers, that guarantee is not
always honoured. See the ‘Note’ for a possible fix for some viewers.

useKerning

logical. Should kerning corrections be included in setting text and calculating
string widths? Defaults to TRUE.

fillOddEven

logical controlling the polygon fill mode: see polygon for details. Defaults to
FALSE.

compress

logical. Should PDF streams be generated with Flate compression? Defaults to
TRUE.

Details

All arguments except file default to values given by pdf.options(). The ultimate defaults are
quoted in the arguments section.

pdf() opens the file file and the PDF commands needed to plot any graphics requested are sent to
that file.

The file argument is interpreted as a C integer format as used by sprintf, with integer argument
the page number. The default gives files 'Rplot001.pdf', ..., 'Rplot999.pdf', 'Rplot1000.pdf',
....

The family argument can be used to specify a PDF-specific font family as the initial/default font for
the device. If additional font families are to be used they should be included in the fonts argument.
If a device-independent R graphics font family is specified (e.g., via par(family = ) in the graphics
package), the PDF device makes use of the PostScript font mappings to convert the R graphics
font family to a PDF-specific font family description. (See the documentation for pdfFonts.)
This device does not embed fonts in the PDF file, so it is only straightforward to use mappings to
the font families that can be assumed to be available in any PDF viewer: "Times" (equivalently
"serif"), "Helvetica" (equivalently "sans") and "Courier" (equivalently "mono"). Other fami-
lies may be specified, but it is the user’s responsibility to ensure that these fonts are available on the
system and third-party software (e.g., Ghostscript) may be required to embed the fonts so that the
PDF can be included in other documents (e.g., LaTeX); see `embedFonts`. The URW-based families described for `postscript` can be used with viewers set up to use URW fonts, which is usual with those based on xpdf or Ghostscript. Since `embedFonts` makes use of Ghostscript, it should be able to embed the URW-based families for use with other viewers.

See `postscript` for details of encodings, as the internal code is shared between the drivers. The native PDF encoding is given in file `PDFDoc.enc`.

The PDF produced is fairly simple, with each page being represented as a single stream (by default compressed and possibly with references to raster images). The R graphics model does not distinguish graphics objects at the level of the driver interface.

The `version` argument declares the version of PDF that gets produced. The version must be at least 1.2 when compression is used, 1.4 for semi-transparent output to be understood, and at least 1.3 if CID fonts are to be used: if any of these features are used the version number will be increased (with a warning). (PDF 1.4 was first supported by Acrobat 5 in 2001; it is very unlikely not to be supported in a current viewer.)

Line widths as controlled by `par(lwd = )` are in multiples of 1/96 inch. Multiples less than 1 are allowed. `pch = ",, with `cex = 1` corresponds to a square of side 1/72 inch, which is also the 'pixel' size assumed for graphics parameters such as "cra".

The `paper` argument sets the '/MediaBox' entry in the file, which defaults to width by height. If it is set to something other than "special", a device region of the specified size is (by default) centred on the rectangle given by the paper size: if either width or height is less than 0.1 or too large to give a total margin of 0.5 inch, it is reset to the corresponding paper dimension minus 0.5. Thus if you want the default behaviour of `postscript` use `pdf(paper = "a4r", width = 0, height = 0)` to centre the device region on a landscape A4 page with 0.25 inch margins.

When the background colour is fully transparent (as is the initial default value), the PDF produced does not paint the background. Most PDF viewers will use a white canvas so the visual effect is if the background were white. This will not be the case when printing onto coloured paper, though.

### Color models

The default color model ("srgb") is sRGB. Model "gray" (or "grey") maps sRGB colors to greyscale using perceived luminosity (biased towards green). "cmyk" outputs in CMYK colorspace.

The simplest possible conversion from sRGB to CMYK is used ([http://en.wikipedia.org/wiki/CMYK_color_model#Mapping_RGB_to_CMYK](http://en.wikipedia.org/wiki/CMYK_color_model#Mapping_RGB_to_CMYK)), and raster images are output in RGB.

Also available for backwards compatibility is model "rgb" which uses uncalibrated RGB and corresponds to the model used with that name in R prior to 2.13.0. Some viewers may render some plots in that colorspace faster than in sRGB, and the plot files will be smaller.

### Conventions

This section describes the implementation of the conventions for graphics devices set out in the "R Internals Manual".

- The default device size is 7 inches square.
- Font sizes are in big points.
- The default font family is Helvetica.
- Line widths are as a multiple of 1/96 inch, with a minimum of 0.01 enforced.
- Circles of any radius are allowed. Unless `useDingbats = FALSE`, opaque circles of less than 10 big points radius are rendered using char 108 in the Dingbats font: all semi-transparent and larger circles using a Bézier curve for each quadrant.
• Colours are by default specified as sRGB.

At very small line widths, the line type may be forced to solid.

Printing

Except on Windows it is possible to print directly from pdf by something like (this is appropriate for a CUPS printing system):

```r
dpdf("|lp -o landscape", paper = "a4r")
```

This forces onefile = TRUE.

Note

If you see problems with PDF output, do remember that the problem is much more likely to be in your viewer than in R. Try another viewer if possible. Symptoms for which the viewer has been at fault are apparent grids on image plots (turn off graphics anti-aliasing in your viewer if you can) and missing or incorrect glyphs in text (viewers silently doing font substitution).

Unfortunately the default viewers on most Linux and OS X systems have these problems, and no obvious way to turn off graphics anti-aliasing.

Acrobat Reader does not use the fonts specified but rather emulates them from multiple-master fonts. This can be seen in imprecise centering of characters, for example the multiply and divide signs in Helvetica. This can be circumvented by embedding fonts where possible. Most other viewers substitute fonts, e.g. URW fonts for the standard Helvetica and Times fonts, and these too often have different font metrics from the true fonts.

Acrobat Reader can be extended by ‘font packs’, and these will be needed for the full use of encodings other than Latin-1 (although they may be offered for download as needed).

On some systems the default plotting character pch = 1 was displayed in some PDF viewers incorrectly as a "q" character. (These seem to be viewers based on the ‘poppler’ PDF rendering library). This may be due to incorrect or incomplete mapping of font names to those used by the system. Adding the following lines to ‘~/.fonts.conf’ or ‘/etc/fonts/local.conf’ may circumvent this problem, although this has largely been corrected on the affected systems.

```xml
<fontconfig>
  <alias binding="same">
    <family>zapf dingbats</family>
    <accept><family>dingbats</family></accept>
  </alias>
</fontconfig>
```

Some further workarounds for problems with symbol fonts on viewers using ‘fontconfig’ are given in the ‘Cairo Fonts’ section of the help for `X11`

There is a different font bug in the `pdf.js` viewer included in Firefox 19 and later: that maps Dingbats to the Symbol font and so displays symbols such `pch = 1` as lambda.

See Also

`pdffonts`, `pdf.options`, `embedFonts`, `Devices`, `postscript`

`cairo_pdf` and (on OS X only) `quartz` for other devices that can produce PDF.

More details of font families and encodings and especially handling text in a non-Latin-1 encoding and embedding fonts can be found in.
Examples

```r
## Not run:
## Test function for encodings
TestChars <- function(encoding = "ISOLatin1", ...) {
  pdf(encoding = encoding, ...)
  par(pty = "s")
  plot(c(-1,16), c(-1,16), type = "n", xlab = "", ylab = "",
       xaxs = "i", yaxs = "i")
  title(paste("Centred chars in encoding", encoding))
  grid(17, 17, lty = 1)
  for(i in c(32:255)) {
    x <- i %% 16
    y <- i %/% 16
    points(x, y, pch = i)
  }
  dev.off()
}
## there will be many warnings.
TestChars("ISOLatin2")
## this does not view properly in older viewers.
TestChars("ISOLatin2", family = "URWHelvetica")
## works well for viewing in gs-based viewers, and often in xpdf.

## End(Not run)
```

---

**pdf.options**

*Auxiliary Function to Set/View Defaults for Arguments of pdf*

**Description**

The auxiliary function `pdf.options` can be used to set or view (if called without arguments) the default values for some of the arguments to `pdf`.

`pdf.options` needs to be called before calling `pdf`, and the default values it sets can be overridden by supplying arguments to `pdf`.

**Usage**

`pdf.options(..., reset = FALSE)`

**Arguments**

- `...` arguments width, height, onefile, family, title, fonts, paper, encoding, pointsize, bg, fg, pagecentre, use dingbats, colormodel, fillodd_even and compress can be supplied.
- `reset` logical: should the defaults be reset to their ‘factory-fresh’ values?
Details

If both `reset = TRUE` and ... are supplied the defaults are first reset to the ‘factory-fresh’ values and then the new values are applied.

Value

A named list of all the defaults. If any arguments are supplied the return values are the old values and the result has the visibility flag turned off.

See Also

`pdf`, `ps.options`.

Examples

```r
pdf.options(bg = "pink")
utils::str(pdf.options())
pdf.options(reset = TRUE) # back to factory-fresh
```

---

**pictex**

A PicTeX Graphics Driver

Description

This function produces simple graphics suitable for inclusion in TeX and LaTeX documents. It dates from the very early days of R and is for historical interest only.

Usage

```r
pictex(file = "Rplots.tex", width = 5, height = 4, debug = FALSE, 
       bg = "white", fg = "black")
```

Arguments

- `file` the file where output will appear.
- `width` The width of the plot in inches.
- `height` the height of the plot in inches.
- `debug` should debugging information be printed.
- `bg` the background color for the plot. Ignored.
- `fg` the foreground color for the plot. Ignored.

Details

This driver is much more basic than the other graphics drivers included in R. It does not have any font metric information, so the use of `plotmath` is not supported.

Line widths are ignored except when setting the spacing of line textures. `pch = "."` corresponds to a square of side 1pt.

This device does not support colour (nor does the PicTeX package), and all colour settings are ignored.
Note that text is recorded in the file as-is, so annotations involving TeX special characters (such as ampersand and underscore) need to be quoted as they would be when entering TeX.

Multiple plots will be placed as separate environments in the output file.

Conventions

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”.

• The default device size is 5 inches by 4 inches.
• There is no pointsize argument: the default size is interpreted as 10 point.
• The only font family is cmss10.
• Line widths are only used when setting the spacing on line textures.
• Circle of any radius are allowed.
• Colour is not supported.

Author(s)

This driver was provided around 1996–7 by Valerio Aimale of the Department of Internal Medicine, University of Genoa, Italy.

References

See Also

postscript, pdf, Devices.
The tikzDevice in the CRAN package of that name for more modern TeX-based graphics (http://pgf.sourceforge.net/), although including PDF figures via pdftex is most common in (La)TeX documents.

Examples

```r
require(graphics)
pictex()
plot(1:11, (-5:5)^2, type = "b", main = "Simple Example Plot")
dev.off()
```

```latex
\documentclass{article}
\usepackage{pictex}
\usepackage{graphics} % for \rotatebox
\begin{document}
\begin{figure}[h] %
\centerline{\input{Rplots.tex}}
```
Description

If the text argument to one of the text-drawing functions (text, mtext, axis, legend) in R is an expression, the argument is interpreted as a mathematical expression and the output will be formatted according to TeX-like rules. Expressions can also be used for titles, sub-titles and x- and y-axis labels (but not for axis labels on persp plots).

In most cases other language objects (names and calls, including formulas) are coerced to expressions and so can also be used.

Details

A mathematical expression must obey the normal rules of syntax for any R expression, but it is interpreted according to very different rules than for normal R expressions.

It is possible to produce many different mathematical symbols, generate sub- or superscripts, produce fractions, etc.

The output from demo(plotmath) includes several tables which show the available features. In these tables, the columns of grey text show sample R expressions, and the columns of black text show the resulting output.

The available features are also described in the tables below:

draw \( x \) in normal size
The symbol font uses Adobe Symbol encoding so, for example, a lower case mu can be obtained either by the special symbol \( \mu \) or by \( \texttt{symb} \). This provides access to symbols that have no special symbol name, for example, the universal, or forall, symbol is \( \texttt{|uppsi=} \). To see what symbols are available in this way use \( \texttt{testchars} \) as given in the examples for \( \texttt{points} \): some are only available on some devices.

Note to TeX users: TeX’s ‘\texttt{\char128}’ is \texttt{\char128}, TeX’s ‘\texttt{\char128}’ is close to epsilon, and there is no equivalent of TeX’s ‘\texttt{\char128}’. TeX’s ‘\texttt{\char128}’ is close to omega1. vartheta, varphi and varsigma are allowed as synonyms for theta1, phi1 and sigma1. sigma1 is also known as stigma, its Unicode name.

Control characters (e.g. ‘\texttt{n}’) are not interpreted in character strings in plotmath, unlike normal plotting.

The fonts used are taken from the current font family, and so can be set by \( \texttt{par} \) in base graphics, and \( \texttt{gpar} \) in package \texttt{grid}.

Note that bold, italic and bolditalic do not apply to symbols, and hence not to the Greek symbols such as \( \mu \) which are displayed in the symbol font. They also do not apply to numeric constants.

**Other symbols**

On many OSes and some graphics devices many other symbols are available as part of the standard text font, and all of the symbols in the Adobe Symbol encoding are in principle available via changing the font face or (see ‘Details’ plotmath: see the examples section of \( \texttt{points} \) for a function to display them. (‘In principle’ because some of the glyphs are missing from some implementations of the symbol font.) Unfortunately, \texttt{postscript} and \texttt{pdf} have support for little more than European
(not Greek) and CJK characters and the Adobe Symbol encoding (and in a few fonts, also Cyrillic characters).

In a UTF-8 locale any Unicode character can be entered, perhaps as a \uxxxx’ or ‘\Uxxxxxxxxxxx’ escape sequence, but the issue is whether the graphics device is able to display the character. The widest range of characters is likely to be available in the X11 device using cairo: see its help page for how installing additional fonts can help. This can often be used to display Greek letters in bold or italic.

In non-UTF-8 locales there is normally no support for symbols not in the languages for which the current encoding was intended.

Examples

```r
require(graphics)
x <- seq(-4, 4, len = 101)
y <- cbind(sin(x), cos(x))
matplot(x, y, type = "l", xaxt = "n",
main = expression(paste(plain(sin) * phi, " and ",
plain(cos) * phi)),
ylab = expression("sin" * phi, "cos" * phi), # only first is taken
xlab = expression(paste("Phase Angle ", phi)),
col.main = "blue")
axis(1, at = c(-pi, -pi/2, 0, pi/2, pi),
labels = expression(-pi, -pi/2, 0, pi/2, pi))
```

```r
## How to combine "math" and numeric variables:
plot(1:10, type="n", xlab="", ylab="", main = "plot math & numbers")
theta <- 1.23 ; mtext(bquote(hat(theta) == .(theta)), line = .25)
for(i in 2:9)
  text(i, i+1, substitute(list(xi, eta) == group("","(x,y),")",
                       list(x = i, y = i+1)))
## note that both of these use calls rather than expressions.
##
text(1, 10, "Derivatives:", adj = 0)
text(1, 9.6, expression( 
  " first: (f * minute)(x) " == (f * minute)(x), adj = 0)
text(1, 9.0, expression( 
  " second: (f * second)(x) " == (f * second)(x), adj = 0)
```

```r
plot(1:10, 1:10)
```
Graphics devices for BMP, JPEG, PNG and TIFF format bitmap files.

Usage

```r
bmp(filename = "Rplot%03d.bmp",
     width = 480, height = 480, units = "px", pointsize = 12,
     bg = "white", res = NA, ...,
     type = c("cairo", "Xlib", "quartz"), antialias)
```

```r
jpeg(filename = "Rplot%03d.jpeg",
      width = 480, height = 480, units = "px", pointsize = 12,
      quality = 75,
      bg = "white", res = NA, ...,
      type = c("cairo", "Xlib", "quartz"), antialias)
```
Arguments

filename the name of the output file. The page number is substituted if a C integer format is included in the character string, as in the default. (The result must be less than PATH_MAX characters long, and may be truncated if not. See postscript for further details.) Tilde expansion is performed where supported by the platform.

width the width of the device.

height the height of the device.

units The units in which height and width are given. Can be px (pixels, the default), in (inches), cm or mm.

pointsize the default pointsize of plotted text, interpreted as big points (1/72 inch) at res ppi.

bg the initial background colour: can be overridden by setting par("bg").

quality the ‘quality’ of the JPEG image, as a percentage. Smaller values will give more compression but also more degradation of the image.

compression the type of compression to be used.

res The nominal resolution in ppi which will be recorded in the bitmap file, if a positive integer. Also used for units other than the default, and to convert points to pixels.

... for type = "Xlib" only, additional arguments to the underlying X11 device such as fonts or family.

For types "cairo" and "quartz", the family argument can be supplied. See the ‘Cairo fonts’ section in the help for X11.

type character string, one of "Xlib" or "quartz" (some OS X builds) or "cairo". The latter will only be available if the system was compiled with support for cairo – otherwise "Xlib" will be used. The default is set by getOption("bitmapType") – the ‘out of the box’ default is "quartz" or "cairo" where available, otherwise "Xlib".

antialias for type = "cairo", giving the type of anti-aliasing (if any) to be used. See X11. The default is set by X11.options. Also for type = "quartz", where antialiasing is used unless antialias = "none".

Details

Plots in PNG and JPEG format can easily be converted to many other bitmap formats, and both can be displayed in modern web browsers. The PNG format is lossless and is best for line diagrams and blocks of colour. The JPEG format is lossy, but may be useful for image plots, for example. BMP
is a standard format on Windows. TIFF is a meta-format: the default format written by tiff is lossless and stores RGB (and alpha where appropriate) values uncompressed—such files are widely accepted, which is their main virtue over PNG.

png supports transparent backgrounds: use bg = "transparent". (Not all PNG viewers render files with transparency correctly.) When transparency is in use in the type = "Xlib" variant a very light grey is used as the background and so appear as transparent if used in the plot. This allows opaque white to be used, as in the example. The type = "cairo", type = "cairo-png" and type = "quartz" variants allow semi-transparent colours, including on a transparent or semi-transparent background.

tiff with types "cairo" and "quartz" supports semi-transparent colours, including on a transparent or semi-transparent background.

R can be compiled without support for some or all of the types for each of these devices: this will be reported if you attempt to use them on a system where they are not supported. For type = "Xlib" they may not be usable unless the X11 display is available to the owner of the R process. type = "cairo" requires cairo 1.2 or later. type = "quartz" uses the quartz device and so is only available where that is (on some OS X builds: see capabilities("aqua")).

By default no resolution is recorded in the file. Viewers will often assume a nominal resolution of 72ppi when none is recorded. As resolutions in PNG files are recorded in pixels/metre, the reported ppi value will be changed slightly.

For graphics parameters that make use of dimensions in inches (including font sizes in points) the resolution used is res (or 72ppi if unset).

png will normally use a palette if there are less than 256 colours on the page, and record a 24-bit RGB file otherwise (or a 32-bit RGBA file if type = "cairo" and non-opaque colours are used). However, type = "cairo-png" uses cairographics' PNG backend which will never use a palette and normally creates a larger 32-bit ARGB file—this may work better for specialist uses with semi-transparent colours.

Quartz-produced PNG and TIFF plots with a transparent background are recorded with a dark grey matte which will show up in some viewers, including Preview on OS X.

Value

A plot device is opened: nothing is returned to the R interpreter.

Warnings

Note that by default the width and height values are in pixels not inches. A warning will be issued if both are less than 20.

If you plot more than one page on one of these devices and do not include something like %d for the sequence number in file, the file will contain the last page plotted.

Differences between OSes

These functions are interfaces to three or more different underlying devices.

- On Windows, devices based on plotting to a hidden screen using Windows’ GDI calls.
- On platforms with support for X11, plotting to a hidden X11 display.
- On OS X when working at the console and when R is compiled with suitable support, using Apple’s Quartz plotting system.
- Where support has been compiled in for cairographics, plotting on cairo surfaces. This may use the native platform support for fonts, or it may use fontconfig to support a wide range of font formats. (This was first available on Windows in R 2.14.0.)
Inevitably there will be differences between the options supported and output produced. Perhaps the most important are support for antialiased fonts and semi-transparent colours: the best results are likely to be obtained with the cairo- or Quartz-based devices where available.

The default extensions are `.jpg` and `.tif` on Windows, and `.jpeg` and `.tiff` elsewhere.

**Conventions**

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”.

- The default device size is in pixels.
- Font sizes are in big points interpreted at res ppi.
- The default font family is Helvetica.
- Line widths in 1/96 inch (interpreted at res ppi), minimum one pixel for type = “Xlib”, 0.01 for type = “cairo”.
- For type = “Xlib” circle radii are in pixels with minimum one.
- Colours are interpreted by the viewing application.

For type = “quartz” see the help for `quartz`.

**Note**

For type = “Xlib” these devices are based on the X11 device. The colour model used will be that set up by `Xlib.options` at the time the first Xlib-based devices was opened (or the first after all such devices have been closed).

`Devices, dev.print`  
`capabilities` to see if these devices are supported by this build of R, and if type = “cairo” is supported.

`bitmap` provides an alternative way to generate plots in many bitmap formats that does not depend on accessing the X11 display but does depend on having GhostScript installed.

**Examples**

```r
## these examples will work only if the devices are available  
## and cairo or an X11 display or an OS X display is available.

## copy current plot to a (large) PNG file  
## Not run: dev.print(png, file = "myplot.png", width = 1024, height = 768)

png(file = "myplot.png", bg = "transparent")
plot(1:10)
rect(1, 5, 3, 7, col = "white")
dev.off()

## will make myplot1.jpeg and myplot2.jpeg
jpeg(file = "myplot%d.jpeg")
```
postscript

Description

postscript starts the graphics device driver for producing PostScript graphics.

Usage

postscript(file = ifelse(onefile, "Rplots.ps", "Rplot%03d.ps"),
          onefile, family, title, fonts, encoding, bg, fg,
          width, height, horizontal, pointsize,
          paper, pagecentre, print.it, command,
          colormodel, usekerning, fillOddEven)

Arguments

file a character string giving the name of the file. If it is ",", the output is piped to
      the command given by the argument command. If it is of the form ": cmd", the
      output is piped to the command given by cmd.
      For use with onefile = FALSE give a printf format such as "Rplot%03d.ps"
      (the default in that case). The string should not otherwise contain a %: if it is re-
      ally necessary, use % in the string for % in the file name. A single integer format
      matching the regular expression "%[0-9 -]@[0-9.]*[diouX]" is allowed.
      Tilde expansion (see path.expand) is done.

onefile logical: if true (the default) allow multiple figures in one file. If false, generate
      a file name containing the page number for each page and use an EPSF header
      and no DocumentMedia comment. Defaults to the TRUE.

family the initial font family to be used, normally as a character string. See the section
      'Families'. Defaults to "Helvetica".

title title string to embed as the Title comment in the file. Defaults to
      "R Graphics Output".

fonts a character vector specifying additional R graphics font family names for font
      families whose declarations will be included in the PostScript file and are avail-
      able for use with the device. See 'Families' below. Defaults to NULL.

encoding the name of an encoding file. Defaults to "default". The latter is interpreted as
      "ISO8859-1.enc" unless the locale is recognized as corresponding to a
      language using ISO 8859-{2,5,7,13,15} or KOI8-{R,U}. The file is looked for
      in the 'enc' directory of package grDevices if the path does not contain a path
      separator. An extension ".enc" can be omitted.

bg the initial background color to be used. If "transparent" (or any other non-
      opaque colour), no background is painted. Defaults to "transparent".

fg the initial foreground color to be used. Defaults to "black".

width, height the width and height of the graphics region in inches. Default to 0.
      If paper != "special" and width or height is less than 0.1 or too large to
      give a total margin of 0.5 inch, the graphics region is reset to the corresponding
      paper dimension minus 0.5.
horizontal the orientation of the printed image, a logical. Defaults to true, that is landscape orientation on paper sizes with width less than height.

pointsize the default point size to be used. Strictly speaking, in bp, that is 1/72 of an inch, but approximately in points. Defaults to 12.

paper the size of paper in the printer. The choices are "a4", "letter" (or "us"), "legal" and "executive" (and these can be capitalized). Also, "special" can be used, when arguments width and height specify the paper size. A further choice is "default" (the default): If this is selected, the papersize is taken from the option "papersize" if that is set and to "a4" if it is unset or empty.

pagecentre logical: should the device region be centred on the page? Defaults to true.

print.it logical: should the file be printed when the device is closed? (This only applies if file is a real file name.) Defaults to false.

command the command to be used for ‘printing’. Defaults to "default", the value of option "printcmd". The length limit is 2*PATH_MAX, typically 8096 bytes.

colormodel a character string describing the color model: currently allowed values as "srgb", "srgb+gray", "rgb", "rgb+nogray", "gray" (or "grey") and "cmyk". Defaults to "srgb". See section ‘Color models’.

useKerning logical. Should kerning corrections be included in setting text and calculating string widths? Defaults to TRUE.

fillOddEven logical controlling the polygon fill mode: see polygon for details. Default FALSE.

Details

All arguments except file default to values given by ps.options(). The ultimate defaults are quoted in the arguments section.

postscript opens the file file and the PostScript commands needed to plot any graphics requested are written to that file. This file can then be printed on a suitable device to obtain hard copy.

The file argument is interpreted as a C integer format as used by sprintf, with integer argument the page number. The default gives files ‘rp001.ps’, …, ‘rp1000.ps’, ….

The postscript produced for a single R plot is EPS (Encapsulated PostScript) compatible, and can be included into other documents, e.g., into LaTeX, using \includegraphics{<filename>}. For use in this way you will probably want to use setEPS() to set the defaults as horizontal = FALSE, onefile = FALSE, paper = "special". Note that the bounding box is for the device region: if you find the white space around the plot region excessive, reduce the margins of the figure region via par(mar = ).

Most of the PostScript prologue used is taken from the R character vector .ps.prolog. This is marked in the output, and can be changed by changing that vector. (This is only advisable for PostScript experts: the standard version is in namespace:grDevices.)

A PostScript device has a default family, which can be set by the user via family. If other font families are to be used when drawing to the PostScript device, these must be declared when the device is created via fonts; the font family names for this argument are R graphics font family names (see the documentation for postscriptFonts).

Line widths as controlled by par(lwd = ) are in multiples of 1/96 inch: multiples less than 1 are allowed. pch = "." with cex = 1 corresponds to a square of side 1/72 inch, which is also the ‘pixel’ size assumed for graphics parameters such as "cra".

When the background colour is fully transparent (as is the initial default value), the PostScript produced does not paint the background. Almost all PostScript viewers will use a white canvas
so the visual effect is if the background were white. This will not be the case when printing onto
coloured paper, though.

Families

Font families are collections of fonts covering the five font faces, (conventionally plain, bold, italic,
bold-italic and symbol) selected by the graphics parameter `par(font = )` or the grid parameter `gpar(fontface = )`. Font families can be specified either as an an initial/default font family for the device via the family argument or after the device is opened by the graphics parameter `par(family = )` or the grid parameter `gpar(fontfamily = )`. Families which will be used in addition to the initial family must be specified in the fonts argument when the device is opened.

Font families are declared via a call to `postscriptFonts`.

The argument family specifies the initial/default font family to be used. In normal use it is one of "AvantGarde", "Bookman", "Courier", "Helvetica", "Helvetica-Narrow", "NewCenturySchoolbook", "Palatino" or "Times", and refers to the standard Adobe PostScript fonts families of those names which are included (or cloned) in all common PostScript devices.

Many PostScript emulators (including those based on ghostscript) use the URW equivalents of these fonts, which are "URW Gothic", "URW Bookman", "Nimbus Mon", "Nimbus San", "Nimbus Sans Cond", "Century Sch", "URWPalladio" and "Nimbus Rom" respectively. If your PostScript device is using URW fonts, you will obtain access to more characters and more appropriate metrics by using these names. To make these easier to remember, "URW Helvetica" == "Nimbus San" and "URW Times" == "Nimbus Rom" are also supported.

Another type of family makes use of CID-keyed fonts for East Asian languages – see `postscriptFonts`.

The family argument is normally a character string naming a font family, but family objects generated by `Type1Font` and `CIDFont` are also accepted. For compatibility with earlier versions of R, the initial family can also be specified as a vector of four or five afm files.

Note that R does not embed the font(s) used in the PostScript output: see `embedFonts` for a utility to help do so.

Viewers and embedding applications frequently substitute fonts for those specified in the family, and the substitute will often have slightly different font metrics. `useKerning = TRUE` spaces the letters in the string using kerning corrections for the intended family: this may look uglier than `useKerning = FALSE`.

Encodings

Encodings describe which glyphs are used to display the character codes (in the range 0–255). Most commonly R uses ISOLatin1 encoding, and the examples for `text` are in that encoding. However, the encoding used on machines running R may well be different, and by using the encoding argument the glyphs can be matched to encoding in use. This suffices for European and Cyrillic languages, but not for CJK languages. For the latter, composite CID fonts are used. These fonts are useful for other languages: for example they may contain Greek glyphs. (The rest of this section applies only when CID fonts are not used.)

None of this will matter if only ASCII characters (codes 32–126) are used as all the encodings (except "TeXtext") agree over that range. Some encodings are supersets of ISOLatin1, too. However, if accented and special characters do not come out as you expect, you may need to change the encoding. Some other encodings are supplied with R: "WinAnsi.enc" and "MacRoman.enc" correspond to the encodings normally used on Windows and Classic Mac OS (at least by Adobe), and "PDFDoc.enc" is the first 256 characters of the Unicode encoding, the standard for PDF. There are also encodings "ISO Latin2.enc", "CP1250.enc", "ISO Latin7.enc" (ISO
8859-13), "CP1257.ENC", and "ISO Latin9.ENC" (ISO 8859-15), "Cyrillic.ENC" (ISO 8859-5), "KOI8-R.ENC", "KOI8-U.ENC", "CP1251.ENC", "Greek.ENC" (ISO 8859-7) and "CP1253.ENC". Note that many glyphs in these encodings are not in the fonts corresponding to the standard families. (The Adobe ones for all but Courier, Helvetica and Times cover little more than Latin-1, whereas the URW ones also cover Latin-2, Latin-7, Latin-9 and Cyrillic but no Greek. The Adobe exceptions cover the Latin character sets, but not the Euro.)

If you specify the encoding, it is your responsibility to ensure that the PostScript font contains the glyphs used. One issue here is the Euro symbol which is in the WinAnsi and MacRoman encodings but may well not be in the PostScript fonts. (It is in the URW variants; it is not in the supplied Adobe Font Metric files.)

There is an exception. Character 45 ("" ) is always set as minus (its value in Adobe ISOLatin1) even though it is hyphen in the other encodings. Hyphen is available as character 173 (octal 0255) in all the Latin encodings, Cyrillic and Greek. (This can be entered as "\uad" in a UTF-8 locale.) There are some discrepancies in accounts of glyphs 39 and 96: the supplied encodings (except CP1250 and CP1251) treat these as ‘quoteright’ and ‘quoteleft’ (rather than ‘quotesingle’/‘acute’ and ‘grave’ respectively), as they are in the Adobe documentation.

TeX fonts

TeX has traditionally made use of fonts such as Computer Modern which are encoded rather differently, in a 7-bit encoding. This encoding can be specified by encoding = "TeXtext.ENC", taking care that the ASCII characters < > \ _ { } are not available in those fonts.

There are supplied families "ComputerModern" and "ComputerModernItalic" which use this encoding, and which are only supported for postscript (and not pdf). They are intended to use with the Type 1 versions of the TeX CM fonts. It will normally be possible to include such output in TeX or LaTeX provided it is processed with dvips -Ppdf -j0 or the equivalent on your system. (~j0 turns off font subsetting.) When family = "ComputerModern" is used, the italic/bold-italic fonts used are slanted fonts (cmmi10 and cmmibx10). To use text italic fonts instead, set family = "ComputerModernItalic".

These families use the TeX math italic and symbol fonts for a comprehensive but incomplete coverage of the glyphs covered by the Adobe symbol font in other families. This is achieved by special-casing the postscript code generated from the supplied ‘CM_symbol_10.afm’.

Color models

The default color model ("srgb") is sRGB.

The alternative "srgb+gray" uses sRGB for colors, but with pure gray colors (including black and white) expressed as greyscales (which results in smaller files and can be advantageous with some printer drivers). Conversely, its files can be rendered much slower on some viewers, and there can be a noticeable discontinuity in color gradients involving gray or white.

Other possibilities are "gray" (or "grey") which used only greyscales (and converts other colours to a luminance), and "cmyk". The simplest possible conversion from sRGB to CMYK is used (http://en.wikipedia.org/wiki/CMYK_color_model#Mapping_RGB_to_CMYK), and raster images are output in RGB.

Color models provided for backwards compatibility are "rgb" (which is RGB+gray) and "rgb-nogray" which use uncalibrated RGB (as used in R prior to 2.13.0). These result in slightly smaller files which may render faster, but do rely on the viewer being properly calibrated.

Printing

A postscript plot can be printed via postscript in two ways.
1. Setting `print.it = TRUE` causes the command given in argument `command` to be called with argument "file" when the device is closed. Note that the plot file is not deleted unless `command` arranges to delete it.

2. `file = ""` or `file = "|cmd"` can be used to print using a pipe. Failure to open the command will probably be reported to the terminal but not to R, in which case close the device by `dev.off()` immediately.

Conventions

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”.

- The default device size is 7 inches square.
- Font sizes are in big points.
- The default font family is Helvetica.
- Line widths are as a multiple of 1/96 inch, with a minimum of 0.01 enforced.
- Circle of any radius are allowed.
- Colours are by default specified as sRGB.

At very small line widths, the line type may be forced to solid.

Raster images are currently limited to opaque colours.

Note

If you see problems with postscript output, do remember that the problem is much more likely to be in your viewer than in R. Try another viewer if possible. Symptoms for which the viewer has been at fault are apparent grids on image plots (turn off graphics anti-aliasing in your viewer if you can) and missing or incorrect glyphs in text (viewers silently doing font substitution).

Unfortunately the default viewers on most Linux and OS X systems have these problems, and no obvious way to turn off graphics anti-aliasing.

Author(s)

Support for Computer Modern fonts is based on a contribution by Brian D’Urso <durso@hussle.harvard.edu>.

`cairo_ps` for another device that can produce PostScript.

More details of font families and encodings and especially handling text in a non-Latin-1 encoding and embedding fonts can be found in

Examples

```r
require(graphics)
## Not run:
# open the file "foo.ps" for graphics output
postscript("foo.ps")
# produce the desired graph(s)
dev.off()  # turn off the postscript device
postscript("|lp -dlw")
# produce the desired graph(s)
dev.off()  # plot will appear on printer

# for URW PostScript devices
postscript("foo.ps", family = "NimbusSan")

## for inclusion in Computer Modern TeX documents, perhaps
postscript("cm_test.eps", width = 4.0, height = 3.0,
  horizontal = FALSE, onefile = FALSE, paper = "special",
  family = "ComputerModern", encoding = "TeXtext.enc")
## The resultant postscript file can be used by dvips -Ppdf -j0.

## To test out encodings, you can use
TestChars <- function(encoding = "ISO8859-1", family = "URWHelvetica")
{
  postscript(encoding = encoding, family = family)
  par(pty = "s")
  plot(c(-1,1), c(-1,1), type = "n", xlab = "", ylab = "",
       xaxs = "i", yaxs = "i")
  title(paste("Centred chars in encoding", encoding))
  grid(17, 17, lty = 1)
  for(i in c(32:255)) {
    x <- i /% 16
    y <- i /% 16
    points(x, y, pch = i)
  }
  dev.off()
}
## there will be many warnings. We use URW to get a complete enough
## set of font metrics.
TestChars()
TestChars("ISO8859-2")
TestChars("WinAnsi")

## End(Not run)
```

Description

These functions handle the translation of a R graphics font family name to a PostScript or PDF font description, used by the `postscript` or `pdf` graphics devices.
Usage

postscriptFonts(...)  
pdfFonts(...)  

Arguments

... either character strings naming mappings to display, or named arguments specifying mappings to add or change.

Details

If these functions are called with no argument they list all the existing mappings, whereas if they are called with named arguments they add (or change) mappings.

A PostScript or PDF device is created with a default font family (see the documentation for postscript), but it is also possible to specify a font family when drawing to the device (for example, see the documentation for "family" in par and for "fontfamily" in gpar in the grid package).

The font family sent to the device is a simple string name, which must be mapped to a set of PostScript fonts. Separate lists of mappings for postscript and pdf devices are maintained for the current R session and can be added to by the user.

The postscriptFonts and pdfFonts functions can be used to list existing mappings and to define new mappings. The Type1Font and CIDFont functions can be used to create new mappings, when the xxxFonts function is used to add them to the database. See the examples.

Default mappings are provided for three device-independent family names: "sans" for a sans-serif font (to "Helvetica"), "serif" for a serif font (to "Times") and "mono" for a monospaced font (to "Courier").

Mappings for a number of standard Adobe fonts (and URW equivalents) are also provided: "AvantGarde", "Bookman", "Courier", "Helvetica", "Helvetica-Narrow", "NewCenturySchoolbook", "Palatino" and "Times": "URWGothic", "URWBookman", "NimbusMon", "NimbusSan" (synonym "URWHelvetica"), "NimbusSanCond", "CenturySch", "URWPalladio" and "NimbusRom" (synonym "URWTimes").

There are also mappings for "ComputerModern" and "ComputerModernItalic".

Finally, there are some default mappings for East Asian locales described in a separate section.

The specification of font metrics and encodings is described in the help for the postscript function.

The fonts are not embedded in the resulting PostScript or PDF file, so software including the PostScript or PDF plot file should either embed the font outlines (usually from '.pfb' or '.pfa' files) or use DSC comments to instruct the print spooler or including application to do so (see also embedFonts).

A font family has both an R-level name, the argument name used when postscriptFonts was called, and an internal name, the family component. These two names are the same for all the pre-defined font families.

Once a font family is in use it cannot be changed. ‘In use’ means that it has been specified via a family or fonts argument to an invocation of the same graphics device already in the R session. (For these purposes xfig counts the same as postscript but only uses some of the predefined mappings.)

Value

A list of one or more font mappings.
East Asian fonts

There are some default mappings for East Asian locales:
"Japan1", "Japan1HeiMin", "Japan1GothicBBB", and "Japan1Ryumin" for Japanese; "Korean" and "Korea1deb" for Korean; “GB1” (Simplified Chinese) for mainland China and Singapore; "CNS1" (Traditional Chinese) for Hong Kong and Taiwan.

These refer to the following fonts

- **Japan1 (PS)**: HeiseiKakuGo-W5
  - Linotype Japanese printer font
- **Japan1 (PDF)**: KozMinPro-Regular-Acro
  - from Adobe Reader 7.0 Japanese Font Pack
- **Japan1HeiMin (PS)**: HeiseiMin-W3
  - Linotype Japanese printer font
- **Japan1HeiMin (PDF)**: HeiseiMin-W3-Acro
  - from Adobe Reader 7.0 Japanese Font Pack
- **Japan1GothicBBB**: GothicBBB-Medium
  - Japanese-market PostScript printer font
- **Japan1Ryumin**: Ryumin-Light
  - Japanese-market PostScript printer font
- **Korean (PS)**: Baekmuk-Batang
  - TrueType font found on some Linux systems
- **Korean (PDF)**: HYMyeongJoStd-Medium-Acro
  - from Adobe Reader 7.0 Korean Font Pack
- **Korea1deb (PS)**: Batang-Regular
  - another name for Baekmuk-Batang
- **Korea1deb (PDF)**: HYGothic-Medium-Acro
  - from Adobe Reader 4.0 Korean Font Pack
- **GB1 (PS)**: BousungEG-Light-GB
  - TrueType font found on some Linux systems
- **GB1 (PDF)**: STSong-Light-Acro
  - from Adobe Reader 7.0 Simplified Chinese Font Pack
- **CNS1 (PS)**: MOEung-Regular
  - Ken Lunde's CJKV resources
- **CNS1 (PDF)**: MSungStd-Light-Acro
  - from Adobe Reader 7.0 Traditional Chinese Font Pack

Baekmuk-Batang can be found at ftp://ftp.mizi.com/pub/baekmuk/. BousungEG-Light-GB can be found at ftp://ftp.gnu.org/pub/non-gnu/chinese-fonts-truetype/. Ken Lunde's CJKV resources are at ftp://ftp.oreilly.com/pub/examples/nutshell/cjkv/adobe/samples/. These will need to be installed or otherwise made available to the postscript/PDF interpreter such as ghostscript (and not all interpreters can handle TrueType fonts).

You may well find that your postscript/PDF interpreters has been set up to provide aliases for many of these fonts. For example, ghostscript on Windows can optionally be installed to map common CJK fonts names to Windows TrueType fonts. (You may want to add the ~Acro versions as well.)

Adding a mapping for a CID-keyed font is for gurus only.

Author(s)

Support for Computer Modern fonts is based on a contribution by Brian D’Urso <durso@hussle.harvard.edu>.
pretty.Date

Pretty Breakpoints for Date-Time Classes

Description

Compute a sequence of about n+1 equally spaced ‘nice’ values which cover the range of the values in x.

Usage

## S3 method for class 'Date'
pretty(x, n = 5, min.n = n %% 2, sep = " ", ...)  
## S3 method for class 'POSIXt'
pretty(x, n = 5, min.n = n %% 2, sep = " ", ...)

Arguments

x  
an object of class "Date" or "POSIXt" (i.e., "POSIXct" or "POSIXlt").
n  
integer giving the desired number of intervals.
min.n  
nonnegative integer giving the minimal number of intervals.
sep  
character string, serving as a separator for certain formats (e.g., between month and year).
...  
further arguments for compatibility with the generic, ignored.

"cmti10.afm", "cmbx110.afm",
"CM_symbol_10.afm"),
encoding = "TeXtext.enc")
postscriptFonts(CMitalic = CMitalic)

## A CID font for Japanese using a different CMap and
## corresponding cmapEncoding.
'Jp_UCS-2' <- CIDFont("TestUCS2",
c("Adobe-Japan1-UniJIS-UCS2-H.afm",
"Adobe-Japan1-UniJIS-UCS2-H.afm",
"Adobe-Japan1-UniJIS-UCS2-H.afm",
"Adobe-Japan1-UniJIS-UCS2-H.afm"),
"UniJIS-UCS2-H", "UCS-2")
pdffonts('Jp_UCS-2' = 'Jp_UCS-2')
names(pdffonts())
ps.options

Value
A vector (of the suitable class) of locations, with attribute "labels" giving corresponding formatted character labels.

See Also
pretty for the default method.

Examples

```r
steps <- list("10 secs", "1 min", "5 mins", "30 mins", "6 hours", "12 hours", "1 DSTday", "2 weeks", "1 month", "6 months", "1 year", "10 years", "50 years", "1000 years")

names(steps) <- paste("span -", unlist(steps))

x <- as.POSIXct("2002-02-02 02:02")
lapply(steps, function(s) {
  at <- pretty(seq(x, by = s, length = 2), n = 5)
  attr(at, "labels")
})
```

---

ps.options  

**Auxiliary Function to Set/View Defaults for Arguments of postscript**

Description
The auxiliary function `ps.options` can be used to set or view (if called without arguments) the default values for some of the arguments to `postscript`.

`ps.options` needs to be called before calling `postscript`, and the default values it sets can be overridden by supplying arguments to `postscript`.

Usage

```r
ps.options(..., reset = FALSE, override.check = FALSE)
```

```r
setEPS(...)  
setPS(....)
```

Arguments

- `...`: arguments `onefile, family, title, fonts, encoding, bg, fg, width, height, horizontal, pointsize, paper, pagecentre, print.it, command, colormodel` and `filloddEven` can be supplied. `onfile, horizontal` and `paper` are ignored for `setEPS` and `setPS`.
- `reset`: logical: should the defaults be reset to their ‘factory-fresh’ values?
- `override.check`: logical argument passed to `check.options`. See the Examples.
Details

If both reset = TRUE and ... are supplied the defaults are first reset to the ‘factory-fresh’ values and then the new values are applied.

For backwards compatibility argument append is accepted but ignored with a warning.

setEPS and setPS are wrappers to set defaults appropriate for figures for inclusion in documents (the default size is 7 inches square unless width or height is supplied) and for spooling to a PostScript printer respectively. For historical reasons the latter is the ultimate default.

Value

A named list of all the previous defaults. If ... or reset = TRUE is supplied the result has the visibility flag turned off.

See Also

postscript.pdf.options

Examples

ps.options(bg = "pink")
utils::str(ps.options())

### error checking of arguments:
ps.options(width = 0:12, onefile = 0, bg = pi)
# override the check for 'width', but not 'bg':
ps.options(width = 0:12, bg = pi, override.check = c(TRUE,FALSE))
utils::str(ps.options())
ps.options(reset = TRUE) # back to factory-fresh

quartz

OS X Quartz Device

Description

quartz starts a graphics device driver for the OS X System. It supports plotting both to the screen (the default) and to various graphics file formats.

Usage

quartz(title, width, height, pointsize, family, antialias, type, file = NULL, bg, canvas, dpi)
quartz.options(..., reset = FALSE)
quartz.save(file, type = "png", device = dev.cur(), dpi = 100, ...)
Arguments

title  title for the Quartz window (applies to on-screen output only), default "Quartz %d". A C-style format for an integer will be substituted by the device number (see the file argument to postscript for further details).

width  the width of the plotting area in inches. Default 7.

height  the height of the plotting area in inches. Default 7.

pointsize  the default pointsize to be used. Default 12.

family  this is the family name of the font that will be used by the device. Default "Arial". This will be the base name of a font as shown in Font Book.

antialias  whether to use antialiasing. Default TRUE.

type  the type of output to use. See ‘Details’ for more information. Default "native".

file  an optional target for the graphics device. The default, NULL, selects a default name where one is needed. See ‘Details’ for more information.

bg  the initial background colour to use for the device. Default "transparent". An opaque colour such as "white" will normally be required on off-screen types that support transparency such as "png" and "tiff".

canvas  canvas colour to use for an on-screen device. Default "white", and will be forced to be an opaque colour.

dpi  resolution of the output. The default (NA_real) for an on-screen display defaults to the resolution of the main screen, and to 72 dpi otherwise. See ‘Details’.

...  Any of the arguments to quartz except file.

reset  logical: should the defaults be reset to their defaults?

device  device number to copy from.

Details

The defaults for all but one of the arguments of quartz are set by quartz.options: the ‘Arguments’ section gives the ‘factory-fresh’ defaults.

The Quartz graphics device supports a variety of output types. On-screen output types are "" or "native" or "Cocoa". Off-screen output types produce output files and utilize the file argument. type = "pdf" gives PDF output. The following bitmap formats may be supported (depending on the OS version): "png", "jpeg", "jpg", "jpeg2000", "tif", "tiff", "gif", "psd" (Adobe Photoshop), "bmp" (Windows bitmap), "sgi" and "pict".

The file argument is used for off-screen drawing. The actual file is only created when the device is closed (e.g. using dev.off()). For the bitmap devices, the page number is substituted if a C integer format is included in the character string, e.g. Rplot%03d.png. (The result must be less than PATH_MAX characters long, and may be truncated if not. See postscript for further details.) If a file argument is not supplied, the default is Rplots.pdf or Rplot%03d.type. Tilde expansion (see path.expand) is done.

If a device-independent R graphics font family is specified (e.g., via par(family =) in the graphics package), the Quartz device makes use of the Quartz font database (see quartzFonts) to convert the R graphics font family to a Quartz-specific font family description. The default conversions are (MonoType TrueType versions of) Helvetica for sans, Times-Roman for serif and Courier for mono.

On-screen devices are launched with a semi-transparent canvas. Once a new plot is created, the canvas is first painted with the canvas colour and then the current background colour (which can be transparent or semi-transparent). Off-screen devices have no canvas colour, and so start with a
translucent background where possible (e.g. `type = "png"` and `type = "tiff"`) – otherwise it appears that a solid white canvas is assumed in the Quartz code. PNG and TIFF files are saved with a dark grey matte which will show up in some viewers, including Preview.

title can be used for on-screen output. It must be a single character string with an optional integer printf-style format that will be substituted by the device number. It is also optionally used (without a format) to give a title to a PDF file.

Calling `quartz()` sets `.Device` to "quartz" for on-screen devices and to "quartz_off_screen" otherwise.

The font family chosen needs to cover the characters to be used: characters not in the font are rendered as empty oblongs. For non-Western-European languages something other than the default of "Arial" is likely to be needed—one choice for Chinese is "MingLiU".

`quartz.save` is a modified version of `dev.copy2pdf` to copy the plot from the current screen device to a `quartz` device, by default to a PNG file.

**Conventions**

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”.

- The default device size is 7 inches square.
- Font sizes are in big points.
- The default font family is Arial.
- Line widths are a multiple of 1/96 inch with no minimum set by R.
- Circle radii are real-valued with no minimum set by R.
- Colours are specified as sRGB.

**Note**

For a long time the default font family was documented as "Helvetica" after it had been changed to "Arial" to work around a deficiency in OS X 10.4. It may be changed back in future.

A fairly common Mac problem is no text appearing on plots due to corrupted or duplicated fonts on your system. You may be able to confirm this by using another font family, e.g. `family = "serif"`. Open the Font Book application (in Applications) and check the fonts that you are using.

**See Also**

`quartzFonts, Devices, png` for way to access the bitmap types of this device via R’s standard bitmap devices.

**Examples**

```r
## Not run:
## put something like this is your .Rprofile to customize the defaults
setHook(packageEvent("grDevices", "onLoad"),
    function(...) grDevices::quartz.options(width = 8, height = 6,
        pointsize = 10))

## End(Not run)
```
quartzFonts

Description

These functions handle the translation of a device-independent R graphics font family name to a quartz font description.

Usage

quartzFont(family)
quartzFonts(...)

Arguments

  family
     a character vector containing the four PostScript font names for plain, bold, italic, and bolditalic versions of a font family.

  ...    either character strings naming mappings to display, or new (named) mappings to define.

Details

A quartz device is created with a default font (see the documentation for quartz), but it is also possible to specify a font family when drawing to the device (for example, see the documentation for gpar in the grid package).

The font family sent to the device is a simple string name, which must be mapped to something more specific to quartz fonts. A list of mappings is maintained and can be modified by the user.

The quartzFonts function can be used to list existing mappings and to define new mappings. The quartzFont function can be used to create a new mapping.

Default mappings are provided for three device-independent font family names: "sans" for a sans-serif font, "serif" for a serif font and "mono" for a monospaced font.

See Also

quartz

Examples

quartzFonts()
quartzFonts("mono")
## Not run:
## for CJK locales you can use something like
quartzFonts(sans = quartzFont(rep("AppleGothic", 4)),
  serif = quartzFont(rep("AppleMyungjo", 4)))
## since the default fonts may well not have the glyphs needed

## End(Not run)
recordGraphics

Record Graphics Operations

Description
Records arbitrary code on the graphics engine display list. Useful for encapsulating calculations with graphical output that depends on the calculations. Intended only for expert use.

Usage
recordGraphics(expr, list, env)

Arguments
expr object of mode expression or call or an unevaluated expression.
list a list defining the environment in which expr is to be evaluated.
env An environment specifying where R looks for objects not found in envir.

Details
The code in expr is evaluated in an environment constructed from list, with env as the parent of that environment.
All three arguments are saved on the graphics engine display list so that on a device resize or copying between devices, the original evaluation environment can be recreated and the code can be re-evaluated to reproduce the graphical output.

Value
The value from evaluating expr.

Warning
This function is not intended for general use. Incorrect or improper use of this function could lead to unintended and/or undesirable results.
An example of acceptable use is querying the current state of a graphics device or graphics system setting and then calling a graphics function.
An example of improper use would be calling the assign function to performing assignments in the global environment.

See Also
eval

Examples
require(graphics)
plot(1:10)
# This rectangle remains 1inch wide when the device is resized
recordGraphics{
   
}
recordPlot

rect(4, 2,
    4 + diff(par("usr")[1:2])/par("pin")[1], 3)
),
list(),
gegetNamespace("graphics"))

recordPlot  Record and Replay Plots

Description

Functions to save the current plot in an R variable, and to replay it.

Usage

recordPlot()
replayPlot(x)

Arguments

x  A saved plot.

Details

These functions record and replay the displaylist of the current graphics device. The returned object is of class "recordedplot", and replayPlot acts as a print method for that class.

The returned object is stored as a pairlist, but the usual methods for examining R objects such as deparse and str are liable to mislead.

Value

recordPlot returns an object of class "recordedplot".
replayPlot has no return value.

Warning

The format of recorded plots may change between R versions. Recorded plots should not be used as a permanent storage format for R plots. There were extensive changes in R 3.0.0, and now only plots from the current session can be replayed.

R will always attempt to replay a recorded plot, but if the plot was recorded with a different R session then bad things may happen.
Description

This function creates colors corresponding to the given intensities (between 0 and max) of the red, green and blue primaries. The colour specification refers to the standard sRGB colorspace (IEC standard 61966).

An alpha transparency value can also be specified (as an opacity, so 0 means fully transparent and max means opaque). If alpha is not specified, an opaque colour is generated.

The names argument may be used to provide names for the colors.

The values returned by these functions can be used with a col= specification in graphics functions or in par.

Usage

`rgb(red, green, blue, alpha, names = NULL, maxColorValue = 1)`

Arguments

- `red, blue, green, alpha` numeric vectors with values in \([0, M]\) where \(M\) is `maxColorValue`. When this is 255, the red, blue, green, and alpha values are coerced to integers in \(0:255\) and the result is computed most efficiently.
- `names` character. The names for the resulting vector.
- `maxColorValue` number giving the maximum of the color values range, see above.

Details

The colors may be specified by passing a matrix or data frame as argument `red`, and leaving `blue` and `green` missing. In this case the first three columns of `red` are taken to be the red, green and blue values.

Semi-transparent colors (\(0 < \alpha < 1\)) are supported only on some devices: at the time of writing on the pdf, windows, quartz and X11(type = “cairo”) devices and associated bitmap devices (jpeg, png, bmp, tiff and bitmap). They are supported by several third-party devices such as those in packages Cairo, cairoDevice and JavaGD. Only some of these devices support semi-transparent backgrounds.

Most other graphics devices plot semi-transparent colors as fully transparent, usually with a warning when first encountered.

Value

A character vector with elements of 7 or 9 characters, "#" followed by the red, blue, green and optionally alpha values in hexadecimal (after rescaling to \(0 \ldots 255\)). The optional alpha values range from \(0\) (fully transparent) to 255 (opaque).

R does not use ‘premultiplied alpha’.

See Also

`col2rgb` for translating R colors to RGB vectors; `rainbow, hsv, hcl, gray`. 
rgb2hsv

**Examples**

```
rgb(0, 1, 0)
rgb((0:15)/15, green = 0, blue = 0, names = paste("red", 0:15, sep = "."))
rgb(0, 0:12, 0, max = 255) # integer input
ramp <- colorRamp(c("red", "white"))
rgb(ramp(seq(0, 1, length = 5)), max = 255)
```

---

**rgb2hsv**  
*RGB to HSV Conversion*

**Description**

`rgb2hsv` transforms colors from RGB space (red/green/blue) into HSV space (hue/saturation/value).

**Usage**

`rgb2hsv(r, g = NULL, b = NULL, maxColorValue = 255)`

**Arguments**

- `r`  
  vector of ‘red’ values in \([0, M]\), \((M = \text{maxColorValue})\) or 3-row rgb matrix.
- `g`  
  vector of ‘green’ values, or `NULL` when `r` is a matrix.
- `b`  
  vector of ‘blue’ values, or `NULL` when `r` is a matrix.
- `maxColorValue`  
  number giving the maximum of the RGB color values range. The default 255 corresponds to the typical \(0:255\) RGB coding as in `col2rgb()`.

**Details**

Value (brightness) gives the amount of light in the color.  
Hue describes the dominant wavelength.  
Saturation is the amount of Hue mixed into the color.  
An HSV colorspace is relative to an RGB colorspace, which in \(R\) is sRGB, which has an implicit gamma correction.

**Value**

A matrix with a column for each color. The three rows of the matrix indicate hue, saturation and value and are named "h", "s", and "v" accordingly.

**Author(s)**

R interface by Wolfram Fischer <wolfram@fischer-zim.ch>;  
C code mainly by Nicholas Lewin-Koh <nikko@haimail.net>.

**See Also**

`hsv`, `col2rgb`, `rgb`.  

## Examples

```r
## These (saturated, bright ones) only differ by hue
(rc <- col2rgb(c("red", "yellow","green","cyan", "blue", "magenta"))))
(hc <- rgb2hsv(rc))
6 * hc["h",] # the hues are equispaced

(rgb3 <- floor(256 * matrix(stats::runif(3*12), 3, 12)))
(hsv3 <- rgb2hsv(rgb3))
## Consistency :
stopifnot(rgb3 == col2rgb(hsv(h = hsv3[1,], s = hsv3[2,], v = hsv3[3,]),
all.equal(hsv3, rgb2hsv(rgb3/255, maxColorValue = 1)))

## A (simplified) pure R version -- originally by Wolfram Fischer --
## showing the exact algorithm:
rgb2hsvR <- function(rgb, gamma = 1, maxColorValue = 255) {
  if(!is.numeric(rgb)) stop("rgb matrix must be numeric")
  d <- dim(rgb)
  if(d[1] != 3) stop("rgb matrix must have 3 rows")
  n <- d[2]
  if(n == 0) return(cbind(c(h = 1, s = 1, v = 1))[,0])
  rgb <- rgb/maxColorValue
  if(gamma != 1) rgb <- rgb ^ (1/gamma)

  ## get the max and min
  v <- apply(rgb, 2, max)
  s <- apply(rgb, 2, min)
  D <- v - s # range

  ## set hue to zero for undefined values (gray has no hue)
  h <- numeric(n)
  notgray <- ( s != v )

  ## blue hue
  idx <- (v == rgb[3,] & notgray )
  if (any(idx))
    h[idx] <- 2/3 + 1/6 * (rgb[1,idx] - rgb[2,idx]) / D[idx]

  ## green hue
  idx <- (v == rgb[2,] & notgray )
  if (any(idx))
    h[idx] <- 1/3 + 1/6 * (rgb[3,idx] - rgb[1,idx]) / D[idx]

  ## red hue
  idx <- (v == rgb[1,] & notgray )
  if (any(idx))

  ## correct for negative red
  idx <- (h < 0)
  h[idx] <- 1+h[idx]

  ## set the saturation
  s[! notgray] <- 0;
  s[notgray] <- 1 - s[notgray] / v[notgray]

  rbind( h = h, s = s, v = v )
```
savePlot

## savePlot

### Description

Save the current page of a cairo `X11()` device to a file.

### Usage

```r
savePlot(filename = paste("Rplot", type, sep = "."),
    type = c("png", "jpeg", "tiff", "bmp"),
    device = dev.cur())
```

### Arguments

- `filename`: filename to save to.
- `type`: file type: only "png" will be accepted for cairo version 1.0.
- `device`: the device to save from.

### Details

Only cairo-based X11 devices are supported.

This works by copying the image surface to a file. For PNG will always be a 24-bit per pixel PNG `DirectClass` file, for JPEG the quality is 75% and for TIFF there is no compression.

For devices with buffering this copies the buffer's image surface, so works even if `dev.hold` has been called.

At present the plot is saved after rendering onto the canvas (default opaque white), so for the default `bg = "transparent"` the effective background colour is the canvas colour.

### Value

Invisible NULL.

### Note

There is a similar function of the same name but more types for windows devices on Windows.

### See Also

`X11, dev.copy, dev.print`
trans3d  

3D to 2D Transformation for Perspective Plots

Description

Projection of 3-dimensional to 2-dimensional points using a 4x4 viewing transformation matrix. Mainly for adding to perspective plots such as persp.

Usage

trans3d(x, y, z, pmat)

Arguments

x, y, z  numeric vectors of equal length, specifying points in 3D space.
pmat     a 4 x 4 viewing transformation matrix, suitable for projecting the 3D coordinates (x, y, z) into the 2D plane using homogeneous 4D coordinates (x, y, z, t); such matrices are returned by persp().

Value

a list with two components
x, y     the projected 2d coordinates of the 3d input (x, y, z).

See Also

persp

Examples

##

Type1Font

Type 1 and CID Fonts

Description

These functions are used to define the translation of a R graphics font family name to a Type 1 or CID font descriptions, used by both the postscript and pdf graphics devices.

Usage

Type1Font(family, metrics, encoding = "default")

CIDFont(family, cmap, cmapEncoding, pdfresource = "")
**Arguments**

- **family**
  A character string giving the name to be used internally for a Type 1 or CID-keyed font family. This needs to uniquely identify each family, so if you modify a family which is in use (see `postscriptFonts`) you need to change the family name.

- **metrics**
  A character vector of four or five strings giving paths to the afm (Adobe Font Metric) files for the font.

- **cmap**
  The name of a CMap file for a CID-keyed font.

- **encoding**
  For Type1Font, the name of an encoding file. Defaults to "default", which maps on Unix-alikes to "ISOLatin1.enc" and on Windows to "WinAnsi.enc". Otherwise, a file name in the ‘enc’ directory of the `grDevices` package, which is used if the path does not contain a path separator. An extension ".enc" can be omitted.

- **cmapEncoding**
  The name of a character encoding to be used with the named CMap file: strings will be translated to this encoding when written to the file.

- **pdfresource**
  A chunk of PDF code; only required for using a CID-keyed font on pdf; users should not be expected to provide this.

**Details**

For Type1Fonts, if four `.afm` files are supplied the fifth is taken to be "Symbol.afm". Relative paths are taken relative to the directory `R_HOME/library/grDevices/afm`. The fifth (symbol) font must be in AdobeSym encoding. However, the glyphs in the first four fonts are referenced by name and any encoding given within the `.afm` files is not used.

The `.afm` files may be compressed with (or without) final extension `.gz`: the files which ship with R are installed as compressed files with this extension.

Glyphs in CID-keyed fonts are accessed by ID (number) and not by name. The CMap file maps encoded strings (usually in a MBCS) to IDs, so cmap and cmapEncoding specifications must match. There are no real bold or italic versions of CID fonts (bold/italic were very rarely used in traditional CJK topography), and for the `pdf` device all four font faces will be identical. However, for the `postscript` device, bold and italic (and bold italic) are emulated.

CID-keyed fonts are intended only for use for the glyphs of CJK languages, which are all monospaced and are all treated as filling the same bounding box. (Thus `plotmath` will work with such characters, but the spacing will be less carefully controlled than with Western glyphs.) The CID-keyed fonts do contain other characters, including a Latin alphabet: non-CJK glyphs are regarded as monospaced with half the width of CJK glyphs. This is often the case, but sometimes Latin glyphs designed for proportional spacing are used (and may look odd). We strongly recommend that CID-keyed fonts are only used for CJK glyphs.

**Value**

A list of class "Type1Font" or "CIDFont".

**See Also**

`postscript, pdf, postscriptFonts, and pdfFonts`
Examples

```r
## This duplicates "ComputerModernItalic".
CMitalic <- Type1Font("ComputerModern2",
    c("CM_regular_10.afm", "CM_boldx_10.afm",
    "cmti10.afm", "cmbx10.afm",
    "CM_symbol_10.afm"),
    encoding = "TeXtext.enc")

## Not run:
## This could be used by
postscript(family = CMitalic)
## or
postscriptFonts(CMitalic = CMitalic)  # once in a session
postscript(family = "CMitalic", encoding = "TeXtext.enc")

## End(Not run)
```

Description

x11 starts a graphics device driver for the X Window System (version 11). This can only be done on machines/accounts that have access to an X server.

x11 is recognized as a synonym for X11.

The R function is a wrapper for two devices, one based on Xlib (http://en.wikipedia.org/wiki/Xlib) and one using cairographics (http://www.cairographics.org).

Usage

```r
X11(display = "", width, height, pointsize, gamma, bg, canvas,
    fonts, family, xps, yps, title, type, antialias)

X11.options(..., reset = FALSE)
```

Arguments

display

the display on which the graphics window will appear. The default is to use the value in the user’s environment variable DISPLAY. This is ignored (with a warning) if an X11 device is already open on another display.

width, height

the width and height of the plotting window, in inches. If NA, taken from the resources and if not specified there defaults to 7 inches. See also ‘Resources’.

dpointsize

the default pointsize to be used. Defaults to 12.

gamma

gamma correction fudge factor. Colours in R are sRGB; if your monitor does not conform to sRGB, you might be able to improve things by tweaking this parameter to apply additional gamma correction to the RGB channels. By default 1 (no additional gamma correction).

bg

colour, the initial background colour. Default "transparent".
The colour of the canvas, which is visible only when the background colour is transparent. Should be an opaque colour (and any alpha value will be ignored). Default "white".

for type = "Xlib" only: X11 font description strings into which weight, slant and size will be substituted. There are two, the first for fonts 1 to 4 and the second for font 5, the symbol font. See section 'Fonts'.

The default family: a length-one character string. This is primarily intended for cairo-based devices, but for type = "Xlib", the X11Fonts() database is used to map family names to fonts (and this argument takes precedence over that one).

integer: initial position of the top left corner of the window, in pixels. Negative values are from the opposite corner, e.g. xpos = -100 says the top right corner should be 100 pixels from the right edge of the screen. If NA (the default), successive devices are cascaded in 20 pixel steps from the top left. See also 'Resources'.

character string, up to 100 bytes. With the default, ",", a suitable title is created internally. A C-style format for an integer will be substituted by the device number (see the file argument to postscript for further details). How non-ASCII titles are handled is implementation-dependent.

character string, one of "Xlib", "cairo", "nbcairo" or "dbcairo". Only the first will be available if the system was compiled without support for cairographics. The default is "cairo" where available except on OS X, otherwise "Xlib".

for cairo types, the type of anti-aliasing (if any) to be used. One of c("default", "none", "gray", "subpixel").

logical: should the defaults be reset to their defaults?

Any of the arguments to X11, plus colortype and maxcubesize (see section 'Colour Rendering').

The defaults for all of the arguments of X11 are set by X11.options: the 'Arguments' section gives the 'factory-fresh' defaults.

The initial size and position are only hints, and may not be acted on by the window manager. Also, some systems (especially laptops) are set up to appear to have a screen of a different size to the physical screen.

Option type selects between two separate devices: R can be built with support for neither, type = "Xlib" or both. Where both are available, types "cairo", "nbcairo" and "dbcairo" offer

• antialiasing of text and lines.
• translucent colours.
• scalable text, including to sizes like 4.5 pt.
• full support for UTF-8, so on systems with suitable fonts you can plot in many languages on a single figure (and this will work even in non-UTF-8 locales). The output should be locale-independent.

There are three variants of the cairo-based device. type = "nbcairo" has no buffering. type = "cairo" has some buffering, and supports dev.hold and dev.flush. type = "dbcairo" buffers output and updates the screen about every 100ms (by default). The refresh interval can be
set (in units of seconds) by e.g. `options(X11updates = 0.25)`: the value is consulted when a device is opened. Updates are only looked for every 50ms (at most), and during heavy graphics computations only every 500ms.

Which version will be fastest depends on the X11 connection and the type of plotting. You will probably want to use a buffered type unless backing store is in use on the X server (which for example it always is on OS X displays), as otherwise repainting when the window is exposed will be slow. On slow connections type = "dbcairo" will probably give the best performance.

Because of known problems with font selection on OS X without Pango (for example, the CRAN distribution), type = "cairo" is not the default there. These problems have included mixing up bold and italic (since worked around), selecting incorrect glyphs and ugly or missing symbol glyphs.

All devices which use an X11 server (including the type = "Xlib" versions of bitmap devices such as `png`) share internal structures, which means that they must use the same display and visual. If you want to change display, first close all such devices.

The cursor shown indicates the state of the device. If quiescent the cursor is an arrow: when the locator is in use it is a crosshair cursor, and when plotting computations are in progress (and this can be detected) it is a watch cursor. (The exact cursors displayed will depend on the window manager in use.)

### X11 Fonts

This section applies only to type = "Xlib".

An initial/default font family for the device can be specified via the `fonts` argument, but if a device-independent R graphics font family is specified (e.g., via `par(family =)` in the graphics package), the X11 device makes use of the X11 font database (see `xlibfonts`) to convert the R graphics font family to an X11-specific font family description. If `family` is supplied as an argument, the X11 font database is used to convert that, but otherwise the argument `fonts` (with default given by `X11.options`) is used.

X11 chooses fonts by matching to a pattern, and it is quite possible that it will choose a font in the wrong encoding or which does not contain glyphs for your language (particularly common in isoh8646-1 fonts).

The `fonts` argument is a two-element character vector, and the first element will be crucial in successfully using non-Western-European fonts. Settings that have proved useful include

"-*mincho-%s-%s-***-%d-***-***-***-***-***" for CJK languages and

"-*cronyx-helvetica-%s-%s-***-%d-***-***-***-***-***" for Russian.

For UTF-8 locales, the XLC_LOCALE databases provide mappings between character encodings, and you may need to add an entry for your locale (e.g. Fedora Core 3 lacked one for `ru RU.utf8`).

### Cairo Fonts

The cairographics-based devices work directly with font family names such as "Helvetica" which can be selected initially by the `family` argument and subsequently by `par` or `gpar`. There are mappings for the three device-independent font families, "sans" for a sans-serif font (to "Helvetica"), "serif" for a serif font (to "Times") and "mono" for a monospaced font (to "Courier").

The font selection is handled by Pango (usually via `fontconfig`) or `fontconfig` (on OS X and perhaps elsewhere). The results depend on the fonts installed on the system running R – setting the environment variable FC_DEBUG to 1 normally allows some tracing of the selection process.

This works best when high-quality scalable fonts are installed, usually in Type 1 or TrueType formats: see the "R Installation and Administration Manual" for advice on how to obtain and install.
such fonts. At present the best rendering (including using kerning) will be achieved with TrueType fonts: see http://www.freedesktop.org/software/fontconfig/fontconfig-user.html for ways to set up your system to prefer them. The default family ("Helvetica") is likely not to use kerning: alternatives which should if you have them installed are "Arial", "DejaVu Sans" and "Liberation Sans" (and perhaps "FreeSans"). For those who prefer fonts with serifs, try "Times New Roman", "DejaVu Serif" and "Liberation Serif". To match LaTeX text, use something like "CM Roman".

Problems with incorrect rendering of symbols (e.g. of quote(pi) and expression(10*degree)) have been seen on Linux systems which have the Wine symbol font installed – fontconfig then prefers this and misinterprets its encoding. Adding the following lines to ‘~/.fonts.conf’ or ‘/etc/fonts/local.conf’ may circumvent this problem by preferring the URW Type 1 symbol font.

<fontconfig>
<match target="pattern">
  <test name="family"><string>Symbol</string></test>
  <edit name="family" mode="prepend" binding="same">
    <string>Standard Symbols L</string>
  </edit>
</match>
</fontconfig>

A test for this is to run at the command line fc-match Symbol. If that shows symbol.ttf that may be the Wine symbol font – use locate symbol.ttf to see if it is found from a directory with ‘wine’ in the name.

Resources

The standard X11 resource geometry can be used to specify the window position and/or size, but will be overridden by values specified as arguments or non-NA defaults set in X11.options. The class looked for is R_x11. Note that the resource specifies the width and height in pixels and not in inches. See for example ‘man X’ (or http://www.xfree86.org/current/X.7.html). An example line in ‘~/.Xresources’ might be

R_x11*geometry: 900x900-0+0

which specifies a 900 x 900 pixel window at the top right of the screen.

Colour Rendering

X11 supports several ‘visual’ types, and nowadays almost all systems support ‘truecolor’ which X11 will use by default. This uses a direct specification of any RGB colour up to the depth supported (usually 8 bits per colour). Other visuals make use of a palette to support fewer colours, only grays or even only black/white. The palette is shared between all X11 clients, so it can be necessary to limit the number of colours used by R.

The default for type = "Xlib" is to use the best possible colour model for the visual of the X11 server: these days this will almost always be ‘truecolor’. This can be overridden by the colortype argument of X11.options. Note: All x11 and type = "Xlib" bmp, jpeg, png and tiff devices share a colortype which is set when the first device to be opened. To change the colortype you need to close all open such devices, and then use X11.options(colortype =).

The colortype types are tried in the order "true", "pseudo", "gray" and "mono" (black or white only). The values "pseudo" and "pseudo.cube" provide two colour strategies for a pseudocolor
visual. The first strategy provides on-demand colour allocation which produces exact colours until the colour resources of the display are exhausted (when plotting will fail). The second allocates (if possible) a standard colour cube, and requested colours are approximated by the closest value in the cube.

With colortype equal to "pseudo.cube" or "gray" successively smaller palettes are tried until one is completely allocated. If allocation of the smallest attempt fails the device will revert to "mono". For "gray" the search starts at 256 grays for a display with depth greater than 8, otherwise with half the available colours. For "pseudo.cube" the maximum cube size is set by X11.options(maxcolors=) and defaults to 256. With that setting the largest cube tried is 4 levels each for RGB, using 64 colours in the palette.

The cairographics-based devices most likely only work (or work correctly) with 'TrueColor' visuals, although in principle this depends on the cairo installation: a warning is given if any other visual is encountered.

type = "Xlib" supports 'TrueColor', 'PseudoColor', 'GrayScale', StaticGray and MonoChrome visuals: 'StaticColor' and 'DirectColor' visuals are handled only in black/white.

**Anti-aliasing**

Anti-aliasing is only supported for cairographics-based devices, and applies to both graphics and fonts. It is generally preferable for lines and text, but can lead to undesirable effects for fills, e.g. for image plots, and so is never used for fills.

antialias = "default" is in principle platform-dependent, but seems most often equivalent to antialias = "gray".

**Conventions**

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”.

- The default device size is 7 inches square.
- Font sizes are in big points.
- The default font family is Helvetica.
- Line widths in 1/96 inch, minimum one pixel for type = "Xlib", 0.01 otherwise.
- For type = "Xlib" circle radii are in pixels with minimum one.
- Colours are interpreted by the X11 server, which is assumed to conform to sRGB.

**Examples**

```r
## Not run:
## put something like this is your .Rprofile to customize the defaults
setHook(packageEvent("grDevices", "onLoad"),
        function(...) grDevices::X11.options(width = 8, height = 6, xpos = 0,
                                        pointsize = 10))

## End(Not run)
```
Description

These functions handle the translation of a device-independent R graphics font family name to an X11 font description.

Usage

\texttt{X11Font(font)}
\texttt{X11Fonts(\ldots)}

Arguments

\texttt{font} a character string containing an X11 font description.
\texttt{\ldots} either character strings naming mappings to display, or new (named) mappings to define.

Details

These functions apply only to an \texttt{X11} device with \texttt{type = "Xlib" - X11(type = "cairo")} uses a different mechanism to select fonts.

Such a device is created with a default font (see the documentation for \texttt{X11}), but it is also possible to specify a font family when drawing to the device (for example, see the documentation for "family" in \texttt{par} and for "fontfamily" in \texttt{gpar} in the \texttt{grid} package).

The font family sent to the device is a simple string name, which must be mapped to something more specific to X11 fonts. A list of mappings is maintained and can be modified by the user.

The \texttt{X11Fonts} function can be used to list existing mappings and to define new mappings. The \texttt{X11Font} function can be used to create a new mapping.

Default mappings are provided for three device-independent font family names: "sans" for a sans-serif font, "serif" for a serif font and "mono" for a monospaced font. Further mappings are provided for "Helvetica" (the device default), "Times", "CyrHelvetica", "CyrTimes" (versions of these fonts with Cyrillic support, at least on Linux), "Arial" (on some platforms including OS X and Solaris) and "Mincho" (a CJK font).

See Also

\texttt{X11}

Examples

\texttt{X11Fonts()}
\texttt{X11Fonts("mono")}
\texttt{utopia <- X11Font("-*-utopia-*-*-*-*-*-*-*-*-*-*-*-*-*-*-*")}
\texttt{X11Fonts(utopia = utopia)}
xfig starts the graphics device driver for producing XFig (version 3.2) graphics.

The auxiliary function `ps.options` can be used to set and view (if called without arguments) default values for the arguments to `xfig` and `postscript`.

**Usage**

```r
xfig(file = ifelse(onefile, "Rplots.fig", "Rplot%03d.fig"),
     onefile = FALSE, encoding = "none",
     paper = "default", horizontal = TRUE,
     width = 0, height = 0, family = "Helvetica",
     pointsize = 12, bg = "transparent", fg = "black",
     pagecentre = TRUE, defaultfont = FALSE, textspecial = FALSE)
```

**Arguments**

- `file` a character string giving the name of the file. For use with `onefile = FALSE` give a C integer format such as "Rplot%03d.fig" (the default in that case). (See `postscript` for further details.)
- `onefile` logical: if true allow multiple figures in one file. If false, assume only one page per file and generate a file number containing the page number.
- `encoding` the encoding in which to write text strings. The default is not to re-encode. This can be any encoding recognized by `iconv`: in a Western UTF-8 locale you probably want to select an 8-bit encoding such as `latin1`, and in an East Asian locale an EUC encoding. If re-encoding fails, the text strings will be written in the current encoding with a warning.
- `paper` the size of paper region. The choices are "A4", "Letter" and "Legal" (and these can be lowercase). A further choice is "default", which is the default. If this is selected, the papersize is taken from the option "papersize" if that is set to a non-empty value, otherwise "A4".
- `horizontal` the orientation of the printed image, a logical. Defaults to true, that is landscape orientation.
- `width`, `height` the width and height of the graphics region in inches. The default is to use the entire page less a 0.5 inch overall margin in each direction. (See `postscript` for further details.)
- `family` the font family to be used. This must be one of "AvantGarde", "Bookman", "Courier", "Helvetica" (the default), "Helvetica-Narrow", "NewCenturySchoolbook", "Palatino" or "Times". Any other value is replaced by "Helvetica", with a warning.
- `pointsize` the default point size to be used.
- `bg` the initial background color to be used.
- `fg` the initial foreground color to be used.
- `pagecentre` logical: should the device region be centred on the page?
defaultfont logical: should the device use xfig’s default font?

textspecial logical: should the device set the textspecial flag for all text elements. This is useful when generating postex from xfig figures.

Details

Although xfig can produce multiple plots in one file, the XFig format does not say how to separate or view them. So onefile = FALSE is the default.

The file argument is interpreted as a C integer format as used by sprintf, with integer argument the page number. The default gives files ‘Rplot001.fig’, ‘Rplot002.fig’, ‘Rplot1000.fig’, ....

Line widths as controlled by par(lwd =) are in multiples of 5/432 inch. Multiples less than 1 are allowed. pch = ".” with cex = 1 corresponds to a square of side 1/72 inch.

Windows users can make use of WinFIG (http://www.schmidt-web-berlin.de/WinFIG.htm, shareware), or XFig under Cygwin.

Conventions

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”.

- The default device size is the paper size with a 0.25 inch border on all sides.
- Font sizes are in big points.
- The default font family is Helvetica.
- Line widths are integers, multiples of 5/432 inch.
- Circle radii are multiples of 1/1200 inch.
- Colours are interpreted by the viewing/printing application.

Note

Only some line textures (0 <= 1ty < 4) are used. Eventually this may be partially remedied, but the XFig file format does not allow as general line textures as the R model. Unimplemented line textures are displayed as dash-double-dotted.

There is a limit of 512 colours (plus white and black) per file.

xy.coords

Extracting Plotting Structures

Description

xy.coords is used by many functions to obtain x and y coordinates for plotting. The use of this common mechanism across all relevant R functions produces a measure of consistency.

Usage

xy.coords(x, y = NULL, xlab = NULL, ylab = NULL, log = NULL, recycle = FALSE)

Arguments

x, y the x and y coordinates of a set of points. Alternatively, a single argument x can be provided.

xlab, ylab names for the x and y variables to be extracted.

log character, "x", "y" or both, as for plot. Sets negative values to NA and gives a warning.

recycle logical; if TRUE, recycle (rep) the shorter of x or y if their lengths differ.

Details

An attempt is made to interpret the arguments x and y in a way suitable for bivariate plotting (or other bivariate procedures).

If y is NULL and x is a

formula: of the form yvar ~ xvar. xvar and yvar are used as x and y variables.

list: containing components x and y, these are used to define plotting coordinates.

time series: the x values are taken to be time(x) and the y values to be the time series.

matrix or data.frame with two or more columns: the first is assumed to contain the x values and the second the y values. Note that is also true if x has columns named "x" and "y"; these names will be irrelevant here.

In any other case, the x argument is coerced to a vector and returned as y component where the resulting x is just the index vector 1:n. In this case, the resulting xlab component is set to "Index".

If x (after transformation as above) inherits from class "POSIXt" it is coerced to class "POSIXct".

Value

A list with the components

x numeric (i.e., "double") vector of abscissa values.

y numeric vector of the same length as x.

xlab character(1) or NULL, the ‘label’ of x.

ylab character(1) or NULL, the ‘label’ of y.
xyTable

Multiplicities of (x,y) Points, e.g., for a Sunflower Plot

Description

Given (x,y) points, determine their multiplicity – checking for equality only up to some (crude kind of) noise. Note that this is special kind of 2D binning.

Usage

xyTable(x, y = NULL, digits)

Arguments

x, y numeric vectors of the same length; alternatively other (x, y) argument combinations as allowed by xy.coords(x, y).

digits integer specifying the significant digits to be used for determining equality of coordinates. These are compared after rounding them via signif(*, digits).

Value

A list with three components of same length,

x x coordinates, rounded and sorted.

y y coordinates, rounded (and sorted within x).

number multiplicities (positive integers); i.e., number[i] is the multiplicity of (x[i], y[i]).

See Also

sunflowerplot which typically uses xyTable(); signif.

Examples

xyTable(iris[, 3:4], digits = 6)

## Discretized uncorrelated Gaussian:

require(stats)
xy <- data.frame(x = round(sort(rnorm(100))), y = rnorm(100))
xyTable(xy, digits = 1)
xyz.coords

Extracting Plotting Structures

Description

Utility for obtaining consistent x, y and z coordinates and labels for three dimensional (3D) plots.

Usage

```r
xyz.coords(x, y = NULL, z = NULL,
            xlab = NULL, ylab = NULL, zlab = NULL,
            log = NULL, recycle = FALSE)
```

Arguments

- `x`, `y`, `z`: the x, y and z coordinates of a set of points. Both y and z can be left at NULL. In this case, an attempt is made to interpret x in a way suitable for plotting. If the argument is a formula `zvar ~ xvar + yvar`, `xvar`, `yvar` and `zvar` are used as x, y and z variables; if the argument is a list containing components `x`, `y` and `z`, these are assumed to define plotting coordinates; if the argument is a matrix or `data.frame` with three or more columns, the first is assumed to contain the x values, the 2nd the y ones, and the 3rd the z ones – independently of any column names that `x` may have. Alternatively two arguments `x` and `y` can be provided (leaving `z` = NULL). One may be real, the other complex; in any other case, the arguments are coerced to vectors and the values plotted against their indices.

- `xlab`, `ylab`, `zlab`: names for the x, y and z variables to be extracted.

- `log`: character, "x", "y", "z" or combinations. Sets negative values to `NA` and gives a warning.

- `recycle`: logical; if TRUE, recycle (rep) the shorter ones of x, y or z if their lengths differ.

Value

A list with the components

- `x`: numeric (i.e., `double`) vector of abscissa values.
- `y`: numeric vector of the same length as x.
- `z`: numeric vector of the same length as x.
- `xlab`: character(1) or NULL, the axis label of x.
- `ylab`: character(1) or NULL, the axis label of y.
- `zlab`: character(1) or NULL, the axis label of z.

References

abline Add Straight Lines to a Plot

Description
This function adds one or more straight lines through the current plot.

Usage
abline(a = NULL, b = NULL, h = NULL, v = NULL, reg = NULL, coef = NULL, untf = FALSE, ...)

745
Arguments

- **a, b**
  - the intercept and slope, single values.

- **untf**
  - logical asking whether to untransform. See ‘Details’.

- **h**
  - the y-value(s) for horizontal line(s).

- **v**
  - the x-value(s) for vertical line(s).

- **coef**
  - a vector of length two giving the intercept and slope.

- **reg**
  - an object with a `coef` method. See ‘Details’.

... graphical parameters such as col, lty and lwd (possibly as vectors: see ‘Details’) and xpd and the line characteristics lend, ljoin and lmitre.

Details

Typical usages are

- `abline(a, b, untf = FALSE, ...)`
- `abline(h =, untf = FALSE, ...)`
- `abline(v =, untf = FALSE, ...)`
- `abline(coef =, untf = FALSE, ...)`
- `abline(reg =, untf = FALSE, ...)`

The first form specifies the line in intercept/slope form (alternatively a can be specified on its own and is taken to contain the slope and intercept in vector form).

The h= and v= forms draw horizontal and vertical lines at the specified coordinates.

The coef form specifies the line by a vector containing the slope and intercept.

reg is a regression object with a `coef` method. If this returns a vector of length 1 then the value is taken to be the slope of a line through the origin, otherwise, the first 2 values are taken to be the intercept and slope.

If untf is true, and one or both axes are log-transformed, then a curve is drawn corresponding to a line in original coordinates, otherwise a line is drawn in the transformed coordinate system. The h and v parameters always refer to original coordinates.

The graphical parameters col, lty and lwd can be specified; see par for details. For the h= and v= usages they can be vectors of length greater than one, recycled as necessary.

Specifying an xpd argument for clipping overrides the global par ("xpd") setting used otherwise.

- `lines` and `segments` for connected and arbitrary lines given by their endpoints. par.
Examples

```r
## Setup up coordinate system (with x == y aspect ratio):
plot(c(-2.3, c(-1.5), type = "n", xlab = "x", ylab = "y", asp = 1)
## the x- and y-axis, and an integer grid
abline(h = 0, v = 0, col = "gray60")
text(1,0, "abline( h = 0 ")", col = "gray60", adj = c(0, -.1))
abline(h = -1:5, v = -2:3, col = "lightgray", lty = 3)
abline(a = 1, b = 2, col = 2)
text(1,3, "abline( 1, 2 )", col = 2, adj = c(-.1, -.1))

## Simple Regression Lines:
require(stats)
sale5 <- c(6, 4, 9, 7, 6, 12, 8, 10, 9, 13)
plot(sale5)
abline(lmfit(1:10, sale5))
abline(lmfit(1:10, sale5, intercept = FALSE), col = 4) # less fitting

z <- lm(dist ~ speed, data = cars)
plot(cars)
abline(z) # equivalent to abline(reg = z) or
abline(coef = coef(z))

## trivial intercept model
abline(mC <- lm(dist ~ 1, data = cars)) ## the same as
abline(a = coef(mC), b = 0, col = "blue")
```

### Description

Draw arrows between pairs of points.

### Usage

```r
arrows(x0, y0, x1 = x0, y1 = y0, length = 0.25, angle = 30,
       code = 2, col = par("fg"), lty = par("lty"),
       lwd = par("lwd"), ...)
```

### Arguments

- **x0, y0**: coordinates of points from which to draw.
- **x1, y1**: coordinates of points to which to draw. At least one must be supplied.
- **length**: length of the edges of the arrow head (in inches).
- **angle**: angle from the shaft of the arrow to the edge of the arrow head.
- **code**: integer code, determining kind of arrows to be drawn.
- **col, lty, lwd**: graphical parameters. possible vectors. NA values in col cause the arrow to be omitted.
- **...**: graphical parameters such as xpd and the line characteristics lend, ljoin and lmitre: see `par`.

---

**arrows**  
*Add Arrows to a Plot*

**Description**

Draw arrows between pairs of points.

**Usage**

```r
arrows(x0, y0, x1 = x0, y1 = y0, length = 0.25, angle = 30,
       code = 2, col = par("fg"), lty = par("lty"),
       lwd = par("lwd"), ...)
```
assocplot

Details
For each i, an arrow is drawn between the point \((x0[i], y0[i])\) and the point \((x1[i], y1[i])\). The coordinate vectors will be recycled to the length of the longest.

If code = 1 an arrowhead is drawn at \((x0[i], y0[i])\) and if code = 2 an arrowhead is drawn at \((x1[i], y1[i])\). If code = 3 a head is drawn at both ends of the arrow. Unless length = 0, when no head is drawn.

The graphical parameters col, lty and lwd can be vectors of length greater than one and will be recycled if necessary.

The direction of a zero-length arrow is indeterminate, and hence so is the direction of the arrowheads. To allow for rounding error, arrowheads are omitted (with a warning) on any arrow of length less than 1/1000 inch.

Note
The first four arguments in the comparable S function are named x1, y1, x2, y2.

References

See Also
segments to draw segments.

Examples
```r
x <- stats::runif(12); y <- stats::rnorm(12)
i <- order(x, y); x <- x[i]; y <- y[i]
plot(x, y, main = "arrows(.) and segments(.)")
## draw arrows from point to point:
s <- seq(length(x)-1)  # one shorter than data
arrows(x[s], y[s], x[s+1], y[s+1], col = 1:3)
s <- s[-length(s)]
segments(x[s], y[s], x[s+2], y[s+2], col = "pink")
```

Description
Produce a Cohen-Friendly association plot indicating deviations from independence of rows and columns in a 2-dimensional contingency table.

Usage
```r
assocplot(x, col = c("black", "red"), space = 0.3,
          main = NULL, xlab = NULL, ylab = NULL)
```
assocplot

Arguments

- **x**: a two-dimensional contingency table in matrix form.
- **col**: a character vector of length two giving the colors used for drawing positive and negative Pearson residuals, respectively.
- **space**: the amount of space (as a fraction of the average rectangle width and height) left between each rectangle.
- **main**: overall title for the plot.
- **xlab**: a label for the x axis. Defaults to the name (if any) of the row dimension in `x`.
- **ylab**: a label for the y axis. Defaults to the name (if any) of the column dimension in `x`.

Details

For a two-way contingency table, the signed contribution to Pearson’s $\chi^2$ for cell $i,j$ is $d_{ij} = (f_{ij} - e_{ij})/\sqrt{e_{ij}}$, where $f_{ij}$ and $e_{ij}$ are the observed and expected counts corresponding to the cell. In the Cohen-Friendly association plot, each cell is represented by a rectangle that has (signed) height proportional to $d_{ij}$ and width proportional to $\sqrt{e_{ij}}$, so that the area of the box is proportional to the difference in observed and expected frequencies. The rectangles in each row are positioned relative to a baseline indicating independence ($d_{ij} = 0$). If the observed frequency of a cell is greater than the expected one, the box rises above the baseline and is shaded in the color specified by the first element of `col`, which defaults to black; otherwise, the box falls below the baseline and is shaded in the color specified by the second element of `col`, which defaults to red.

A more flexible and extensible implementation of association plots written in the grid graphics system is provided in the function `assoc` in the contributed package `vcd` (Meyer, Zeileis and Hornik, 2005).

Examples

```r
## Aggregate over sex:
x <- margin.table(HairEyeColor, c(1, 2))
x
assocplot(x, main = "Relation between hair and eye color")
```
Axis

Generic Function to Add an Axis to a Plot

Description

Generic function to add a suitable axis to the current plot.

Usage

Axis(x = NULL, at = NULL, ..., side, labels = NULL)

Arguments

- x: an object which indicates the range over which an axis should be drawn
- at: the points at which tick-marks are to be drawn.
- side: an integer specifying which side of the plot the axis is to be drawn on. The axis is placed as follows: 1=below, 2=left, 3=above and 4=right.
- labels: this can either be a logical value specifying whether (numerical) annotations are to be made at the tickmarks, or a character or expression vector of labels to be placed at the tickpoints. If this is specified as a character or expression vector, at should be supplied and they should be the same length.
- ...: Arguments to be passed to methods and perhaps then to axis.

Details

This is a generic function. It works in a slightly non-standard way: if x is supplied and non-NULL it dispatches on x, otherwise if at is supplied and non-NULL it dispatches on at, and the default action is to call axis, omitting argument x.

The idea is that for plots for which either or both of the axes are numerical but with a special interpretation, the standard plotting functions (including boxplot, contour, coplot, filled.contour, pairs, plot.default, rug and stripchart) will set up user coordinates and Axis will be called to label them appropriately.

There are "Date" and "POSIXt" methods which can pass an argument format on to the appropriate axis method (see axis.POSIXct).

Value

The numeric locations on the axis scale at which tick marks were drawn when the plot was first drawn (see 'Details').

This function is usually invoked for its side effect, which is to add an axis to an already existing plot.

See Also

axis.
Add an Axis to a Plot

Description

Adds an axis to the current plot, allowing the specification of the side, position, labels, and other options.

Usage

```
axis(side, at = NULL, labels = TRUE, tick = TRUE, line = NA,
pos = NA, outer = FALSE, font = NA, lty = "solid",
lwd = 1, lwd.ticks = lwd, col = NULL, col.ticks = NULL,
hadj = NA, padj = NA, ...)
```

Arguments

- `side`: an integer specifying which side of the plot the axis is to be drawn on. The axis is placed as follows: 1=below, 2=left, 3=above and 4=right.
- `at`: the points at which tick-marks are to be drawn. Non-finite (infinite, NaN or NA) values are omitted. By default (when NULL) tickmark locations are computed, see 'Details' below.
- `labels`: this can either be a logical value specifying whether (numerical) annotations are to be made at the tickmarks, or a character or expression vector of labels to be placed at the tickpoints. (Other objects are coerced by `as.graphics Annotation`.) If this is not logical, `at` should also be supplied and of the same length. If labels is of length zero after coercion, it has the same effect as supplying `true`.
- `tick`: a logical value specifying whether tickmarks and an axis line should be drawn.
- `line`: the number of lines into the margin at which the axis line will be drawn, if not NA.
- `pos`: the coordinate at which the axis line is to be drawn: if not NA this overrides the value of `line`.
- `outer`: a logical value indicating whether the axis should be drawn in the outer plot margin, rather than the standard plot margin.
- `font`: font for text. Defaults to `par("font")`.
- `lty`: line type for both the axis line and the tick marks.
- `lwd`, `lwd.ticks`: line widths for the axis line and the tick marks. Zero or negative values will suppress the line or ticks.
- `col`, `col.ticks`: colors for the axis line and the tick marks respectively. `col = NULL` means to use `par("fg")`, possibly specified inline, and `col.ticks = NULL` means to use whatever color `col` resolved to.
- `hadj`: adjustment (see `par("adj")`) for all labels parallel ('horizontal') to the reading direction. If this is not a finite value, the default is used (centring for strings parallel to the axis, justification of the end nearest the axis otherwise).
- `padj`: adjustment for each tick label perpendicular to the reading direction. For labels parallel to the axes, `padj = 0` means right or top alignment, and `padj = 1` means left or bottom alignment. This can be a vector given a value for each string, and will be recycled as necessary.
If padj is not a finite value (the default), the value of par("las") determines the adjustment. For strings plotted perpendicular to the axis the default is to centre the string.

... other graphical parameters may also be passed as arguments to this function, particularly, cex.axis, col.axis and font.axis for axis annotation, mgp and xaxp or yaxp for positioning, tck or tcl for tick mark length and direction, las for vertical/horizontal label orientation, or fg instead of col, and xpd for clipping. See par on these.

Parameters xaxt (sides 1 and 3) and yaxt (sides 2 and 4) control if the axis is plotted at all.

Note that lab will partial match to argument labels unless the latter is also supplied. (Since the default axes have already been set up by plot.window, lab will not be acted on by axis.)

Details

The axis line is drawn from the lowest to the highest value of at, but will be clipped at the plot region. By default, only ticks which are drawn from points within the plot region (up to a tolerance for rounding error) are plotted, but the ticks and their labels may well extend outside the plot region. Use xpd = TRUE or xpd = NA to allow axes to extend further.

When at = NULL, pretty tick mark locations are computed internally (the same way axTicks(side) would) from par("xaxt") or "yaxt" and par("xlog") (or "ylog"). Note that these locations may change if an on-screen plot is resized (for example, if the plot argument asp (see plot.window) is set.)

If labels is not specified, the numeric values supplied or calculated for at are converted to character strings as if they were a numeric vector printed by print.default(digits = 7).

The code tries hard not to draw overlapping tick labels, and so will omit labels where they would abut or overlap previously drawn labels. This can result in, for example, every other tick being labelled. (The ticks are drawn left to right or bottom to top, and space at least the size of an ‘m’ is left between labels.)

If either line or pos is set, they (rather than par("mgp")[3]) determine the position of the axis line and tick marks, and the tick labels are placed par("mgp")[2] further lines into (or towards for pos) the margin.

Several of the graphics parameters affect the way axes are drawn. The vertical (for sides 1 and 3) positions of the axis and the tick labels are controlled by mgp[2:3] and mex, the size and direction of the ticks is controlled by tck and tcl and the appearance of the tick labels by cex.axis, col.axis and font.axis with orientation controlled by las (but not srt, unlike S which uses srt if at is supplied and las if it is not). Note that adj is not supported and labels are always centered. See par for details.

Value

The numeric locations on the axis scale at which tick marks were drawn when the plot was first drawn (see ‘Details’).

This function is usually invoked for its side effect, which is to add an axis to an already existing plot.

References

See Also

`axis` for a generic interface.

`axTicks` returns the axis tick locations corresponding to `at = NULL`; `pretty` is more flexible for computing pretty tick coordinates and does *not* depend on (nor adapt to) the coordinate system in use.

Several graphics parameters affecting the appearance are documented in `par`.

Examples

```r
require(stats) # for rnorm
plot(1:4, rnorm(4), axes = FALSE)
axis(1, 1:4, LETTERS[1:4])
axis(2)
box() # to make it look "as usual"

plot(1:7, rnorm(7), main = "axis() examples",
     type = "s", xaxt = "n", frame = FALSE, col = "red")
axis(1, 1:7, LETTERS[1:7], col.axis = "blue")
# unusual options:
axis(4, col = "violet", col.axis = "dark violet", lwd = 2)
axis(3, col = "gold", lty = 2, lwd = 0.5)

# one way to have a custom x axis
plot(1:10, xaxt = "n")
axis(1, xaxp = c(2, 9, 7))
```

axis.POSIXct

Date and Date-time Plotting Functions

Description

Functions to plot objects of classes "POSIXlt", "POSIXct" and "Date" representing calendar dates and times.

Usage

```r
axis.POSIXct(side, x, at, format, labels = TRUE, ...)
axis.Date(side, x, at, format, labels = TRUE, ...)
```

Arguments

- `x`, `at` A date-time or date object.
- `side` See `axis`.
- `format` See `strptime`.
- `labels` Either a logical value specifying whether annotations are to be made at the tickmarks, or a vector of character strings to be placed at the tickpoints.
- `...` Further arguments to be passed from or to other methods, typically graphical parameters.
Details

`axis.POSIXct` and `axis.Date` work quite hard to choose suitable time units (years, months, days, hours, minutes or seconds) and a sensible output format, but this can be overridden by supplying a format specification.

If `at` is supplied it specifies the locations of the ticks and labels whereas if `x` is specified a suitable grid of labels is chosen. Printing of tick labels can be suppressed by using `labels = FALSE`.

The date-times for a "POSIXct" input are interpreted in the timezone given by the "tzone" attribute if there is one, otherwise the current timezone.

The way the date-times are rendered (especially month names) is controlled by the locale setting of category "LC_TIME" (see `Sys.setlocale`).

Value

The locations on the axis scale at which tick marks were drawn.

Note

These functions are the workhorse for methods for `Axis`. Prior to R 2.12.0 there were also `plot` methods for the date-time classes, but the default method has also handled those for a long time.

See Also

`DateTimeClasses`, `Dates` for details of the classes.

`Axis`.

Examples

```r
with(beaver1, {
  time <- strptime(paste(1990, day, time %/% 100, time %% 100),
    "%Y %j %H %M")
  plot(time, temp, type = "l") # axis at 4-hour intervals.
  # now label every hour on the time axis
  plot(time, temp, type = "l", xaxt = "n")
  r <- as.POSIXct(round(range(time), "hours"))
  axis.POSIXct(1, at = seq(r[1], r[2], by = "hour"), format = "%H")
  })

plot(.leap.seconds, seq_along(.leap.seconds), type = "n", xaxt = "n",
    xlab = "leap seconds", ylab = "", bty = "n")
rug(.leap.seconds)
## or as dates
lps <- as.Date(.leap.seconds)
plot(lps, seq_along(.leap.seconds),
    type = "n", xaxt = "n", xlab = "leap seconds",
    ylab = "", bty = "n")
rug(lps)
## 100 random dates in a 10-week period
random.dates <- as.Date("2001/1/1") + 70*sort(stats::runif(100))
plot(random.dates, 1:100)
# or for a better axis labelling
plot(random.dates, 1:100, xaxt = "n")
axis.Date(1, at = seq(as.Date("2001/1/1"), max(random.dates)+6, "weeks"))
axis.Date(1, at = seq(as.Date("2001/1/1"), max(random.dates)+6, "days"),
```
labels = FALSE, tcl = -0.2)

axTicks

**Compute Axis Tickmark Locations**

**Description**

Compute pretty tickmark locations, the same way as R does internally. This is only non-trivial when log coordinates are active. By default, gives the at values which axis(side) would use.

**Usage**

axTicks(side, axp = NULL, usr = NULL, log = NULL, nintLog = NULL)

**Arguments**

- **side**: integer in 1:4, as for axis.
- **axp**: numeric vector of length three, defaulting to par("xaxp") or par("yaxp") depending on the side argument (par("xaxp") if side is 1 or 3, par("yaxp") if side is 2 or 4).
- **usr**: numeric vector of length two giving user coordinate limits, defaulting to the relevant portion of par("usr") (par("usr")[1:2] or par("usr")[3:4] for side in (1,3) or (2,4) respectively).
- **log**: logical indicating if log coordinates are active; defaults to par("xlog") or par("ylog") depending on side.
- **nintLog**: (only used when log is true): approximate (lower bound for the) number of tick intervals; defaults to par("lab")[j] where j is 1 or 2 depending on side. Set this to Inf if you want the same behavior as in earlier R versions (than 2.14.x).

**Details**

The axp, usr, and log arguments must be consistent as their default values (the par(..) results) are. If you specify all three (as non-NULL), the graphics environment is not used at all. Note that the meaning of axp differs significantly when log is TRUE; see the documentation on par(xaxp = .).

axTicks() can be used an R interface to the C function CreateAtVector() in \'.\%/src/main/plot.c' which is called by axis(side, *) when no argument at is specified. The delicate case, log = TRUE, now makes use of axisTicks (in package grDevices) unless nintLog = Inf which exists for back compatibility.

**Value**

numeric vector of coordinate values at which axis tickmarks can be drawn. By default, when only the first argument is specified, these values should be identical to those that axis(side) would use or has used. Note that the values are decreasing when usr is ("reverse axis" case).

**See Also**

axis, par, pretty uses the same algorithm (but independently of the graphics environment) and has more options. However it is not available for log = TRUE.

axisTicks() (package grDevices).
Examples

```r
plot(1:7, 10*21:27)
axTicks(1)
axTicks(2)
stopifnot(identical(axTicks(1), axTicks(3)),
          identical(axTicks(2), axTicks(4)))

## Show how axTicks() and axis() correspond:
opt <- par(mfrow = c(3, 1))
for(x in 0:9999 * c(1, 2, 8)) {
  plot(x, 9, log = "x")
  cat(formatC(par("xaxp"), width = 5), ";", T <- axTicks(1), "\n")
  rug(T, col = adjustcolor("red", 0.5), lwd = 4)
}
par(opt)

x <- 9.9*10^(-3:10)
plot(x, 1:14, log = "x")
axTicks(1) # now length 5, in R <= 2.13.x gave the following
axTicks(1, nintLog = Inf) # rather too many

## An example using axTicks() without reference to an existing plot
## (copying R's internal procedures for setting axis ranges etc.),
## You do need to supply _all_ of axp, usr, log, nintLog
## standard logarithmic y axis labels
ylims <- c(0.2, 88)
get_axp <- function(x) 10*c(ceiling(x[1]), floor(x[2]))
## mimic par("yaxs") == "i"
usr.i <- log10(ylims)
(aT.i <- axTicks(side = 2, usr = usr.i, 
                 exp = c(get_axp(usr.i), n = 3), log = TRUE, nintLog = 5))
## mimic (default) par("yaxs") == "r"
usr.r <- extendrange(r = log10(ylims), f = 0.04)
(aT.r <- axTicks(side = 2, usr = usr.r, 
                 exp = c(get_axp(usr.r), 3), log = TRUE, nintLog = 5))

## Prove that we got it right:
plot(0:1, ylims, log = "y", yaxs = "i")
stopifnot(all.equal(aT.i, axTicks(side = 2)))
plot(0:1, ylims, log = "y", yaxs = "r")
stopifnot(all.equal(aT.r, axTicks(side = 2)))
```

---

**barplot**

**Bar Plots**

**Description**

Creates a bar plot with vertical or horizontal bars.

**Usage**

```r
barplot(height, ...)
```
## Default S3 method:

```r
defult <function>(height, width = 1, space = NULL,
                 names.arg = NULL, legend.text = NULL, beside = FALSE,
                 horiz = FALSE, density = NULL, angle = 45,
                 col = NULL, border = par("fg"),
                 main = NULL, sub = NULL, xlab = NULL, ylab = NULL,
                 xlim = NULL, ylim = NULL, xpd = TRUE, log = "",
                 axes = TRUE, axisnames = TRUE,
                 cex.axis = par("cex.axis"), cex.names = par("cex.axis"),
                 inside = TRUE, plot = TRUE, axis.lty = 0, offset = 0,
                 add = FALSE, args.legend = NULL, ...)```

### Arguments

- **height**: either a vector or matrix of values describing the bars which make up the plot. If `height` is a vector, the plot consists of a sequence of rectangular bars with heights given by the values in the vector. If `height` is a matrix and `beside` is `FALSE` then each bar of the plot corresponds to a column of `height`, with the values in the column giving the heights of stacked sub-bars making up the bar. If `height` is a matrix and `beside` is `TRUE`, then the values in each column are juxtaposed rather than stacked.

- **width**: optional vector of bar widths. Re-cycled to length the number of bars drawn. Specifying a single value will have no visible effect unless `xlim` is specified.

- **space**: the amount of space (as a fraction of the average bar width) left before each bar. May be given as a single number or one number per bar. If `height` is a matrix and `beside` is `TRUE`, `space` may be specified by two numbers, where the first is the space between bars in the same group, and the second the space between the groups. If not given explicitly, it defaults to `c(0, 0)` if `height` is a matrix and `beside` is `TRUE`, and to 0.2 otherwise.

- **names.arg**: a vector of names to be plotted below each bar or group of bars. If this argument is omitted, then the names are taken from the `names` attribute of `height` if this is a vector, or the column names if it is a matrix.

- **legend.text**: a vector of text used to construct a legend for the plot, or a logical indicating whether a legend should be included. This is only useful when `height` is a matrix. In that case given legend labels should correspond to the rows of `height`; if `legend.text` is `TRUE`, the row names of `height` will be used as labels if they are non-null.

- **beside**: a logical value. If `FALSE`, the columns of `height` are portrayed as stacked bars, and if `TRUE` the columns are portrayed as juxtaposed bars.

- **horiz**: a logical value. If `FALSE`, the bars are drawn vertically with the first bar to the left. If `TRUE`, the bars are drawn horizontally with the first at the bottom.

- **density**: a vector giving the density of shading lines, in lines per inch, for the bars or bar components. The default value of `NULL` means that no shading lines are drawn. Non-positive values of `density` also inhibit the drawing of shading lines.

- **angle**: the slope of shading lines, given as an angle in degrees (counter-clockwise), for the bars or bar components.

- **col**: a vector of colors for the bars or bar components. By default, grey is used if `height` is a vector, and a gamma-corrected grey palette if `height` is a matrix.

- **border**: the color to be used for the border of the bars. Use `border = NA` to omit borders. If there are shading lines, `border = TRUE` means use the same colour for the border as for the shading lines.
main, sub overall and sub title for the plot.
xlab a label for the x axis.
ylab a label for the y axis.
xlim limits for the x axis.
ylim limits for the y axis.
xpd logical. Should bars be allowed to go outside region?
log string specifying if axis scales should be logarithmic; see plot.default.
axes logical. If TRUE, a vertical (or horizontal, if horiz is true) axis is drawn.
axisnames logical. If TRUE, and if there are names.arg (see above), the other axis is drawn (with lty = 0) and labeled.
cex.axis expansion factor for numeric axis labels.
cex.names expansion factor for axis names (bar labels).
inside logical. If TRUE, the lines which divide adjacent (non-stacked!) bars will be drawn. Only applies when space = 0 (which it partly is when beside = TRUE).
plot logical. If FALSE, nothing is plotted.
axis.lty the graphics parameter lty applied to the axis and tick marks of the categorical (default horizontal) axis. Note that by default the axis is suppressed.
offset a vector indicating how much the bars should be shifted relative to the x axis.
add logical specifying if bars should be added to an already existing plot; defaults to FALSE.
args.legend list of additional arguments to pass to legend(); names of the list are used as argument names. Only used if legend.text is supplied.
... arguments to be passed to/from other methods. For the default method these can include further arguments (such as axes, asp and main) and graphical parameters (see par) which are passed to plot.window(), title() and axis.

Details

This is a generic function, it currently only has a default method. A formula interface may be added eventually.

Value

A numeric vector (or matrix, when beside = TRUE), say mp, giving the coordinates of all the bar midpoints drawn, useful for adding to the graph.

If beside is true, use colMeans(mp) for the midpoints of each group of bars, see example.

                     y = c(840, 200) / 840 * 100, 
                     z = c(37, 17) / 37 * 100),
        beside = FALSE,
        width = c(465, 840, 37),
        col = c(1, 2),

box

**Draw a Box around a Plot**

**Description**

This function draws a box around the current plot in the given color and linetype. The `bty` parameter determines the type of box drawn. See `par` for details.

**Usage**

```r
box(which = "plot", lty = "solid", ...)
```

**Arguments**

- `which` character, one of "plot", "figure", "inner" and "outer".
- `lty` line type of the box.
- `...` further graphical parameters, such as `bty`, `col`, or `lwd`, see `par`. Note that `xpd` is not accepted as clipping is always to the device region.

**Details**

The choice of colour is complicated. If `col` was supplied and is not `NA`, it is used. Otherwise, if `fg` was supplied and is not `NA`, it is used. The final default is `par("col")`.

**References**

**See Also**

- `rect` for drawing of arbitrary rectangles.

**Examples**

```r
plot(1:7, abs(stats::rnorm(7)), type = "h", axes = FALSE)
axis(1, at = 1:7, labels = letters[1:7])
box(lty = '1373', col = 'red')
```
boxplot  

Box Plots

Description

Produce box-and-whisker plot(s) of the given (grouped) values.

Usage

boxplot(x, ...)

## S3 method for class 'formula'
boxplot(formula, data = NULL, ..., subset, na.action = NULL)

## Default S3 method:
boxplot(x, ..., range = 1.5, width = NULL, varwidth = FALSE,
notch = FALSE, outline = TRUE, names, plot = TRUE,
border = par("fg"), col = NULL, log = "",
pars = list(boxwex = 0.8, staplewex = 0.5, outwex = 0.5),
horizontal = FALSE, add = FALSE, at = NULL)

Arguments

formula 
a formula, such as y ~ grp, where y is a numeric vector of data values to be
split into groups according to the grouping variable grp (usually a factor).
data 
a data.frame (or list) from which the variables in formula should be taken.
subset 
an optional vector specifying a subset of observations to be used for plotting.
na.action 
a function which indicates what should happen when the data contain NAs. The
default is to ignore missing values in either the response or the group.
x 
for specifying data from which the boxplots are to be produced. Either a numeric
vector, or a single list containing such vectors. Additional unnamed arguments
specify further data as separate vectors (each corresponding to a component
boxplot). NAs are allowed in the data.
... 
For the formula method, named arguments to be passed to the default method.
For the default method, unnamed arguments are additional data vectors (unless x
is a list when they are ignored), and named arguments are arguments and graphical
parameters to be passed to bxp in addition to the ones given by argument
pars (and override those in pars). Note that bxp may or may not make use of
graphical parameters it is passed: see its documentation.
range 
this determines how far the plot whiskers extend out from the box. If range is
positive, the whiskers extend to the most extreme data point which is no more
than range times the interquartile range from the box. A value of zero causes
the whiskers to extend to the data extremes.
width 
a vector giving the relative widths of the boxes making up the plot.
varwidth 
if varwidth is TRUE, the boxes are drawn with widths proportional to the square-
roots of the number of observations in the groups.
notch 
if notch is TRUE, a notch is drawn in each side of the boxes. If the notches of
two plots do not overlap this is ‘strong evidence’ that the two medians differ
(Chambers et al., 1983, p. 62). See boxplot.stats for the calculations used.
If `outline` is not true, the outliers are not drawn (as points whereas S+ uses lines).

**names**

Group labels which will be printed under each boxplot. Can be a character vector or an expression (see `plotmath`).

**boxwex**

A scale factor to be applied to all boxes. When there are only a few groups, the appearance of the plot can be improved by making the boxes narrower.

**staplewex**

Staple line width expansion, proportional to box width.

**outwex**

Outlier line width expansion, proportional to box width.

**plot**

If TRUE (the default) then a boxplot is produced. If not, the summaries which the boxplots are based on are returned.

**border**

An optional vector of colors for the outlines of the boxplots. The values in `border` are recycled if the length of `border` is less than the number of plots.

**col**

If `col` is non-null it is assumed to contain colors to be used to colour the bodies of the box plots. By default they are in the background colour.

**log**

Character indicating if x or y or both coordinates should be plotted in log scale.

**pars**

A list of (potentially many) more graphical parameters, e.g., `boxwex` or `outpch`; these are passed to `bxp` (if `plot` is true); for details, see there.

**horizontal**

Logical indicating if the boxplots should be horizontal; default `FALSE` means vertical boxes.

**add**

Logical, if true `add` boxplot to current plot.

**at**

Numeric vector giving the locations where the boxplots should be drawn, particularly when `add = TRUE`; defaults to `1:n` where `n` is the number of boxes.

### Details

The generic function `boxplot` currently has a default method (`boxplot.default`) and a formula interface (`boxplot.formula`).

If multiple groups are supplied either as multiple arguments or via a formula, parallel boxplots will be plotted, in the order of the arguments or the order of the levels of the factor (see `factor`).

Missing values are ignored when forming boxplots.

### Value

List with the following components:

- **stats**
  A matrix, each column contains the extreme of the lower whisker, the lower hinge, the median, the upper hinge and the extreme of the upper whisker for one group/plot. If all the inputs have the same class attribute, so will this component.

- **n**
  A vector with the number of observations in each group.

- **conf**
  A matrix where each column contains the lower and upper extremes of the notch.

- **out**
  The values of any data points which lie beyond the extremes of the whiskers.

- **group**
  A vector of the same length as `out` whose elements indicate to which group the outlier belongs.

- **names**
  A vector of names for the groups.
References

See also *boxplot.stats*.

See Also

*boxplot.stats* which does the computation, *bxp* for the plotting and more examples; and *stripchart* for an alternative (with small data sets).

Examples

```r
## boxplot on a formula:
boxplot(count ~ spray, data = InsectSprays, col = "lightgray")
# *add* notches (somewhat funny here):
boxplot(count ~ spray, data = InsectSprays,
        notch = TRUE, add = TRUE, col = "blue")

boxplot(decrease ~ treatment, data = OrchardSprays,
        log = "y", col = "bisque")

rb <- boxplot(decrease ~ treatment, data = OrchardSprays, col = "bisque")
title("Comparing boxplot(s) and non-robust mean +/- SD")

mn.t <- tapply(OrchardSprays$decrease, OrchardSprays$treatment, mean)
sd.t <- tapply(OrchardSprays$decrease, OrchardSprays$treatment, sd)
x <- 0.3 + seq(rb$n)
points(x, mn.t, col = "orange", pch = 18)
arrows(x, mn.t - sd.t, xi, mn.t + sd.t,
        code = 3, col = "pink", angle = 75, length = .1)

## boxplot on a matrix:
mat <- cbind(Uni05 = rnorm(100),
             "ST" = rt(100, df = 5),
             Gam2 = rgamma(100, shape = 2))
boxplot(as.data.frame(mat),
        main = "boxplot(as.data.frame(mat), main = ...)"
par(las = 1) # all axis labels horizontal
boxplot(as.data.frame(mat), main = "boxplot(*, horizontal = TRUE)",
        horizontal = TRUE)

## Using 'at = ' and adding boxplots -- example idea by Roger Bivand:

boxplot(len ~ dose, data = ToothGrowth,
        boxwex = 0.25, at = 1:3 - 0.2,
        subset = supp == "VC", col = "yellow",
        main = "Guinea Pigs' Tooth Growth",
        xlab = "Vitamin C dose mg",
        ylab = "tooth length",
        xlim = c(0.5, 3.5), ylim = c(0, 35), yaxs = "i")

boxplot(len ~ dose, data = ToothGrowth, add = TRUE,
        boxwex = 0.25, at = 1:3 + 0.2,
        subset = supp == "OJ", col = "orange")
```
legend(2, 9, c("Ascorbic acid", "Orange juice"),
    fill = c("yellow", "orange"))

## more examples in help(bxp)

---

**boxplot.matrix**

*Draw a Boxplot for each Column (Row) of a Matrix*

**Description**

Interpreting the columns (or rows) of a matrix as different groups, draw a boxplot for each.

**Usage**

```r
## S3 method for class 'matrix'
boxplot(x, use.cols = TRUE, ...)
```

**Arguments**

- `x` a numeric matrix.
- `use.cols` logical indicating if columns (by default) or rows (`use.cols = FALSE`) should be plotted.
- `...` Further arguments to `boxplot`.

**Value**

A list as for `boxplot`.

**Author(s)**

Martin Maechler, 1995, for S+, then R package `sfsmisc`.

**See Also**

- `boxplot.default` which already works nowadays with data.frames; `boxplot.formula`, `plot.factor` which work with (the more general concept) of a grouping factor.

**Examples**

```r
## Very similar to the example in ?boxplot
mat <- cbind(Uni05 = rnorm(100)/21, Norm = rnorm(100),
    T5 = rt(100, df = 5), Gam2 = rgamma(100, shape = 2))
boxplot(mat, main = "boxplot.matrix(...., main = ...)",
    notch = TRUE, col = 1:4)
```
**Description**

`bxp` draws box plots based on the given summaries in `z`. It is usually called from within `boxplot`, but can be invoked directly.

**Usage**

```r
bxp(z, notch = FALSE, width = NULL, varwidth = FALSE, outline = TRUE, notch.frac = 0.5, log = ",", border = par("fg"), pars = NULL, frame.plot = axes, horizontal = FALSE, add = FALSE, at = NULL, show.names = NULL, ...)
```

**Arguments**

- `z`: a list containing data summaries to be used in constructing the plots. These are usually the result of a call to `boxplot`, but can be generated in any fashion.
- `notch`: if `notch` is `TRUE`, a notch is drawn in each side of the boxes. If the notches of two plots do not overlap then the medians are significantly different at the 5 percent level.
- `width`: a vector giving the relative widths of the boxes making up the plot.
- `varwidth`: if `varwidth` is `TRUE`, the boxes are drawn with widths proportional to the square-roots of the number of observations in the groups.
- `outline`: if `outline` is not `true`, the outliers are not drawn.
- `notch.frac`: numeric in (0,1). When `notch = TRUE`, the fraction of the box width that the notches should use.
- `border`: character or numeric (vector), the color of the box borders. Is recycled for multiple boxes. Is used as default for the `boxcol`, `medcol`, `whiskcol`, `staplecol`, and `outcol` options (see below).
- `log`: character, indicating if any axis should be drawn in logarithmic scale, as in `plot.default`.
- `frame.plot`: logical, indicating if a ‘frame’ (box) should be drawn; defaults to `TRUE`, unless `axes = FALSE` is specified.
- `horizontal`: logical indicating if the boxplots should be horizontal; default `FALSE` means vertical boxes.
- `add`: logical, if `true` `add` boxplot to current plot.
- `at`: numeric vector giving the locations where the boxplots should be drawn, particularly when `add = TRUE`; defaults to `1:n` where `n` is the number of boxes.
- `show.names`: Set to `TRUE` or `FALSE` to override the defaults on whether an x-axis label is printed for each group.
- `pars,...`: **graphical parameters** (etc) can be passed as arguments to this function, either as a list (pars) or normally(...), see the following. (Those in ... take precedence over those in pars.)
Currently, yaxs and ylim are used ‘along the boxplot’, i.e., vertically, when horizontal is false, and xlim horizontally. xaxt, yaxt, las, cex.axis, and col.axis are passed to axis, and main, cex.main, col.main, sub, cex.sub, col.sub, xlab, ylab, cex.lab, and col.lab are passed to title.

In addition, axes is accepted (see plot.window), with default TRUE.

The following arguments (or pars components) allow further customization of the boxplot graphics. Their defaults are typically determined from the non-prefixed version (e.g., boxlty from lty), either from the specified argument or pars component or the corresponding par one.

**boxwex**: a scale factor to be applied to all boxes. When there are only a few groups, the appearance of the plot can be improved by making the boxes narrower. The default depends on at and typically is 0.8.

**staplewex, outwex**: staple and outlier line width expansion, proportional to box width; both default to 0.5.

**boxlty, boxlwd, boxcol, boxfill**: box outline type, width, color, and fill color (which currently defaults to col and will in future default to par("bg")).

**medlty, medlwd, medpch, medcex, medcol, medbg**: median line type, line width, point character, point size expansion, color, and background color. The default medpch = NA suppresses the point, and medlty = "blank" does so for the line. Note that medlwd defaults to 3 × the default lwd.

**whisklty, whisklwd, whiskcol**: whisker line type (default: "dashed"), width, and color.

**stapletlty, staplelwd, staplecol**: staple (= end of whisker) line type, width, and color.

**outlty, outlwd, outpch, outcex, outcol, outbg**: outlier line type, line width, point character, point size expansion, color, and background color. The default outlty = "blank" suppresses the lines and outpch = NA suppresses points.

**Value**

An invisible vector, actually identical to the at argument, with the coordinates ("x" if horizontal is false, "y" otherwise) of box centers, useful for adding to the plot.

**Note**

When add = FALSE, xlim now defaults to xlim = range(at, *) + c(-0.5, 0.5). It will usually be a good idea to specify xlim if the "x" axis has a log scale or width is far from uniform.

**Author(s)**

The R Core development team and Arni Magnusson (then at U Washington) who has provided most changes for the box*, med*, whisk*, staple*, and out* arguments.

boxplot(z, boxfill = "light gray", outlty = 2, bg = "pink", lwd = 2,
medcol = "dark blue", medcex = 2, medpch = 20)
Description

Computes and plots conditional densities describing how the conditional distribution of a categorical variable y changes over a numerical variable x.

Usage

```r
cdplot(x, y)
```

## Default S3 method:
```r
cdplot(x, y, 
plot = TRUE, tol.ylab = 0.05, ylevels = NULL, 
bw = "nrd0", n = 512, from = NULL, to = NULL, 
col = NULL, border = 1, main = "", xlab = NULL, ylab = NULL, 
yaxlabels = NULL, xlim = NULL, ylim = c(0, 1), 
subset = NULL)
```

## S3 method for class 'formula'
```r
cdplot(formula, data = list(), 
plot = TRUE, tol.ylab = 0.05, ylevels = NULL, 
bw = "nrd0", n = 512, from = NULL, to = NULL, 
col = NULL, border = 1, main = "", xlab = NULL, ylab = NULL, 
yaxlabels = NULL, xlim = NULL, ylim = c(0, 1), 
subset = NULL)
```

Arguments

- `x` an object, the default method expects a single numerical variable (or an object coercible to this).
- `y` a "factor" interpreted to be the dependent variable
- `formula` a "formula" of type `y ~ x` with a single dependent "factor" and a single numerical explanatory variable.
- `data` an optional data frame.
- `plot` logical. Should the computed conditional densities be plotted?
- `tol.ylab` convenience tolerance parameter for y-axis annotation. If the distance between two labels drops under this threshold, they are plotted equidistantly.
- `ylevels` a character or numeric vector specifying in which order the levels of the dependent variable should be plotted.
- `bw, n, from, to, ...` arguments passed to `density`.
- `col` a vector of fill colors of the same length as `levels(y)`. The default is to call `gray.colors`.
- `border` border color of shaded polygons.
- `main, xlab, ylab` character strings for annotation
- `yaxlabels` character vector for annotation of y axis, defaults to `levels(y)`.
- `xlim, ylim` the range of x and y values with sensible defaults.
- `subset` an optional vector specifying a subset of observations to be used for plotting.
cdplot

Details
cdplot computes the conditional densities of x given the levels of y weighted by the marginal distribution of y. The densities are derived cumulatively over the levels of y.

This visualization technique is similar to spinograms (see spineplot) and plots \( P(y|x) \) against x. The conditional probabilities are not derived by discretization (as in the spinogram), but using a smoothing approach via density.

Note, that the estimates of the conditional densities are more reliable for high-density regions of x. Conversely, the are less reliable in regions with only few x observations.

Value
The conditional density functions (cumulative over the levels of y) are returned invisibly.

     xlab = "Temperature", ylab = "Conditional failure probability")
lines(53:81, 1 - cdens[[1]][53:81], col = 2)
```
clip

Set Clipping Region

Description

Set clipping region in user coordinates

Usage

clip(x1, x2, y1, y2)

Arguments

x1, x2, y1, y2  user coordinates of clipping rectangle

Details

How the clipping rectangle is set depends on the setting of par("xpd"): this function changes the current setting until the next high-level plotting command resets it.

Clipping of lines, rectangles and polygons is done in the graphics engine, but clipping of text is if possible done in the device, so the effect of clipping text is device-dependent (and may result in text not wholly within the clipping region being omitted entirely).

Exactly when the clipping region will be reset can be hard to predict. plot.new always resets it. Functions such as lines and text only reset it if par("xpd") has been changed. However, functions such as box, mtext, title and plot.dendrogram can manipulate the xpd setting.

See Also

par

Examples

x <- rnorm(1000)
hist(x, xlim = c(-4,4))
usr <- par("usr")
clip(usr[1], -2, usr[3], usr[4])
hist(x, col = 'red', add = TRUE)
clip(2, usr[2], usr[3], usr[4])
hist(x, col = 'blue', add = TRUE)
do.call("clip", as.list(usr))  # reset to plot region
contour

Display Contours

Description

Create a contour plot, or add contour lines to an existing plot.

Usage

```r
contour(x, ...) 
```

```r
## Default S3 method: 
contour(x = seq(0, 1, length.out = nrow(z)),
y = seq(0, 1, length.out = ncol(z)),
z,
nlevels = 10, levels = pretty(zlim, nlevels),
labels = NULL,
xlim = range(x, finite = TRUE),
ylim = range(y, finite = TRUE),
zlim = range(z, finite = TRUE),
labcex = 0.6, drawlabels = TRUE, method = "flattest",
vfont, axes = TRUE, frame.plot = axes,
col = par("fg"), lty = par("lty"), lwd = par("lwd"),
add = FALSE, ...) 
```

Arguments

- `x, y` locations of grid lines at which the values in `z` are measured. These must be in ascending order. By default, equally spaced values from 0 to 1 are used. If `x` is a list, its components `x$x` and `x$y` are used for `x` and `y`, respectively. If the list has component `z` this is used for `z`.
- `z` a matrix containing the values to be plotted (NA's are allowed). Note that `x` can be used instead of `z` for convenience.
- `nlevels` number of contour levels desired if `levels` is not supplied.
- `levels` numeric vector of levels at which to draw contour lines.
- `labels` a vector giving the labels for the contour lines. If NULL then the levels are used as labels, otherwise this is coerced by `as.character`.
- `labcex` cex for contour labelling. This is an absolute size, not a multiple of `par("cex")`.
- `drawlabels` logical. Contours are labelled if TRUE.
- `method` character string specifying where the labels will be located. Possible values are "simple", "edge" and "flattest" (the default). See the 'Details' section.
- `vfont` if NULL, the current font family and face are used for the contour labels. If a character vector of length 2 then Hershey vector fonts are used for the contour labels. The first element of the vector selects a typeface and the second element selects a fontindex (see `text` for more information). The default is `NULL` on graphics devices with high-quality rotation of text and `c("sans serif", "plain")` otherwise.
- `xlim, ylim, zlim` x-, y- and z-limits for the plot.
axes, frame.plot  logical indicating whether axes or a box should be drawn, see plot.default.
col  color for the lines drawn.
lty  line type for the lines drawn.
lwd  line width for the lines drawn.
add  logical. If TRUE, add to a current plot.
...

Details

countour is a generic function with only a default method in base R.
The methods for positioning the labels on contours are "simple" (draw at the edge of the plot,
overlaid by the contour line), "edge" (draw at the edge of the plot, embedded in the contour line,
with no labels overlapping) and "flat test" (draw on the flattest section of the contour, embedded
in the contour line, with no labels overlapping). The second and third may not draw a label on every
contour line.

For information about vector fonts, see the help for text and Hershey.
Notice that contour interprets the z matrix as a table of f(x[i], y[j]) values, so that the x axis
corresponds to row number and the y axis to column number, with column 1 at the bottom, i.e. a 90
degree counter-clockwise rotation of the conventional textual layout.

Alternatively, use contourplot from the lattice package where the formula notation allows to use
vectors x, y, and z of the same length.

There is limited control over the axes and frame as arguments col, lwd and lty refer to the contour
lines (rather than being general graphical parameters). For more control, add contours to a plot, or
add axes and frame to a contour plot.

convertXY

Convert between Graphics Coordinate Systems

Description

Convert between graphics coordinate systems.

Usage

grconvertX(x, from = "user", to = "user")
grconvertY(y, from = "user", to = "user")

Arguments

x, y       numeric vector of coordinates.
from, to   character strings giving the coordinate systems to convert between.
Details

The coordinate systems are

"user" user coordinates.
"inches" inches.
"device" the device coordinate system.
"ndc" normalized device coordinates.
"nfc" normalized figure coordinates.
"npc" normalized plot coordinates.
"nic" normalized inner region coordinates. (The ‘inner region’ is that inside the outer margins.)

(These names can be partially matched.) For the ‘normalized’ coordinate systems the lower left has value 0 and the top right value 1.

Device coordinates are those in which the device works: they are usually in pixels where that makes sense and in big points (1/72 inch) otherwise (e.g. pdf and postscript).

Value

A numeric vector of the same length as the input.

Examples

```r
op <- par(omd=c(0.1, 0.9, 0.1, 0.9), mfrow = c(1, 2))
plot(1:4)
for(tp in c("in", "dev", "ndc", "nfc", "npc", "nic"))
  print(grconvertX(c(1.0, 4.0), tp))
par(op)
```

Description

This function produces two variants of the conditioning plots discussed in the reference below.

Usage

```r
coplot(formula, data, given.values, panel = points, rows, columns,
   show.given = TRUE, col = par("fg"), pch = par("pch"),
   bar.bg = c(num = gray(0.8), fac = gray(0.95)),
   xlab = c(x.name, paste("Given ":, a.name)),
   ylab = c(y.name, paste("Given ":, b.name)),
   subscripts = FALSE,
   axlabels = function(f) abbreviate(levels(f)),
   number = 6, overlap = 0.5, xlim, ylim, ...)
cop.intervals(x, number = 6, overlap = 0.5)
```
**coplot**

**Arguments**

- **formula**: a formula describing the form of conditioning plot. A formula of the form \( y \sim x \mid a \) indicates that plots of \( y \) versus \( x \) should be produced conditional on the variable \( a \). A formula of the form \( y \sim x \mid a \times b \) indicates that plots of \( y \) versus \( x \) should be produced conditional on the two variables \( a \) and \( b \).

- **data**: a data frame containing values for any variables in the formula. By default the environment where `coplot` was called from is used.

- **given.values**: a value or list of two values which determine how the conditioning on \( a \) and \( b \) is to take place.

  When there is no \( b \) (i.e., conditioning only on \( a \)), usually this is a matrix with two columns each row of which gives an interval, to be conditioned on, but is can also be a single vector of numbers or a set of factor levels (if the variable being conditioned on is a factor). In this case (no \( b \)), the result of `co.intervals` can be used directly as `given.values` argument.

- **panel**: a function \((x, y, col, pch, \ldots)\) which gives the action to be carried out in each panel of the display. The default is `points`.

- **rows**: the panels of the plot are laid out in a \( rows \times columns \) array. `rows` gives the number of rows in the array.

- **columns**: the number of columns in the panel layout array.

- **show.given**: logical (possibly of length 2 for 2 conditioning variables): should conditioning plots be shown for the corresponding conditioning variables (default `TRUE`).

- **col**: a vector of colors to be used to plot the points. If too short, the values are recycled.

- **pch**: a vector of plotting symbols or characters. If too short, the values are recycled.

- **bar.bg**: a named vector with components "num" and "fac" giving the background colors for the (shingle) bars, for numeric and factor conditioning variables respectively.

- **xlab**: character; labels to use for the x axis and the first conditioning variable. If only one label is given, it is used for the x axis and the default label is used for the conditioning variable.

- **ylab**: character; labels to use for the y axis and any second conditioning variable.

- **subscripts**: logical: if true the panel function is given an additional (third) argument `subscripts` giving the subscripts of the data passed to that panel.

- **axlabels**: function for creating axis (tick) labels when x or y are factors.

- **number**: integer; the number of conditioning intervals, for \( a \) and \( b \), possibly of length 2. It is only used if the corresponding conditioning variable is not a factor.

- **overlap**: numeric < 1; the fraction of overlap of the conditioning variables, possibly of length 2 for x and y direction. When overlap < 0, there will be gaps between the data slices.

- **xlim**: the range for the x axis.

- **ylim**: the range for the y axis.

- **...**: additional arguments to the panel function.

- **x**: a numeric vector.
coplot

Details

In the case of a single conditioning variable a, when both rows and columns are unspecified, a 'close to square' layout is chosen with columns >= rows.

In the case of multiple rows, the order of the panel plots is from the bottom and from the left (corresponding to increasing a, typically).

A panel function should not attempt to start a new plot, but just plot within a given coordinate system: thus plot and boxplot are not panel functions.

The rendering of arguments xlab and ylab is not controlled by par arguments cex.lab and font.lab even though they are plotted by mtext rather than title.

Value

`co.intervals(., number, .)` returns a (number × 2) matrix, say ci, where ci[k,] is the range of x values for the k-th interval.

References

See Also

`pairs`, `panel.smooth`, `points`.

Examples

```r
## Tonga Trench Earthquakes
coplot(lat ~ long | depth, data = quakes)
given.depth <- co.intervals(quakes$depth, number = 4, overlap = .1)
coplot(lat ~ long | depth, data = quakes, given.v = given.depth, rows = 1)

## Conditioning on 2 variables:
ll.dm <- lat ~ long | depth * mag
coplot(ll.dm, data = quakes)
coplot(ll.dm, data = quakes, number = c(4, 7), show.given = c(TRUE, FALSE))
coplot(ll.dm, data = quakes, number = c(3, 7),
       overlap = c(-.5, .1)) # negative overlap DROPS values

## given two factors
Index <- seq(length = nrow(warpbreaks)) # to get nicer default labels
coplot(breaks ~ Index | wool * tension, data = warpbreaks,
       show.given = 0:1)
coplot(breaks ~ Index | wool * tension, data = warpbreaks,
       col = "red", bg = "pink", pch = 21,
       bar.bg = c(fac = "light blue"))

## Example with empty panels:
with(data.frame(state.x77),
    { coplot(Life.Exp ~ Income | Illiteracy * state.region, number = 3,
      panel = function(x, y, ...) panel.smooth(x, y, span = .8, ...))
    })
```

```r
## y ~ factor -- not really sensible, but 'show off':
coplot(Life.Exp ~ state.region | Income * state.division,
       panel = panel.smooth)
```
Description

Draws a curve corresponding to a function over the interval \([\text{from}, \text{to}]\). \texttt{curve} can plot also an expression in the variable \texttt{xname}, default ‘\textquote{x}’.

Usage

\begin{verbatim}
curve(expr, from = NULL, to = NULL, n = 101, add = FALSE, 
    type = "l", xname = "x", xlab = xname, ylab = NULL, 
    log = NULL, xlim = NULL, ...)
\end{verbatim}

## S3 method for class 'function'
plot(x, y = 0, to = 1, from = y, xlim = NULL, ylab = NULL, ...)

Arguments

- **expr**: The name of a function, or a \texttt{call} or an \texttt{expression} written as a function of \texttt{x} which will evaluate to an object of the same length as \texttt{x}.
- **x**: a ‘vectorizing’ numeric \texttt{R} function.
- **y**: alias for \texttt{from} for compatibility with \texttt{plot}.
- **from, to**: the range over which the function will be plotted.
- **n**: integer; the number of \texttt{x} values at which to evaluate.
- **add**: logical; if \texttt{TRUE} add to an already existing plot; if \texttt{NA} start a new plot taking the defaults for the limits and log-scaling of the \texttt{x}-axis from the previous plot. Taken as \texttt{FALSE} (with a warning if a different value is supplied) if no graphics device is open.
- **xlim**: \texttt{NULL} or a numeric vector of length 2; if non-\texttt{NULL} it provides the defaults for \texttt{c(from, to)} and, unless \texttt{add = TRUE}, selects the \texttt{x}-limits of the plot – see \texttt{plot.window}.
- **type**: plot type: see \texttt{plot.default}.
- **xname**: character string giving the name to be used for the \texttt{x} axis.
- **xlab, ylab, log, ...**: labels and \texttt{graphical parameters} can also be specified as arguments. See ‘Details’ for the interpretation of the default for \texttt{log}.

For the "function" method of \texttt{plot}, \ldots can include any of the other arguments of \texttt{curve}, except \texttt{expr}. 
The function or expression `expr` (for `curve`) or function `x` (for `plot`) is evaluated at `n` points equally spaced over the range `[from, to]`. The points determined in this way are then plotted.

If either `from` or `to` is NULL, it defaults to the corresponding element of `xlim` if that is not NULL.

What happens when neither `from` nor `xlim` specifies both x-limits is a complex story. For `plot(<function>)` and for `curve(add = FALSE)` the defaults are `(0,1)`. For `curve(add = NA)` and `curve(add = TRUE)` the defaults are taken from the x-limits used for the previous plot. (This differs from versions of R prior to 2.14.0.)

The value of `log` is used both to specify the plot axes (unless `add = TRUE`) and how ‘equally spaced’ is interpreted: if the x component indicates log-scaling, the points at which the expression or function is plotted are equally spaced on log scale.

The default value of `log` is taken from the current plot when `add = TRUE`, whereas if `add = NA` the x component is taken from the existing plot (if any) and the y component defaults to linear. For `add = FALSE` the default is "".

This used to be a quick hack which now seems to serve a useful purpose, but can give bad results for functions which are not smooth.

For expensive-to-compute expressions, you should use smarter tools.

The way `curve` handles `expr` has caused confusion. It first looks to see if `expr` is a name (also known as a symbol), in which case it is taken to be the name of a function, and `expr` is replaced by a call to `expr` with a single argument with name given by `xname`. Otherwise it checks that `expr` is either a call or an expression, and that it contains a reference to the variable given by `xname` (using `all.vars`): anything else is an error. Then `expr` is evaluated in an environment which supplies a vector of name given by `xname` of length `n`, and should evaluate to an object of length `n`. Note that this means that `curve(x, ...)` is taken as a request to plot a function named `x` (and it is used as such in the function method for `plot`).

The `plot` method can be called directly as `plot.function`.

### Value

A list with components `x` and `y` of the points that were drawn is returned invisibly.

### Warning

For historical reasons, `add` is allowed as an argument to the "function" method of `plot`, but its behaviour may surprise you. It is recommended to use `add` only with `curve`.

### See Also

`splinefun` for spline interpolation, `lines`.

### Examples

```r
plot(qnorm) # default range c(0, 1) is appropriate here,
    # but end values are -/+Inf and so are omitted.
plot(qlogis, main = "The Inverse Logit: qlogis()")
abline(h = 0, v = 0:2/2, lty = 3, col = "gray")

curve(sin, -2*pi, 2*pi, xname = "t")
curve(tan, xname = "t", add = NA,
    main = "curve(tan) --> same x-scale as previous plot")
```
dotchart

op <- par(mfrow = c(2, 2))
curve(x^3 - 3*x, -2, 2)
curve(x^2 - 2, add = TRUE, col = "violet")

## simple and advanced versions, quite similar:
plot(cos, -pi, 3*pi)
curve(cos, xlim = c(-pi, 3*pi), n = 1001, col = "blue", add = TRUE)

chippy <- function(x) sin(cos(x)*exp(-x/2))
curve(chippy, -8, 7, n = 2001)
plot (chippy, -8, -5)
for(ll in c("", "x", "y", "xy"))
  curve(log(1+x), 1, 100, log = ll, sub = paste0("log = ", ll, ", ""))
par(op)

dotchart

Cleveland's Dot Plots

Description

Draw a Cleveland dot plot.

Usage

dotchart(x, labels = NULL, groups = NULL, gdata = NULL,
         cex = par("cex"), pch = 21, gpch = 21, bg = par("bg"),
         color = par("fg"), gcolor = par("fg"), lcolor = "gray",
         xlim = range(x[is.numeric(x)]),
         main = NULL, xlab = NULL, ylab = NULL, ...)

Arguments

- **x**: either a vector or matrix of numeric values (NAs are allowed). If x is a matrix
  the overall plot consists of juxtaposed dotplots for each row. Inputs which satisfy
  is.numeric(x) but not is.vector(x) || is.matrix(x) are coerced by
  as.numeric, with a warning.
- **labels**: a vector of labels for each point. For vectors the default is to use names(x) and
  for matrices the row labels dimnames(x)[[1]].
- **groups**: an optional factor indicating how the elements of x are grouped. If x is a matrix,
  groups will default to the columns of x.
- **gdata**: data values for the groups. This is typically a summary such as the median or
  mean of each group.
- **cex**: the character size to be used. Setting cex to a value smaller than one can be a
  useful way of avoiding label overlap. Unlike many other graphics functions, this
  sets the actual size, not a multiple of par("cex").
- **pch**: the plotting character or symbol to be used.
- **gpch**: the plotting character or symbol to be used for group values.
- **bg**: the background color of plotting characters or symbols to be used; use
  par(bg= *) to set the background color of the whole plot.
filled.contour

- **color**: the color(s) to be used for points and labels.
- **gcolor**: the single color to be used for group labels and values.
- **lcolor**: the color(s) to be used for the horizontal lines.
- **xlim**: horizontal range for the plot, see `plot.window`, e.g.
- **main**: overall title for the plot, see `title`.
- **xlab, ylab**: axis annotations as in `title`.

... *graphical parameters* can also be specified as arguments.

**Value**

This function is invoked for its side effect, which is to produce two variants of dotplots as described in Cleveland (1985).

Dot plots are a reasonable substitute for bar plots.

**References**

**Examples**

```r
dotchart(VADeaths, main = "Death Rates in Virginia - 1940")
op <- par(xaxs = "i")  # 0 -- 100%
dotchart(t(VADeaths), xlim = c(0,100),
         main = "Death Rates in Virginia - 1940")
par(op)
```

**filled.contour**  
*Level (Contour) Plots*

**Description**

This function produces a contour plot with the areas between the contours filled in solid color (Cleveland calls this a level plot). A key showing how the colors map to z values is shown to the right of the plot.

**Usage**

```r
filled.contour(x = seq(0, 1, length.out = nrow(z)),
               y = seq(0, 1, length.out = ncol(z)),
               z,
               xlim = range(x, finite = TRUE),
               ylim = range(y, finite = TRUE),
               zlim = range(z, finite = TRUE),
               levels = pretty(zlim, nlevels), nlevels = 20,
               color.palette = cm.colors,
               col = color.palette(length(levels) - 1),
```
filled.contour

plot.title, plot.axes, key.title, key.axes,
asp = NA, xaxs = "i", yaxs = "i", las = 1,
axes = TRUE, frame.plot = axes, ...)

.filled.contour(x, y, z, levels, col)

Arguments

x, y locations of grid lines at which the values in z are measured. These must be in ascending order. (The rest of this description does not apply to .filled.contour.) By default, equally spaced values from 0 to 1 are used. If x is a list, its components x$x and x$y are used for x and y, respectively. If the list has component z this is used for z.

z a numeric matrix containing the values to be plotted. Note that x can be used instead of z for convenience.

xlim x limits for the plot.

ylim y limits for the plot.

zlim z limits for the plot.

levels a set of levels which are used to partition the range of z. Must be strictly increasing (and finite). Areas with z values between consecutive levels are painted with the same color.

nlevels if levels is not specified, the range of z, values is divided into approximately this many levels.

color.palette a color palette function to be used to assign colors in the plot.

col an explicit set of colors to be used in the plot. This argument overrides any palette function specification. There should be one less color than levels.

plot.title statements which add titles to the main plot.

plot.axes statements which draw axes (and a box) on the main plot. This overrides the default axes.

key.title statements which add titles for the plot key.

key.axes statements which draw axes on the plot key. This overrides the default axis.

asp the y/x aspect ratio, see plot.window.

xaxs the x axis style. The default is to use internal labeling.

yaxs the y axis style. The default is to use internal labeling.

las the style of labeling to be used. The default is to use horizontal labeling.

axes, frame.plot

... logicals indicating if axes and a box should be drawn, as in plot.default.

Details

The values to be plotted can contain NAs. Rectangles with two or more corner values are NA are omitted entirely: where there is a single NA value the triangle opposite the NA is omitted.

Values to be plotted can be infinite: the effect is similar to that described for NA values.

.filled.contour is a ‘bare bones’ interface to add just the contour plot to an already-set-up plot region. It is intended for programmatic use, and the programmer is responsible for checking the conditions on the arguments.
Note

filled.contour uses the layout function and so is restricted to a full page display.

The output produced by filled.contour is actually a combination of two plots; one is the filled contour and one is the legend. Two separate coordinate systems are set up for these two plots, but they are only used internally – once the function has returned these coordinate systems are lost. If you want to annotate the main contour plot, for example to add points, you can specify graphics commands in the plot.axes argument. See the examples.

require(grDevices) # for colours
filled.contour(volcano, color = terrain.colors, asp = 1) # simple

x <- 10*1:nrow(volcano)
y <- 10*1:ncol(volcano)
filled.contour(x, y, volcano, color = terrain.colors,
plot.title = title(main = "The Topography of Maunga Whau",
xlab = "Meters North", ylab = "Meters West"),
plot.axes = { axis(1, seq(100, 800, by = 100))
axis(2, seq(100, 800, by = 100)) },
key.title = title(main = "Height\n(meters)"),
key.axes = axis(4, seq(0, 100, by = 10)) ) # maybe also asp = 1
mtext(paste("filled.contour(.) from", R.version.string),
side = 1, line = 4, adj = 1, cex = .66)

# Annotating a filled contour plot
a <- expand.grid(1:20, 1:20)
b <- matrix(a[,1] + a[,2], 20)
filled.contour(x = 1:20, y = 1:20, z = b,
plot.axes = { axis(1); axis(2); points(10, 10 ) })

## Persian Rug Art:
x <- y <- seq(-4*pi, 4*pi, len = 27)
r <- sqrt(outter(x^2, y^2, "+")
filled.contour(cos(r^2)*exp(-r/(2*pi)), axes = FALSE)
## rather, the key *should* be labeled:
filled.contour(cos(r^2)*exp(-r/(2*pi)), frame.plot = FALSE,
plot.axes = {})
Description

Creates a fourfold display of a 2 by 2 by \( k \) contingency table on the current graphics device, allowing for the visual inspection of the association between two dichotomous variables in one or several populations (strata).

Usage

\[
\text{fourfoldplot}(x, \text{color} = c("#99CCFF", "#6699CC"), \\
\text{conf.level} = 0.95, \\
\text{std} = c("margins", "ind.max", "all.max"), \\
\text{margin} = c(1, 2), \text{space} = 0.2, \text{main} = \text{NULL}, \\
\text{mfrow} = \text{NULL}, \text{mfcol} = \text{NULL})
\]

Arguments

- \( x \) a 2 by 2 by \( k \) contingency table in array form, or as a 2 by 2 matrix if \( k \) is 1.
- \( \text{color} \) a vector of length 2 specifying the colors to use for the smaller and larger diagonals of each 2 by 2 table.
- \( \text{conf.level} \) confidence level used for the confidence rings on the odds ratios. Must be a single nonnegative number less than 1; if set to 0, confidence rings are suppressed.
- \( \text{std} \) a character string specifying how to standardize the table. Must be one of "margins", "ind.max", or "all.max", and can be abbreviated by the initial letter. If set to "margins", each 2 by 2 table is standardized to equate the odds ratios specified by margin while preserving the odds ratio. If "ind.max" or "all.max", the tables are either individually or simultaneously standardized to a maximal cell frequency of 1.
- \( \text{margin} \) a numeric vector with the margins to equate. Must be one of 1, 2, or c(1, 2) (the default), which corresponds to standardizing the row, column, or both margins in each 2 by 2 table. Only used if \( \text{std} \) equals "margins".
- \( \text{space} \) the amount of space (as a fraction of the maximal radius of the quarter circles) used for the row and column labels.
- \( \text{main} \) character string for the fourfold title.
- \( \text{mfrow} \) a numeric vector of the form c(nr, nc), indicating that the displays for the 2 by 2 tables should be arranged in an nr by nc layout, filled by rows.
- \( \text{mfcol} \) a numeric vector of the form c(nr, nc), indicating that the displays for the 2 by 2 tables should be arranged in an nr by nc layout, filled by columns.

Details

The fourfold display is designed for the display of 2 by 2 by \( k \) tables. Following suitable standardization, the cell frequencies \( f_{ij} \) of each 2 by 2 table are shown as a quarter circle whose radius is proportional to \( \sqrt{f_{ij}} \) so that its area is proportional to the cell frequency. An association (odds ratio different from 1) between the binary row and column variables is indicated by the tendency of diagonally opposite cells in one direction to differ in size from those
in the other direction; color is used to show this direction. Confidence rings for the odds ratio allow a visual test of the null of no association; the rings for adjacent quadrants overlap if and only if the observed counts are consistent with the null hypothesis.

Typically, the number $k$ corresponds to the number of levels of a stratifying variable, and it is of interest to see whether the association is homogeneous across strata. The fourfold display visualizes the pattern of association. Note that the confidence rings for the individual odds ratios are not adjusted for multiple testing.

## standardized to equate the margins for admission. but not
## for sex.
## Figure 3 in Friendly (1994).
fourfoldplot(x, margin = 2)
```

Description

This function (`frame`) is an alias for `plot.new` causes the completion of plotting in the current plot (if there is one) and an advance to a new graphics frame. This is used in all high-level plotting functions and also useful for skipping plots when a multi-figure region is in use.
The new page is painted with the background colour (`par("bg")`), which is often transparent. For devices with a canvas colour (the on-screen devices X11, windows and quartz), the window is first painted with the canvas colour and then the background colour.

There are two hooks called "before.plot.new" and "plot.new" (see `setHook`) called immediately before and after advancing the frame. The latter is used in the testing code to annotate the new page. The hook function(s) are called with no argument. (If the value is a character string, `get` is called on it from within the `graphics` namespace.)

`plot.window, plot.default`.

grid

*Add Grid to a Plot*

**Description**

`grid` adds an nx by ny rectangular grid to an existing plot.

**Usage**

```
grid(nx = NULL, ny = nx, col = "lightgray", lty = "dotted", lwd = par("lwd"), equilogs = TRUE)
```

**Arguments**

- `nx, ny`: number of cells of the grid in x and y direction. When NULL, as per default, the grid aligns with the tick marks on the corresponding default axis (i.e., tickmarks as computed by `axTicks`). When `NA`, no grid lines are drawn in the corresponding direction.
- `col`: character or (integer) numeric; color of the grid lines.
- `lty`: character or (integer) numeric; line type of the grid lines.
- `lwd`: non-negative numeric giving line width of the grid lines.
- `equilogs`: logical, only used when `log` coordinates and alignment with the axis tick marks are active. Setting `equilogs = FALSE` in that case gives *non equidistant* tick aligned grid lines.
Note
If more fine tuning is required, use `abline(h = ., v = .)` directly.

References

See Also
`plot, abline, lines, points`.

Examples
```r
plot(1:3)
grid(NA, 5, lwd = 2) # grid only in y-direction

### maybe change the desired number of tick marks: par(lab = c(mx, my, 7))
op <- par(mfcol = 1:2)
with(iris, {
  plot(Sepal.Length, Sepal.Width, col = as.integer(Species),
       xlim = c(4, 8), ylim = c(2, 4.5), panel.first = grid(),
       main = "with(iris, plot(...., panel.first = grid(), ..))")
  plot(Sepal.Length, Sepal.Width, col = as.integer(Species),
       panel.first = grid(3, lty = 1, lwd = 2),
       main = "... panel.first = grid(3, lty = 1, lwd = 2), ..")
})
par(op)
```
Arguments

x  
a vector of values for which the histogram is desired.

breaks  
one of:
  • a vector giving the breakpoints between histogram cells,
  • a function to compute the vector of breakpoints,
  • a single number giving the number of cells for the histogram,
  • a character string naming an algorithm to compute the number of cells (see ‘Details’),
  • a function to compute the number of cells.

In the last three cases the number is a suggestion only; the breakpoints will be set to pretty values. If breaks is a function, the x vector is supplied to it as the only argument.

freq  
logical; if TRUE, the histogram graphic is a representation of frequencies, the counts component of the result; if FALSE, probability densities, component density, are plotted (so that the histogram has a total area of one). Defaults to TRUE if and only if breaks are equidistant (and probability is not specified).

probability  
an alias for !freq, for S compatibility.

include.lowest  
logical; if TRUE, an x[i] equal to the breaks value will be included in the first (or last, for right = FALSE) bar. This will be ignored (with a warning) unless breaks is a vector.

right  
logical; if TRUE, the histogram cells are right-closed (left open) intervals.

density  
the density of shading lines, in lines per inch. The default value of NULL means that no shading lines are drawn. Non-positive values of density also inhibit the drawing of shading lines.

angle  
the slope of shading lines, given as an angle in degrees (counter-clockwise).

col  
a colour to be used to fill the bars. The default of NULL yields unfilled bars.

border  
the color of the border around the bars. The default is to use the standard foreground color.

main, xlab, ylab  
these arguments to title have useful defaults here.

xlim, ylim  
the range of x and y values with sensible defaults. Note that xlim is not used to define the histogram (breaks), but only for plotting (when plot = TRUE).

axes  
logical. If TRUE (default), axes are draw if the plot is drawn.

plot  
logical. If TRUE (default), a histogram is plotted, otherwise a list of breaks and counts is returned. In the latter case, a warning is used if (typically graphical) arguments are specified that only apply to the plot = TRUE case.

labels  
logical or character. Additionally draw labels on top of bars, if not FALSE; see plot.histogram.

nclass  
numeric (integer). For S(-PLUS) compatibility only, nclass is equivalent to breaks for a scalar or character argument.

warn.unused  
logical. If plot = FALSE and warn.unused = TRUE, a warning will be issued when graphical parameters are passed to hist.default().

...  
further arguments and graphical parameters passed to plot.histogram and thence to title and axis (if plot = TRUE).
Details

The definition of histogram differs by source (with country-specific biases). R’s default with equi-spaced breaks (also the default) is to plot the counts in the cells defined by breaks. Thus the height of a rectangle is proportional to the number of points falling into the cell, as is the area provided the breaks are equally-spaced.

The default with non-equi-spaced breaks is to give a plot of area one, in which the area of the rectangles is the fraction of the data points falling in the cells.

If right = TRUE (default), the histogram cells are intervals of the form \([a, b]\), i.e., they include their right-hand endpoint, but not their left one, with the exception of the first cell when include.lowest is TRUE.

For right = FALSE, the intervals are of the form \([a, b]\), and include.lowest means ‘include highest’.

A numerical tolerance of \(10^{-7}\) times the median bin size is applied when counting entries on the edges of bins. This is not included in the reported breaks nor (as from R 2.11.0) in the calculation of density.

The default for breaks is "Sturges": see `nclass.Sturges`. Other names for which algorithms are supplied are "Scott" and "FD" / "Freedman-Diaconis" (with corresponding functions `nclass.scott` and `nclass.FD`). Case is ignored and partial matching is used. Alternatively, a function can be supplied which will compute the intended number of breaks or the actual breakpoints as a function of \(x\).

Value

an object of class “histogram” which is a list with components:

- `breaks` the \(n + 1\) cell boundaries (= breaks if that was a vector). These are the nominal breaks, not with the boundary fuzz.
- `counts` \(n\) integers; for each cell, the number of \(x[]\) inside.
- `density` values \(\hat{f}(x_i)\), as estimated density values. If \(\text{all}(|\text{diff(breaks)}| == 1)\), they are the relative frequencies \(\text{counts}/n\) and in general satisfy \(\sum_i \hat{f}(x_i)(b_{i+1} - b_i) = 1\), where \(b_i = \text{breaks}[i]\).
- `mids` the \(n\) cell midpoints.
- `xname` a character string with the actual \(x\) argument name.
- `equidist` logical, indicating if the distances between breaks are all the same.

Prior to R 3.0.0 there was a component `intensities`, the same as density, for long-term back compatibility.

Typical plots with vertical bars are *not* histograms. Consider `barplot` or `plot(*, type = "h")` for such bar plots.
Examples

```r
op <- par(mfrow = c(2, 2))
hist(islands)
utils::str(hist(islands, col = "gray", labels = TRUE))

hist(sqrt(islands), breaks = 12, col = "lightblue", border = "pink")
##-- For non-equidistant breaks, counts should NOT be graphed unscaled:
r <- hist(sqrt(islands), breaks = c(4+0.5, 10*3:5, 70, 100, 140),
          col = "blue1")
text(r$mids, r$density, r$counts, adj = c(.5, -.5), col = "blue3")
sapply(r[2:3], sum)
sum(r$density * diff(r$breaks)) # == 1
lines(r, lty = 3, border = "purple") # --> lines.histogram(*)
par(op)

require(utils) # for str
str(hist(islands, breaks = 12, plot = FALSE)) #-> 10 (~= 12) breaks
str(hist(islands, breaks = c(12,20,36,80,200,1000,17000), plot = FALSE))

hist(islands, breaks = c(12,20,36,80,200,1000,17000), freq = TRUE,
     main = "WRONG histogram") # and warning

require(stats)
set.seed(14)
x <- rchisq(100, df = 4)

## Comparing data with a model distribution should be done with qqplot()!
qqplot(x, qchisq(ppoints(x), df = 4)); abline(0, 1, col = 2, lty = 2)

## if you really insist on using hist() ... :
hist(x, freq = FALSE, ylim = c(0, 0.2))
curve(dchisq(x, df = 4), col = 2, lty = 2, lwd = 2, add = TRUE)
```

Description

Method for `hist` applied to date or date-time objects.

Usage

```r
## S3 method for class 'POSIXt'
hist(x, breaks, ..., xlab = deparse(substitute(x)),
     plot = TRUE, freq = FALSE,
     start.on.monday = TRUE, format)

## S3 method for class 'Date'
hist(x, breaks, ..., xlab = deparse(substitute(x)),
     plot = TRUE, freq = FALSE,
     start.on.monday = TRUE, format)
```
Arguments

x an object inheriting from class "POSIXt" or "Date".
breaks a vector of cut points or number giving the number of intervals which x is to be cut into or an interval specification, one of "days", "weeks", "months", "quarters" or "years", plus "secs", "mins", "hrs" for date-time objects.
... graphical parameters, or arguments to hist.default such as include.lowest, right and labels.
xlab a character string giving the label for the x axis, if plotted.
plot logical. If TRUE (default), a histogram is plotted, otherwise a list of breaks and counts is returned.
freq logical; if TRUE, the histogram graphic is a representation of frequencies, i.e., the counts component of the result; if FALSE, relative frequencies (probabilities) are plotted.
start.on.monday logical. If breaks = "weeks", should the week start on Mondays or Sundays?
format for the x-axis labels. See strftime.

Details

Note that unlike the default method, breaks is a required argument.
Using breaks = "quarters" will create intervals of 3 calendar months, with the intervals beginning on January 1, April 1, July 1 or October 1, based upon min(x) as appropriate.

Value

An object of class "histogram": see hist.

See Also

seq.POSIXt, axis.POSIXct, hist

Examples

hist(.leap.seconds, "years", freq = TRUE)
hist(.leap.seconds,
    seq(ISOdate(1970, 1, 1), ISOdate(2015, 1, 1), "5 years")

### 100 random dates in a 10-week period
random.dates <- as.Date("2001/1/1") + 70*stats::runif(100)
hist(random.dates, "weeks", format = "%d %b")

Identify Points in a Scatter Plot

identify reads the position of the graphics pointer when the (first) mouse button is pressed. It then searches the coordinates given in x and y for the point closest to the pointer. If this point is close enough to the pointer, its index will be returned as part of the value of the call.
Usage

identify(x, y = NULL, labels = seq_along(x), pos = FALSE, n = length(x), plot = TRUE, atpen = FALSE, offset = 0.5, tolerance = 0.25, ...)  

Arguments

x, y coordinates of points in a scatter plot. Alternatively, any object which defines coordinates (a plotting structure, time series etc: see xy.coords) can be given as x, and y left missing.

labels an optional character vector giving labels for the points. Will be coerced using as.character, and recycled if necessary to the length of x. Excess labels will be discarded, with a warning.

pos if pos is TRUE, a component is added to the return value which indicates where text was plotted relative to each identified point: see Value.

n the maximum number of points to be identified.

plot logical: if plot is TRUE, the labels are printed near the points and if FALSE they are omitted.

atpen logical: if TRUE and plot = TRUE, the lower-left corners of the labels are plotted at the points clicked rather than relative to the points.

offset the distance (in character widths) which separates the label from identified points. Negative values are allowed. Not used if atpen = TRUE.

tolerance the maximal distance (in inches) for the pointer to be ‘close enough’ to a point.

... further arguments passed to par such as cex, col and font.

Details

identify is a generic function, and only the default method is described here.

identify is only supported on screen devices such as X11, windows and quartz. On other devices the call will do nothing.

Clicking near (as defined by tolerance) a point adds it to the list of identified points. Points can be identified only once, and if the point has already been identified or the click is not near any of the points a message is printed immediately on the R console.

If plot is TRUE, the point is labelled with the corresponding element of labels. If atpen is false (the default) the labels are placed below, to the left, above or to the right of the identified point, depending on where the pointer was relative to the point. If atpen is true, the labels are placed with the bottom left of the string’s box at the pointer.

For the usual X11 device the identification process is terminated by pressing any mouse button other than the first. For the quartz device the process is terminated by pressing either the pop-up menu equivalent (usually second mouse button or Ctrl-click) or the ESC key.

On most devices which support identify, successful selection of a point is indicated by a bell sound unless options(locatorBell = FALSE) has been set.

If the window is resized or hidden and then exposed before the identification process has terminated, any labels drawn by identify will disappear. These will reappear once the identification process has terminated and the window is resized or hidden and exposed again. This is because the labels
drawn by identify are not recorded in the device’s display list until the identification process has terminated.

If you interrupt the identify call this leaves the graphics device in an undefined state, with points labelled but labels not recorded in the display list. Copying a device in that state will give unpredictable results.

**Value**

If pos is FALSE, an integer vector containing the indices of the identified points, in the order they were identified.

If pos is TRUE, a list containing a component ind, indicating which points were identified and a component pos, indicating where the labels were placed relative to the identified points (1=below, 2=left, 3=above, 4=right and 0=no offset, used if atpen = TRUE).

**Technicalities**

The algorithm used for placing labels is the same as used by text if pos is specified there, the difference being that the position of the pointer relative the identified point determines pos in identify.

For labels placed to the left of a point, the right-hand edge of the string’s box is placed offset units to the left of the point, and analogously for points to the right. The baseline of the text is placed below the point so as to approximately centre string vertically. For labels placed above or below a point, the string is centered horizontally on the point. For labels placed above, the baseline of the text is placed offset units above the point, and for those placed below, the baseline is placed so that the top of the string’s box is approximately offset units below the point. If you want more precise placement (e.g. centering) use plot = FALSE and plot via text or points: see the examples.

**Examples**

```r
## A function to use identify to select points, and overplot the
## points with another symbol as they are selected
identifyPch <- function(x, y = NULL, n = length(x), pch = 19, ...)
{
  xy <- xy.coords(x, y); x <- xy$x; y <- xy$y
  sel <- rep(FALSE, length(x)); res <- integer(0)
  while(sum(sel) < n) {
    ans <- identify(x[!sel], y[!sel], n = 1, plot = FALSE, ...)
    if(!length(ans)) break
    ans <- which(!sel)[ans]
    points(x[ans], y[ans], pch = pch)
    sel[ans] <- TRUE
  }
  res <- c(res, ans)
  res
}

```
Description

Creates a grid of colored or gray-scale rectangles with colors corresponding to the values in \( z \). This can be used to display three-dimensional or spatial data aka *images*. This is a generic function.

The functions `heat.colors`, `terrain.colors` and `topo.colors` create heat-spectrum (red to white) and topographical color schemes suitable for displaying ordered data, with \( n \) giving the number of colors desired.

Usage

```r
image(x, ...)  
## Default S3 method:
image(x, y, z, zlim, xlim, ylim, col = heat.colors(12),
      add = FALSE, xaxs = "i", yaxs = "i", xlab, ylab,
      breaks, oldstyle = FALSE, useRaster, ...)
```

Arguments

- \( x, y \): locations of grid lines at which the values in \( z \) are measured. These must be finite, non-missing and in (strictly) ascending order. By default, equally spaced values from 0 to 1 are used. If \( x \) is a list, its components \( x \_x \) and \( x \_y \) are used for \( x \) and \( y \), respectively. If the list has component \( z \) this is used for \( z \).
- \( z \): a matrix containing the values to be plotted (NAs are allowed). Note that \( x \) can be used instead of \( z \) for convenience.
- \( zlim \): the minimum and maximum \( z \) values for which colors should be plotted, defaulting to the range of the finite values of \( z \). Each of the given colors will be used to color an equispaced interval of this range. The midpoints of the intervals cover the range, so that values just outside the range will be plotted.
- \( xlim, ylim \): ranges for the plotted \( x \) and \( y \) values, defaulting to the ranges of \( x \) and \( y \).
- \( col \): a list of colors such as that generated by `rainbow`, `heat.colors`, `topo.colors`, `terrain.colors` or similar functions.
- \( add \): logical; if TRUE, add to current plot (and disregard the following four arguments). This is rarely useful because `image` ‘paints’ over existing graphics.
- \( xaxs, yaxs \): style of \( x \) and \( y \) axis. The default "i" is appropriate for images. See `par`.
- \( xlab, ylab \): each a character string giving the labels for the \( x \) and \( y \) axis. Default to the ‘call names’ of \( x \) or \( y \), or to "" if these were unspecified.
- \( breaks \): a set of finite numeric breakpoints for the colours: must have one more breakpoint than colour and be in increasing order. Unsorted vectors will be sorted, with a warning.
- \( oldstyle \): logical. If true the midpoints of the colour intervals are equally spaced, and \( zlim[1] \) and \( zlim[2] \) were taken to be midpoints. The default is to have colour intervals of equal lengths between the limits.
useRaster logical; if TRUE a bitmap raster is used to plot the image instead of polygons. The grid must be regular in that case, otherwise an error is raised. For the behaviour when this is not specified, see ‘Details’.

... graphical parameters for plot may also be passed as arguments to this function, as can the plot aspect ratio asp and axes (see plot.window).

Details
The length of x should be equal to the nrow(z)+1 or nrow(z). In the first case x specifies the boundaries between the cells: in the second case x specifies the midpoints of the cells. Similar reasoning applies to y. It probably only makes sense to specify the midpoints of an equally-spaced grid. If you specify just one row or column and a length-one x or y, the whole user area in the corresponding direction is filled. For logarithmic x or y axes the boundaries between cells must be specified.

Rectangles corresponding to missing values are not plotted (and so are transparent and (unless add = TRUE) the default background painted in par("bg") will show though and if that is transparent, the canvas colour will be seen).

If breaks is specified then zlim is unused and the algorithm used follows cut, so intervals are closed on the right and open on the left except for the lowest interval which is closed at both ends.

The axes (where plotted) make use of the classes of xlim and ylim (and hence by default the classes of x and y): this will mean that for example dates are labelled as such. (As from R 3.0.1.)

Notice that image interprets the z matrix as a table of f(x[i], y[j]) values, so that the x axis corresponds to row number and the y axis to column number, with column 1 at the bottom, i.e. a 90 degree counter-clockwise rotation of the conventional printed layout of a matrix.

Images for large z on a regular grid are rendered more efficiently with useRaster = TRUE and can prevent rare anti-aliasing artifacts, but may not be supported by all graphics devices. Some devices (such as postscript and X11(type = "Xlib") which do not support semi-transparent colours may emit missing values as white rather than transparent, and there may be limitations on the size of a raster image. (Problems with the rendering of raster images have been reported by users of windows() devices under Remote Desktop, at least under its default settings.)

The graphics files in PDF and PostScript can be much smaller under this option.

If useRaster is not specified, raster images are used when the getOption("preferRaster") is true, the grid is regular and either dev.capabilities("raster") is "yes" or it is "non-missing" and there are no missing values.

Note
Originally based on a function by Thomas Lumley.

dev.capabilities to see if useRaster = TRUE is supported on the current device.
Examples

```r
require(grDevices) # for colours
x <- y <- seq(-4*pi, 4*pi, len = 27)
r <- sqrt(outer(x^2, y^2, "+"))
image(z = z <- cos(r^2)*exp(-r/6), col = gray((0:32)/32))
image(z, axes = FALSE, main = "Math can be beautiful ...",
     xlab = expression(cos(r^2) * e^{(-r/6)}))
contour(z, add = TRUE, drawlabels = FALSE)

# Volcano data visualized as matrix. Need to transpose and flip
# matrix horizontally.
image(t(volcano)[ncol(volcano):1,])

# A prettier display of the volcano
x <- 10*(1:nrow(volcano))
y <- 10*(1:ncol(volcano))
image(x, y, volcano, col = terrain.colors(100), axes = FALSE)
contour(x, y, volcano, levels = seq(90, 200, by = 5),
     add = TRUE, col = "peru")
axis(1, at = seq(100, 800, by = 100))
axis(2, at = seq(100, 600, by = 100))
box()
title(main = "Maung Whau Volcano", font.main = 4)
```

Description

`layout` divides the device up into as many rows and columns as there are in matrix `mat`, with the column-widths and the row-heights specified in the respective arguments.

Usage

```r
layout(mat, widths = rep.int(1, ncol(mat)),
       heights = rep.int(1, nrow(mat)), respect = FALSE)
layout.show(n = 1)
1cm(x)
```

Arguments

- `mat`: a matrix object specifying the location of the next $N$ figures on the output device. Each value in the matrix must be 0 or a positive integer. If $N$ is the largest positive integer in the matrix, then the integers $\{1, \ldots, N - 1\}$ must also appear at least once in the matrix.
- `widths`: a vector of values for the widths of columns on the device. Relative widths are specified with numeric values. Absolute widths (in centimetres) are specified with the `1cm()` function (see examples).
- `heights`: a vector of values for the heights of rows on the device. Relative and absolute heights can be specified, see `widths` above.
layout

The respect argument controls whether a unit column-width is the same physical measurement on
the device as a unit row-height.

There is a limit (currently 200) for the numbers of rows and columns in the layout, and also for the
total number of cells (10007).

layout.show(n) plots (part of) the current layout, namely the outlines of the next n figures.
lcm is a trivial function, to be used as the interface for specifying absolute dimensions for the
widths and heights arguments of layout().

Value

layout returns the number of figures, \( N \), see above.

Warnings

These functions are totally incompatible with the other mechanisms for arranging plots on a device:
par(mfrow), par(mfcol) and split.screen.

par with arguments mfrow, mfcol, or mfg.

Examples

def.par <- par(no.readonly = TRUE) # save default, for resetting...

## divide the device into two rows and two columns
## allocate figure 1 all of row 1
## allocate figure 2 the intersection of column 2 and row 2
layout(matrix(c(1,1,0,2), 2, 2, byrow = TRUE))
## show the regions that have been allocated to each plot
layout.show(2)
## Add Legends to Plots

This function can be used to add legends to plots. Note that a call to the function `locator(1)` can be used in place of the x and y arguments.

### Usage

```r
legend(x, y = NULL, legend, fill = NULL, col = par("col"),
       border = "black", lty, lwd, pch,
       angle = 45, density = NULL, bty = "o", bg = par("bg"),
       box.lwd = par("lwd"), box.lty = par("lty"), box.col = par("fg"),
       pt.bg = NA, cex = 1, pt.cex = cex, pt.lwd = lwd,
       xjust = 0, yjust = 1, x.intersp = 1, y.intersp = 1,
       adj = c(0, 0.5), text.width = NULL, text.col = par("col"),
       text.font = NULL, merge = do.lines && has.pch, trace = FALSE,
       plot = TRUE, ncol = 1, horiz = FALSE, title = NULL,
       inset = 0, xpd, title.col = text.col, title.adj = 0.5,
       seg.len = 2)
```
Arguments

`x, y`  the x and y co-ordinates to be used to position the legend. They can be specified by keyword or in any way which is accepted by `xy.coords`; See ‘Details’.

`legend`  a character or expression vector of length ≥ 1 to appear in the legend. Other objects will be coerced by `as.graphicsAnnot`.

`fill`  if specified, this argument will cause boxes filled with the specified colors (or shaded in the specified colors) to appear beside the legend text.

`col`  the color of points or lines appearing in the legend.

`border`  the color for the boxes (used only if `fill` is specified).

`lty, lwd`  the line types and widths for lines appearing in the legend. One of these two must be specified for line drawing.

`pch`  the plotting symbols appearing in the legend, as numeric vector or a vector of 1-character strings (see `points`). Unlike points, this can all be specified as a single multi-character string. Must be specified for symbol drawing.

`angle`  angle of shading lines.

`density`  the density of shading lines, if numeric and positive. If `NULL` or negative or `NA` color filling is assumed.

`bty`  the type of box to be drawn around the legend. The allowed values are "o" (the default) and "n".

`bg`  the background color for the legend box. (Note that this is only used if `bty` != "n".)

`box.lty, box.lwd, box.col`  the line type, width and color for the legend box (if `bty` = "o").

`pt.bg`  the background color for the `points`, corresponding to its argument `bg`.

`cex`  character expansion factor relative to current `par("cex")`. Used for text, and provides the default for `pt.cex` and `title.cex`.

`pt.cex`  expansion factor(s) for the points.

`pt.lwd`  line width for the points, defaults to the one for lines, or if that is not set, to `par("lwd")`.

`xjust`  how the legend is to be justified relative to the legend x location. A value of 0 means left justified, 0.5 means centered and 1 means right justified.

`yjust`  the same as `xjust` for the legend y location.

`x.intersp`  character interspacing factor for horizontal (x) spacing.

`y.intersp`  the same for vertical (y) line distances.

`adj`  numeric of length 1 or 2; the string adjustment for legend text. Useful for y-adjustment when `labels` are `plotmath` expressions.

`text.width`  the width of the legend text in x ("user") coordinates. (Should be positive even for a reversed x axis.) Defaults to the proper value computed by `strwidth(legend)`.

`text.col`  the color used for the legend text.

`text.font`  the font used for the legend text, see `text`.

`merge`  logical; if `TRUE`, merge points and lines but not filled boxes. Defaults to `TRUE` if there are points and lines.

`trace`  logical; if `TRUE`, shows how `legend` does all its magical computations.
plot logical. If FALSE, nothing is plotted but the sizes are returned.
ncol the number of columns in which to set the legend items (default is 1, a vertical legend).
horiz logical; if TRUE, set the legend horizontally rather than vertically (specifying horiz overrides the ncol specification).
title a character string or length-one expression giving a title to be placed at the top of the legend. Other objects will be coerced by as.graphicsAnnot.
inset inset distance(s) from the margins as a fraction of the plot region when legend is placed by keyword.
xpd if supplied, a value of the graphical parameter xpd to be used while the legend is being drawn.
title.col color for title.
title.adj horizontal adjustment for title: see the help for par("adj").
seg.len the length of lines drawn to illustrate lty and/or lwd (in units of character widths).

Details

Arguments x, y, legend are interpreted in a non-standard way to allow the coordinates to be specified via one or two arguments. If legend is missing and y is not numeric, it is assumed that the second argument is intended to be legend and that the first argument specifies the coordinates.

The coordinates can be specified in any way which is accepted by xy.coords. If this gives the coordinates of one point, it is used as the top-left coordinate of the rectangle containing the legend. If it gives the coordinates of two points, these specify opposite corners of the rectangle (either pair of corners, in any order).

The location may also be specified by setting x to a single keyword from the list "bottomright", "bottom", "bottomleft", "left", "topleft", "top", "topright", "right" and "center". This places the legend on the inside of the plot frame at the given location. Partial argument matching is used. The optional inset argument specifies how far the legend is inset from the plot margins. If a single value is given, it is used for both margins; if two values are given, the first is used for x-distance, the second for y-distance.

Attribute arguments such as col, pch, lty, etc, are recycled if necessary: merge is not. Set entries of lty to 0 or set entries of lwd to NA to suppress lines in corresponding legend entries; set pch values to NA to suppress points.

Points are drawn after lines in order that they can cover the line with their background color pt.bg, if applicable.

See the examples for how to right-justify labels.

R 2.0.x.0 omitted negative pch values. Since they are not used for Unicode points, values -31:-1 are still silently omitted, as are NA and "" values.

Value

A list with list components

rect a list with components

w, h positive numbers giving width and height of the legend’s box.
left, top x and y coordinates of upper left corner of the box.

text a list with components
x, y numeric vectors of length length(legend), giving the x and y coordinates of the legend’s text(s).

returned invisibly.

hist(x, main = "Mean and Median of a Skewed Distribution")
abline(v = mean(x), col = 2, lty = 2, lwd = 2)
abline(v = median(x), col = 3, lty = 3, lwd = 2)
ex12 <- expression(bar(x) == sum(over(x[i], n), i == 1, n),
                     hat(x) == median(x[i], i == 1, n))
utils::str(legend(4.1, 30, ex12, col = 2:3, lty = 2:3, lwd = 2))

### 'Filled' boxes -- for more, see example(plot.factor)
op <- par(bg = "white") # to get an opaque box for the legend
plot(cut(weight, 3) ~ group, data = PlantGrowth, col = NULL,
     # density = 16*(1:3))
par(op)

### Using 'ncol' :
x <- 0:64/64
matplot(x, outer(x, 1:7, function(x, k) sin(k * pi * x)),
        type = "o", col = 1:7, ylim = c(-1, 1.5), pch = "*"
op <- par(bg = "antiquewhite")
legend(0, 1.5, paste("sin("), c("", "pi x"), col = 1:7, lty = 1:7,
          pch = "x", ncol = 3, lwd = 2)
legend(0, 1.2, paste("sin("), c("", "pi x"), col = 1:7, lty = 1:7,
          pch = "x", cex = 0.8)
legend(0, -1, paste("sin("), c("", "pi x"), col = 1:4, lty = 1:4,
          ncol = 2, cex = 0.8)
legend(0, -4, paste("sin("), c("", "pi x"), col = 4:6, pch = 24,
          ncol = 2, cex = 1.5, lwd = 2, pt.bg = "pink", pt.cex = 1.3)
par(op)

### point covering line :
y <- sin(3*pi*x)
plot(x, y, type = "l", col = "blue",
     main = "points with bg & legend(*, pt.bg")
```

Points(x, y, pch = 21, bg = "white")
legend(.4, 1, "sin(c x)", pch = 21, pt.bg = "white", lty = 1, col = "blue")

## legends with titles at different locations
plot(x, y, type = "n")
legend("bottomright", "(x,y)", pch = 1, title = "bottomright")
legend("bottom", "(x,y)", pch = 1, title = "bottom")
legend("bottomleft", "(x,y)", pch = 1, title = "bottomleft")
legend("left", "(x,y)", pch = 1, title = "left")
legend("topleft", "(x,y)", pch = 1, title = "topleft, inset = .05",
inset = .05)
legend("top", "(x,y)", pch = 1, title = "top")
legend("topright", "(x,y)", pch = 1, title = "topright, inset = .02",
inset = .02)
legend("right", "(x,y)", pch = 1, title = "right")
legend("center", "(x,y)", pch = 1, title = "center")

# using text.font (and text.col):
op <- par(mfrow = c(2, 2), mar = rep(2.1, 4))
c6 <- terrain.colors(10)[1:6]
for(i in 1:4) {
  plot(1, type = "n", axes = FALSE, ann = FALSE); title(paste("text.font =", i))
  legend("top", legend = LETTERS[1:6], col = c6,
         ncol = 2, cex = 2, lwd = 3, text.font = i, text.col = c6)
}
par(op)

---

**lines**

*Add Connected Line Segments to a Plot*

**Description**

A generic function taking coordinates given in various ways and joining the corresponding points with line segments.

**Usage**

`lines(x, ...)`

## Default S3 method:
`lines(x, y = NULL, type = "l", ...)`

**Arguments**

- `x`, `y` coordinate vectors of points to join.
- `type` character indicating the type of plotting; actually any of the types as in `plot.default`.
- `...` Further graphical parameters (see `par`) may also be supplied as arguments, particularly, line type, lty, line width, lwd, color, col and for type = "b", pch. Also the line characteristics lend, ljoin and lmitre.
**Details**

The coordinates can be passed in a plotting structure (a list with x and y components), a two-column matrix, a time series, .... See `xy.coords`. If supplied separately, they must be of the same length.

The coordinates can contain `NA` values. If a point contains `NA` in either its x or y value, it is omitted from the plot, and lines are not drawn to or from such points. Thus missing values can be used to achieve breaks in lines.

For `type = "h"`, `col` can be a vector and will be recycled as needed.

`lwd` can be a vector: its first element will apply to lines but the whole vector to symbols (recycled as necessary).

**References**

**See Also**

`lines.formula` for the formula method; `points`, particularly for `type %in% c("p","b","o")`, `plot`, and the workhorse function `plot.xy`.

`abline` for drawing (single) straight lines.

`par` for line type (`lty`) specification and how to specify colors.

**Examples**

```r
# draw a smooth line through a scatter plot
plot(cars, main = "Stopping Distance versus Speed")
lines(stats::lowess(cars))
```

**Graphical Input**

Reads the position of the graphics cursor when the (first) mouse button is pressed.

**Usage**

```r
locator(n = 512, type = "n", ...)
```

**Arguments**

- **n**
  - the maximum number of points to locate. Valid values start at 1.

- **type**
  - One of "n", "p", "l" or "o". If "p" or "o" the points are plotted; if "l" or "o" they are joined by lines.

- **...**
  - additional graphics parameters used if `type != "n"` for plotting the locations.
Details

locator is only supported on screen devices such as X11, windows and quartz. On other devices the call will do nothing.

Unless the process is terminated prematurely by the user (see below) at most n positions are determined.

For the usual X11 device the identification process is terminated by pressing any mouse button other than the first. For the quartz device the process is terminated by pressing the ESC key.

The current graphics parameters apply just as if plot.default has been called with the same value of type. The plotting of the points and lines is subject to clipping, but locations outside the current clipping rectangle will be returned.

On most devices which support locator, successful selection of a point is indicated by a bell sound unless options(locatorBell = FALSE) has been set.

If the window is resized or hidden and then exposed before the input process has terminated, any lines or points drawn by locator will disappear. These will reappear once the input process has terminated and the window is resized or hidden and exposed again. This is because the points and lines drawn by locator are not recorded in the device’s display list until the input process has terminated.

Value

A list containing x and y components which are the coordinates of the identified points in the user coordinate system, i.e., the one specified by par("usr").

dev.capabilities to see if it is supported.

matplot

Plot Columns of Matrices

Description

Plot the columns of one matrix against the columns of another.

Usage

matplot(x, y, type = "p", lty = 1:5, lwd = 1, lend = par("lend"),
        pch = NULL,
        col = 1:6, cex = NULL, bg = NA,
        xlab = NULL, ylab = NULL, xlim = NULL, ylim = NULL,
        ..., add = FALSE, verbose =getOption("verbose"))

matpoints(x, y, type = "p", lty = 1:5, lwd = 1, pch = NULL,
Arguments

\texttt{x, y} vectors or matrices of data for plotting. The number of rows should match. If one of them are missing, the other is taken as \texttt{y} and an \texttt{x} vector of 1:n is used. Missing values (\texttt{NAs}) are allowed.

\texttt{type} character string (length 1 vector) or vector of 1-character strings indicating the type of plot for each column of \texttt{y}, see \texttt{plot} for all possible types. The first character of \texttt{type} defines the first plot, the second character the second, etc. Characters in \texttt{type} are cycled through; e.g., \texttt{"bp"} alternately plots points and lines.

\texttt{lty, lwd, lend} vector of line types, widths, and end styles. The first element is for the first column, the second element for the second column, etc., even if lines are not plotted for all columns. Line types will be used cyclically until all plots are drawn.

\texttt{pch} character string or vector of 1-characters or integers for plotting characters, see \texttt{points}. The first character is the plotting-character for the first plot, the second for the second, etc. The default is the digits (1 through 9, 0) then the lowercase and uppercase letters.

\texttt{col} vector of colors. Colors are used cyclically.

\texttt{cex} vector of character expansion sizes, used cyclically. This works as a multiple of \texttt{par("cex"). NULL is equivalent to 1.0.}

\texttt{bg} vector of background (fill) colors for the open plot symbols given by \texttt{pch = 21:25} as in \texttt{points}. The default \texttt{NA} corresponds to the one of the underlying function \texttt{plot.xy}.

\texttt{xlab, ylab} titles for \texttt{x} and \texttt{y} axes, as in \texttt{plot}.

\texttt{xlim, ylim} ranges of \texttt{x} and \texttt{y} axes, as in \texttt{plot}.

... Graphical parameters (see \texttt{par}) and any further arguments of \texttt{plot}, typically \texttt{plot.default}, may also be supplied as arguments to this function. Hence, the high-level graphics control arguments described under \texttt{par} and the arguments to \texttt{title} may be supplied to this function.

\texttt{add} logical. If \texttt{TRUE}, plots are added to current one, using \texttt{points} and \texttt{lines}.

\texttt{verbose} logical. If \texttt{TRUE}, write one line of what is done.

Details

Points involving missing values are not plotted. The first column of \texttt{x} is plotted against the first column of \texttt{y}, the second column of \texttt{x} against the second column of \texttt{y}, etc. If one matrix has fewer columns, plotting will cycle back through the columns again. (In particular, either \texttt{x} or \texttt{y} may be a vector, against which all columns of the other argument will be plotted.) The first element of \texttt{col, cex, lty, lwd} is used to plot the axes as well as the first line. Because plotting symbols are drawn with lines and because these functions may be changing the line style, you should probably specify \texttt{lty = 1} when using plotting symbols.
Side Effects

Function `matplot` generates a new plot; `matpoints` and `matlines` add to the current one.

```

mosaicplot

par(op)

mosaicplot  Mosaic Plots

Description

Plots a mosaic on the current graphics device.

Usage

mosaicplot(x, ...)

## Default S3 method:
mosaicplot(x, main = deparse(substitute(x)),
          sub = NULL, xlab = NULL, ylab = NULL,
          sort = NULL, off = NULL, dir = NULL,
          color = NULL, shade = FALSE, margin = NULL,
          cex.axis = 0.66, las = par("las"), border = NULL,
          type = c("pearson", "deviance", "FT"), ...)

## S3 method for class 'formula'
mosaicplot(formula, data = NULL, ...
          main = deparse(substitute(data)), subset,
          na.action = stats::na.omit)

Arguments

x  a contingency table in array form, with optional category labels specified in the
dimnames(x) attribute. The table is best created by the table() command.

main  character string for the mosaic title.

sub  character string for the mosaic sub-title (at bottom).

xlab, ylab  x- and y-axis labels used for the plot; by default, the first and second element of
names(dimnames(X)) (i.e., the name of the first and second variable in X).

sort  vector ordering of the variables, containing a permutation of the integers
1:length(dim(x)) (the default).

off  vector of offsets to determine percentage spacing at each level of the mosaic
(appropriate values are between 0 and 20, and the default is 20 times the number
of splits for 2-dimensional tables, and 10 otherwise. Rescaled to maximally 50,
and recycled if necessary.

dir  vector of split directions ("v" for vertical and "h" for horizontal) for each level
of the mosaic, one direction for each dimension of the contingency table. The
default consists of alternating directions, beginning with a vertical split.

color  logical or (recycling) vector of colors for color shading, used only when shade
is FALSE, or NULL (default). By default, grey boxes are drawn. color = TRUE
uses a gamma-corrected grey palette. color = FALSE gives empty boxes with
no shading.
shade 
a logical indicating whether to produce extended mosaic plots, or a numeric vector of at most 5 distinct positive numbers giving the absolute values of the cut points for the residuals. By default, shade is FALSE, and simple mosaics are created. Using shade = TRUE cuts absolute values at 2 and 4.

margin 
a list of vectors with the marginal totals to be fit in the log-linear model. By default, an independence model is fitted. See loglin for further information.

cex.axis 
The magnification to be used for axis annotation, as a multiple of par("cex").

las 
numeric; the style of axis labels, see par.

border 
colour of borders of cells: see polygon.

type 
a character string indicating the type of residual to be represented. Must be one of "pearsn" (giving components of Pearson's \(\chi^2\)), "deviance" (giving components of the likelihood ratio \(\chi^2\)), or "FT" for the Freeman-Tukey residuals. The value of this argument can be abbreviated.

formula 
a formula, such as \(y \sim x\).

data 
a data frame (or list), or a contingency table from which the variables in formula should be taken.

... 
further arguments to be passed to or from methods.

subset 
an optional vector specifying a subset of observations in the data frame to be used for plotting.

na.action 
a function which indicates what should happen when the data contains variables to be cross-tabulated, and these variables contain NAs. The default is to omit cases which have an NA in any variable. Since the tabulation will omit all cases containing missing values, this will only be useful if the na.action function replaces missing values.

Details

This is a generic function. It currently has a default method (mosaicplot.default) and a formula interface (mosaicplot.formula).

Extended mosaic displays visualize standardized residuals of a loglinear model for the table by color and outline of the mosaic's tiles. (Standardized residuals are often referred to a standard normal distribution.) Cells representing negative residuals are drawn in shaded of red and with broken borders; positive ones are drawn in blue with solid borders.

For the formula method, if data is an object inheriting from class "table" or class "ftable" or an array with more than 2 dimensions, it is taken as a contingency table, and hence all entries should be non-negative. In this case the left-hand side of formula should be empty and the variables on the right-hand side should be taken from the names of the dimnames attribute of the contingency table. A marginal table of these variables is computed, and a mosaic plot of that table is produced. Otherwise, data should be a data frame or matrix, list or environment containing the variables to be cross-tabulated. In this case, after possibly selecting a subset of the data as specified by the subset argument, a contingency table is computed from the variables given in formula, and a mosaic is produced from this.

See Emerson (1998) for more information and a case study with television viewer data from Nielsen Media Research.

Missing values are not supported except via an na.action function when data contains variables to be cross-tabulated.

A more flexible and extensible implementation of mosaic plots written in the grid graphics system is provided in the function mosaic in the contributed package vcd (Meyer, Zeileis and Hornik, 2005).
mosaicplot

## of independence and too few brown eyed blonde females.
## The corresponding model is:
fm <- loglin(HairEyeColor, list(1, 2, 3))
pchisq(fm$pearson, fm$df, lower.tail = FALSE)

mosaicplot(HairEyeColor, shade = TRUE, margin = list(1:2, 3))
## Model of joint independence of sex from hair and eye color. Males
## are underrepresented among people with brown hair and eyes, and are
## overrepresented among people with brown hair and blue eyes.
## The corresponding model is:
fem <- loglin(HairEyeColor, list(1:2, 3))
pchisq(fm$pearson, fm$df, lower.tail = FALSE)

## Formula interface for raw data: visualize cross-tabulation of numbers
## of gears and carburettors in Motor Trend car data.
mosaicplot(~ gear + carb, data = mtcars, color = TRUE, las = 1)
# color recycling
mosaicplot(~ gear + carb, data = mtcars, color = 2:3, las = 1)
\textit{mtext} \quad \textit{Write Text into the Margins of a Plot}

\textbf{Description}
Text is written in one of the four margins of the current figure region or one of the outer margins of the device region.

\textbf{Usage}
\begin{verbatim}
mtext(text, side = 3, line = 0, outer = FALSE, at = NA,
   adj = NA, padd = NA, cex = NA, col = NA, font = NA, ...)
\end{verbatim}

\textbf{Arguments}
\begin{itemize}
\item \texttt{text} \quad a character or \texttt{expression} vector specifying the \texttt{text} to be written. Other objects are coerced by \texttt{as.graphicsAnnot}.
\item \texttt{side} \quad on which side of the plot (1=bottom, 2=left, 3=top, 4=right).
\item \texttt{line} \quad on which MARgin line, starting at 0 counting outwards.
\item \texttt{outer} \quad use outer margins if available.
\item \texttt{at} \quad give location of each string in user coordinates. If the component of \texttt{at} corresponding to a particular text item is not a finite value (the default), the location will be determined by \texttt{adj}.
\item \texttt{adj} \quad adjustment for each string in reading direction. For strings parallel to the axes, \texttt{adj} = 0 means left or bottom alignment, and \texttt{adj} = 1 means right or top alignment.
   \begin{itemize}
   \item If \texttt{adj} is not a finite value (the default), the value of \texttt{par("las")} determines the adjustment. For strings plotted parallel to the axis the default is to centre the string.
   \end{itemize}
\item \texttt{padd} \quad adjustment for each string perpendicular to the reading direction (which is controlled by \texttt{adj}). For strings parallel to the axes, \texttt{padd} = 0 means right or top alignment, and \texttt{padd} = 1 means left or bottom alignment.
   \begin{itemize}
   \item If \texttt{padd} is not a finite value (the default), the value of \texttt{par("las")} determines the adjustment. For strings plotted perpendicular to the axis the default is to centre the string.
   \end{itemize}
\item \texttt{cex} \quad character expansion factor. \texttt{NULL} and \texttt{NA} are equivalent to 1.0. This is an absolute measure, not scaled by \texttt{par("cex")} or by setting \texttt{par("mtext")} or \texttt{par("mtext")}. Can be a vector.
\item \texttt{col} \quad color to use. Can be a vector. \texttt{NA} values (the default) mean use \texttt{par("col")}.
\item \texttt{font} \quad font for text. Can be a vector. \texttt{NA} values (the default) mean use \texttt{par("font")}.
\item \texttt{...} \quad Further graphical parameters (see \texttt{par}), including \texttt{family}, \texttt{lasp} and \texttt{xpd}. (The latter defaults to the figure region unless \texttt{outer = TRUE}, otherwise the device region. It can only be increased.)
\end{itemize}
Details

The user coordinates in the outer margins always range from zero to one, and are not affected by
the user coordinates in the figure region(s) — R differs here from other implementations of S.
All of the named arguments can be vectors, and recycling will take place to plot as many strings as
the longest of the vector arguments.

Note that a vector adj has a different meaning from text. adj = 0.5 will centre the string, but for
outer = TRUE on the device region rather than the plot region.

Parameter las will determine the orientation of the string(s). For strings plotted perpendicular to
the axis the default justification is to place the end of the string nearest the axis on the specified line.
(Note that this differs from S, which uses srt if at is supplied and las if it is not. Parameter srt is
ignored in R.)

Note that if the text is to be plotted perpendicular to the axis, adj determines the justification of the
string and the position along the axis unless at is specified.

Graphics parameter "ylbias" (see par) determines how the text baseline is placed relative to the
nominal line.

Side Effects

The given text is written onto the current plot.

Examples

plot(1:10, (-4:5)^2, main = "Parabola Points", xlab = "xlab")
mtext("10 of them")
for(s in 1:4)
    mtext(paste("mtext(..., line= -1, (side, col, font) = ", s,
    ", cex = ", (1+s)/2, ")"), line = -1,
    side = s, col = s, font = s, cex = (1+s)/2)
mtext("mtext(..., line= -2)", line = -2)
mtext("mtext(..., line= -2, adj = 0)", line = -2, adj = 0)
## log axis :
plot(1:10, exp(1:10), log = "y", main = "log =\"y\"", xlab = "xlab")
for(s in 1:4) mtext(paste("mtext(...,side="", s ,"")", side = s)

Description

A matrix of scatterplots is produced.
Usage

pairs(x, ...)

## S3 method for class 'formula'
pairs(formula, data = NULL, ..., subset,
       na.action = stats::na.pass)

## Default S3 method:
pairs(x, labels, panel = points, ...,
      lower.panel = panel, upper.panel = panel,
      diag.panel = NULL, text.panel = textPanel,
      label.pos = 0.5 + has.diag/3, line.main = 3,
      cex.labels = NULL, font.labels = 1,
      rowlattop = TRUE, gap = 1, log = "")

Arguments

x       the coordinates of points given as numeric columns of a matrix or data frame. Logical and factor columns are converted to numeric in the same way that data.matrix does.
formula a formula, such as ~ x + y + z. Each term will give a separate variable in the pairs plot, so terms should be numeric vectors. (A response will be interpreted as another variable, but not treated specially, so it is confusing to use one.)
data a data.frame (or list) from which the variables in formula should be taken.
subset an optional vector specifying a subset of observations to be used for plotting.
na.action a function which indicates what should happen when the data contain NAs. The default is to pass missing values on to the panel functions, but na.action = na.omit will cause cases with missing values in any of the variables to be omitted entirely.
labels the names of the variables.
panel function(x, y, ...) which is used to plot the contents of each panel of the display.
... arguments to be passed to or from methods.
Also, graphical parameters can be given as can arguments to plot such as main. par(”oma”) will be set appropriately unless specified.
lower.panel, upper.panel separate panel functions (or NULL) to be used below and above the diagonal respectively.
diag.panel optional function(x, ...) to be applied on the diagonals.
text.panel optional function(x, y, labels, cex, font, ...) to be applied on the diagonals.
label.pos y position of labels in the text panel.
line.main if main is specified, line.main gives the line argument to mtext() which draws the title. You may want to specify oma when changing line.main.
cex.labels, font.labels graphics parameters for the text panel.
rowlattop logical. Should the layout be matrix-like with row 1 at the top, or graph-like with row 1 at the bottom?
pairs

```r

gap  distance between subplots, in margin lines.

log  a character string indicating if logarithmic axes are to be used: see plot.default. log = "xy" specifies logarithmic axes for all variables.

Details

The \textit{ij}th scatterplot contains \texttt{x[i,j]} plotted against \texttt{x[j,i]}. The scatterplot can be customised by setting panel functions to appear as something completely different. The off-diagonal panel functions are passed the appropriate columns of \texttt{x} as \texttt{x} and \texttt{y}: the diagonal panel function (if any) is passed a single column, and the text.panel function is passed a single \((x, y)\) location and the column name. Setting some of these panel functions to \texttt{NULL} is equivalent to \texttt{not} drawing anything there.

The \textit{graphical parameters} \texttt{pch} and \texttt{col} can be used to specify a vector of plotting symbols and colors to be used in the plots.

The \textit{graphical parameter} \texttt{oma} will be set by \texttt{pairs.default} unless supplied as an argument.

A panel function should not attempt to start a new plot, but just plot within a given coordinate system: thus \texttt{plot} and \texttt{boxplot} are not panel functions.

By default, missing values are passed to the panel functions and will often be ignored within a panel. However, for the formula method and \texttt{na.action = na.omit}, all cases which contain a missing values for any of the variables are omitted completely (including when the scales are selected).

  par(usr = c(usr[1:2], 0, 1.5))
  h <- hist(x, plot = FALSE)
  breaks <- h$breaks; nb <- length(breaks)
  y <- h$counts; y <- y/max(y)
  rect(breaks[-nb], 0, breaks[-1], y, col = "cyan", ...)}

pairs(USJudgeRatings[1:5], panel = panel.smooth)
```
panel.smooth

Simple Panel Plot

Description
An example of a simple useful panel function to be used as argument in e.g., coplot or pairs.

Usage
panel.smooth(x, y, col = par("col"), bg = NA, pch = par("pch"),
  cex = 1, col.smooth = "red", span = 2/3, iter = 3,
  ...)

Arguments
x, y numeric vectors of the same length
col, bg, pch, cex numeric or character codes for the color(s), point type and size of points; see also par.
col.smooth color to be used by lines for drawing the smooths.
span smoothing parameter f for lowess, see there.
iternumber of robustness iterations for lowess.
... further arguments to lines.

See Also
coplot and pairs where panel.smooth is typically used; lowess which does the smoothing.

Examples
pairs(swiss, panel = panel.smooth, pch = ".") # emphasize the smooths
pairs(swiss, panel = panel.smooth, lwd = 2, cex = 1.5, col = "blue") # hmm...
Description

par can be used to set or query graphical parameters. Parameters can be set by specifying them as arguments to par in tag = value form, or by passing them as a list of tagged values.

Usage

par(..., no.readonly = FALSE)

<highlevel plot> (... ,<tag> = <value>)

Arguments

... arguments in tag = value form, or a list of tagged values. The tags must come from the names of graphical parameters described in the ‘Graphical Parameters’ section.

no.readonly logical; if TRUE and there are no other arguments, only parameters are returned which can be set by a subsequent par() call on the same device.

Details

Each device has its own set of graphical parameters. If the current device is the null device, par will open a new device before querying/setting parameters. (What device is controlled by options("device").)

Parameters are queried by giving one or more character vectors of parameter names to par.

par() (no arguments) or par(no.readonly = TRUE) is used to get all the graphical parameters (as a named list). Their names are currently taken from the unexported variable graphics::.pars.

R.O. indicates read-only arguments: These may only be used in queries and cannot be set. ("cin", "cra", "csi", "cxy", "din" and "page" are always read-only.)

Several parameters can only be set by a call to par():

- "ask",
- "fig","fin",
- "height",
- "new",
- "oma", "omd", "omi",
- "pin", "plt", "ps", "pty",
- "usr",
- "xlog", "ylog",
- "ylbias"
The remaining parameters can also be set as arguments (often via \ldots) to high-level plot functions such as \code{plot.default, plot.window, points, lines, abline, axis, title, text, mtext, segments, symbols, arrows, polygon, rect, box, contour, filled.contour} and \code{image}. Such settings will be active during the execution of the function, only. However, see the comments on \code{bg}, \code{cex}, \code{col}, \code{lty}, \code{lwd} and \code{pch} which may be taken as arguments to certain plot functions rather than as graphical parameters.

The meaning of 'character size' is not well-defined: this is set up for the device taking \code{pointsize} into account but often not the actual font family in use. Internally the corresponding pars (\code{cra, cin, cxy} and \code{csi}) are used only to set the inter-line spacing used to convert \code{mar} and \code{oma} to physical margins. (The same inter-line spacing multiplied by \code{lheight} is used for multi-line strings in \code{text} and \code{strheight}.)

Note that graphical parameters are suggestions: plotting functions and devices need not make use of them (and this is particularly true of non-default methods for e.g. \code{plot}).

\section*{Value}

When parameters are set, their previous values are returned in an invisible named list. Such a list can be passed as an argument to \code{par} to restore the parameter values. Use \code{par(no.readonly = TRUE)} for the full list of parameters that can be restored. However, restoring all of these is not wise: see the 'Note' section.

When just one parameter is queried, the value of that parameter is returned as (atomic) vector. When two or more parameters are queried, their values are returned in a list, with the list names giving the parameters.

Note the inconsistency: setting one parameter returns a list, but querying one parameter returns a vector.

\section*{Graphical Parameters}

\textbf{adj} The value of \texttt{adj} determines the way in which text strings are justified in \code{text, mtext} and \code{title}. A value of \texttt{0} produces left-justified text, \texttt{0.5} (the default) centered text and \texttt{1} right-justified text. (Any value in \texttt{[0,1]} is allowed, and on most devices values outside that interval will also work.)

Note that the \texttt{adj \texttt{argument of text}} also allows \texttt{adj = c(x, y)} for different adjustment in x- and y-directions. Note that whereas for \code{text} it refers to positioning of text about a point, for \code{mtext} and \code{title} it controls placement within the plot or device region.

\textbf{ann} If set to \code{FALSE}, high-level plotting functions calling \code{plot.default} do not annotate the plots they produce with axis titles and overall titles. The default is to do annotation.

\textbf{ask} logical. If \code{TRUE} (and the \proglang{R} session is interactive) the user is asked for input, before a new figure is drawn. As this applies to the device, it also affects output by packages \code{grid} and \code{lattice}. It can be set even on non-screen devices but may have no effect there. This not really a graphics parameter, and its use is deprecated in favour of \code{devAskNewPage}.

\textbf{bg} The color to be used for the background of the device region. When called from \code{par()} it also sets \code{new = FALSE}. See section "Color Specification" for suitable values. For many devices the initial value is set from the \code{bg} argument of the device, and for the rest it is normally "white".

Note that some graphics functions such as \code{plot.default} and \code{points} have an \texttt{argument of this name with a different meaning}.

\textbf{bty} A character string which determined the type of \code{box} which is drawn about plots. If \texttt{bty} is one of "o" (the default), "1", "7", "c", "u", or "]" the resulting box resembles the corresponding upper case letter. A value of "n" suppresses the box.
par

A numerical value giving the amount by which plotting text and symbols should be magnified relative to the default. This starts as 1 when a device is opened, and is reset when the layout is changed, e.g. by setting mfrow.

Note that some graphics functions such as plot.default have an argument of this name which multiplies this graphical parameter, and some functions such as points and text accept a vector of values which are recycled.

cex.axis The magnification to be used for axis annotation relative to the current setting of cex.
cex.lab The magnification to be used for x and y labels relative to the current setting of cex.
cex.main The magnification to be used for main titles relative to the current setting of cex.
cex.sub The magnification to be used for sub-titles relative to the current setting of cex.
cin R.O.; character size (width, height) in inches. These are the same measurements as cra, expressed in different units.

col A specification for the default plotting color. See section ‘Color Specification’.

Some functions such as lines and text accept a vector of values which are recycled and may be interpreted slightly differently.
col.axis The color to be used for axis annotation. Defaults to "black".
col.lab The color to be used for x and y labels. Defaults to "black".
col.main The color to be used for plot main titles. Defaults to "black".
col.sub The color to be used for plot sub-titles. Defaults to "black".
cra R.O.; size of default character (width, height) in ‘rasters’ (pixels). Some devices have no concept of pixels and so assume an arbitrary pixel size, usually 1/72 inch. These are the same measurements as cin, expressed in different units.
crt A numerical value specifying (in degrees) how single characters should be rotated. It is unwise to expect values other than multiples of 90 to work. Compare with srt which does string rotation.
csi R.O.; height of (default-sized) characters in inches. The same as par("cin")[2].
cxy R.O.; size of default character (width, height) in user coordinate units. par("cxy") is par("cin")/par("pin") scaled to user coordinates. Note that c(strwidth(ch), strheight(ch)) for a given string ch is usually much more precise.
din R.O.; the device dimensions, (width, height), in inches. See also dev.size, which is updated immediately when an on-screen device windows is re-sized.
err (Unimplemented; R is silent when points outside the plot region are not plotted.) The degree of error reporting desired.
family The name of a font family for drawing text. The maximum allowed length is 200 bytes. This name gets mapped by each graphics device to a device-specific font description. The default value is "" which means that the default device fonts will be used (and what those are should be listed on the help page for the device). Standard values are "serif", "sans" and "mono", and the Hershey font families are also available. (Different devices may define others, and some devices will ignore this setting completely.) This can be specified inline for text.

fg The color to be used for the foreground of plots. This is the default color used for things like axes and boxes around plots. When called from par() this also sets parameter col to the same value. See section ‘Color Specification’. A few devices have an argument to set the initial value, which is otherwise "black".
A numerical vector of the form c(x1, x2, y1, y2) which gives the (NDC) coordinates of the figure region in the display region of the device. If you set this, unlike S, you start a new plot, so to add to an existing plot use new = TRUE as well.

The figure region dimensions, (width, height), in inches. If you set this, unlike S, you start a new plot.

An integer which specifies which font to use for text. If possible, device drivers arrange so that 1 corresponds to plain text (the default), 2 to bold face, 3 to italic and 4 to bold italic. Also, font 5 is expected to be the symbol font, in Adobe symbol encoding. On some devices font families can be selected by family to choose different sets of 5 fonts.

The font to be used for axis annotation.

The font to be used for x and y labels.

The font to be used for plot main titles.

The font to be used for plot sub-titles.

A numerical vector of the form c(x, y, len) which modifies the default way that axes are annotated. The values of x and y give the (approximate) number of tickmarks on the x and y axes and len specifies the label length. The default is c(5, 5, 7). Note that this only affects the way the parameters xaxp and yaxp are set when the user coordinate system is set up, and is not consulted when axes are drawn. len is unimplemented in R.

numeric in {0,1,2,3}; the style of axis labels.

0: always parallel to the axis [default],
1: always horizontal,
2: always perpendicular to the axis,
3: always vertical.

Also supported by mtext. Note that string/character rotation via argument srt to par does not affect the axis labels.

The line end style. This can be specified as an integer or string:

0 and "round" mean rounded line caps [default];
1 and "butt" mean butt line caps;
2 and "square" mean square line caps.

The line height multiplier. The height of a line of text (used to vertically space multi-line text) is found by multiplying the character height both by the current character expansion and by the line height multiplier. Default value is 1. Used in text and strheight.

The line join style. This can be specified as an integer or string:

0 and "round" mean rounded line joins [default];
1 and "mitre" mean mitred line joins;
2 and "bevel" mean bevelled line joins.

The line mitre limit. This controls when mitred line joins are automatically converted into bevelled line joins. The value must be larger than 1 and the default is 10. Not all devices will honour this setting.

The line type. Line types can either be specified as an integer (0=blank, 1=solid (default), 2=dashed, 3=dotted, 4=dotdash, 5=longdash, 6=twodash) or as one of the character strings "blank", "solid", "dashed", "dotted", "dotdash", "longdash" or "twodash", where "blank" uses ‘invisible lines’ (i.e., does not draw them). Alternatively, a string of up to 8 characters (from c(1:9, "A";"F")) may be given, giving the length of line segments which are alternatively drawn and skipped. See section ‘Line Type Specification’. Functions such as lines and segments accept a vector of values which are recycled.
ld The line width, a positive number, defaulting to 1. The interpretation is device-specific, and some devices do not implement line widths less than one. (See the help on the device for details of the interpretation.)

Functions such as lines and segments accept a vector of values which are recycled: in such uses lines corresponding to values NA or NaN are omitted. The interpretation of 0 is device-specific.

mai A numerical vector of the form c(bottom, left, top, right) which gives the margin size specified in inches.

mar A numerical vector of the form c(bottom, left, top, right) which gives the number of lines of margin to be specified on the four sides of the plot. The default is c(5, 4, 4, 2) + 0.1.

mex mex is a character size expansion factor which is used to describe coordinates in the margins of plots. Note that this does not change the font size, rather specifies the size of font (as a multiple of csi) used to convert between mar and mai, and between oma and omi. This starts as 1 when the device is opened, and is reset when the layout is changed (alongside resetting cex).

mfcol, mfr A vector of the form c(nr, nc). Subsequent figures will be drawn in an nr-by-nc array on the device by columns (mfcol), or rows (mfr), respectively.

In a layout with exactly two rows and columns the base value of "cex" is reduced by a factor of 0.83: if there are three or more of either rows or columns, the reduction factor is 0.66.

Setting a layout resets the base value of cex and that of mex to 1.

If either of these is queried it will give the current layout, so querying cannot tell you the order in which the array will be filled.

Consider the alternatives, layout and split.screen.

mfg A numerical vector of the form c(i, j) where i and j indicate which figure in an array of figures is to be drawn next (if setting) or is being drawn (if enquiring). The array must already have been set by mfcol or mfr.

For compatibility with S, the form c(i, j, nr, nc) is also accepted, when nr and nc should be the current number of rows and number of columns. Mismatches will be ignored, with a warning.

mgp The margin line (in mex units) for the axis title, axis labels and axis line. Note that mgp[1] affects title whereas mgp[2:3] affect axis. The default is c(3, 1, 0).
mch - The height in inches of symbols to be drawn when the value of pch is an integer. Completely ignored in R.

new - logical, defaulting to FALSE. If set to TRUE, the next high-level plotting command (actually plot.new) should not clean the frame before drawing as if it were on a new device. It is an error (ignored with a warning) to try to use new = TRUE on a device that does not currently contain a high-level plot.

oma - A vector of the form c(bottom, left, top, right) giving the size of the outer margins in lines of text.

oma - A vector of the form c(x1, x2, y1, y2) giving the region inside outer margins in NDC (= normalized device coordinates), i.e., as a fraction (in [0, 1]) of the device region.

omi - A vector of the form c(bottom, left, top, right) giving the size of the outer margins in inches.

page - R.O.; A boolean value indicating whether the next call to plot.new is going to start a new page. This value may be FALSE if there are multiple figures on the page.

pch - Either an integer specifying a symbol or a single character to be used as the default in plotting points. See points for possible values and their interpretation. Note that only integers and single-character strings can be set as a graphics parameter (and not NA nor NULL).

Some functions such as points accept a vector of values which are recycled.

pin - The current plot dimensions, (width, height), in inches.

plt - A vector of the form c(x1, x2, y1, y2) giving the coordinates of the plot region as fractions of the current figure region.

ps - integer; the point size of text (but not symbols). Unlike the pointsize argument of most devices, this does not change the relationship between mar and mai (nor oma and omi).

What is meant by ‘point size’ is device-specific, but most devices mean a multiple of 1bp, that is 1/72 of an inch.

pty - A character specifying the type of plot region to be used; “s” generates a square plotting region and “m” generates the maximal plotting region.

smo - (Unimplemented) a value which indicates how smooth circles and circular arcs should be.

srt - The string rotation in degrees. See the comment about cht. Only supported by text.
tck The length of tick marks as a fraction of the smaller of the width or height of the plotting region. If tck >= 0.5 it is interpreted as a fraction of the relevant side, so if tck = 1 grid lines are drawn. The default setting (tck = NA) is to use tck = -0.5.

tcl The length of tick marks as a fraction of the height of a line of text. The default value is -0.5; setting tcl = NA sets tck = -0.01 which is S' default.

usr A vector of the form c(x1, x2, y1, y2) giving the extremes of the user coordinates of the plotting region. When a logarithmic scale is in use (i.e., par("xlog") is true, see below), then the x-limits will be $10^\{\text{par("usr")}\}[1:2]$. Similarly for the y-axis.

xaxp A vector of the form c(x1, x2, n) giving the coordinates of the extreme tick marks and the number of intervals between tick-marks when par("xlog") is false. Otherwise, when log coordinates are active, the three values have a different meaning: For a small range, n is negative, and the ticks are as in the linear case, otherwise, n is in 1:3, specifying a case number, and x1 and x2 are the lowest and highest power of 10 inside the user coordinates, $10^\{\text{par("usr")}\}[1:2]$. (The "usr" coordinates are log10-transformed here!)

n = 1 will produce tick marks at $10^j$ for integer j,

n = 2 gives marks $\pm10^j$ with $k \in \{1,5\}$,

n = 3 gives marks $\pm10^j$ with $k \in \{1,2,5\}$.

See axTicks() for a pure R implementation of this.

This parameter is reset when a user coordinate system is set up, for example by starting a new page or by calling plot.window or setting par("usr"): n is taken from par("usr") (standard) finds an axis with pretty labels within which the original data range fits. It affects the default behaviour of subsequent calls to axis for sides 1 or 3.

It is only relevant to default numeric axis systems, and not for example to dates.

xaxs The style of axis interval calculation to be used for the x-axis. Possible values are "r", "i", "e", "s", "d". The styles are generally controlled by the range of data or xlim, if given. Style "r" (regular) first extends the data range by 4 percent at each end and then finds an axis with pretty labels that fits within the extended range. Style "i" (internal) just finds an axis with pretty labels that fits within the original data range. Style "s" (standard) finds an axis with pretty labels within which the original data range fits. Style "e" (extended) is like style "s", except that it is also ensures that there is room for plotting symbols within the bounding box. Style "d" (direct) specifies that the current axis should be used on subsequent plots.

(Only "r" and "i" styles have been implemented in R.)

xaxt A character which specifies the x axis type. Specifying "n" suppresses plotting of the axis. The standard value is "s": for compatibility with S values "1" and "t" are accepted but are equivalent to "s": any value other than "n" implies plotting.

xlog A logical value (see log in plot.default). If TRUE, a logarithmic scale is in use (e.g., after plot(x, log = "x"). For a new device, it defaults to FALSE, i.e., linear scale.

xpd A logical value or NA. If FALSE, all plotting is clipped to the plot region, if TRUE, all plotting is clipped to the figure region, and if NA, all plotting is clipped to the device region. See also clip.

yaxp A vector of the form c(y1, y2, n) giving the coordinates of the extreme tick marks and the number of intervals between tick-marks unless for log coordinates, see xaxp above.

yaxs The style of axis interval calculation to be used for the y-axis. See xaxs above.

yaxt A character which specifies the y axis type. Specifying "n" suppresses plotting.

ylbias A positive real value used in the positioning of text in the margins by axis and mtext. The default is in principle device-specific, but currently 0.2 for all of R's own devices. Set this to 0.2 for compatibility with R < 2.14.0 on x11 and windows() devices.

ylog A logical value; see xlog above.
Color Specification

Colors can be specified in several different ways. The simplest way is with a character string giving the color name (e.g., "red"). A list of the possible colors can be obtained with the function `colors`. Alternatively, colors can be specified directly in terms of their RGB components with a string of the form "#RRGGBB" where each of the pairs RR, GG, BB consist of two hexadecimal digits giving a value in the range 00 to FF. Colors can also be specified by giving an index into a small table of colors, the `palette`: indices wrap round so with the default palette of size 8, 10 is the same as 2. This provides compatibility with S. Index 0 corresponds to the background color. Note that the palette (apart from 0 which is per-device) is a per-session setting.

Negative integer colors were accepted prior to R 3.0.0, but treated inconsistently. They are now errors.

Additionally, "transparent" is transparent, useful for filled areas (such as the background!), and just invisible for things like lines or text. In most circumstances (integer) NA is equivalent to "transparent" (but not for `text` and `mtext`).

Semi-transparent colors are available for use on devices that support them.

The functions `rgb`, `hsv`, `hcl`, `gray` and `rainbow` provide additional ways of generating colors.

It was possible to specify color numbers as strings prior to R 3.0.0.

Line Type Specification

Line types can either be specified by giving an index into a small built-in table of line types (1 = solid, 2 = dashed, etc, see `lty` above) or directly as the lengths of on/off stretches of line. This is done with a string of an even number (up to eight) of characters, namely non-zero (hexadecimal) digits which give the lengths in consecutive positions in the string. For example, the string "33" specifies three units on followed by three off and "3313" specifies three units on followed by three off followed by one on and finally three off. The 'units' here are (on most devices) proportional to `wd`, and with `wd` = 1 are in pixels or points or 1/96 inch.

The five standard dash-dot line types (`lty = 2:6`) correspond to c("44", "13", "1343", "73", "2262").

Note that NA is not a valid value for `lty`.

Examples

op <- par(mfrow = c(2, 2), # 2 x 2 pictures on one plot
    pty = "s") # square plotting region,
          # independent of device size

## At end of plotting, reset to previous settings:
par(op)

## Alternatively,
op <- par(no.readonly = TRUE) # the whole list of settable par's.
## do lots of plotting and par(.) calls, then reset:
par(op)
## Note this is not in general good practice
par("ylog") # FALSE
plot(1 : 12, log = "y")
par("ylog") # TRUE

plot(1:2, xaxs = "i") # 'inner axis' w/o extra space
par(c("usr", "xaxp"))

( nr.prof <-
c(prof = c(pilots = 16, lawyers = 11, farmers = 10, salesmen = 9, physicians = 9,

---

persp

**Perspective Plots**

**Description**

This function draws perspective plots of a surface over the x–y plane. `persp` is a generic function.

**Usage**

`persp(x, ...)`

`## Default S3 method:`
`persp(x = seq(0, 1, length.out = nrow(z)),
    y = seq(0, 1, length.out = ncol(z)),
    z, xlim = range(x), ylim = range(y),
    zlim = range(z, na.rm = TRUE),
    xlab = NULL, ylab = NULL, zlab = NULL,
    main = NULL, sub = NULL,
    theta = 0, phi = 15, r = sqrt(3), d = 1,
    scale = TRUE, expand = 1,
    col = "white", border = NULL, ltheta = -135, lphi = 0,
    shade = NA, box = TRUE, axes = TRUE, nticks = 5,
    ticktype = "simple", ...)`

**Arguments**

- **x, y**
  locations of grid lines at which the values in z are measured. These must be in ascending order. By default, equally spaced values from 0 to 1 are used. If x is a list, its components x$x and x$y are used for x and y, respectively.

- **z**
  a matrix containing the values to be plotted (NAs are allowed). Note that x can be used instead of z for convenience.

- **xlim, ylim, zlim**
  x-, y- and z-limits. These should be chosen to cover the range of values of the surface: see 'Details'.

- **xlab, ylab, zlab**
  titles for the axes. N.B. These must be character strings; expressions are not accepted. Numbers will be coerced to character strings.

- **main, sub**
  main and sub title, as for `title`.

- **theta, phi**
  angles defining the viewing direction. theta gives the azimuthal direction and phi the colatitude.

- **r**
  the distance of the eyepoint from the centre of the plotting box.
persp

d a value which can be used to vary the strength of the perspective transformation. Values of d greater than 1 will lessen the perspective effect and values less and 1 will exaggerate it.

scale before viewing the x, y and z coordinates of the points defining the surface are transformed to the interval [0,1]. If scale is TRUE the x, y and z coordinates are transformed separately. If scale is FALSE the coordinates are scaled so that aspect ratios are retained. This is useful for rendering things like DEM information.

expand a expansion factor applied to the z coordinates. Often used with 0 < expand < 1 to shrink the plotting box in the z direction.

col the color(s) of the surface facets. Transparent colours are ignored. This is recycled to the \((nx-1)(ny-1)\) facets.

border the color of the line drawn around the surface facets. The default, NULL, corresponds to par("fg"). A value of NA will disable the drawing of borders: this is sometimes useful when the surface is shaded.

ltheta, lphi if finite values are specified for ltheta and lphi, the surface is shaded as though it was being illuminated from the direction specified by azimuth ltheta and colatitude lphi.

shade the shade at a surface facet is computed as \(((1+d)/2)^{\text{shade}}\), where d is the dot product of a unit vector normal to the facet and a unit vector in the direction of a light source. Values of shade close to one yield shading similar to a point light source model and values close to zero produce no shading. Values in the range 0.5 to 0.75 provide an approximation to daylight illumination.

box should the bounding box for the surface be displayed. The default is TRUE.

axes should ticks and labels be added to the box. The default is TRUE. If box is FALSE then no ticks or labels are drawn.

ticktype character: "simple" draws just an arrow parallel to the axis to indicate direction of increase; "detailed" draws normal ticks as per 2D plots.

nticks the (approximate) number of tick marks to draw on the axes. Has no effect if ticktype is "simple".

... additional graphical parameters (see par).

Details

The plots are produced by first transforming the \((x,y,z)\) coordinates to the interval \([0,1]\) using the limits supplied or computed from the range of the data. The surface is then viewed by looking at the origin from a direction defined by \(\theta\) and \(\phi\). If \(\theta\) and \(\phi\) are both zero the viewing direction is directly down the negative y axis. Changing \(\theta\) will vary the azimuth and changing \(\phi\) the colatitude.

There is a hook called "persp" (see setHook) called after the plot is completed, which is used in the testing code to annotate the plot page. The hook function(s) are called with no argument.

Notice that persp interprets the \(z\) matrix as a table of \(f(x[i], y[j])\) values, so that the x axis corresponds to row number and the y axis to column number, with column 1 at the bottom, so that with the standard rotation angles, the top left corner of the matrix is displayed at the left hand side, closest to the user.

The sizes and fonts of the axis labels and the annotations for ticktype = "detailed" are controlled by graphics parameters "cex.lab"/"font.lab" and "cex.axis"/"font.axis" respectively.
The bounding box is drawn with edges of faces facing away from the viewer (and hence at the back of the box) with solid lines and other edges dashed and on top of the surface. This (and the plotting of the axes) assumes that the axis limits are chosen so that the surface is within the box, and the function will warn if this is not the case.

Value

`persp()` returns the viewing transformation matrix, say VT, a 4 x 4 matrix suitable for projecting 3D coordinates \((x, y, z)\) into the 2D plane using homogeneous 4D coordinates \((x, y, z, t)\). It can be used to superimpose additional graphical elements on the 3D plot, by `lines()` or `points()`, using the function `trans3d()`.

References

See Also

`contour` and `image`; `trans3d`.

Rotatable 3D plots can be produced by package `rgl`: other ways to produce static perspective plots are available in packages `lattice` and `scatterplot3d`.

Examples

```r
require(grDevices) # for trans3d

lines(trans3d(xr, yr, f(xr, yr), res), col = "pink", lwd = 2)
```
## Visualizing a simple DEM model

```r
z <- 2 * volcano  # Exaggerate the relief
dx <- 10 * (1:nrow(z))  # 10 meter spacing (S to N)
dy <- 10 * (1:ncol(z))  # 10 meter spacing (E to W)

# Don't draw the grid lines: border = NA
par(bg = "slategray")
persp(x, y, z, theta = 135, phi = 30, col = "green3",
     ltheta = -120, shade = 0.75, border = NA, box = FALSE)
```

## Surface colours corresponding to z-values

```r
par(bg = "white")
x <- seq(-1.95, 1.95, length = 30)
y <- seq(-1.95, 1.95, length = 35)
z <- outer(x, y, function(a, b) a*b^2)
nrz <- nrow(z)
ncz <- ncol(z)

# Create a function interpolating colors in the range of specified colors
jet.colors <- colorRampPalette( c("blue", "green") )

# Generate the desired number of colors from this palette
ncol <- 100
color <- jet.colors(ncol)

# Compute the z-value at the facet centres
zf <- z[-1, -1] + z[-1, -ncz] + z[-nrz, -1] + z[-nrz, -ncz]

# Recode facet z-values into color indices
facetcol <- cut(zf, ncol)
persp(x, y, z, col = color[facetcol], phi = 30, theta = -30)
```

---

### Pie Charts

#### Description

Draw a pie chart.

#### Usage

```r
pie(x, labels = names(x), edges = 200, radius = 0.8,
    clockwise = FALSE, init.angle = if(clockwise) 90 else 0,
    density = NULL, angle = 45, col = NULL, border = NULL,
    lty = NULL, main = NULL, ...)  
```

#### Arguments

- `x` a vector of non-negative numerical quantities. The values in `x` are displayed as the areas of pie slices.
- `labels` one or more expressions or character strings giving names for the slices. Other objects are coerced by `as.graphicsAnnot`. For empty or NA (after coercion to character) labels, no label nor pointing line is drawn.
edges the circular outline of the pie is approximated by a polygon with this many edges.

radius the pie is drawn centered in a square box whose sides range from \(-1\) to 1. If the character strings labeling the slices are long it may be necessary to use a smaller radius.

clockwise logical indicating if slices are drawn clockwise or counter clockwise (i.e., mathematically positive direction), the latter is default.

init.angle number specifying the starting angle (in degrees) for the slices. Defaults to \(0\) (i.e., ‘3 o’clock’) unless clockwise is true where init.angle defaults to \(90\) (degrees), (i.e., ‘12 o’clock’).

density the density of shading lines, in lines per inch. The default value of NULL means that no shading lines are drawn. Non-positive values of density also inhibit the drawing of shading lines.

angle the slope of shading lines, given as an angle in degrees (counter-clockwise).

col a vector of colors to be used in filling or shading the slices. If missing a set of 6 pastel colours is used, unless density is specified when par("fg") is used.

border, lty (possibly vectors) arguments passed to polygon which draws each slice.

main an overall title for the plot.

... graphical parameters can be given as arguments to pie. They will affect the main title and labels only.

Note

Pie charts are a very bad way of displaying information. The eye is good at judging linear measures and bad at judging relative areas. A bar chart or dot chart is a preferable way of displaying this type of data.

Cleveland (1985), page 264: “Data that can be shown by pie charts always can be shown by a dot chart. This means that judgements of position along a common scale can be made instead of the less accurate angle judgements.” This statement is based on the empirical investigations of Cleveland and McGill as well as investigations by perceptual psychologists.

dotchart.

Examples

```
require(grDevices)
pie(rep(1, 24), col = rainbow(24), radius = 0.9)

pie.sales <- c(0.12, 0.3, 0.26, 0.16, 0.04, 0.12)
names(pie.sales) <- c("Blueberry", "Cherry",
      "Apple", "Boston Cream", "Other", "Vanilla Cream")
pie(pie.sales) # default colours
pie(pie.sales, col = c("purple", "violetred1", "green3",
```
plot

"cornsilk", "cyan", "white")
pie(pie.sales, col = gray(seq(0.4, 1.0, length = 6)))
pie(pie.sales, density = 10, angle = 15 + 10 * 1:6)
pie(pie.sales, clockwise = TRUE, main = "pie(*, clockwise = TRUE)")
segments(0, 0, 0, 1, col = "red", lwd = 2)
text(0, 1, "init.angle = 90", col = "red")

n <- 200
pie(rep(1, n), labels = "", col = rainbow(n), border = NA,
    main = "pie(*, labels="", col=rainbow(n), border=NA,...")

plot

Generic X-Y Plotting

Description

Generic function for plotting of R objects. For more details about the graphical parameter arguments, see par.

For simple scatter plots, plot.default will be used. However, there are plot methods for many R objects, including functions, dataframes, density objects, etc. Use methods(plot) and the documentation for these.

Usage

plot(x, y, ...)

Arguments

x the coordinates of points in the plot. Alternatively, a single plotting structure, function or any R object with a plot method can be provided.
y the y coordinates of points in the plot, optional if x is an appropriate structure.
... Arguments to be passed to methods, such as graphical parameters (see par).

type what type of plot should be drawn. Possible types are
  • "p" for points,
  • "l" for lines,
  • "b" for both,
  • "c" for the lines part alone of "b",
  • "o" for both 'overplotted',
  • "h" for 'histogram' like (or 'high-density') vertical lines,
  • "s" for stair steps,
  • "S" for other steps, see 'Details' below,
  • "n" for no plotting.

All other types give a warning or an error; using, e.g., type = "punkte" being equivalent to type = "p" for S compatibility. Note that some methods, e.g. plot.factor, do not accept this.

main an overall title for the plot: see title.
sub a sub title for the plot: see title.
xlab a title for the x axis: see title.
ylab a title for the y axis: see title.
asp the y/x aspect ratio, see plot.window.
Details

The two step types differ in their x-y preference: Going from \((x_1, y_1)\) to \((x_2, y_2)\) with \(x_1 < x_2\), type = "s" moves first horizontal, then vertical, whereas type = "S" moves the other way around.

See Also

plot.default, plot.formula and other methods; points, lines, par.

For X-Y-Z plotting see contour, persp and image.

Examples

require(stats)
plot(cars)
lines(lowess(cars))

plot(sin, -pi, 2*pi) # see ?plot.function

## Discrete Distribution Plot:
plot(table(rpois(100, 5)), type = "h", col = "red", lwd = 10,
     main = "rpois(100, lambda = 5)"
)

## Simple quantiles/ECDF, see ecdf() (library(stats)) for a better one:
plot(x <- sort(rnorm(47)), type = "s", main = "plot(x, type = \"s\")")
points(x, cex = .5, col = "dark red")

plot.data.frame  
Plot Method for Data Frames

Description

plot.data.frame, a method for the plot generic. It is designed for a quick look at numeric data frames.

Usage

## S3 method for class 'data.frame'
plot(x, ...)

Arguments

x  
object of class data.frame.

...  
further arguments to stripchart, plot.default or pairs.

Details

This is intended for data frames with numeric columns. For more than two columns it first calls data.matrix to convert the data frame to a numeric matrix and then calls pairs to produce a scatterplot matrix. This can fail and may well be inappropriate: for example numerical conversion of dates will lose their special meaning and a warning will be given.

For a two-column data frame it plots the second column against the first by the most appropriate method for the first column.

For a single numeric column it uses stripchart, and for other single-column data frames tries to find a plot method for the single column.
Description

Draw a scatter plot with decorations such as axes and titles in the active graphics window.

Usage

```
plot.default(x, y = NULL, type = "p", xlim = NULL, ylim = NULL,
    log = "", main = NULL, sub = NULL, xlab = NULL, ylab = NULL,
    ann = par("ann"), axes = TRUE, frame.plot = axes,
    panel.first = NULL, panel.last = NULL, asp = NA, ...)  
```

Arguments

- `x, y`: the x and y arguments provide the x and y coordinates for the plot. Any reasonable way of defining the coordinates is acceptable. See the function `xy.coords` for details. If supplied separately, they must be of the same length.
- `type`: 1-character string giving the type of plot desired. The following values are possible, for details, see `plot`: "p" for points, "l" for lines, "b" for both points and lines, "c" for empty points joined by lines, "o" for overplotted points and lines, "s" and "S" for stair steps and "h" for histogram-like vertical lines. Finally, "n" does not produce any points or lines.
- `xlim`: the x limits (x1, x2) of the plot. Note that x1 > x2 is allowed and leads to a 'reversed axis'. The default value, NULL, indicates that the range of the finite values to be plotted should be used.
- `ylim`: the y limits of the plot.
- `log`: a character string which contains "x" if the x axis is to be logarithmic, "y" if the y axis is to be logarithmic and "xy" or "yx" if both axes are to be logarithmic.
- `main`: a main title for the plot, see also `title`.
- `sub`: a sub title for the plot.
- `xlab`: a label for the x axis, defaults to a description of x.
- `ylab`: a label for the y axis, defaults to a description of y.
ann a logical value indicating whether the default annotation (title and x and y axis labels) should appear on the plot.

axes a logical value indicating whether both axes should be drawn on the plot. Use graphical parameter "xaxt" or "yaxt" to suppress just one of the axes.

frame.plot a logical indicating whether a box should be drawn around the plot.

panel.first an 'expression' to be evaluated after the plot axes are set up but before any plotting takes place. This can be useful for drawing background grids or scatterplot smooths. Note that this works by lazy evaluation: passing this argument from other plot methods may well not work since it may be evaluated too early.

panel.last an expression to be evaluated after plotting has taken place but before the axes, title and box are added. See the comments about panel.first.

asp the y/x aspect ratio, see plot.window.

... other graphical parameters (see par and section ‘Details’ below).

Details
Commonly used graphical parameters are:

col The colors for lines and points. Multiple colors can be specified so that each point can be given its own color. If there are fewer colors than points they are recycled in the standard fashion. Lines will all be plotted in the first colour specified.

colbg a vector of background colors for open plot symbols, see points. Note: this is not the same setting as par("bg").

colpch a vector of plotting characters or symbols: see points.

cex a numerical vector giving the amount by which plotting characters and symbols should be scaled relative to the default. This works as a multiple of par("cex"). NULL and NA are equivalent to 1.0. Note that this does not affect annotation: see below.

cex.main, col.main, font.main, etc settings for main- and sub-title and axis annotation, see title and par.

cex.lty a vector of line types, see par.

Note
The presence of panel.first and panel.last is a historical anomaly: default plots do not have 'panels', unlike e.g. pairs plots. For more control, use lower-level plotting functions: plot.default calls in turn some of plot.new, plot.window, plot.xy, axis, box and title, and plots can be built up by calling these individually, or by calling plot(type = "n") and adding further elements.

References

See Also
plot, plot.window, xy.coords.
Examples

```r
Speed <- cars$speed
distance <- cars$dist
plot(Speed, distance, panel.first = grid(8, 8),
     pch = 0, cex = 1.2, col = "blue")
plot(Speed, distance,
     panel.first = lines(stats:::lowess(Speed, Distance), lty = "dashed"),
     pch = 0, cex = 1.2, col = "blue")

## Show the different plot types
x <- 0:12
y <- sin(pi/5 * x)
op <- par(mfrow = c(3,3), mar = .1+ c(2,2,3,1))
for (tp in c("p","l","b","c","o","h","s","S","n")(s)) {
  plot(y ~ x, type = tp, main = paste("plot(*, type = \"", tp, \"\")\))
  if(tp == "S") {
    lines(x, y, type = "s", col = "red", lty = 2)
    mtext("lines(*, type = \"s\", ...)", col = "red", cex = 0.8)
  }
}
par(op)

## Log-Log Plot with custom axes
x <- seq(1, 5, length = 41)
y <- expression(e^(-frac(1,2) * (log[10](x))^2))
op <- par(mfrow = c(2,1), mar = mar("mar") + c(0,1,0,0))
plot(x^1x, y, log = "xy", type = "l", col = "purple",
     main = "Log-Log plot", ylab = yl, xlab = "x"
plot(x^1x, y, log = "xy", type = "o", pch = ".", col = "forestgreen",
     main = "Log-Log plot with custom axes", ylab = yl, xlab = "x",
     axes = FALSE, frame.plot = TRUE)
my.at <- 10^(1:5)
axis(1, at = my.at, labels = formatC(my.at, format = "fg"))
at.y <- 10^(-5:-1)
axis(2, at = at.y, labels = formatC(at.y, format = "fg"), col.axis = "red")
par(op)
```

Description

Plot univariate effects of one or more factors, typically for a designed experiment as analyzed by `aov()`.

Usage

```r
plot.design(x, y = NULL, fun = mean, data = NULL, ...,
     ylim = NULL, xlab = "Factors", ylab = NULL,
     main = NULL, ask = NULL, xaxt = par("xaxt"),
     axes = TRUE, xtick = FALSE)
```
Arguments

- **x**: either a data frame containing the design factors and optionally the response, or a `formula` or `terms` object.
- **y**: the response, if not given in `x`.
- **fun**: a function (or name of one) to be applied to each subset. It must return one number for a numeric (vector) input.
- **data**: data frame containing the variables referenced by `x` when that is formula-like.
- **...**: graphical parameters such as `col`, see `par`.
- **ylim**: range of `y` values, as in `plot.default`.
- **xlab**: x axis label, see `title`.
- **ylab**: y axis label with a ‘smart’ default.
- **main**: main title, see `title`.
- **ask**: logical indicating if the user should be asked before a new page is started – in the case of multiple `y`’s.
- **xaxt**: character giving the type of x axis.
- **axes**: logical indicating if axes should be drawn.
- **xtick**: logical indicating if ticks (one per factor) should be drawn on the x axis.

Details

The supplied function will be called once for each level of each factor in the design and the plot will show these summary values. The levels of a particular factor are shown along a vertical line, and the overall value of `fun()` for the response is drawn as a horizontal line.

Note

A big effort was taken to make this closely compatible to the S version. However, `col` (and `fg`) specifications have different effects.

In S this was a method of the `plot` generic function for design objects.

### plot.factor

*Plotting Factor Variables*

#### Description

This functions implements a scatterplot method for `factor` arguments of the `generic plot` function. If `y` is missing `barplot` is produced. For numeric `y` a `boxplot` is used, and for a factor `y` a `spineplot` is shown. For any other type of `y` the next plot method is called, normally `plot.default`.

#### Usage

```r
## S3 method for class 'factor'
plot(x, y, legend.text = NULL, ...)```

#### Arguments

- `x, y` numeric or factor. `y` may be missing.
- `legend.text` character vector for annotation of `y` axis in the case of a factor `y`: defaults to `levels(y)`. This sets the `yaxlabels` argument of `spineplot`.
- `...` Further arguments to `barplot`, `boxplot`, `spineplot` or `plot` as appropriate. All of these accept graphical parameters (see `par`) and annotation arguments passed to `title` and `axes = FALSE`. None accept type.

#### See Also

`plot.default`, `plot.formula`, `barplot`, `boxplot`, `spineplot`. 
Examples

require(grDevices)

plot(weight ~ group, data = PlantGrowth)  # numeric vector ~ factor
plot(cut(weight, 2) ~ group, data = PlantGrowth)  # factor ~ factor
## passing "...":
plot(cut(weight, 3) ~ group, data = PlantGrowth,
     col = hcl(c(0, 120, 240), 50, 70))

plot(PlantGrowth$group, axes = FALSE, main = "no axes")  # extremely silly

---

plot.formula  

Formula Notation for Scatterplots

Description

Specify a scatterplot or add points, lines, or text via a formula.

Usage

```
## S3 method for class 'formula'
plot(formula, data = parent.frame(), ..., subset,
     ylab = varnames[response], ask = dev.interactive())

## S3 method for class 'formula'
points(formula, data = parent.frame(), ..., subset)

## S3 method for class 'formula'
lines(formula, data = parent.frame(), ..., subset)

## S3 method for class 'formula'
text(formula, data = parent.frame(), ..., subset)
```

Arguments

- `formula`: a formula, such as `y ~ x`.
- `data`: a data.frame (or list) from which the variables in formula should be taken. A matrix is converted to a data frame.
- `...`: Arguments to be passed to or from other methods. `horizontal = TRUE` is also accepted.
- `subset`: an optional vector specifying a subset of observations to be used in the fitting process.
- `ylab`: the y label of the plot(s).
- `ask`: logical, see `par`.  

Details

For the lines, points and text methods the formula should be of the form \( y \sim x \) or \( y \sim 1 \) with a left-hand side and a single term on the right-hand side. The plot method accepts other forms discussed later in this section.

Both the terms in the formula and the \( \ldots \) arguments are evaluated in data enclosed in `parent.frame()` if `data` is a list or a data frame. The terms of the formula and those arguments in \( \ldots \) that are of the same length as `data` are subjected to the subsetting specified in `subset`. A plot against the running index can be specified as `plot(y \sim 1)`.

If the formula in the plot method contains more than one term on the right-hand side, a series of plots is produced of the response against each non-response term.

For the plot method the formula can be of the form \( \sim z \, \sim y \, \sim z \) : the variables specified on the right-hand side are collected into a data frame, subsetted if specified, and displayed by `plot.data.frame`.

Missing values are not considered in these methods, and in particular cases with missing values are not removed.

If `y` is an object (i.e. has a `class` attribute) then `plot.formula` looks for a plot method for that class first. Otherwise, the class of `x` will determine the type of the plot. For factors this will be a parallel boxplot, and argument `horizontal = TRUE` can be specified (see `boxplot`).

Note that some arguments will need to be protected from premature evaluation by enclosing them in `quote`: currently this is done automatically for `main`, `sub` and `xlab`. For example, it is needed for the `panel.first` and `panel.last` arguments passed to `plot.default`.

Value

These functions are invoked for their side effect of drawing on the active graphics device.

See Also

`plot.default`, `points`, `lines`, `plot.factor`.

Examples

```
op <- par(mfrow = c(2,1))
plot(Ozone ~ Wind, data = airquality, pch = as.character(Month))
plot(Ozone ~ Wind, data = airquality, pch = as.character(Month),
     subset = Month != 7)
par(op)

## text.formula() can be very natural:
w <- within(warpbreaks, {
    time <- seq_along(breaks); W.T <- wool:tension })
plot(breaks ~ time, data = wb, type = "b")
text(breaks ~ time, data = wb, label = W.T, col = 1+as.integer(wool))
```
plot.histogram

Plot Histograms

Description

These are methods for objects of class "histogram", typically produced by hist.

Usage

## S3 method for class 'histogram'
plot(x, freq = equidist, density = NULL, angle = 45,
col = NULL, border = par("fg"), lty = NULL,
main = paste("Histogram of",
paste(x$xname, collapse = "\n")),
sub = NULL, xlab = x$xname, ylab,
xlim = range(x$breaks), ylim = NULL,
axes = TRUE, labels = FALSE, add = FALSE,
ann = TRUE, ...)

## S3 method for class 'histogram'
lines(x, ...)

Arguments

x
a histogram object, or a list with components density, mid, etc, see hist for information about the components of x.

col
a colour to be used to fill the bars. The default of NULL yields unfilled bars.

freq
logical; if TRUE, the histogram graphic is to present a representation of frequencies, i.e, x$counts; if FALSE, relative frequencies (probabilities), i.e., x$density, are plotted. The default is true for equidistant breaks and false otherwise.

col
the color of the border around the bars.

angle, density
select shading of bars by lines: see rect.

lty
the line type used for the bars, see also lines.

main, sub, xlab, ylab
these arguments to title have useful defaults here.

xlim, ylim
the range of x and y values with sensible defaults.

axes
logical, indicating if axes should be drawn.

labels
logical or character. Additionally draw labels on top of bars, if not FALSE; if TRUE, draw the counts or rounded densities; if labels is a character, draw itself.

add
logical. If TRUE, only the bars are added to the current plot. This is what lines.histogram(*) does.

ann
logical. Should annotations (titles and axis titles) be plotted?

...
further graphical parameters to title and axis.
Details

lines.histogram(*) is the same as plot.histogram(*, add = TRUE).

See Also

hist, stem, density.

Examples

(wwt <- hist(women$weight, nclass = 7, plot = FALSE))
plot(wwt, labels = TRUE) # default main & xlab using wwt$xname
plot(wwt, border = "dark blue", col = "light blue",
     main = "Histogram of 15 women’s weights", xlab = "weight [pounds]")

## Fake "lines" example, using non-default labels:
w2 <- wwt; w2$counts <- w2$counts - 1
lines(w2, col = "Midnight Blue", labels = ifelse(w2$counts, "> 1", "1"))

plot.table

Plot Methods for table Objects

Description

This is a method of the generic plot function for (contingency) table objects. Whereas for two- and more dimensional tables, a mosaicplot is drawn, one-dimensional ones are plotted as bars.

Usage

## S3 method for class 'table'
plot(x, type = "h", ylim = c(0, max(x)), lwd = 2,
      xlab = NULL, ylab = NULL, frame.plot = is.num, ...)

## S3 method for class 'table'
points(x, y = NULL, type = "h", lwd = 2, ...)

## S3 method for class 'table'
lines(x, y = NULL, type = "h", lwd = 2, ...)

Arguments

x a table (like) object.

y Must be NULL: there to protect against incorrect calls.

type plotting type.

ylim range of y-axis.

lwd line width for bars when type = "h" is used in the 1D case.

xlab, ylab x- and y-axis labels.

frame.plot logical indicating if a frame (box) should be drawn in the 1D case. Defaults to true when x has dimnames coerce-able to numbers.

... further graphical arguments, see plot.default. axes = FALSE is accepted.
plot.window

Set up World Coordinates for Graphics Window

Description

This function sets up the world coordinate system for a graphics window. It is called by higher level functions such as plot.default (after plot.new).

Usage

plot.window(xlim, ylim, log = "", asp = NA, ...)

Arguments

xlim, ylim numeric vectors of length 2, giving the x and y coordinates ranges.
log character; indicating which axes should be in log scale.
asp numeric, giving the aspect ratio y/x, see ‘Details’.
... further graphical parameters as in par. The relevant ones are xaxs, yaxs and lab.

Details

asp: If asp is a finite positive value then the window is set up so that one data unit in the x direction is equal in length to asp × one data unit in the y direction.

Note that in this case, par("usr") is no longer determined by, e.g., par("xaxs"), but rather by asp and the device’s aspect ratio. (See what happens if you interactively resize the plot device after running the example below!)

The special case asp == 1 produces plots where distances between points are represented accurately on screen. Values with asp > 1 can be used to produce more accurate maps when using latitude and longitude.

Note that the coordinate ranges will be extended by 4% if the appropriate graphical parameter xaxs or yaxs has value "s" (which is the default).

To reverse an axis, use xlim or ylim of the form c(hi, lo).

The function attempts to produce a plausible set of scales if one or both of xlim and ylim is of length one or the two values given are identical, but it is better to avoid that case.

See Also

plot.factor, the plot method for factors.

Examples

## 1-d tables
(Poisson.tab <- table(N = stats::rpois(200, lambda = 5)))
plot(Poisson.tab, main = "plot(table(rpois(200, lambda = 5))")
plot(table(state.division))

## 4-D :
plot(Titanic, main ="plot(Titanic, main= *)")
Usually, one should rather use the higher-level functions such as `plot`, `hist`, `image`, .... instead and refer to their help pages for explanation of the arguments.

A side-effect of the call is to set up the `usr`, `xaxp` and `yaxp` graphical parameters. (It is for the latter two that `lab` is used.)

**See Also**

`xy.coords`, `plot.xy`, `plot.default`.

`par` for the graphical parameters mentioned.

**Examples**

```r
### An example for the use of 'asp' :
require(stats) # normally loaded
loc <- cmdscale(euordist)
rx <- range(x <- loc[,1])
ry <- range(y <- -loc[,2])
plot(x, y, type = "n", asp = 1, xlab = "", ylab = "")
abline(h = pretty(rx, 10), v = pretty(ry, 10), col = "lightgray")
text(x, y, labels(euordist), cex = 0.8)
```

---

**plot.xy**

**Basic Internal Plot Function**

**Description**

This is the internal function that does the basic plotting of points and lines. Usually, one should rather use the higher level functions instead and refer to their help pages for explanation of the arguments.

**Usage**

```r
plot.xy(xy, type, pch = par("pch"), lty = par("lty"),
       col = par("col"), bg = NA,
       cex = 1, lwd = par("lwd"), ...)            
```

**Arguments**

- `xy` A four-element list as results from `xy.coords`.
- `type` 1 character code: see `plot.default`. NULL is accepted as a synonym for "p".
- `pch` character or integer code for kind of points, see `points.default`.
- `lty` line type code, see `lines`.
- `col` color code or name, see `colors`, `palette`. Here NULL means colour 0.
- `bg` background (fill) color for the open plot symbols 21:25: see `points.default`.
- `cex` character expansion.
- `lwd` line width, also used for (non-filled) plot symbols, see `lines` and `points`.
- `...` further graphical parameters such as `xpd`, `lend`, `ljoin` and `lmitre`. 
The arguments `pch`, `col`, `bg`, `cex`, `lwd` may be vectors and may be recycled, depending on type: see `points` and `lines` for specifics. In particular note that `lwd` is treated as a vector for points and as a single (first) value for lines.

`cex` is a numeric factor in addition to `par("cex")` which affects symbols and characters as drawn by type "p", "o", "b" and "c".

See Also

`plot`, `plot.default`, `points`, `lines`.

Examples

```r
points.default # to see how it calls "plot.xy(xy.coords(x, y), ..."
```

Description

`points` is a generic function to draw a sequence of points at the specified coordinates. The specified character(s) are plotted, centered at the coordinates.

Usage

```r
points(x, ...) # Default S3 method:
points(x, y = NULL, type = "p", ...)
```

Arguments

- `x`, `y` coordinate vectors of points to plot.
- `type` character indicating the type of plotting; actually any of the types as in `plot.default`.
- `...` Further graphical parameters may also be supplied as arguments. See ‘Details’.

Details

The coordinates can be passed in a plotting structure (a list with `x` and `y` components), a two-column matrix, a time series, .... See `xy.coords`. If supplied separately, they must be of the same length.

Graphical parameters commonly used are

- `pch` plotting 'character', i.e., symbol to use. This can either be a single character or an integer code for one of a set of graphics symbols. The full set of S symbols is available with `pch = 0:18`, see the examples below. (NB: R uses circles instead of the octagons used in S.)
  Value `pch = "."` (equivalently `pch = 46`) is handled specially. It is a rectangle of side 0.01 inch (scaled by `cex`). In addition, if `cex = 1` (the default), each side is at least one pixel (1/72 inch on the `pdf`, `postscript` and `xfig` devices).
  For other text symbols, `cex = 1` corresponds to the default fontsize of the device, often specified by an argument `pointsize`. For `pch` in `0:25` the default size is about 75% of the character height (see `par("cex")`).
co1  color code or name, see \texttt{par}.
bg  background (fill) color for the open plot symbols given by \texttt{pch} = 21:25.
cex  character (or symbol) expansion: a numerical vector. This works as a multiple of \texttt{par("cex").}
lwd  line width for drawing symbols see \texttt{par}.

Others less commonly used are \texttt{1ty} and \texttt{lwd} for types such as "b" and "l".
The \texttt{graphical parameters} \texttt{pch, co1, bg, cex} and \texttt{lwd} can be vectors (which will be recycled as needed) giving a value for each point plotted. If lines are to be plotted (e.g. for type = "b") the first element of \texttt{lwd} is used.
Points whose \texttt{x}, \texttt{y}, \texttt{pch}, \texttt{co1} or \texttt{cex} value is \texttt{NA} are omitted from the plot.

'pch' values

Values of \texttt{pch} are stored internally as integers. The interpretation is
- \texttt{NA\_integer\_}: no symbol.
- \texttt{0:18}: S-compatible vector symbols.
- \texttt{19:25}: further R vector symbols.
- \texttt{26:31}: unused (and ignored).
- \texttt{32:127}: ASCII characters.
- \texttt{128:255 native characters only in a single-byte locale and for the symbol font. (128:159 are only used on Windows.)}
- \texttt{32 \ldots}: Unicode point (where supported).

Note that unlike S (which uses octagons), symbols 1, 10, 13 and 16 use circles. The filled shapes 15:18 do not include a border.

\begin{verbatim}
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25
□ ○ △ □ × ◊ ▽ ▼ ■ ● ▲ ◆ ◆ ◆ ◆ ◆ ○ □ ◊ △ ▼
\end{verbatim}

The following R plotting symbols are can be obtained with \texttt{pch} = 19:25: those with 21:25 can be colored and filled with different colors: \texttt{co1} gives the border color and \texttt{bg} the background color (which is "grey" in the figure)
- \texttt{pch} = 19: solid circle,
- \texttt{pch} = 20: bullet (smaller solid circle, 2/3 the size of 19),
- \texttt{pch} = 21: filled circle,
- \texttt{pch} = 22: filled square,
- \texttt{pch} = 23: filled diamond,
- \texttt{pch} = 24: filled triangle point-up,
- \texttt{pch} = 25: filled triangle point down.

Note that all of these both fill the shape and draw a border. Some care in interpretation is needed when semi-transparent colours are used for both fill and border (and the result might be device-specific and even viewer-specific for pdf).

The difference between \texttt{pch} = 16 and \texttt{pch} = 19 is that the latter uses a border and so is perceptibly larger when \texttt{lwd} is large relative to \texttt{cex}.  
Values `pch = 26:31` are currently unused and `pch = 32:127` give the ASCII characters. In a single-byte locale `pch = 128:255` give the corresponding character (if any) in the locale’s character set. Where supported by the OS, negative values specify a Unicode point, so e.g. `-0x2642L` is a ‘male sign’ and `-0x20ACL` is the Euro.

A character string consisting of a single character is converted to an integer: `32:127` for ASCII characters, and usually to the Unicode point number otherwise. (In non-Latin-1 single-byte locales, `128:255` will be used for 8-bit characters.)

If `pch` supplied is a logical, integer or character `NA` or an empty character string the point is omitted from the plot.

If `pch` is `NULL` or otherwise of length 0, `par("pch")` is used.

If the symbol font (`par(font = 5)`) is used, numerical values should be used for `pch`: the range is `c(32:126, 160:254)` in all locales (but 240 is not defined (used for ‘apple’ on Mac OS) and 160, Euro, may not be present).

### Note

A single-byte encoding may include the characters in `pch = 128:255`, and if it does, a font may not include all (or even any) of them.

Not all negative numbers are valid as Unicode points, and no check is done. A display device is likely to use a rectangle for (or omit) Unicode points that do not exist or which it does not have a glyph.

What happens for very small or zero values of `cex` is device-dependent: symbols or characters may become invisible or they may be plotted at a fixed minimum size. As from R 2.15.0, circles of zero radius will not be plotted.

### Examples

```r
require(stats) # for rnorm
plot(-4:4, -4:4, type = "n") # setting up coord. system
points(rnorm(200), rnorm(200), col = "red")
points(rnorm(100)/2, rnorm(100)/2, col = "blue", cex = 1.5)
op <- par(bg = "light blue")
x <- seq(0, 2*pi, len = 51)
## something "between type='b' and type='o':"
plot(x, sin(x), type = "o", pch = 21, bg = par("bg"), col = "blue", cex = .6,
     main = 'plot(..., type="o", pch=21, bg=par("bg"))'
     par(op)

## Not run:
## The figure was produced by calls like
png("pch.png", height = 0.7, width = 7, res = 100, units = "in")
par(mar = rep(0,4))
```
plot(c(-1, 26), 0:1, type = "n", axes = FALSE)
text(0:25, 0.6, 0:25, cex = 0.5)
points(0:25, rep(0.3, 26), pch = 0:25, bg = "grey")

## End(Not run)

### Showing all the extra & some char graphics symbols

pchShow <-
  function(extras = c("x", ".", "e", "0", "+", "-", ":", ",", ":", ":"),
    cex = 3, # good for both .Device= "postscript" and "x11"
    col = "red3", bg = "gold", coltext = "brown", cextext = 1.2,
    main = paste("plot symbols : points (... pch = *", cex = ",
    tex","))

{  
  nex <- length(extras)
  np <- 26 + nex
  ipch <- 0:(np-1)
  k <- floor(sqrt(np))
  dd <- c(-1, 1)/2
  rx <- dd + range(1x <- ipch %% k)
  ry <- dd + range(1y <- 3 + k-1) - ipch %% k
  pch <- as.list(ipch) # list with integers & strings
  if(nex > 0) pch[26+1:nex] <- as.list(extras)
  plot(rx, ry, type = "n", axes = FALSE, xlab = ",", ylab = ",", main = main)
  abline(v = ix, h = iy, col = "lightgray", lty = "dotted")
  for(i in 1:nx) {
    pc <- pch[[i]]
    # 'col' symbols with a 'bg'-colored interior (where available):
    points(1x[i], 1y[i], pch = pc, col = col, bg = bg, cex = cex)
    if(cextext > 0)
      text(1x[i] - 0.3, 1y[i], pc, col = coltext, cex = cextext)
  }
}

pchShow()

### test code for various pch specifications

# Try this in various font families (including Hershey)
# and locales. Use sign = -1 asserts we want Latin-1.
# Standard cases in a MBCS locale will not plot the top half.

TestChars <- function(sign = 1, font = 1, ...)

{  
  MB <- t10n_info()$MBCS
  r <- if(font == 5) ( sign <- 1; c(32:126, 160:254)
    ) else if(MB) 32:126 else 32:255
  if (sign == -1) r <- c(32:126, 160:255)
  par(pty = "s")
  plot(c(-1,16), c(-1,16), type = "n", xlab = ",", ylab = ",",
    xaxs = "i", yaxs = "i",
    main = sprintf("sign = %d, font = %d", sign, font))
  grid(17, 17, lty = 1); mtext(paste("MBCS: ", MB))
  for(i in r) try(points(0.16, 0.16, pch = sign*i, font = font,...))
}

TestChars()
polygon

**Polygon Drawing**

**Description**

polygon draws the polygons whose vertices are given in x and y.

**Usage**

```r
polygon(x, y = NULL, density = NULL, angle = 45,
        border = NULL, col = NA, lty = par("lty"),
        ..., fillOddEven = FALSE)
```

**Arguments**

- `x`, `y` vectors containing the coordinates of the vertices of the polygon.
- `density` the density of shading lines, in lines per inch. The default value of `NULL` means that no shading lines are drawn. A zero value of `density` means no shading nor filling whereas negative values and `NA` suppress shading (and so allow color filling).
- `angle` the slope of shading lines, given as an angle in degrees (counter-clockwise).
- `col` the color for filling the polygon. The default, `NA`, is to leave polygons unfilled, unless `density` is specified. (For back-compatibility, `NULL` is equivalent to `NA`.) If `density` is specified with a positive value this gives the color of the shading lines.
- `border` the color to draw the border. The default, `NULL`, means to use `par("fg")`. Use `border = NA` to omit borders.
  For compatibility with S, `border` can also be logical, in which case `FALSE` is equivalent to `NA` (borders omitted) and `TRUE` is equivalent to `NULL` (use the foreground colour).
- `lty` the line type to be used, as in `par`.
- `...` graphical parameters such as `xpd`, `lend`, `ljoin` and `lmitre` can be given as arguments.
- `fillOddEven` logical controlling the polygon shading mode: see below for details. Default `FALSE`.

**Details**

The coordinates can be passed in a plotting structure (a list with `x` and `y` components), a two-column matrix, .... See `xy.coords`.

It is assumed that the polygon is to be closed by joining the last point to the first point.

The coordinates can contain missing values. The behaviour is similar to that of `lines`, except that instead of breaking a line into several lines, `NA` values break the polygon into several complete polygons (including closing the last point to the first point). See the examples below.
When multiple polygons are produced, the values of density, angle, col, border, and lty are recycled in the usual manner.

Shading of polygons is only implemented for linear plots: if either axis is on log scale then shading is omitted, with a warning.

**Bugs**

Self-intersecting polygons may be filled using either the “odd-even” or “non-zero” rule. These fill a region if the polygon border encircles it an odd or non-zero number of times, respectively. Shading lines are handled internally by R according to the fillOddEven argument, but device-based solid fills depend on the graphics device. The windows, pdf and postscript devices have their own fillOddEven argument to control this.

**Author(s)**

The code implementing polygon shading was donated by Kevin Buhr <buhr@stat.wisc.edu>.

**References**

segments for even more flexibility. lines, rect, box, abline.

par for how to specify colors.

**Examples**

```r
x <- c(1:9, 8:1)
y <- c(1, 2*(5:3), 2, -1, 17, 9, 8, 2:9)
op <- par(mfcol = c(3, 1))
for(xpd in c(FALSE, TRUE, NA)) {
  plot(1:10, main = paste("xpd =", xpd))
  box("figure", col = "pink", lwd = 3)
  polygon(x, y, xpd = xpd, col = "orange", lty = 2, lwd = 2, border = "red")
}
par(op)

n <- 100
xx <- c(0:n, n:0)
yy <- c(c(0, cumsum(stats::rnorm(n))), rev(c(0, cumsum(stats::rnorm(n))))))
plot(xx, yy, type = "n", xlab = "Time", ylab = "Distance")
polygon(xx, yy, col = "gray", border = "red")
title("Distance Between Brownian Motions")

# Multiple polygons from NA values
# and recycling of col, border, and lty
op <- par(mfrow = c(2, 1))
plot(c(1, 9), 1:2, type = "n")
polygon(1:9, c(2,1,2,1,1,2,1,2,1),
  col = c("red", "blue"),
  border = c("green", "yellow"),
  lwd = 3, lty = c("dashed", "solid"))
```
polypath

Path Drawing

description

path draws a path whose vertices are given in x and y.

Usage

polypath(x, y = NULL,
border = NULL, col = NA, lty = par("lty"),
rule = "winding", ...)

Arguments

x, y vectors containing the coordinates of the vertices of the path.
col the color for filling the path. The default, NA, is to leave paths unfilled, unless density is specified. (For back-compatibility, NULL is equivalent to NA.) If density is specified with a positive value this gives the color of the shading lines.
border the color to draw the border. The default, NULL, means to use par("fg"). Use border = NA to omit borders.
For compatibility with S, border can also be logical, in which case FALSE is equivalent to NA (borders omitted) and TRUE is equivalent to NULL (use the foreground colour).
lty the line type to be used, as in par.
rule character value specifying the path fill mode: either "winding" or "evenodd".
... graphical parameters such as xpd, lend, ljoin and lmitre can be given as arguments.

details

The coordinates can be passed in a plotting structure (a list with x and y components), a two-column matrix, .... See xy.coords.
It is assumed that the path is to be closed by joining the last point to the first point.
The coordinates can contain missing values. The behaviour is similar to that of polygon, except that instead of breaking a polygon into several polygons, NA values break the path into several sub-paths (including closing the last point to the first point in each sub-path). See the examples below.

plot(c(1, 9), 1:2, type = "n")
polygon(1:9, c(2,1,2,1,NA,2,1,2,1),
col = c("red", "blue"),
border = c("green", "yellow"),
    lwd = 3, lty = c("dashed", "solid"))
par(op)

# Line-shaded polygons
plot(c(1, 9), 1:2, type = "n")
polygon(1:9, c(2,1,2,1,NA,2,1,2,1),
    density = c(10, 20), angle = c(-45, 45))
The distinction between a path and a polygon is that the former can contain holes, as interpreted by the fill rule; these fill a region if the path border encircles it an odd or non-zero number of times, respectively.

Hatched shading (as implemented for polygon()) is not (currently) supported.

Not all graphics devices support this function: for example xfig and pictex do not.

par(op)
```
rasterImage

**Draw One or More Raster Images**

**Description**

rasterImage draws a raster image at the given locations and sizes.

**Usage**

```r
rasterImage(image, xleft, ybottom, xright, ytop, angle = 0, interpolate = TRUE, ...)
```

**Arguments**

- `image`: a raster object, or an object that can be coerced to one by `as.raster`.
- `xleft`: a vector (or scalar) of left x positions.
- `ybottom`: a vector (or scalar) of bottom y positions.
- `xright`: a vector (or scalar) of right x positions.
- `ytop`: a vector (or scalar) of top y positions.
- `angle`: angle of rotation (in degrees, anti-clockwise from positive x-axis, about the bottom-left corner).
- `interpolate`: a logical vector (or scalar) indicating whether to apply linear interpolation to the image when drawing.
- `...`: graphical parameters.

**Details**

The positions supplied, i.e., `xleft`, ..., are relative to the current plotting region. If the x-axis goes from 100 to 200 then `xleft` should be larger than 100 and `xright` should be less than 200. The position vectors will be recycled to the length of the longest.

Plotting raster images is not supported on all devices and may have limitations where supported, for example (e.g. for postscript and X11(type = "Xlib") is restricted to opaque colors). Problems with the rendering of raster images have been reported by users of windows() devices under Remote Desktop, at least under its default settings.

You should not expect a raster image to be re-sized when an on-screen device is re-sized: whether it is is device-dependent.

**See Also**

- `rect`, `polygon`, and `segments` and others for flexible ways to draw shapes.
- `dev.capabilities` to see if it is supported.
Examples

```r
require(grDevices)
## set up the plot region:
op <- par(bg = "thistle")
plot(c(100, 250), c(300, 450), type = "n", xlab = ",", ylab = ",")
image <- as.raster(matrix(0:1, ncol = 5, nrow = 3))
rasterImage(image, 100, 300, 150, 350, interpolate = FALSE)
rasterImage(image, 100, 400, 150, 450)
rasterImage(image, 200, 300, 200 + xinch(.5), 300 + yinch(.3),
            interpolate = FALSE)
rasterImage(image, 200, 400, 250, 450, angle = 15, interpolate = FALSE)
par(op)
```

---

**rect**

*Draw One or More Rectangles*

**Description**

rect draws a rectangle (or sequence of rectangles) with the given coordinates, fill and border colors.

**Usage**

```r
rect(xleft, ybottom, xright, ytop, density = NULL, angle = 45,
col = NA, border = NULL, lty = par("lty"), lwd = par("lwd"),
...)
```

**Arguments**

- `xleft` a vector (or scalar) of left x positions.
- `ybottom` a vector (or scalar) of bottom y positions.
- `xright` a vector (or scalar) of right x positions.
- `ytop` a vector (or scalar) of top y positions.
- `density` the density of shading lines, in lines per inch. The default value of NULL means that no shading lines are drawn. A zero value of density means no shading lines whereas negative values (and NA) suppress shading (and so allow color filling).
- `angle` angle (in degrees) of the shading lines.
- `col` color(s) to fill or shade the rectangle(s) with. The default NA (or also NULL) means do not fill, i.e., draw transparent rectangles, unless density is specified.
- `border` color for rectangle border(s). The default means par("fg"). Use border = NA to omit borders. If there are shading lines, border = TRUE means use the same colour for the border as for the shading lines.
- `lty` line type for borders and shading; defaults to "solid".
- `lwd` line width for borders and shading. Note that the use of lwd = 0 (as in the examples) is device-dependent.
- `...` **graphical parameters** such as xpd, lend, ljoin and lmitre can be given as arguments.
rug

Add a Rug to a Plot

Description

Adds a rug representation (1-d plot) of the data to the plot.

Details

The positions supplied, i.e., xleft, ..., are relative to the current plotting region. If the x-axis goes from 100 to 200 then xleft must be larger than 100 and xright must be less than 200. The position vectors will be recycled to the length of the longest.

It is a graphics primitive used in hist, barplot, legend, etc.

See Also

box for the standard box around the plot; polygon and segments for flexible line drawing.
par for how to specify colors.

Examples

```r
require(grDevices)
## set up the plot region:
op <- par(bg = "thistle")
plot(c(100, 250), c(300, 450), type = "n", xlab = "", ylab = "",
     main = "2 x 11 rectangles; \text{rect}(100+i,300+i,  150+i,380+i)"
     i <- 4*x(0:10)
## draw rectangles with bottom left (100, 300)+i
## and top right (150, 380)+i
rect(100+i, 300+i, 150+i, 380+i, col = rainbow(11, start = 0.7, end = 0.1))
rect(240-i, 320+i, 250-i, 410+i, col = heat.colors(11), lwd = i/5)
## Background alternating ( transparent / "bg" ) :
j <- 10*x(0:5)
rect(125+j, 360+j, 141+j, 405+j/2, col = c(NA,0),
     border = "gold", lwd = 2)
rect(125+j, 296+j/2, 141+j, 331+j/5, col = c(NA,"midnightblue"))
mtext("+ 2 x 6 \text{rect}(\ast, col = c(NA,0)) and col = c(NA,\"m..blue\")")
## an example showing colouring and shading
plot(c(100, 200), c(300, 450), type= "n", xlab = "", ylab = "")
rect(100, 300, 125, 350) # transparent
rect(100, 400, 125, 450, col = "green", border = "blue") # coloured
rect(115, 375, 150, 425, col = par("bg"), border = "transparent")
rect(150, 300, 175, 350, density = 10, border = "red")
rect(150, 400, 175, 450, density = 30, col = "blue",
     angle = -30, border = "transparent")
legend(180, 450, legend = 1:4, fill = c(NA, "green", par("fg"), "blue"),
       density = c(NA, NA, 10, 30), angle = c(NA, NA, 30, -30))
par(op)
```
Usage

rug(x, ticksize = 0.03, side = 1, lwd = 0.5, col = par("fg"),
quiet = getOption("warn") < 0, ...)

Arguments

x A numeric vector
ticksize The length of the ticks making up the ‘rug’. Positive lengths give inwards ticks.
side On which side of the plot box the rug will be plotted. Normally 1 (bottom) or 3 (top).
lwd The line width of the ticks. Some devices will round the default width up to 1.
col The colour the ticks are plotted in.
quiet logical indicating if there should be a warning about clipped values.
... further arguments, passed to `axis`, such as `line` or `pos` for specifying the location of the rug.

Details

Because of the way `rug` is implemented, only values of `x` that fall within the plot region are included. There will be a warning if any finite values are omitted, but non-finite values are omitted silently.

References

See Also

`jitter` which you may want for ties in `x`.

Examples

```r
require(stats) # both 'density' and its default method
with(faithful, {
  plot(density(eruptions, bw = 0.15))
  rug(eruptions)
  rug(jitter(eruptions, amount = 0.01), side = 3, col = "light blue")
})
```

---

**screen**  
Creating and Controlling Multiple Screens on a Single Device

Description

`split.screen` defines a number of regions within the current device which can, to some extent, be treated as separate graphics devices. It is useful for generating multiple plots on a single device. Screens can themselves be split, allowing for quite complex arrangements of plots. `screen` is used to select which screen to draw in. `erase.screen` is used to clear a single screen, which it does by filling with the background colour. `close.screen` removes the specified screen definition(s).
Usage

```r
split.screen(figs, screen, erase = TRUE)
screen(n = , new = TRUE)
erase.screen(n = )
close.screen(n, all.screens = FALSE)
```

Arguments

- **figs**: A two-element vector describing the number of rows and the number of columns in a screen matrix or a matrix with 4 columns. If a matrix, then each row describes a screen with values for the left, right, bottom, and top of the screen (in that order) in NDC units, that is 0 at the lower left corner of the device surface, and 1 at the upper right corner.
- **screen**: A number giving the screen to be split. It defaults to the current screen if there is one, otherwise the whole device region.
- **erase**: logical: should be selected screen be cleared?
- **n**: A number indicating which screen to prepare for drawing (screen), erase (erase.screen), or close (close.screen). (close.screen will accept a vector of screen numbers.)
- **new**: A logical value indicating whether the screen should be erased as part of the preparation for drawing in the screen.
- **all.screens**: A logical value indicating whether all of the screens should be closed.

Details

The first call to `split.screen` places R into split-screen mode. The other split-screen functions only work within this mode. While in this mode, certain other commands should be avoided (see the Warnings section below). Split-screen mode is exited by the command `close.screen(all = TRUE).

If the current screen is closed, `close.screen` sets the current screen to be the next larger screen number if there is one, otherwise to the first available screen.

Value

- `split.screen` returns a vector of screen numbers for the newly-created screens. With no arguments, `split.screen` returns a vector of valid screen numbers.
- `screen` invisibly returns the number of the selected screen. With no arguments, `screen` returns the number of the current screen.
- `close.screen` returns a vector of valid screen numbers.
- `screen`, `erase.screen`, and `close.screen` all return `FALSE` if R is not in split-screen mode.

Warnings

The recommended way to use these functions is to completely draw a plot and all additions (i.e. points and lines) to the base plot, prior to selecting and plotting on another screen. The behavior associated with returning to a screen to add to an existing plot is unpredictable and may result in problems that are not readily visible.

These functions are totally incompatible with the other mechanisms for arranging plots on a device: `par(mfrow), par(mfcol) and layout()`.
The functions are also incompatible with some plotting functions, such as `coplot`, which make use of these other mechanisms.

`erase.screen` will appear not to work if the background colour is transparent (as it is by default on most devices).

**References**

**See Also**

`par`, `layout`, `Devices`, `dev.*`

**Examples**

```r
if (interactive()) {
  par(bg = "white")  # default is likely to be transparent
  split.screen(c(2, 1))   # split display into two screens
  split.screen(c(1, 3), screen = 2)  # now split the bottom half into 3
  screen(1)  # prepare screen 1 for output
  plot(10:1)
  screen(4)  # prepare screen 4 for output
  plot(10:1)
  close.screen(all = TRUE)  # exit split-screen mode

  split.screen(c(2, 1))  # split display into two screens
  split.screen(c(1, 2), 2)  # split bottom half in two
  plot(1:10)               # screen 3 is active, draw plot
  erase.screen()           # forgot label, erase and redraw
  plot(1:10, ylab = "ylab 3")
  screen(1)               # prepare screen 1 for output
  plot(1:10)
  screen(4)               # prepare screen 4 for output
  plot(1:10, ylab = "ylab 4")
  screen(1, FALSE)        # return to screen 1, but do not clear
  plot(10:1, axes = FALSE, lty = 2, ylab = "")  # overlay second plot
  axis(4)                 # add tic marks to right-hand axis
  title("Plot 1")         #
  close.screen(all = TRUE) # exit split-screen mode
}
```

**Description**

*Add Line Segments to a Plot*

Draw line segments between pairs of points.

**Usage**

```r
segments(x0, y0, x1 = x0, y1 = y0,
        col = par("fg"), lty = par("lty"), lwd = par("lwd"),
        ...)```
smoothScatter

Arguments

- `x0, y0`: coordinates of points from which to draw.
- `x1, y1`: coordinates of points to which to draw. At least one must be supplied.
- `col, lty, lwd`: graphical parameters as in `par`, possibly vectors. NA values in `col` cause the segment to be omitted.
- ... further graphical parameters (from `par`), such as `xpd` and the line characteristics `lend`, `ljoin` and `lmitre`.

Details

For each `i`, a line segment is drawn between the point `(x0[i], y0[i])` and the point `(x1[i], y1[i])`. The coordinate vectors will be recycled to the length of the longest.

The graphical parameters `col, lty` and `lwd` can be vectors of length greater than one and will be recycled if necessary.

References

See Also

`arrows, polygon` for slightly easier and less flexible line drawing, and `lines` for the usual polygons.

Examples

```r
x <- stats::runif(12); y <- stats::rnorm(12)
i <- order(x, y); x <- x[i]; y <- y[i]
plot(x, y, main = "arrows(.) and segments(.)")
## draw arrows from point to point :
s <- seq(length(x)-1) # one shorter than data
arrows(x[s], y[s], x[s+1], y[s+1], col= 1:3)
s <- s[-length(s)]
segments(x[s], y[s], x[s+2], y[s+2], col= 'pink')
```

smoothScatter

**Scatterplots with Smoothed Densities Color Representation**

smoothScatter produces a smoothed color density representation of the scatterplot, obtained through a kernel density estimate. `densCols` produces a vector containing colors which encode the local densities at each point in a scatterplot.

Usage

```r
smoothScatter(x, y = NULL, nbin = 128, bandwidth,
              colramp = colorRampPalette(c("white", "blues9")),
              nrpoints = 100, pch = ".", cex = 1, col = "black",
              transformation = function(x) x^*.25,
              postPlotHook = box,
              xlab = NULL, ylab = NULL, xlim, ylim,
              xaxis = par("xaxs"), yaxis = par("yaxs"), ...)
```
Arguments

\( x, y \)

the \( x \) and \( y \) arguments provide the \( x \) and \( y \) coordinates for the plot. Any reasonable way of defining the coordinates is acceptable. See the function \texttt{xy.coords} for details. If supplied separately, they must be of the same length.

\( \text{nbin} \)

numeric vector of length one (for both directions) or two (for \( x \) and \( y \) separately) specifying the number of equally spaced grid points for the density estimation; directly used as \texttt{gridsize} in \texttt{bkde2d()}.

\( \text{bandwidth} \)

numeric vector (length 1 or 2) of smoothing bandwidth(s). If missing, a more or less useful default is used. \texttt{bandwidth} is subsequently passed to function \texttt{bkde2d}.

\( \text{colramp} \)

function accepting an integer \( n \) as an argument and returning \( n \) colors.

\( \text{nrpoints} \)

number of points to be superimposed on the density image. The first \( \text{nrpoints} \) points from those areas of lowest regional densities will be plotted. Adding points to the plot allows for the identification of outliers. If all points are to be plotted, choose \( \text{nrpoints} = \infty \).

\( \text{pch}, \text{cex}, \text{col} \)

arguments passed to \texttt{points}, when \( \text{nrpoints} > 0 \): point symbol, character expansion factor and color, see also \texttt{par}.

\( \text{transformation} \)

function mapping the density scale to the color scale.

\( \text{postPlotHook} \)

either \texttt{NULL} or a function which will be called (with no arguments) after \texttt{image}.

\( \text{xlab}, \text{ylab} \)

character strings to be used as axis labels, passed to \texttt{image}.

\( \text{xlim}, \text{ylim} \)

numeric vectors of length 2 specifying axis limits.

\( \text{xaxs}, \text{yaxs}, \ldots \)

further arguments, passed to \texttt{image}.

Details

\texttt{smoothScatter} produces a smoothed version of a scatter plot. Two dimensional (kernel density) smoothing is performed by \texttt{bkde2d} from package \texttt{KernSmooth}. See the examples for how to use this function together with \texttt{pairs}.

Author(s)

Florian Hahne at FHCRC, originally

See Also

\texttt{bkde2d} from package \texttt{KernSmooth}; \texttt{densCols} which uses the same smoothing computations and \texttt{blue9} in package \texttt{grDevices}.

\texttt{scatter.smooth} adds a \texttt{loess} regression smoother to a scatter plot.

Examples

```r
## A largish data set
n <- 10000
x1 <- matrix(rnorm(n), ncol = 2)
x2 <- matrix(rnorm(n, mean = 3, sd = 1.5), ncol = 2)
x <- rbind(x1, x2)

oldpar <- par(mfrow = c(2, 2))
smoothScatter(x, nrpoints = 0)
```
spineplot

Spine Plots and Spinograms

Description

Spine plots are a special cases of mosaic plots, and can be seen as a generalization of stacked (or highlighted) bar plots. Analogously, spinograms are an extension of histograms.

Usage

spineplot(x, ...)

## Default S3 method:
spineplot(x, y = NULL,
  breaks = NULL, tol.ylab = 0.05, off = NULL,
  ylevels = NULL, col = NULL,
  main = "", xlab = NULL, ylab = NULL,
  xaxlabels = NULL, yaxlabels = NULL,
  xlim = NULL, ylim = c(0, 1), axes = TRUE, ...)

## S3 method for class 'formula'
spineplot(formula, data = NULL,
  breaks = NULL, tol.ylab = 0.05, off = NULL,
  ylevels = NULL, col = NULL,
  main = "", xlab = NULL, ylab = NULL,
  xaxlabels = NULL, yaxlabels = NULL,
  xlim = NULL, ylim = c(0, 1), axes = TRUE, ...,
  subset = NULL)

Arguments

x
  an object, the default method expects either a single variable (interpreted to be
  the explanatory variable) or a 2-way table. See details.

y
  a "factor" interpreted to be the dependent variable
formulan a "formula" of type y ~ x with a single dependent "factor" and a single
explanatory variable.
data an optional data frame.
breaks if the explanatory variable is numeric, this controls how it is discretized. breaks
is passed to hist and can be a list of arguments.
tol.ylab convenience tolerance parameter for y-axis annotation. If the distance between
two labels drops under this threshold, they are plotted equidistantly.
off vertical offset between the bars (in per cent). It is fixed to 0 for spinograms and
defaults to 2 for spine plots.
ylevels a character or numeric vector specifying in which order the levels of the depen-
dent variable should be plotted.
col a vector of fill colors of the same length as levels(y). The default is to call
gray.colors.

main, xlab, ylab character strings for annotation
xaxlabels, yaxlabels character vectors for annotation of x and y axis. Default to levels(y) and
levels(x), respectively for the spine plot. For xaxlabels in the spinogram,
the breaks are used.
xlim, ylim the range of x and y values with sensible defaults.
axes logical. If FALSE all axes (including those giving level names) are suppressed.
... additional arguments passed to rect.
subset an optional vector specifying a subset of observations to be used for plotting.

Details

spineplot creates either a spinogram or a spine plot. It can be called via spineplot(x, y) or
spineplot(y ~ x) where y is interpreted to be the dependent variable (and has to be categorical)
and x the explanatory variable. x can be either categorical (then a spine plot is created) or numerical
(then a spinogram is plotted). Additionally, spineplot can also be called with only a single
argument which then has to be a 2-way table, interpreted to correspond to table(x, y).

Both, spine plots and spinograms, are essentially mosaic plots with special formatting of spacing
and shading. Conceptually, they plot P(y|x) against P(x). For the spine plot (where both x and y
are categorical), both quantities are approximated by the corresponding empirical relative frequencies.
For the spinogram (where x is numerical), x is first discretized (by calling hist with breaks
argument) and then empirical relative frequencies are taken.

Thus, spine plots can also be seen as a generalization of stacked bar plots where not the heights
but the widths of the bars corresponds to the relative frequencies of x. The heights of the bars then
correspond to the conditional relative frequencies of y in every x group. Analogously, spinograms
extend stacked histograms.

Value

The table visualized is returned invisibly.

```

**Star (Spider/Radar) Plots and Segment Diagrams**
Description

Draw star plots or segment diagrams of a multivariate data set. With one single location, also draws ‘spider’ (or ‘radar’) plots.

Usage

stars(x, full = TRUE, scale = TRUE, radius = TRUE, 
labels = dimnames(x)[[1]], locations = NULL, 
nrow = NULL, ncol = NULL, len = 1, 
key.loc = NULL, key.labels = dimnames(x)[[2]], 
key.xpd = TRUE, 
xlim = NULL, ylim = NULL, flip.labels = NULL, 
draw.segments = FALSE, 
col.segments = 1:nseg, col.stars = NA, col.lines = NA, 
axes = FALSE, frame.plot = axes, 
main = NULL, sub = NULL, xlab = "", ylab = "", 
cex = 0.8, lwd = 0.25, lty = par("lty"), xpd = FALSE, 
mar = pmin(par("mar"), 
1.1 + c(2*axes+, (xlab != ""), 2*axes+ (ylab != ""), 1, 0)), 
add = FALSE, plot = TRUE, ...)

Arguments

x
matrix or data frame of data. One star or segment plot will be produced for each row of x. Missing values (NA) are allowed, but they are treated as if they were 0 (after scaling, if relevant).

full
logical flag: if TRUE, the segment plots will occupy a full circle. Otherwise, they occupy the (upper) semicircle only.

scale
logical flag: if TRUE, the columns of the data matrix are scaled independently so that the maximum value in each column is 1 and the minimum is 0. If FALSE, the presumption is that the data have been scaled by some other algorithm to the range [0, 1].

radius
logical flag: in TRUE, the radii corresponding to each variable in the data will be drawn.

labels
vector of character strings for labeling the plots. Unlike the S function stars, no attempt is made to construct labels if labels = NULL.

locations
Either two column matrix with the x and y coordinates used to place each of the segment plots; or numeric of length 2 when all plots should be superimposed (for a ‘spider plot’). By default, locations = NULL, the segment plots will be placed in a rectangular grid.

nrow, ncol
integers giving the number of rows and columns to use when locations is NULL. By default, nrow == ncol, a square layout will be used.

len
scale factor for the length of radii or segments.

key.loc
vector with x and y coordinates of the unit key.

key.labels
vector of character strings for labeling the segments of the unit key. If omitted, the second component of dimnames(x) is used, if available.

key.xpd
clipping switch for the unit key (drawing and labeling), see par(“xpd”).

xlim
vector with the range of x coordinates to plot.
stars

ylim vector with the range of y coordinates to plot.
flip.labels logical indicating if the label locations should flip up and down from diagram to diagram. Defaults to a somewhat smart heuristic.
draw.segments logical. If TRUE draw a segment diagram.
col.segments color vector (integer or character, see par), each specifying a color for one of the segments (variables). Ignored if draw.segments = FALSE.
col.stars color vector (integer or character, see par), each specifying a color for one of the stars (cases). Ignored if draw.segments = TRUE.
col.lines color vector (integer or character, see par), each specifying a color for one of the lines (cases). Ignored if draw.segments = TRUE.
axes logical flag: if TRUE axes are added to the plot.
frame.plot logical flag: if TRUE, the plot region is framed.
main a main title for the plot.
sub a sub title for the plot.
axlab a label for the x axis.
ylab a label for the y axis.
cex character expansion factor for the labels.
lwd line width used for drawing.
lty line type used for drawing.
xpd logical or NA indicating if clipping should be done, see par(xpd = ).
mar argument to par(mar = *), typically choosing smaller margins than by default.
... further arguments, passed to the first call of plot(), see plot.default and to box() if frame.plot is true.
add logical, if TRUE add stars to current plot.
plot logical, if FALSE, nothing is plotted.

Details

Missing values are treated as 0.

Each star plot or segment diagram represents one row of the input x. Variables (columns) start on the right and wind counterclockwise around the circle. The size of the (scaled) column is shown by the distance from the center to the point on the star or the radius of the segment representing the variable.

Only one page of output is produced.

Value

Returns the locations of the plots in a two column matrix, invisibly when plot = TRUE.

Note

This code started life as spatial star plots by David A. Andrews. See http://www.udallas.edu:8888/~andrews/software/software.html.

Prior to 1.4.1, scaling only shifted the maximum to 1, although documented as here.

Examples

```r
require(grDevices)
sstars(mtcars[, 1:7], key.loc = c(14, 2),
main = "Motor Trend Cars : stars(*, full = F)", full = FALSE)
sstars(mtcars[, 1:7], key.loc = c(14, 1.5),
main = "Motor Trend Cars : full stars()", flip.labels = FALSE)

## 'Spider' or 'Radar' plot:
sstars(mtcars[, 1:7], locations = c(0, 0), radius = FALSE,
key.loc = c(0, 0), main = "Motor Trend Cars", lty = 2)

## Segment Diagrams:
palette(rainbow(12, s = 0.6, v = 0.75))
sstars(mtcars[, 1:7], len = 0.8, key.loc = c(12, 1.5),
main = "Motor Trend Cars", draw.segments = TRUE)
sstars(mtcars[, 1:7], len = 0.6, key.loc = c(1.5, 0),
main = "Motor Trend Cars", draw.segments = TRUE,
frame.plot = TRUE, nrow = 4, cex = .7)

## scale linearly (not affinely) to [0, 1]
USJudge <- apply(USJudgeRatings, 2, function(x) x/max(x))
Jnam <- row.names(USJudgeRatings)
Snam <- abbreviate(substring(Jnam, 1, regexpr("[.,]", Jnam) - 1), 7)
sstars(USJudge, labels = Jnam, scale = FALSE,
key.loc = c(13, 1.5), main = "Judge not ...", len = 0.8)
sstars(USJudge, labels = Snam, scale = FALSE,
key.loc = c(13, 1.5), radius = FALSE)

loc <- stars(USJudge, labels = NULL, scale = FALSE,
radius = FALSE, frame.plot = TRUE,
key.loc = c(13, 1.5), main = "Judge not ...", len = 1.2)
text(loc, Snam, col = "blue", cex = 0.8, xpd = TRUE)

## 'Segments':
sstars(USJudge, draw.segments = TRUE, scale = FALSE, key.loc = c(13,1.5))

## 'Spider':
sstars(USJudgeRatings, locations = c(0, 0), scale = FALSE, radius = FALSE,
col.stars = 1:10, key.loc = c(0, 0), main = "US Judges rated")
## Same as above, but with colored lines instead of filled polygons.
sstars(USJudgeRatings, locations = c(0, 0), scale = FALSE, radius = FALSE,
col.lines = 1:10, key.loc = c(0, 0), main = "US Judges rated")
## 'Radar-Segments'
```
stem produces a stem-and-leaf plot of the values in x. The parameter scale can be used to expand the scale of the plot. A value of scale = 2 will cause the plot to be roughly twice as long as the default.

stem(x, scale = 1, width = 80, atom = 1e-08)

Arguments

x  a numeric vector.
scale  This controls the plot length.
width  The desired width of plot.
atom  a tolerance.

Details

Infinite and missing values in x are discarded.

Examples

stem(islands)
stem(log10(islands))
stripchart  I-D Scatter Plots

Description

stripchart produces one dimensional scatter plots (or dot plots) of the given data. These plots are a good alternative to boxplots when sample sizes are small.

Usage

stripchart(x, ...)

## S3 method for class 'formula'
stripchart(x, data = NULL, dlab = NULL, ..., subset, na.action = NULL)

## Default S3 method:
stripchart(x, method = "overplot", jitter = 0.1, offset = 1/3, vertical = FALSE, group.names, add = FALSE, at = NULL, xlim = NULL, ylim = NULL, ylab = NULL, xlab = NULL, dlab = "", glab = "", log = "", pch = 0, col = par("fg"), cex = par("cex"), axes = TRUE, frame.plot = axes, ...)

Arguments

x
the data from which the plots are to be produced. In the default method the data can be specified as a single numeric vector, or as list of numeric vectors, each corresponding to a component plot. In the formula method, a symbolic specification of the form y ~ g can be given, indicating the observations in the vector y are to be grouped according to the levels of the factor g. NAs are allowed in the data.

data
a data.frame (or list) from which the variables in x should be taken.

subset
an optional vector specifying a subset of observations to be used for plotting.

na.action
a function which indicates what should happen when the data contain NAs. The default is to ignore missing values in either the response or the group.

...
additional parameters passed to the default method, or by it to plot, points, axis and title to control the appearance of the plot.

method
the method to be used to separate coincident points. The default method "overplot" causes such points to be overplotted, but it is also possible to specify "jitter" to jitter the points, or "stack" have coincident points stacked. The last method only makes sense for very granular data.

jitter
when method = "jitter" is used, jitter gives the amount of jittering applied.

offset
when stacking is used, points are stacked this many line-heights (symbol widths) apart.

vertical
when vertical is TRUE the plots are drawn vertically rather than the default horizontal.
group.names
   group labels which will be printed alongside (or underneath) each plot.
add
   logical, if true add the chart to the current plot.
at
   numeric vector giving the locations where the charts should be drawn, particularly when add = TRUE; defaults to 1:n where n is the number of boxes.
ylab, xlab
   labels: see title.
dlab, glab
   alternate way to specify axis labels: see 'Details'.
xlim, ylim
   plot limits: see plot.window.
log
   on which axes to use a log scale: see plot.default
pch, col, cex
   Graphical parameters: see par.
axes, frame.plot
   Axis control: see plot.default

Details

Extensive examples of the use of this kind of plot can be found in Box, Hunter and Hunter or Seber and Wild.

The dlab and glab labels may be used instead of xlab and ylab if those are not specified. dlab applies to the continuous data axis (the X axis unless vertical is TRUE), glab to the group axis.

Examples

```r
x <- stats::rnorm(50)
xr <- round(x, 1)
stripchart(x); m <- mean(par("usr"))[1:2])
   text(m, 1.04, "stripchart(x, \"overplot\")")
stripchart(xr, method = "stack", add = TRUE, at = 1.2)
   text(m, 1.35, "stripchart(round(x,1), \"stack\")")
stripchart(xr, method = "jitter", add = TRUE, at = 0.7)
   text(m, 0.85, "stripchart(round(x,1), \"jitter\")")
stripchart(decrease ~ treatment, main = "stripchart(OrchardSprays)",
   vertical = TRUE, log = "y", data = OrchardSprays)
stripchart(decrease ~ treatment, at = c(1:8)*2,
   main = "stripchart(OrchardSprays)",
   vertical = TRUE, log = "y", data = OrchardSprays)
```

strwidth

Plotting Dimensions of Character Strings and Math Expressions

Description

These functions compute the width or height, respectively, of the given strings or mathematical expressions s[i] on the current plotting device in user coordinates, inches or as fraction of the figure width par("fin").

Usage

```r
strwidth(s, units = "user", cex = NULL, font = NULL, vfont = NULL, ...)
strheight(s, units = "user", cex = NULL, font = NULL, vfont = NULL, ...)
```
Arguments

s a character or expression vector whose dimensions are to be determined. Other objects are coerced by `as.graphicsAnnot`.

units character indicating in which units `s` is measured; should be one of "user", "inches", "figure"; partial matching is performed.

cex numeric character expansion factor; multiplied by `par("cex")` yields the final character size; the default NULL is equivalent to 1.

font, vfont, ... additional information about the font, possibly including the graphics parameter "family": see `text`.

Details

Note that the ‘height’ of a string is determined only by the number of linefeeds ("\n") it contains: it is the (number of linefeeds - 1) times the line spacing plus the height of "M" in the selected font. For an expression it is the height of the bounding box as computed by `plotmath`. Thus in both cases it is an estimate of how far above the final baseline the typeset object extends. (It may also extend below the baseline.) The inter-line spacing is controlled by `cex`, `par("1height")` and the ‘point size’ (but not the actual font in use).

Measurements in "user" units (the default) are only available after `plot.new` has been called – otherwise an error is thrown.

Value

Numeric vector with the same length as `s`, giving the estimate of width or height for each `s[i]`. NA strings are given width and height 0 (as they are not plotted).

text, nchar

Examples

```r
str.ex <- c("W", "w", "I", ".", "WwI.")
op <- parpty = "s"); plot(1:100, 1:100, type = "n")
sw <- strwidth(str.ex); sw
all.equal(sum(sw[1:4]), sw[5])
#- since the last string contains the others

sw.i <- strwidth(str.ex, "inches"); 25.4 * sw.i # width in [mm]
unique(sw / sw.i)
# constant factor: 1 value
mean(sw.i / strwidth(str.ex, "fig")) / par("fin")[1] # = 1: are the same

# See how letters fall in classes
all.lett <- c(letters, LETTERS)
shL <- strheight(all.lett, units = "inches") * 72 # 'big points'
table(shL) # all have same heights ...
mean(shL)/par("cin")[2] # around 0.6

(swL <- strwidth(all.lett, units = "inches") * 72) # 'big points'
split(all.lett, factor(round(swL, 2)))
```
sunflowerplot <- expression(sum(x[i], i=1,n), e^{i \times pi} == -1)
strwidth(sumex)
strheight(sumex)

par(op) <- reset to previous setting

sunflowerplot  Produce a Sunflower Scatter Plot

Description

Multiple points are plotted as 'sunflowers' with multiple leaves ('petals') such that overplotting is visualized instead of accidental and invisible.

Usage

sunflowerplot(x, ...)

## Default S3 method:
sunflowerplot(x, y = NULL, number, log = "", digits = 6,
  xlab = NULL, ylab = NULL, xlim = NULL, ylim = NULL,
  add = FALSE, rotate = FALSE,
  pch = 16, cex = 0.8, cex.fact = 1.5,
  col = par("col"), bg = NA, size = 1/8, seg.col = 2,
  seg.lwd = 1.5, ...)

## S3 method for class 'formula'
sunflowerplot(formula, data = NULL, xlab = NULL, ylab = NULL, ylim = NULL,
  subset, na.action = NULL)

Arguments

x numeric vector of x-coordinates of length n, say, or another valid plotting structure, as for plot.default, see also xy.coords.
y numeric vector of y-coordinates of length n.
number integer vector of length n. number[i] = number of replicates for (x[i], y[i]), may be 0. Default (missing(number)): compute the exact multiplicity of the points x[i], y[i], via xyTable().
log character indicating log coordinate scale, see plot.default.
digits when number is computed (i.e., not specified), x and y are rounded to digits significant digits before multiplicities are computed.
xlab, ylab character label for x-, or y-axis, respectively.
xlim, ylim numeric(2) limiting the extents of the x-, or y-axis.
add logical; should the plot be added on a previous one? Default is FALSE.
rotate logical; if TRUE, randomly rotate the sunflowers (preventing artefacts).
pch plotting character to be used for points (number[i]==1) and center of sunflowers.
sunflowerplot

- **cex**: numeric; character size expansion of center points (s. pch).
- **cex.factor**: numeric *shrinking* factor to be used for the center points when there are flower leaves, i.e., `cex / cex.factor` is used for these.
- **col, bg**: colors for the plot symbols, passed to `plot.default`.
- **size**: of sunflower leaves in inches, 1[in] := 2.54[cm]. Default: 1/8", approximately 3.2mm.
- **seg.col**: color to be used for the segments which make the sunflowers leaves, see `par(col=)`; `col = "gold"` reminds of real sunflowers.
- **seg.lwd**: numeric; the line width for the leaves’ segments.
- **formula**: a formula, such as `y ~ x`.
- **data**: a data.frame (or list) from which the variables in `formula` should be taken.
- **subset**: an optional vector specifying a subset of observations to be used in the fitting process.
- **na.action**: a function which indicates what should happen when the data contain NAs. The default is to ignore case with missing values.

**Details**

This is a generic function with default and formula methods.

For `number[i] == 1`, a (slightly enlarged) usual plotting symbol (pch) is drawn. For `number[i] > 1`, a small plotting symbol is drawn and `number[i]` equi-angular `‘rays’` emanate from it.

If `rotate = TRUE` and `number[i] >= 2`, a random direction is chosen (instead of the y-axis) for the first ray. The goal is to jitter the orientations of the sunflowers in order to prevent artefactual visual impressions.

**Value**

A list with three components of same length,

- **x**: x coordinates
- **y**: y coordinates
- **number**: number

Use `xyTable()` (from package grDevices) if you are only interested in this return value.

**Side Effects**

A scatter plot is drawn with ‘sunflowers’ as symbols.

density, xyTable

Examples

require(stats)
require(grDevices)

## 'number' is computed automatically:
sunflowerplot(iris[, 3:4])
## Imitating Chambers et al., p.109, closely:
sunflowerplot(iris[, 3:4], cex = .2, cex.fact = 1, size = .035, seg.lwd = .8)
## or
sunflowerplot(Petal.Width ~ Petal.Length, data = iris,
  cex = .2, cex.fact = 1, size = .035, seg.lwd = .8)

sunflowerplot(x = sort(2*round(rnorm(100))), y = round(rnorm(100), 0),
  main = "Sunflower Plot of Rounded N(0,1)"
)
## Similarly using a "xyTable" argument:
xyT <- xyTable(x = sort(2*round(rnorm(100))), y = round(rnorm(100), 0),
  digits = 3)
utils::str(xyT, vec.len = 20)
sunflowerplot(xyT, main = "2nd Sunflower Plot of Rounded N(0,1)"
)

## A 'marked point process' (explicit 'number' argument):
sunflowerplot(rnorm(100), rnorm(100), number = rpois(n = 100, lambda = 2),
  main = "Sunflower plot (marked point process)",
  rotate = TRUE, col = "blue4")

symbols                  Draw Symbols (Circles, Squares, Stars, Thermometers, Boxplots)

Description

This function draws symbols on a plot. One of six symbols; circles, squares, rectangles, stars, thermometers, and boxplots, can be plotted at a specified set of x and y coordinates. Specific aspects of the symbols, such as relative size, can be customized by additional parameters.

Usage

symbols(x, y = NULL, circles, squares, rectangles, stars,
  thermometers, boxplots, inches = TRUE, add = FALSE,
  fg = par("col"), bg = NA,
  xlab = NULL, ylab = NULL, main = NULL,
  xlim = NULL, ylim = NULL, ...)
Arguments

- **x, y**: the x and y co-ordinates for the centres of the symbols. They can be specified in any way which is accepted by `xy.coords`.
- **circles**: a vector giving the radii of the circles.
- **squares**: a vector giving the length of the sides of the squares.
- **rectangles**: a matrix with two columns. The first column gives widths and the second the heights of rectangles.
- **stars**: a matrix with three or more columns giving the lengths of the rays from the center of the stars. NA values are replaced by zeroes.
- **thermometers**: a matrix with three or four columns. The first two columns give the width and height of the thermometer symbols. If there are three columns, the third is taken as a proportion: the thermometers are filled (using colour fg) from their base to this proportion of their height. If there are four columns, the third and fourth columns are taken as proportions and the thermometers are filled between these two proportions of their heights. The part of the box not filled in fg will be filled in the background colour (default transparent) given by bg.
- **boxplots**: a matrix with five columns. The first two columns give the width and height of the boxes, the next two columns give the lengths of the lower and upper whiskers and the fifth the proportion (with a warning if not in \([0,1]\)) of the way up the box that the median line is drawn.
- **inches**: TRUE, FALSE or a positive number. See ‘Details’.
- **add**: if add is TRUE, the symbols are added to an existing plot, otherwise a new plot is created.
- **fg**: colour(s) the symbols are drawn in.
- **bg**: if specified, the symbols are filled with colour(s), the vector bg being recycled to the number of symbols. The default is to leave the symbols unfilled.
- **xlab**: the x label of the plot if add is not true. Defaults to the deparsed expression used for x.
- **ylab**: the y label of the plot. Unused if add = TRUE.
- **main**: a main title for the plot. Unused if add = TRUE.
- **xlim**: numeric vector of length 2 giving the x limits for the plot. Unused if add = TRUE.
- **ylim**: numeric vector of length 2 giving the y limits for the plot. Unused if add = TRUE.
- **...**: graphics parameters can also be passed to this function, as can the plot aspect ratio asp (see `plot.window`).

Details

Observations which have missing coordinates or missing size parameters are not plotted. The exception to this is **stars**. In that case, the length of any ray which is NA is reset to zero.

Argument **inches** controls the sizes of the symbols. If TRUE (the default), the symbols are scaled so that the largest dimension of any symbol is one inch. If a positive number is given the symbols are scaled to make largest dimension this size in inches (so TRUE and 1 are equivalent). If inches is FALSE, the units are taken to be those of the appropriate axes. (For circles, squares and stars the units of the x axis are used. For boxplots, the lengths of the whiskers are regarded as dimensions
alongside width and height when scaling by inches, and are otherwise interpreted in the units of
the y axis.)

Circles of radius zero are plotted at radius one pixel (which is device-dependent). Circles of a very
small non-zero radius may or may not be visible, and may be smaller than circles of radius zero.
On windows devices circles are plotted at radius at least one pixel as some Windows versions omit
smaller circles.

Brooks/Cole.

See Also

stars for drawing stars with a bit more flexibility.

If you are thinking about doing ‘bubble plots’ by symbols(*, circles=*) you should really
consider using sunflowerplot instead.

Examples

require(stats); require(grDevices)
x <- 1:10
y <- sort(10*runif(10))
z <- runif(10)
z3 <- cbind(z, 2*runif(10), runif(10))
symbols(x, y, thermometers = cbind(.5, 1, z), inches = .5, fg = 1:10)
symbols(x, y, thermometers = z3, inches = FALSE)
text(x, y, apply(format(round(z3, digits = 2)), 1, paste, collapse = ","),
     adj = c(-.2,0), cex = .75, col = "purple", xpd = NA)

## Note that example(trees) shows more sensible plots!
N <- nrow(trees)
with(trees, {
  ## Girth is diameter in inches
  symbols(Height, Volume, circles = Girth/24, inches = FALSE,
          main = "Trees' Girth") # xlab and ylab automatically
  ## Colours too:
  op <- palette(rainbow(N, end = 0.9))
symbols(Height, Volume, circles = Girth/16, inches = FALSE, bg = 1:N,
         fg = "gray30", main = "symbols(*, circles = Girth/16, bg = 1:N")
  palette(op)
})

---

text

Add Text to a Plot

description

text draws the strings given in the vector labels at the coordinates given by x and y. y may be
missing since xy.coords(x, y) is used for construction of the coordinates.
text(x, y, ...)  
## Default S3 method:  
text(x = NULL, y = NULL, labels = if (is.null(x)) NULL else seq_along(x), adj = NULL,  
pos = NULL, offset = 0.5, vfont = NULL,  
cex = 1, col = NULL, font = NULL, ...)  

Arguments  

- **x, y** numeric vectors of coordinates where the text labels should be written. If the length of x and y differs, the shorter one is recycled.  
- **labels** a character vector or expression specifying the text to be written. An attempt is made to coerce other language objects (names and calls) to expressions, and vectors and other classed objects to character vectors by `as.character`. If labels is longer than x and y, the coordinates are recycled to the length of labels.  
- **adj** one or two values in \([0, 1]\) which specify the x (and optionally y) adjustment of the labels. On most devices values outside that interval will also work.  
- **pos** a position specifier for the text. If specified this overrides any adj value given. Values of 1, 2, 3 and 4, respectively indicate positions below, to the left of, above and to the right of the specified coordinates.  
- **offset** when pos is specified, this value gives the offset of the label from the specified coordinate in fractions of a character width.  
- **vfont** NULL for the current font family, or a character vector of length 2 for Hershey vector fonts. The first element of the vector selects a typeface and the second element selects a style. Ignored if labels is an expression.  
- **cex** numeric character expansion factor; multiplied by `par("cex")` yields the final character size. NULL and NA are equivalent to 1.0.  
- **col, font** the color and (if vfont = NULL) font to be used, possibly vectors. These default to the values of the global graphical parameters in `par()`.  
- **...** further graphical parameters (from `par`), such as `srt`, `family` and `xpd`.  

Details  

labels must be of type `character` or `expression` (or be coercible to such a type). In the latter case, quite a bit of mathematical notation is available such as sub- and superscripts, greek letters, fractions, etc.  

adj allows adjustment of the text with respect to (x, y). Values of 0, 0.5, and 1 specify left/bottom, middle and right/top alignment, respectively. The default is for centered text, i.e., `adj = c(0.5, NA)`. Accurate vertical centering needs character metric information on individual characters which is only available on some devices. Vertical alignment is done slightly differently for character strings and for expressions: adj = c(0, 0) means to left-justify and to align on the baseline for strings but on the bottom of the bounding box for expressions. This also affects vertical centering: for strings the centering excludes any descenders whereas for expressions it includes them. Using NA for strings centers them, including descenders.  

The pos and offset arguments can be used in conjunction with values returned by `identify` to recreate an interactively labelled plot.  

Text can be rotated by using graphical parameters `srt` (see `par`); this rotates about the centre set by adj.
Graphical parameters col, cex and font can be vectors and will then be applied cyclically to the labels (and extra values will be ignored). NA values of font are replaced by par("font"), and similarly for col.

Labels whose x, y or labels value is NA are omitted from the plot.

What happens when font = 5 (the symbol font) is selected can be both device- and locale-dependent. Most often labels will be interpreted in the Adobe symbol encoding, so e.g. "d" is delta, and "\300" is aleph.

**Euro symbol**

The Euro symbol was introduced relatively recently and may not be available in older fonts. In recent versions of Adobe symbol fonts it is character 160, so text(x, y, "\xA0”, font = 5) may work. People using Western European locales on Unix-alikes can probably select ISO-8859-15 (Latin-9) which has the Euro as character 165: this can also be used for postscript and pdf. It is ‘\u20ac’ in Unicode, which can be used in UTF-8 locales.

The Euro should be rendered correctly by X11 in UTF-8 locales, but the corresponding single-byte encoding in postscript and pdf will need to be selected as ISO-Latin9.enc.

Plot Annotation

Description

This function can be used to add labels to a plot. Its first four principal arguments can also be used as arguments in most high-level plotting functions. They must be of type character or expression. In the latter case, quite a bit of mathematical notation is available such as sub- and superscripts, greek letters, fractions, etc: see plotmath

Usage

title(main = NULL, sub = NULL, xlab = NULL, ylab = NULL,
line = NA, outer = FALSE, ...)

Arguments

main
The main title (on top) using font and size (character expansion) par("font.main") and color par("col.main").

sub
Sub-title (at bottom) using font and size par("font.sub") and color par("col.sub").

xlab
X axis label using font and character expansion par("font.lab") and color par("col.lab").

ylab
Y axis label, same font attributes as xlab.

line
specifying a value for line overrides the default placement of labels, and places them this many lines outwards from the plot edge.

outer
a logical value. If TRUE, the titles are placed in the outer margins of the plot.

...

further graphical parameters from par. Use e.g., col.main or cex.sub instead of just col or cex. adj controls the justification of the titles. xpd can be used to set the clipping region: this defaults to the figure region unless outer = TRUE, otherwise the device region and can only be increased. mgp controls the default placing of the axis titles.

Details

The labels passed to title can be character strings or language objects (names, calls or expressions), or a list containing the string to be plotted, and a selection of the optional modifying graphical parameters cex=, col= and font=. Other objects will be coerced by as.graphicsAnnot.

The position of main defaults to being vertically centered in (outer) margin 3 and justified horizontally according to par("adj") on the plot region (device region for outer = TRUE).

The positions of xlab, ylab and sub are line (default for xlab and ylab being par("mgp")[1] and increased by 1 for sub) lines (of height par("mex")) into the appropriate margin, justified in the text direction according to par("adj") on the plot/device region.

`mtext`, `text`; `plotmath` for details on mathematical annotation.

Examples

```r
plot(cars, main = ")" )  # here, could use main directly
title(main = "Stopping Distance versus Speed"

plot(cars, main = "")
title(main = list("Stopping Distance versus Speed", cex = 1.5,
      col = "red", font = 3))

## Specifying "...":
plot(1, col.axis = "sky blue", col.lab = "thistle")
title("Main Title", sub = "sub title",
      cex.main = 2, font.main = 4, col.main = "blue",
      cex.sub = 0.75, font.sub = 3, col.sub = "red")

x <- seq(-4, 4, len = 101)
y <- cbind(sin(x), cos(x))
matplot(x, y, type = "I", xaxt = "n",
      main = expression(paste(plain(sin) \* phi, " and ",
                          plain(cos) \* phi)),
      ylab = expression("sin" \* phi, "cos" \* phi)), # only lst is taken
      xlab = expression(paste("Phase Angle ", phi)),
      col.main = "blue")

axis(1, at = c(-pi, -pi/2, 0, pi/2, pi),
      labels = expression(-pi, -pi/2, 0, pi/2, pi))
abline(h = 0, v = pi/2 * c(-1,1), lty = 2, lwd = .1, col = "gray70")
```

---

### Graphical Units

**units**

**Description**

`xinch` and `yinch` convert the specified number of inches given as their arguments into the correct units for plotting with graphics functions. Usually, this only makes sense when normal coordinates are used, i.e., no log scale (see the `log` argument to `par`).

`xyinch` does the same for a pair of numbers `xy`, simultaneously.

**Usage**

```r
xinch(x = 1, warn.log = TRUE)
yinch(y = 1, warn.log = TRUE)
xyinch(xy = 1, warn.log = TRUE)
```

**Arguments**

- `x`, `y` numeric vector
- `xy` numeric of length 1 or 2.
- `warn.log` logical; if TRUE, a warning is printed in case of active log scale.
Examples

```r
all(c(xin(), yin()) == xyin()) # TRUE

ixin()  
ixin # see that is really    delta("usr") / "pin"

## plot labels offset 0.12 inches to the right
## of plotted symbols in a plot
with(mtcars, {
  plot(mpg, disp, pch = 19, main = "Motor Trend Cars")
  text(mpg + xin(0.12), disp, row.names(mtcars),
       adj = 0, cex = .7, col = "blue")
})
```

xspline Draw an X-spline

Description

Draw an X-spline, a curve drawn relative to control points.

Usage

```r
xspline(x, y = NULL, shape = 0, open = TRUE, repEnds = TRUE,
         draw = TRUE, border = par("fg"), col = NA, ...)
```

Arguments

- `x, y` vectors containing the coordinates of the vertices of the polygon. See `xy.coords` for alternatives.
- `shape` A numeric vector of values between -1 and 1, which control the shape of the spline relative to the control points.
- `open` A logical value indicating whether the spline is an open or a closed shape.
- `repEnds` For open X-splines, a logical value indicating whether the first and last control points should be replicated for drawing the curve. Ignored for closed X-splines.
- `draw` logical: should the X-spline be drawn? If false, a set of line segments to draw the curve is returned, and nothing is drawn.
- `border` the color to draw the curve. Use `border = NA` to omit borders.
- `col` the color for filling the shape. The default, NA, is to leave unfilled.
- `...` graphical parameters such as `lty`, `xpd`, `lend`, `ljoin` and `lmitre` can be given as arguments.

Details

An X-spline is a line drawn relative to control points. For each control point, the line may pass through (interpolate) the control point or it may only approach (approximate) the control point; the behaviour is determined by a shape parameter for each control point.

If the shape parameter is greater than zero, the spline approximates the control points (and is very similar to a cubic B-spline when the shape is 1). If the shape parameter is less than zero, the spline
interpolates the control points (and is very similar to a Catmull-Rom spline when the shape is -1). If the shape parameter is 0, the spline forms a sharp corner at that control point.

For open X-splines, the start and end control points must have a shape of 0 (and non-zero values are silently converted to zero).

For open X-splines, by default the start and end control points are replicated before the curve is drawn. A curve is drawn between (interpolating or approximating) the second and third of each set of four control points, so this default behaviour ensures that the resulting curve starts at the first control point you have specified and ends at the last control point. The default behaviour can be turned off via the repends argument.

**Value**

If `draw = TRUE`, `NULL` otherwise a list with elements `x` and `y` which could be passed to `lines`, `polygon` and so on.

Invisible in both cases.

**Note**

Two-dimensional splines need to be created in an isotropic coordinate system. Device coordinates are used (with an anisotropy correction if needed.)

**References**

**See Also**

`polygon`.

`par` for how to specify colors.

**Examples**

```r
## based on examples in ?grid.xspline
xsplineTest <- function(s, open = TRUE,
    x = c(1,1,3,3)/4, y = c(1,3,3,1)/4, ...)
    plot(c(0,1), c(0,1), type = "n", axes = FALSE, xlab = "", ylab = "")
    points(x, y, pch = 19)
    xspline(x, y, s, open, ...)
    text(x+0.05*c(-1,-1,1,1), y+0.05*c(-1,1,1,-1), s)
)
op <- par(mfrow = c(3,3), mar = rep(0,4), oma = c(0,0,2,0))
xsplineTest(c(0, -1, -1, 0))
xsplineTest(c(0, -1, 0, 0))
xsplineTest(c(0, -1, 1, 0))
xsplineTest(c(0, 0, -1, 0))
xsplineTest(c(0, 0, 0, 0))
xsplineTest(c(0, 0, 1, 0))
xsplineTest(c(0, 1, -1, 0))
xsplineTest(c(0, 1, 0, 0))
xsplineTest(c(0, 1, 1, 0))
title("Open X-splines", outer = TRUE)
```
```r
par(mfrow = c(3,3), mar = rep(0,4), oma = c(0,0,2,0))
xsplineTest(c(0, -1, -1, 0), FALSE, col = "grey80")
xsplineTest(c(0, -1, 0, 0), FALSE, col = "grey80")
xsplineTest(c(0, -1, 1, 0), FALSE, col = "grey80")
xsplineTest(c(0, 0, -1, 0), FALSE, col = "grey80")
xsplineTest(c(0, 0, 0, 0), FALSE, col = "grey80")
xsplineTest(c(0, 0, 1, 0), FALSE, col = "grey80")
xsplineTest(c(0, 1, -1, 0), FALSE, col = "grey80")
xsplineTest(c(0, 1, 0, 0), FALSE, col = "grey80")
xsplineTest(c(0, 1, 1, 0), FALSE, col = "grey80")
title("Closed x-splines", outer = TRUE)
par(op)

x <- sort(stats::rnorm(5))
y <- sort(stats::rnorm(5))
plot(x, y, pch = 19)
res <- xspline(x, y, 1, draw = FALSE)
lines(res)
## the end points may be very close together,
## so use last few for direction
nr <- length(res)
arrows(res$x[1], res$y[1], res$x[4], res$y[4], code = 1, length = 0.1)
arrows(res$x[nr-3], res$y[nr-3], res$x[nr], res$y[nr], code = 2, length = 0.1)
```
Chapter 6

The grid package

grid-package  The Grid Graphics Package

Description
A rewrite of the graphics layout capabilities, plus some support for interaction.

Details
This package contains a graphics system which supplements S-style graphics (see the graphics package).

Further information is available in the following vignettes:

- grid: Introduction to grid (.doc/grid.pdf)
- displaylist: Display Lists in grid (.doc/displaylist.pdf)
- frame: Frames and packing grobs (.doc/frame.pdf)
- grobs: Working with grid grobs (.doc/grobs.pdf)
- interactive: Editing grid Graphics (.doc/interactive.pdf)
- locndimn: Locations versus Dimensions (.doc/locndimn.pdf)
- moveline: Demonstrating move-to and line-to (.doc/moveline.pdf)
- nonfinite: How grid responds to non-finite values (.doc/nonfinite.pdf)
- plotexample: Writing grid Code (.doc/plotexample.pdf)
- rotated: Rotated Viewports (.doc/rotated.pdf)
- saveload: Persistent representations (.doc/saveload.pdf)
- sharing: Modifying multiple grobs simultaneously (.doc/sharing.pdf)
- viewports: Working with grid viewports (.doc/viewports.pdf)

For a complete list of functions with individual help pages, use library(help="grid").

Maintainer: R Core Team <R-core@r-project.org>
absolute.size

References

---

**absolute.size**  
*Absolute Size of a Grob*

**Description**

This function converts a unit object into absolute units. Absolute units are unaffected, but non-absolute units are converted into "null" units.

**Usage**

```r
absolute.size(unit)
```

**Arguments**

- `unit`: An object of class "unit".

**Details**

Absolute units are things like "inches", "cm", and "lines". Non-absolute units are "npc" and "native".

This function is designed to be used in `widthDetails` and `heightDetails` methods.

**Value**

An object of class "unit".

**Author(s)**

Paul Murrell

**See Also**

`widthDetails` and `heightDetails` methods.
Describe arrows to add to a line.

**Description**

Produces a description of what arrows to add to a line. The result can be passed to a function that draws a line, e.g., `grid.lines`.

**Usage**

```r
arrow(angle = 30, length = unit(0.25, "inches"),
      ends = "last", type = "open")
```

**Arguments**

- **angle**: The angle of the arrow head in degrees (smaller numbers produce narrower, pointier arrows). Essentially describes the width of the arrow head.
- **length**: A unit specifying the length of the arrow head (from tip to base).
- **ends**: One of "last", "first", or "both", indicating which ends of the line to draw arrow heads.
- **type**: One of "open" or "closed" indicating whether the arrow head should be a closed triangle.

**Examples**

```r
arrow()
```

calculate metric information for text

**Description**

This function returns the ascent, descent, and width metric information for a character or expression vector.

**Usage**

```r
calcStringMetric(text)
```

**Arguments**

- **text**: A character or expression vector.

**Value**

A list with three numeric components named ascent, descent, and width. All values are in inches.
WARNING

The metric information from this function is based on the font settings that are in effect when this function is called. It will not necessarily correspond to the metric information of any text that is drawn on the page.

      gp=gpar(col=rgb(1,0,0,.5)))
  }
}
tests <- list("t",}
convertNative

Convert a Unit Object to Native units

Description

This function is deprecated in grid version 0.8 and will be made defunct in grid version 1.9.
You should use the convertUnit() function or one of its close allies instead.

This function returns a numeric vector containing the specified x or y locations or dimensions, converted to "user" or "data" units, relative to the current viewport.

Usage

convertNative(unit, dimension="x", type="location")

Arguments

unit

A unit object.

dimension

Either "x" or "y".

type

Either "location" or "dimension".

Value

A numeric vector.

WARNING

If you draw objects based on output from these conversion functions, then resize your device, the objects will be drawn incorrectly – the base R display list will not recalculate these conversions. This means that you can only rely on the results of these calculations if the size of your device is fixed.
dataViewport

Create a Viewport with Scales based on Data

Description

This is a convenience function for producing a viewport with x- and/or y-scales based on numeric values passed to the function.

Usage

dataViewport(xData = NULL, yData = NULL, xscale = NULL, yscale = NULL, extension = 0.05, ...)

Arguments

- **xData**: A numeric vector of data.
- **yData**: A numeric vector of data.
- **xscale**: A numeric vector (length 2).
- **yscale**: A numeric vector (length 2).
- **extension**: A numeric. If length greater than 1, then first value is used to extend the xscale and second value is used to extend the yscale.
- **...**: All other arguments will be passed to a call to the `viewport()` function.
If `xscale` is not specified then the values in `x` are used to generate an x-scale based on the range of `x`, extended by the proportion specified in `extension`. Similarly for the y-scale.

### Value

A grid viewport object.

### Author(s)

Paul Murrell

### See Also

`viewport` and `plotViewport`.

### Description

These generic hook functions are called whenever a grid grob is drawn. They provide an opportunity for customising the drawing of a new class derived from grob (or gTree).

### Usage

```r
drawDetails(x, recording)
drawDetails(x, recording)
predrawDetails(x)
postDrawDetails(x)
```

### Arguments

- `x` A grid grob.
- `recording` A logical value indicating whether a grob is being added to the display list or redrawn from the display list.

### Details

These functions are called by the `grid.draw` methods for grobs and gTrees.

`predrawDetails` is called first during the drawing of a grob. This is where any additional viewports should be pushed (see, for example, `grid:::predrawDetails.frame`). Note that the default behaviour for grobs is to push any viewports in the `vp` slot, and for gTrees is to also push and up any viewports in the `childrenvp` slot so there is typically nothing to do here.

`drawDetails` is called next and is where any additional calculations and graphical output should occur (see, for example, `grid:::drawDetails.xaxis`). Note that the default behaviour for gTrees is to draw all grobs in the `children` slot so there is typically nothing to do here.

`postDrawDetails` is called last and should reverse anything done in `predrawDetails` (i.e., pop or up any viewports that were pushed; again, see, for example, `grid:::postDrawDetails.frame`).
Note that the default behaviour for grobs is to pop any viewports that were pushed so there is typically nothing to do here.

Note that preDrawDetails and postDrawDetails are also called in the calculation of "grobwidth" and "grobheight" units.

Value

None of these functions are expected to return a value.

Author(s)

Paul Murrell

See Also

grid.draw

Description

This generic hook function is called whenever a grid grob is edited via grid.edit or editGrob. This provides an opportunity for customising the editing of a new class derived from grob (or gTree).

Usage

editDetails(x, specs)

Arguments

x A grid grob.

specs A list of named elements. The names indicate the grob slots to modify and the values are the new values for the slots.

Details

This function is called by grid.edit and editGrob. A method should be written for classes derived from grob or gTree if a change in a slot has an effect on other slots in the grob or children of a gTree (e.g., see grid::editDetails.xaxis).

Note that the slot already has the new value.

Value

The function MUST return the modified grob.

Author(s)

Paul Murrell
gEdit

Create and Apply Edit Objects

Description

The functions gEdit and gEditList create objects representing an edit operation (essentially a list of arguments to editGrob).

The functions applyEdit and applyEdits apply one or more edit operations to a graphical object. These functions are most useful for developers creating new graphical functions and objects.

Usage

```
gEdit(...)  
gEditList(...)  
applyEdit(x, edit)  
applyEdits(x, edits)
```

Arguments

```
...  one or more arguments to the editGrob function (for gEdit) or one or more "gEdit" objects (for gEditList).

x    a grob (grid graphical object).

edit a "gEdit" object.

edits either a "gEdit" object or a "gEditList" object.
```

Value

```
gEdit returns an object of class "gEdit".

gEditList returns an object of class "gEditList".

applyEdit and applyEditList return the modified grob.
```

Author(s)

Paul Murrell

See Also

```
grid.edit  
grob  
editGrob
```

Examples

```
grid.rect(gp=gpar(col="red"))  
# same thing, but more verbose
grid.draw(applyEdit(rectGrob(), gEdit(gp=gpar(col="red"))))
```
**gpar**

List the names of grobs on the display list

Description

Returns a character vector containing the names of all top-level grobs on the display list.

Usage

```r
getNames()
```

Value

A character vector.

Author(s)

Paul Murrell

Examples

```r
grid.grill()
getNames()
```

---

**gpar**

Handling Grid Graphical Parameters

Description

gpar() should be used to create a set of graphical parameter settings. It returns an object of class "gpar". This is basically a list of name-value pairs.

get.gpar() can be used to query the current graphical parameter settings.

Usage

```r
gpar(...)  
get.gpar(names = NULL)
```

Arguments

- `...` Any number of named arguments.
- `names` A character vector of valid graphical parameter names.
Details

All grid viewports and (predefined) graphical objects have a slot called gp, which contains a "gp" object. When a viewport is pushed onto the viewport stack and when a graphical object is drawn, the settings in the "gp" object are enforced. In this way, the graphical output is modified by the gp settings until the graphical object has finished drawing, or until the viewport is popped off the viewport stack, or until some other viewport or graphical object is pushed or begins drawing.

The default parameter settings are defined by the ROOT viewport, which takes its settings from the graphics device. These defaults may differ between devices (e.g., the default fill setting is different for a PNG device compared to a PDF device).

Valid parameter names are:

- col: Colour for lines and borders.
- fill: Colour for filling rectangles, polygons, ...
- alpha: Alpha channel for transparency
- lty: Line type
- lwd: Line width
- lex: Multiplier applied to line width
- lineend: Line end style (round, butt, square)
- linejoin: Line join style (round, mitre, bevel)
- linemitre: Line mitre limit (number greater than 1)
- fontsize: The size of text (in points)
- cex: Multiplier applied to fontsize
- fontfamily: The font family
- fontface: The font face (bold, italic, ...)
- lineheight: The height of a line as a multiple of the size of text
- font: Font face (alias for fontface; for backward compatibility)

For more details of many of these, see the help for the corresponding graphical parameter par in base graphics. (This may have a slightly different name, e.g. lend, ljoin, lmitre, family.)

Colours can be specified in one of the forms returned by rgb, as a name (see colors) or as a non-negative integer index into the current palette (with zero being taken as transparent). (Prior to R 3.0.0 negative integer values were allowed and taken as transparent: they are now an error.)

The alpha setting is combined with the alpha channel for individual colours by multiplying (with both alpha settings normalised to the range 0 to 1).

The size of text is fontsize*cex. The size of a line is fontsize*cex*lineheight.

The cex setting is cumulative; if a viewport is pushed with a cex of 0.5 then another viewport is pushed with a cex of 0.5, the effective cex is 0.25.

The alpha and cex settings are also cumulative.

Changes to the fontfamily may be ignored by some devices, but is supported by PostScript, PDF, X11, Windows, and Quartz. The fontfamily may be used to specify one of the Hershey Font families (e.g., HersheySerif) and this specification will be honoured on all devices.

The specification of fontface can be an integer or a string. If an integer, then it follows the R base graphics standard: 1 = plain, 2 = bold, 3 = italic, 4 = bold italic. If a string, then valid values are: "plain", "bold", "italic", "oblique", and "bold.italic". For the special case of the HersheySerif font family, "cyrillic", "cyrillic.oblique", and "EUC" are also available.

All parameter values can be vectors of multiple values. (This will not always make sense – for example, viewports will only take notice of the first parameter value.)
The gamma parameter is defunct since R 2.7.0.

get.gpar() returns all current graphical parameter settings.

Value

An object of class "gpar".

Hershey.

Examples

gp <- get.gpar()
utils::str(gp)
## These *do* nothing but produce a "gpar" object:
gpar(col = "red")
gpar(col = "blue", lty = "solid", lwd = 3, fontsize = 16)
get.gpar(c("col", "lty"))
grid.newpage()
vp <- viewport(w = .8, h = .8, gp = gpar(col="blue"))
grid.draw(gTree(children=List(rectGrob(gp = gpar(col="red"))),
                textGrob(paste("The rect is its own colour (red)",
                         "but this text is the colour",
                         "set by the gTree (green)",
                         sep = "\n"))),
    gp = gpar(col="green"), vp = vp))
grid.text("This text is the colour set by the viewport (blue)",
    y = 1, just = c("center", "bottom"),
    gp = gpar(fontsize=20), vp = vp)
grid.newpage()
## example with multiple values for a parameter
pushViewport(viewport())
grid.points(1:10/11, 1:10/11, gp = gpar(col=1:10))
popViewport()

---

gPath

Concatenate Grob Names

Description

This function can be used to generate a grob path for use in grid.edit and friends.

A grob path is a list of nested grob names.

Usage

gPath(...)
Grid Graphics

Description
General information about the grid graphics package.

Details
Grid graphics provides an alternative to the standard R graphics. The user is able to define arbitrary rectangular regions (called viewports) on the graphics device and define a number of coordinate systems for each region. Drawing can be specified to occur in any viewport using any of the available coordinate systems.

Grid graphics and standard R graphics do not mix!
Type `library(help = grid)` to see a list of (public) Grid graphics functions.

Author(s)
Paul Murrell

See Also
`viewport`, `grid.layout`, and `unit`.

Arguments
... Character values which are grob names.

Details
Grob names must only be unique amongst grobs which share the same parent in a gTree.

This function can be used to generate a specification for a grob that includes the grob’s parent’s name (and the name of its parent and so on).

For interactive use, it is possible to directly specify a path, but it is strongly recommended that this function is used otherwise in case the path separator is changed in future versions of grid.

Value
A `gPath` object.

See Also

Grid Viewports

Examples

```r
## Diagram of a simple layout
grid.show.layout(grid.layout(4,2,
    heights=unit(rep(1, 4),
       c("lines", "lines", "lines", "null")),
    widths=unit(c(1, 1), "inches")))

## Diagram of a sample viewport
grid.show.viewport(viewport(x=0.6, y=0.6,
                              w=unit(1, "inches"), h=unit(1, "inches")))

## A flash plotting example
grid.multipanel(vp=viewport(c(0.5, 0.5, 0.8, 0.8)))
```

Description

These functions create viewports, which describe rectangular regions on a graphics device and define a number of coordinate systems within those regions.

Usage

```r
viewport(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
    width = unit(1, "npc"), height = unit(1, "npc"),
    default.units = "npc", just = "centre",
    gp = gpar(), clip = "inherit",
    xscale = c(0, 1), yscale = c(0, 1),
    angle = 0,
    layout = NULL,
    layout.pos.row = NULL, layout.pos.col = NULL,
    name = NULL)
```

Arguments

- `x` A numeric vector or unit object specifying x-location.
- `y` A numeric vector or unit object specifying y-location.
- `width` A numeric vector or unit object specifying width.
- `height` A numeric vector or unit object specifying height.
- `default.units` A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
- `just` A string or numeric vector specifying the justification of the viewport relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment.
- `gp` An object of class `gpar`, typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
One of "on", "inherit", or "off", indicating whether to clip to the extent of this viewport, inherit the clipping region from the parent viewport, or turn clipping off altogether. For back-compatibility, a logical value of TRUE corresponds to "on" and FALSE corresponds to "inherit".

A numeric vector of length two indicating the minimum and maximum on the x-scale.

yscale
A numeric vector of length two indicating the minimum and maximum on the y-scale.

A numeric value indicating the angle of rotation of the viewport. Positive values indicate the amount of rotation, in degrees, anticlockwise from the positive x-axis.

A Grid layout object which splits the viewport into subregions.

A numeric vector giving the rows occupied by this viewport in its parent’s layout.

A numeric vector giving the columns occupied by this viewport in its parent’s layout.

A character value to uniquely identify the viewport once it has been pushed onto the viewport tree.

Any number of grid viewport objects.

A vpList object.

The location and size of a viewport are relative to the coordinate systems defined by the viewport’s parent (either a graphical device or another viewport). The location and size can be specified in a very flexible way by specifying them with unit objects. When specifying the location of a viewport, specifying both layout.pos.row and layout.pos.col as NULL indicates that the viewport ignores its parent’s layout and specifies its own location and size (via its locn). If only one of layout.pos.row and layout.pos.col is NULL, this means occupy ALL of the appropriate row(s)/column(s). For example, layout.pos.row = 1 and layout.pos.col = NULL means occupy all of row 1. Specifying non-NULL values for both layout.pos.row and layout.pos.col means occupy the intersection of the appropriate rows and columns. If a vector of length two is specified for layout.pos.row or layout.pos.col, this indicates a range of rows or columns to occupy. For example, layout.pos.row = c(1, 3) and layout.pos.col = c(2, 4) means occupy cells in the intersection of rows 1, 2, and 3, and columns, 2, 3, and 4.

Clipping obeys only the most recent viewport clip setting. For example, if you clip to viewport1, then clip to viewport2, the clipping region is determined wholly by viewport2, the size and shape of viewport1 is irrelevant (until viewport2 is popped of course).

If a viewport is rotated (because of its own angle setting or because it is within another viewport which is rotated) then the clip flag is ignored.

Viewport names need not be unique. When pushed, viewports sharing the same parent must have unique names, which means that if you push a viewport with the same name as an existing viewport, the existing viewport will be replaced in the viewport tree. A viewport name can be any string, but grid uses the reserved name "ROOT" for the top-level viewport. Also, when specifying a viewport name in downViewport and seekViewport, it is possible to provide a viewport path, which consists of several names concatenated using the separator (currently ::). Consequently, it is not advisable to use this separator in viewport names.

The viewports in a vpList are pushed in parallel. The viewports in a vpStack are pushed in series. When a vpTree is pushed, the parent is pushed first, then the children are pushed in parallel.
Value

An R object of class `viewport`.

    just=c("left", "top"),
    gp=gpar(fontsize=8))
}
```

grid.add  Add a Grid Graphical Object

**Description**

Add a grob to a gTree or a descendant of a gTree.

**Usage**

```r
grid.add(gPath, child, strict = FALSE, grep = FALSE,
global = FALSE, allDevices = FALSE, redraw = TRUE)
```

```r
addGrob(gTree, child, gPath = NULL, strict = FALSE, grep = FALSE,
global = FALSE, warn = TRUE)
```

```r
setChildren(x, children)
```

**Arguments**

- `gTree, x`  A gTree object.
- `gPath`  A gPath object. For grid.add this specifies a gTree on the display list. For addGrob this specifies a descendant of the specified gTree.
- `child`  A grob object.
- `children`  A gList object.
- `strict`  A boolean indicating whether the gPath must be matched exactly.
- `grep`  A boolean indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE) means that every odd element of the gPath will be treated as a regular expression).
- `global`  A boolean indicating whether the function should affect just the first match of the gPath, or whether all matches should be affected.
- `warn`  A logical to indicate whether failing to find the specified gPath should trigger an error.
- `allDevices`  A boolean indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.
- `redraw`  A logical value to indicate whether to redraw the grob.
grid.arrows

Details

addGrob copies the specified grob and returns a modified grob.

grid.add destructively modifies a grob on the display list. If redraw is TRUE it then redraws everything to reflect the change.

setChildren is a basic function for setting all children of a gTree at once (instead of repeated calls to addGrob).

Value

addGrob returns a grob object; grid.add returns NULL.

grob, getGrob, addGrob, removeGrob.

grid.arrows

Draw Arrows

Description

Functions to create and draw arrows at either end of a line, or at either end of a line.to, lines, or segments grob.

These functions have been deprecated in favour of arrow arguments to the line-related primitives.

Usage

grid.arrows(x = c(0.25, 0.75), y = 0.5, default.units = "npc",
           grob = NULL,
           angle = 30, length = unit(0.25, "inches"),
           ends = "last", type = "open", name = NULL,
           gp = gpar(), draw = TRUE, vp = NULL)

arrowsGrob(x = c(0.25, 0.75), y = 0.5, default.units = "npc",
           grob = NULL,
           angle = 30, length = unit(0.25, "inches"),
           ends = "last", type = "open", name = NULL,
           gp = gpar(), vp = NULL)

Arguments

x A numeric vector or unit object specifying x-values.
y A numeric vector or unit object specifying y-values.
default.units A string indicating the default units to use if x or y are only given as numeric vectors.
grob A grob to add arrows to; currently can only be a line.to, lines, or segments grob.
angle
A numeric specifying (half) the width of the arrow head (in degrees).

length
A unit object specifying the length of the arrow head.

ends
One of "first", "last", or "both", indicating which end of the line to add arrow heads.

type
Either "open" or "closed" to indicate the type of arrow head.

name
A character identifier.

gp
An object of class gpar, typically the output from a call to the function gpar.
This is basically a list of graphical parameter settings.

draw
A logical value indicating whether graphics output should be produced.

vp
A Grid viewport object (or NULL).

Details
Both functions create an arrows grob (a graphical object describing arrows), but only grid.arrows() draws the arrows (and then only if draw is TRUE).

If the grob argument is specified, this overrides any x and/or y arguments.

Value
An arrows grob. grid.arrows() returns the value invisibly.

    layout.pos.row=1))
grid.rect(gp=gpar(col="grey"))
grid.arrows(x=unit(0:80/100, "npc"),
Draw a Bezier Curve

Description

These functions create and draw Bezier Curves (a curve drawn relative to 4 control points).
Usage

```r
grid.bezier(...)  
bezierGrob(x = c(0, 0.5, 1, 0.5), y = c(0.5, 1, 0.5, 0),  
           id = NULL, id.lengths = NULL,  
           default.units = "npc", arrow = NULL,  
           name = NULL, gp = gpar(), vp = NULL)
```

Arguments

- `x` A numeric vector or unit object specifying x-locations of spline control points.
- `y` A numeric vector or unit object specifying y-locations of spline control points.
- `id` A numeric vector used to separate locations in `x` and `y` into multiple beziers. All locations with the same `id` belong to the same bezier.
- `id.lengths` A numeric vector used to separate locations in `x` and `y` into multiple beziers. Specifies consecutive blocks of locations which make up separate beziers.
- `default.units` A string indicating the default units to use if `x` or `y` are only given as numeric vectors.
- `arrow` A list describing arrow heads to place at either end of the bezier, as produced by the `arrow` function.
- `name` A character identifier.
- `gp` An object of class `gpar`, typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- `vp` A Grid viewport object (or NULL).
- `...` Arguments to be passed to `bezierGrob`.

Details

Both functions create a beziergrob (a graphical object describing a Bezier curve), but only `grid.bezier` draws the Bezier curve.

A Bezier curve is a line drawn relative to 4 control points.

Missing values are not allowed for `x` and `y` (i.e., it is not valid for a control point to be missing).

The curve is currently drawn using an approximation based on X-splines.

Value

A grob object.

See Also

- `Grid`, `viewport`, `arrow`
- `grid.xspline`

Examples

```r
x <- c(0.2, 0.2, 0.4, 0.4)  
y <- c(0.2, 0.4, 0.4, 0.2)

grid.newpage()  
grid.bezier(x, y)
```
grid.cap

Capture a raster image

Description

Capture the current contents of a graphics device as a raster (bitmap) image.

Usage

grid.cap()

Details

This function is only implemented for on-screen graphics devices.

Value

A matrix of R colour names.

Author(s)

Paul Murrell

See Also

grid.raster
dev.capabilities to see if it is supported.

Examples

```r
grid.bezier(c(x, x + .4), c(y + .4, y + .4),
            id=rep(1:2, each=4))
grid.segments(.4, .6, .6, .6)
grid.bezier(x, y,
            gp=gpar(lwd=3, fill="black"),
            arrow=arrow(type="closed"),
            vp=viewport(x=.9))
```

```r
caption <- grid.cap()
caption <- dev.capabilities()
grid.raster(caption, width=.5, height=.5, interpolate=FALSE)
```

## End(Not run)
**grid.circle**

**Draw a Circle**

**Description**

Functions to create and draw a circle.

**Usage**

```r
grid.circle(x=0.5, y=0.5, r=0.5, default.units="npc", name=NULL, gp=gpar(), draw=TRUE, vp=NULL)
circleGrob(x=0.5, y=0.5, r=0.5, default.units="npc", name=NULL, gp=gpar(), vp=NULL)
```

**Arguments**

- `x`: A numeric vector or unit object specifying x-locations.
- `y`: A numeric vector or unit object specifying y-locations.
- `r`: A numeric vector or unit object specifying radii.
- `default.units`: A string indicating the default units to use if `x`, `y`, `width`, or `height` are only given as numeric vectors.
- `name`: A character identifier.
- `gp`: An object of class `gpar`, typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- `draw`: A logical value indicating whether graphics output should be produced.
- `vp`: A Grid viewport object (or NULL).

**Details**

Both functions create a circle grob (a graphical object describing a circle), but only `grid.circle()` draws the circle (and then only if `draw` is TRUE).

The radius may be given in any units; if the units are relative (e.g., "npc" or "native") then the radius will be different depending on whether it is interpreted as a width or as a height. In such cases, the smaller of these two values will be the result. To see the effect, type `grid.circle()` and adjust the size of the window.

What happens for very small radii is device-dependent: the circle may become invisible or be shown at a fixed minimum size. As from R 2.15.0, circles of zero radius will not be plotted.

**Value**

A circle grob. `grid.circle()` returns the value invisibly.

**Warning**

Negative values for the radius are silently converted to their absolute value.

**Author(s)**

Paul Murrell
grid.clip

Set the Clipping Region

Description

These functions set the clipping region within the current viewport without altering the current coordinate system.

Usage

grid.clip(...)
clipGrob(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
width = unit(1, "npc"), height = unit(1, "npc"),
just = "centre", hjust = NULL, vjust = NULL,
default.units = "npc", name = NULL, vp = NULL)

Arguments

x
A numeric vector or unit object specifying x-location.
y
A numeric vector or unit object specifying y-location.
width
A numeric vector or unit object specifying width.
height
A numeric vector or unit object specifying height.
just
The justification of the clip rectangle relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment.
hjust
A numeric vector specifying horizontal justification. If specified, overrides the just setting.
vjust
A numeric vector specifying vertical justification. If specified, overrides the just setting.
default.units
A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
name
A character identifier.
vp
A Grid viewport object (or NULL).
...
Arguments passed to clipGrob.

Details

Both functions create a clip rectangle (a graphical object describing a clip rectangle), but only grid.clip enforces the clipping.

Pushing or popping a viewport always overrides the clip region set by a clip grob, regardless of whether that viewport explicitly enforces a clipping region.
Value

clipGrob returns a clip grob.

Author(s)

Paul Murrell

See Also

Grid, viewport

Examples

# draw across entire viewport, but clipped
grid.clip(x = 0.3, width = 0.1)
grid.lines(gp=gpar(col="green", lwd=5))
# draw across entire viewport, but clipped (in different place)
grid.clip(x = 0.7, width = 0.1)
grid.lines(gp=gpar(col="red", lwd=5))
# Viewport sets new clip region
pushViewport(viewport(width=0.5, height=0.5, clip=TRUE))
grid.lines(gp=gpar(col="grey", lwd=3))
# Return to original viewport; get
# clip region from previous grid.clip()
# (NOT from previous viewport clip region)
popViewport()
grid.lines(gp=gpar(col="black"))
Value

A collection grob.

Author(s)

Paul Murrell

grid.grob.

grid.convert  Convert Between Different grid Coordinate Systems

Description

These functions take a unit object and convert it to an equivalent unit object in a different coordinate system.

Usage

convertX(x, unitTo, valueOnly = FALSE)
convertY(x, unitTo, valueOnly = FALSE)
convertWidth(x, unitTo, valueOnly = FALSE)
convertHeight(x, unitTo, valueOnly = FALSE)
convertUnit(x, unitTo,
  axisFrom = "x", typeFrom = "location",
  axisTo = axisFrom, typeTo = typeFrom,
  valueOnly = FALSE)
grid.convertX(x, unitTo, valueOnly = FALSE)
grid.convertY(x, unitTo, valueOnly = FALSE)
grid.convertWidth(x, unitTo, valueOnly = FALSE)
grid.convertHeight(x, unitTo, valueOnly = FALSE)
grid.convert(x, unitTo,
  axisFrom = "x", typeFrom = "location",
  axisTo = axisFrom, typeTo = typeFrom,
  valueOnly = FALSE)

Arguments

x  A unit object.
unitTo The coordinate system to convert the unit to. See the unit function for valid coordinate systems.
axisFrom Either "x" or "y" to indicate whether the unit object represents a value in the x- or y-direction.
typeFrom Either "location" or "dimension" to indicate whether the unit object represents a location or a length.
axisTo Same as axisFrom, but applies to the unit object that is to be created.
typeTo Same as typeFrom, but applies to the unit object that is to be created.
valueOnly A logical indicating. If TRUE then the function does not return a unit object, but rather only the converted numeric values.
Details

The `convertUnit` function allows for general-purpose conversions. The other four functions are just more convenient front-ends to it for the most common conversions.

The conversions occur within the current viewport.

It is not currently possible to convert to all valid coordinate systems (e.g., "strwidth" or "grob-width"). I'm not sure if all of these are impossible, they just seem implausible at this stage.

In normal usage of grid, these functions should not be necessary. If you want to express a location or dimension in inches rather than user coordinates then you should simply do something like `unit(1, "inches")` rather than something like `unit(0.134, "native")`.

In some cases, however, it is necessary for the user to perform calculations on a unit value and this function becomes necessary. In such cases, please take note of the warning below.

The grid.* versions are just previous incarnations which have been deprecated.

Value

A unit object in the specified coordinate system (unless `valueOnly` is `TRUE` in which case the returned value is a numeric).

Warning

The conversion is only valid for the current device size. If the device is resized then at least some conversions will become invalid. For example, suppose that I create a unit object as follows:

```r
oneinch <- convertUnit(unit(1, "inches"), "native")
```

Now if I resize the device, the unit object in `oneinch` no longer corresponds to a physical length of 1 inch.

`unit`

Examples

```r
## A tautology
convertX(unit(), "inches", "inches")
## The physical units
convertX(unit(2.54, "cm", "inches")
convertX(unit(25.4, "mm", "inches")
convertX(unit(72.27, "points", "inches")
convertX(unit(1/12*72.27, "picas", "inches")
convertX(unit(72, "bigpts", "inches")
convertX(unit(1157/1238*72.27, "dida", "inches")
convertX(unit(1/12*1157/1238*72.27, "cicero", "inches")
convertX(unit(65536/72.27, "scaledpts", "inches")
convertX(unit(1/2.54, "inches", "cm")
convertX(unit(1/25.4, "inches", "mm")
convertX(unit(1/72.27, "inches", "points")
convertX(unit(1/12*72.27, "inches", "picas")
convertX(unit(1/72, "inches", "bigpts")
convertX(unit(1157/1238*72.27, "inches", "dida")
convertX(unit(1/12*1157/1238*72.27, "inches", "cicero")
```
grid.copy

Make a Copy of a Grid Graphical Object

Description

This function is redundant and will disappear in future versions.

Usage

grid.copy(grob)

Arguments

grob A grob object.

Value

A copy of the grob object.

Author(s)

Paul Murrell

See Also

grid.grob.
**grid.curve**  

**Draw a Curve Between Locations**

**Description**

These functions create and draw a curve from one location to another.

**Usage**

```r
grid.curve(...)  
curveGrob(x1, y1, x2, y2, default.units = "npc",  
  curvature = 1, angle = 90, ncp = 1, shape = 0.5,  
  square = TRUE, squareShape = 1,  
  inflect = FALSE, arrow = NULL, open = TRUE,  
  debug = FALSE,  
  name = NULL, gp = gpar(), vp = NULL)  
arccurvature(theta)
```

**Arguments**

- **x1**: A numeric vector or unit object specifying the x-location of the start point.
- **y1**: A numeric vector or unit object specifying the y-location of the start point.
- **x2**: A numeric vector or unit object specifying the x-location of the end point.
- **y2**: A numeric vector or unit object specifying the y-location of the end point.
- **default.units**: A string indicating the default units to use if `x1`, `y1`, `x2` or `y2` are only given as numeric values.
- **curvature**: A numeric value giving the amount of curvature. Negative values produce left-hand curves, positive values produce right-hand curves, and zero produces a straight line.
- **angle**: A numeric value between 0 and 180, giving an amount to skew the control points of the curve. Values less than 90 skew the curve towards the start point and values greater than 90 skew the curve towards the end point.
- **ncp**: The number of control points used to draw the curve. More control points creates a smoother curve.
- **shape**: A numeric vector of values between -1 and 1, which control the shape of the curve relative to its control points. See `grid.xspline` for more details.
- **square**: A logical value that controls whether control points for the curve are created city-block fashion or obliquely. When `ncp` is 1 and `angle` is 90, this is typically `TRUE`, otherwise this should probably be set to `FALSE` (see Examples below).
- **squareShape**: A shape value to control the behaviour of the curve relative to any additional control point that is inserted if `square` is `TRUE`.
- **inflect**: A logical value specifying whether the curve should be cut in half and inverted (see Examples below).
- **arrow**: A list describing arrow heads to place at either end of the curve, as produced by the `arrow` function.
- **open**: A logical value indicating whether to close the curve (connect the start and end points).
debug  A logical value indicating whether debugging information should be drawn.
name   A character identifier.
gp     An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
vp     A Grid viewport object (or NULL).
...    Arguments to be passed to curveGrob.
theta  An angle (in degrees).

Details
Both functions create a curve grob (a graphical object describing an curve), but only grid.curve draws the curve.
The arcCurvature function can be used to calculate a curvature such that control points are generated on an arc corresponding to angle theta. This is typically used in conjunction with a large ncp to produce a curve corresponding to the desired arc.

Value
A grob object.

Examples
```r
curveTest <- function(i, j, ...) {
  pushViewport(viewport(layout.pos.col=j, layout.pos.row=i))
  do.call("grid.curve", c(list(x1=.25, y1=.25, x2=.75, y2=.75), list(...)))
  grid.text(sub("list\{\{.*\}\}\"", "\\\\",
              deparse(substitute(list(...)))),
             y=unit(1, "npc"))
  popViewport()
}
# grid.newpage()
pushViewport(plotViewport(c(0, 0, 1, 0),
                         layout=grid.layout(2, 1, heights=c(2, 1))))
pushViewport(viewport(layout.pos.row=1,
                         layout=grid.layout(3, 3, respect=TRUE)))
curveTest(1, 1)
curveTest(1, 2, inflect=TRUE)
curveTest(1, 3, angle=135)
curveTest(2, 1, arrow=arrow())
curveTest(2, 2, ncp=8)
curveTest(2, 3, shape=0)
curveTest(3, 1, curvature=-1)
curveTest(3, 2, square=FALSE)
curveTest(3, 3, debug=TRUE)
popViewport()
pushViewport(viewport(layout.pos.row=2,
                         layout=grid.layout(3, 3)))
curveTest(1, 1)
curveTest(1, 2, inflect=TRUE)
curveTest(1, 3, angle=135)
```
grid.delay

```
curveTest(2, 1, arrow=arrow())
curveTest(2, 2, ncp=8)
curveTest(2, 3, shape=0)
curveTest(3, 1, curvature=-1)
curveTest(3, 2, square=FALSE)
curveTest(3, 3, debug=TRUE)
popViewport(2)
```

---

**Description**

Evaluates an expression that includes both calculations and generating a grob that depends on the calculations so that both the calculations and the grob generation will be rerun when the scene is redrawn (e.g., device resize or editing).

Intended only for expert use.

**Usage**

```
delayGrob(expr, list, name=NULL, gp=NULL, vp=NULL)
grid.delay(expr, list, name=NULL, gp=NULL, vp=NULL)
```

**Arguments**

- `expr` object of mode `expression` or call or an unevaluated expression.
- `list` a list defining the environment in which `expr` is to be evaluated.
- `name` A character identifier.
- `gp` An object of class `gpar`, typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- `vp` A Grid viewport object (or NULL).

**Details**

A grob is created of special class "delayedgrob" (and drawn, in the case of `grid.delay`). The `makeContent` method for this class evaluates the expression with the list as the evaluation environment (and the grid Namespace as the parent of that environment).

The `expr` argument should return a grob as its result.

These functions are analogues of the `grid.record()` and `recordGrob()` functions; the difference is that these functions are based on the `makeContent()` hook, while those functions are based on the `drawDetails()` hook.

**Note**

This function must be used instead of the function `recordGraphics`; all of the dire warnings about using `recordGraphics` responsibly also apply here.

**Author(s)**

Paul Murrell
grid.display.list

Control the Grid Display List

Description

Turn the Grid display list on or off.

Usage

grid.display.list(on=TRUE)
engine.display.list(on=TRUE)

Arguments

on A logical value to indicate whether the display list should be on or off.

Details

All drawing and viewport-setting operations are (by default) recorded in the Grid display list. This allows redrawing to occur following an editing operation.

This display list could get very large so it may be useful to turn it off in some cases; this will of course disable redrawing.

All graphics output is also recorded on the main display list of the R graphics engine (by default). This supports redrawing following a device resize and allows copying between devices.

Turning off this display list means that grid will redraw from its own display list for device resizes and copies. This will be slower than using the graphics engine display list.

Value

None.

WARNING

Turning the display list on causes the display list to be erased!

Turning off both the grid display list and the graphics engine display list will result in no redrawing whatsoever.

Author(s)

Paul Murrell

Examples

grid.delay(
  w <- convertWidth(unit(1, "inches"), "npc")
  rectGrob(width=w)
  ),
  list())
grid.DLapply  Modify the Grid Display List

Description

Call a function on each element of the current display list and replace the element with the result.

Usage

grid.DLapply(FUN, ...)

Arguments

- **FUN**: A function.
- **...**: Further arguments to pass to `FUN`.

Details

This is an insanely dangerous function (for the grid display list).

Two token efforts are made to try to avoid ending up with complete garbage on the display list:

1. The display list is only replaced once all new elements have been generated (so an error during generation does not result in a half-finished display list).
2. All new elements must be either `NULL` or inherit from the class of the element that they are replacing.

Value

The side effect of this function is to modify the grid display list.

See Also

- Grid.

Examples

```r
grid.newpage()
grid.rect(width=.5, height=.5, gp=gpar(fill="grey"))
grid.DLapply(function(x) { if (is.grob(x)) x$gp <- gpar(); x })
grid.refresh()
```
grid.draw

**Draw a grid grob**

**Description**

Produces graphical output from a graphical object.

**Usage**

```r
grid.draw(x, recording=TRUE)
```

**Arguments**

- `x`: An object of class "grob" or NULL.
- `recording`: A logical value to indicate whether the drawing operation should be recorded on the Grid display list.

**Details**

This is a generic function with methods for grob and gTree objects.

The grob and gTree methods automatically push any viewports in a vp slot and automatically apply any gpar settings in a gp slot. In addition, the gTree method pushes and ups any viewports in a childrenvp slot and automatically calls `grid.draw` for any grobs in a children slot.

The methods for grob and gTree call the generic hook functions `preDrawDetails`, `drawDetails`, and `postDrawDetails` to allow classes derived from grob or gTree to perform additional viewport pushing/popping and produce additional output beyond the default behaviour for grobs and gTrees.

**Value**

None.

**Author(s)**

Paul Murrell

**See Also**

`grob`

**Examples**

```r
grid.newpage()
## Create a graphical object, but don't draw it
l <- linesGrob()
## Draw it
ggrid.draw(l)
```
**grid.edit**  
*Edit the Description of a Grid Graphical Object*

**Description**
Changes the value of one of the slots of a grob and redraws the grob.

**Usage**

\[
grid.edit(gPath, ..., strict = FALSE, grep = FALSE,  
global = FALSE, allDevices = FALSE, redraw = TRUE)  
\]

\[
grid.gedit(..., grep = TRUE, global = TRUE)  
\]

\[
editGrob(grob, gPath = NULL, ..., strict = FALSE, grep = FALSE,  
global = FALSE, warn = TRUE)  
\]

**Arguments**

- **grob**  
  A grob object.

- **...**  
  Zero or more named arguments specifying new slot values.

- **gPath**  
  A gPath object. For `grid.edit` this specifies a grob on the display list. For `editGrob` this specifies a descendant of the specified grob.

- **strict**  
  A boolean indicating whether the gPath must be matched exactly.

- **grep**  
  A boolean indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE) means that every odd element of the gPath will be treated as a regular expression).

- **global**  
  A boolean indicating whether the function should affect just the first match of the gPath, or whether all matches should be affected.

- **warn**  
  A logical to indicate whether failing to find the specified gPath should trigger an error.

- **allDevices**  
  A boolean indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.

- **redraw**  
  A logical value to indicate whether to redraw the grob.

**Details**

`editGrob` copies the specified grob and returns a modified grob.

`grid.edit` destructively modifies a grob on the display list. If `redraw` is TRUE it then redraws everything to reflect the change.

Both functions call `editDetails` to allow a grob to perform custom actions and `validDetails` to check that the modified grob is still coherent.

`grid.gedit` (g for global) is just a convenience wrapper for `grid.edit` with different defaults.

**Value**

`editGrob` returns a grob object; `grid.edit` returns `NULL`.
**grid.force**

**Author(s)**
Paul Murrell

**See Also**
grob, getGrob, addGrob, removeGrob.

**Examples**

```r
grid.newpage()
grid.xaxis(name = "xa", vp = viewport(width=.5, height=.5))
grid.edit("xa", gp = gpar(col="red"))
# won't work because no ticks (at is NULL)
try(grid.edit(gPath("xa", "ticks"), gp = gpar(col="green")))
grid.edit("xa", at = 1:4/5)
# Now it should work
try(grid.edit(gPath("xa", "ticks"), gp = gpar(col="green")))
```

---

**grid.force**

*Force a grob into its components*

**Description**

Some grobs only generate their content to draw at drawing time; this function replaces such grobs with their at-drawing-time content.

**Usage**

```r
grid.force(redraw = TRUE)
grid.revert(redraw = TRUE)
```

**Arguments**

- `redraw` logical value indicating whether to redraw the grid scene after the forcing operation.

**Details**

Some grobs wait until drawing time to generate what content will actually be drawn (an axis, as produced by `grid.xaxis()`, with an at or NULL is a good example because it has to see what viewport it is going to be drawn in before it can decide what tick marks to draw).

The content of such grobs (e.g., the tick marks) are not usually visible to `grid.ls()` or accessible to `grid.edit()`.

The `grid.force()` function replaces a grob with its at-drawing-time contents. For example, an axis will be replaced by a vanilla gTree with lines and text representing the axis tick marks that were actually drawn. This makes the tick marks visible to `grid.ls()` and accessible to `grid.edit()`.

The `grid.revert()` function reverses the effect of `grid.force()`, replacing forced content with the original grob.
Note

These functions only have an effect for grobs that generate their content at drawing time using makeContent() and makeContext() methods (not for grobs that generate their content at drawing time using preDrawDetails() and drawDetails() methods).

grid.frame Create a Frame for Packing Objects

Description

These functions, together with grid.pack, grid.place, packGrob, and placeGrob are part of a GUI-builder-like interface to constructing graphical images. The idea is that you create a frame with this function then use grid.pack or whatever to pack/place objects into the frame.

Usage

grid.frame(layout=NULL, name=NULL, gp=gpar(), vp=NULL, draw=TRUE)
frameGrob(layout=NULL, name=NULL, gp=gpar(), vp=NULL)

Arguments

layout A Grid layout, or NULL. This can be used to initialise the frame with a number of rows and columns, with initial widths and heights, etc.
name A character identifier.
vp An object of class viewport, or NULL.
gp An object of class gpar; typically the output from a call to the function gpar.
draw Should the frame be drawn.

Details

Both functions create a frame grob (a graphical object describing a frame), but only grid.frame() draws the frame (and then only if draw is TRUE). Nothing will actually be drawn, but it will put the frame on the display list, which means that the output will be dynamically updated as objects are packed into the frame. Possibly useful for debugging.
grid.function

**Value**

A frame grob. `grid.frame()` returns the value invisibly.

**Author(s)**

Paul Murrell

**See Also**

`grid.pack`

**Examples**

```r
grid.newpage()
grid.frame(name="gf", draw=TRUE)
ggrid.pack("gf", rectGrob(gp=gpar(fill="grey")), width=unit(1, "null"))
ggrid.pack("gf", textGrob("hi there"), side="right")
```

---

- **grid.function**
  - *Draw a curve representing a function*

**Description**

Draw a curve representing a function.

**Usage**

```r
ggrid.function(...) 
functionGrob(f, n = 101, range = "x", units = "native", 
name = NULL, gp=gpar(), vp = NULL)
```

```r
ggrid.abline(intercept, slope, ...)
```

**Arguments**

- **f**
  - A function that must take a single argument and return a list with two numeric components named `x` and `y`.

- **n**
  - The number values that will be generated as input to the function `f`.

- **range**
  - Either "x", "y", or a numeric vector. See the ‘Details’ section.

- **units**
  - A string indicating the units to use for the `x` and `y` values generated by the function.

- **intercept**
  - Numeric.

- **slope**
  - Numeric.

- **...**
  - Arguments passed to `grid.function()`

- **name**
  - A character identifier.

- **gp**
  - An object of class `gpar`, typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.

- **vp**
  - A Grid viewport object (or NULL).
Details

n values are generated and passed to the function f and a series of lines are drawn through the resulting x and y values.

The generation of the n values depends on the value of range. In the default case, dim is "x", which means that a set of x values are generated covering the range of the current viewport scale in the x-dimension. If dim is "y" then values are generated from the current y-scale instead. If range is a numeric vector, then values are generated from that range.

grid.abline() provides a simple front-end for a straight line parameterized by intercept and slope.

Value

A function grob.

Examples

```r
# abline
# NOTE: in ROOT viewport on screen, (0, 0) at top-left
# and "native" is pixels!
grid.function(function(x) list(x=x, y=0 + 1*x))
# a more "normal" viewport with default normalized "native" coords
grid.newpage()
pushViewport(viewport())
grid.function(function(x) list(x=x, y=0 + 1*x))
# slightly simpler
grid.newpage()
pushViewport(viewport())
grid.abline()
# sine curve
grid.newpage()
pushViewport(viewport(xscale=c(0, 2*pi), yscale=c(-1, 1))))
grid.function(function(x) list(x=x, y=sin(x)))
# constrained sine curve
grid.newpage()
pushViewport(viewport(xscale=c(0, 2*pi), yscale=c(-1, 1))))
grid.function(function(x) list(x=x, y=sin(x)),
range=0:1)
# inverse sine curve
grid.newpage()
pushViewport(viewport(xscale=c(-1, 1), yscale=c(0, 2*pi))))
grid.function(function(y) list(x=sin(y), y=y),
range="y")
# parametric function
grid.newpage()
pushViewport(viewport(xscale=c(-1, 1), yscale=c(-1, 1))))
grid.function(function(t) list(x=cos(t), y=sin(t)),
range=c(0, 9*pi/5))
```
grid.get

Description
Retrieve a grob or a descendant of a grob.

Usage
grid.get(gPath, strict = FALSE, grep = FALSE, global = FALSE, allDevices = FALSE)
grid.get(..., grep = TRUE, global = TRUE)
ggetGrb(gTree, gPath, strict = FALSE, grep = FALSE, global = FALSE)

Arguments
gTree A gTree object.
gPath A gPath object. For grid.get this specifies a grob on the display list. For ggetGrob this specifies a descendant of the specified gTree.
strict A boolean indicating whether the gPath must be matched exactly.
grep A boolean indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE) means that every odd element of the gPath will be treated as a regular expression).
global A boolean indicating whether the function should affect just the first match of the gPath, or whether all matches should be affected.
allDevices A boolean indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.
... Arguments that are passed to grid.get.

Details
grid.gget (g for global) is just a convenience wrapper for grid.get with different defaults.

Value
A grob object.

Examples

```r
grid.xaxis(name="xa")
grid.get("xa")
grid.get(gPath("xa", "ticks"))

grid.draw(gTree(name="gt", children=gList(xaxisGrob(name="axis"))))
grid.get(gPath("gt", "axis", "ticks"))
```

grid.grab  

Grab the current grid output

Description

Creates a gTree object from the current grid display list or from a scene generated by user-specified code.

Usage

```r
grid.grab(warn = 2, wrap = FALSE, ...)
grid.grabExpr(expr, warn = 2, wrap = FALSE, ...)
```

Arguments

- **expr**: An expression to be evaluated. Typically, some calls to grid drawing functions.
- **warn**: An integer specifying the amount of warnings to emit. 0 means no warnings, 1 means warn when it is certain that the grab will not faithfully represent the original scene. 2 means warn if there’s any possibility that the grab will not faithfully represent the original scene.
- **wrap**: A logical indicating how the output should be captured. If TRUE, each non-grob element on the display list is captured by wrapping it in a grob.
- **...**: arguments passed to gTree, for example, a name and/or class for the gTree that is created.

Details

There are four ways to capture grid output as a gTree.

There are two functions for capturing output: use `grid.grab` to capture an existing drawing and `grid.grabExpr` to capture the output from an expression (without drawing anything).

For each of these functions, the output can be captured in two ways. One way tries to be clever and make a gTree with a childrenvp slot containing all viewports on the display list (including those that are popped) and every grob on the display list as a child of the new gTree; each child has a vpPath in the vp slot so that it is drawn in the appropriate viewport. In other words, the gTree contains all elements on the display list, but in a slightly altered form.

The other way, `wrap=TRUE`, is to create a grob for every element on the display list (and make all of those grobs children of the gTree).
The first approach creates a more compact and elegant gTree, which is more flexible to work with, but is not guaranteed to faithfully replicate all possible grid output. The second approach is more brute force, and harder to work with, but should always faithfully replicate the original output.

**Value**

A gTree object.

**See Also**

gTree

**Examples**

```r
pushViewport(viewport(w=.5, h=.5))
grid.rect()
grid.points(stats::runif(10), stats::runif(10))
popViewport()
grab <- grid.grab()
grid.newpage()
grid.draw(grab)
```

---

**grid.grill**

*Draw a Grill*

**Description**

This function draws a grill within a Grid viewport.

**Usage**

```r
grid.grill(h = unit(seq(0.25, 0.75, 0.25), "npc"),
   v = unit(seq(0.25, 0.75, 0.25), "npc"),
   default.units = "npc", gp=gpar(col = "grey"), vp = NULL)
```

**Arguments**

- **h**
  - A numeric vector or unit object indicating the horizontal location of the vertical grill lines.
- **v**
  - A numeric vector or unit object indicating the vertical location of the horizontal grill lines.
- **default.units**
  - A string indicating the default units to use if h or v are only given as numeric vectors.
- **gp**
  - An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
- **vp**
  - A Grid viewport object.

**Value**

None.
grid.grob

Grid, viewport.

grid.grob  Create a Grid Graphical Object

Description

These functions create grid graphical objects.

Usage

grid.grob(list.struct, cl = NULL, draw = TRUE)
grob(..., name = NULL, gp = NULL, vp = NULL, cl = NULL)
gTree(..., name = NULL, gp = NULL, vp = NULL, children = NULL,
        childrenvp = NULL, cl = NULL)
grobTree(..., name = NULL, gp = NULL, vp = NULL,
        childrenvp = NULL, cl = NULL)
childNames(gTree)
gList(...)
is.grob(x)

Arguments

...  For grob and gTree, the named slots describing important features of the graphical object. For gList and grobTree, a series of grob objects.
list.struct  a list (preferably with each element named).
name  a character identifier for the grob. Used to find the grob on the display list and/or as a child of another grob.
children  a "gList" object.
childrenvp  a viewport object (or NULL).
gp  A gpar object. Typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
vp  a viewport object (or NULL).
cl  string giving the class attribute for the list.struct.
draw  logical indicating whether to produce graphical output.
gTree  a "gTree" object.
x  An R object.
Details

These functions can be used to create a basic "grob", "gTree", or "gLst" object, or a new class derived from one of these.

A grid graphical object ("grob") is a description of a graphical item. These basic classes provide default behaviour for validating, drawing, and modifying graphical objects. Both call the function validDetails to check that the object returned is coherent.

A "gTree" can have other grobs as children; when a gTree is drawn, it draws all of its children. Before drawing its children, a gTree pushes its childrenvp slot and then navigates back up (calls upViewport) so that the children can specify their location within the childrenvp via a vpPath.

Grob names need not be unique in general, but all children of a gTree must have different names. A grob name can be any string, though it is not advisable to use the gPath separator (currently ::) in grob names.

The function childNames returns the names of the grobs which are children of a gTree.

All grid primitives (grid.lines, grid.rect, ...) and some higher-level grid components (e.g., grid.xaxis and grid.yaxis) are derived from these classes.

grobTree is just a convenient wrapper for gTree when the only components of the gTree are grobs (so all unnamed arguments become children of the gTree).

grid.grob is deprecated.

Value

An R object of class "grob", a graphical object.

Author(s)

Paul Murrell

See Also

grid.draw, grid.edit, grid.get.

grid.layout Create a Grid Layout

Description

This function returns a Grid layout, which describes a subdivision of a rectangular region.

Usage

grid.layout(nrow = 1, ncol = 1,
    widths = unit(rep(1, ncol), "null"),
    heights = unit(rep(1, nrow), "null"),
    default.units = "null", respect = FALSE,
    just="centre")
Arguments

- **nrow**: An integer describing the number of rows in the layout.
- **ncol**: An integer describing the number of columns in the layout.
- **widths**: A numeric vector or unit object describing the widths of the columns in the layout.
- **heights**: A numeric vector or unit object describing the heights of the rows in the layout.
- **default.units**: A string indicating the default units to use if widths or heights are only given as numeric vectors.
- **respect**: A logical value or a numeric matrix. If a logical, this indicates whether row heights and column widths should respect each other. If a matrix, non-zero values indicate that the corresponding row and column should be respected (see examples below).
- **just**: A string or numeric vector specifying how the layout should be justified if it is not the same size as its parent viewport. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment. NOTE that in this context, "left", for example, means align the left edge of the left-most layout column with the left edge of the parent viewport.

Details

The unit objects given for the `widths` and `heights` of a layout may use a special units that only has meaning for layouts. This is the "null" unit, which indicates what relative fraction of the available width/height the column/row occupies. See the reference for a better description of relative widths and heights in layouts.

Value

A Grid layout object.

WARNING

This function must NOT be confused with the base R graphics function `layout`. In particular, do not use `layout` in combination with Grid graphics. The documentation for `layout` may provide some useful information and this function should behave identically in comparable situations. The `grid.layout` function has added the ability to specify a broader range of units for row heights and column widths, and allows for nested layouts (see `viewport`).

**grid.lines**  
*Draw Lines in a Grid Viewport*

**Description**

These functions create and draw a series of lines.

**Usage**

```r
grid.lines(x = unit(c(0, 1), "npc"),
y = unit(c(0, 1), "npc"),
default.units = "npc",
arrow = NULL, name = NULL,
gp=gpar(), draw = TRUE, vp = NULL)
linesGrob(x = unit(c(0, 1), "npc"),
y = unit(c(0, 1), "npc"),
default.units = "npc",
arrow = NULL, name = NULL,
gp=gpar(), vp = NULL)
grid.polyline(...)
polylineGrob(x = unit(c(0, 1), "npc"),
y = unit(c(0, 1), "npc"),
id=NULL, id:lengths=NULL,
default.units = "npc",
arrow = NULL, name = NULL,
gp=gpar(), vp = NULL)
```
Arguments

- `x`: A numeric vector or unit object specifying x-values.
- `y`: A numeric vector or unit object specifying y-values.
- `default.units`: A string indicating the default units to use if x or y are only given as numeric vectors.
- `arrow`: A list describing arrow heads to place at either end of the line, as produced by the `arrow` function.
- `name`: A character identifier.
- `gp`: An object of class `gpar`, typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- `draw`: A logical value indicating whether graphics output should be produced.
- `vp`: A Grid viewport object (or NULL).
- `id`: A numeric vector used to separate locations in x and y into multiple lines. All locations with the same id belong to the same line.
- `id.lengths`: A numeric vector used to separate locations in x and y into multiple lines. Specifies consecutive blocks of locations which make up separate lines.
- `...`: Arguments passed to `polylineGrob`.

Details

The first two functions create a lines grob (a graphical object describing lines), and `grid.lines` draws the lines (if `draw` is TRUE).

The second two functions create or draw a polyline grob, which is just like a lines grob, except that there can be multiple distinct lines drawn.

Value

A lines grob or a polyline grob. `grid.lines` returns a lines grob invisibly.

`Grid`, `viewport`, `arrow`

Examples

```r
grid.lines()
# Using id (NOTE: locations are not in consecutive blocks)
grid.newpage()
grid.polyline(x=c((0:4)/10, rep(.5, 5), (10:6)/10, rep(.5, 5)),
             y=c(rep(.5, 5), (10:6)/10, rep(.5, 5), (0:4)/10),
             id=rep(1:5, 4),
             gp=gpar(col=1:5, lwd=3))
# Using id.lengths
grid.newpage()
grid.polyline(x=outer(c(0, .5, 1, .5), 5:1/5),
               y=outer(c(.5, 1, .5, 0), 5:1/5),
               id.lengths=rep(4, 5),
               gp=gpar(col=1:5, lwd=3))
```
grid.locator

Capture a Mouse Click

Description

Allows the user to click the mouse once within the current graphics device and returns the location of the mouse click within the current viewport, in the specified coordinate system.

Usage

grid.locator(unit = "native")

Arguments

unit

The coordinate system in which to return the location of the mouse click. See the unit function for valid coordinate systems.

Details

This function is modal (like the graphics package function locator) so the command line and graphics drawing is blocked until the use has clicked the mouse in the current device.

Value

A unit object representing the location of the mouse click within the current viewport, in the specified coordinate system.

If the user did not click mouse button 1, the function (invisibly) returns NULL.

Author(s)

Paul Murrell

See Also

viewport, unit, locator in package graphics, and for an application see trellis.focus and panel.identify in package lattice.

Examples

if (interactive()) {
  ## Need to write a more sophisticated unit as.character method
  unittrim <- function(unit) {
    sub("^[0-9]+\.[0-9]+\]$^", \\
      as.character(unit))
  }
  do.click <- function(unit) {
    click.locn <- grid.locator(unit)
    grid.segments(unit.c(click.locn$x, unit(0, "npc")),
                 unit.c(unit(0, "npc"), click.locn$y),
                 click.locn$x, click.locn$y,
                 gp=gpar(lty="dashed", col="grey"))
    grid.points(click.locn$x, click.locn$y, pch=16, size=unit(1, "mm"))
    clickx <- unittrim(click.locn$x)
    clicky <- unittrim(click.locn$y)
grid.ls

List the names of grobs or viewports

Description

Returns a listing of the names of grobs or viewports.
This is a generic function with methods for grobs (including gTrees) and viewports (including vpTrees).

Usage

grid.ls(x=NULL, grobs=TRUE, viewports=FALSE, fullNames=FALSE,
recursive=TRUE, print=TRUE, flatten=TRUE, ...)

nestedListing(x, gindent=" ", vpindent=gindent)
pathListing(x, gvpSep=" |", gAlign=TRUE)
grobPathListing(x, ...)

Arguments

x A grob or viewport or NULL. If NULL, the current grid display list is listed.
For print functions, this should be the result of a call to grid.ls.
grobs A logical value indicating whether to list grobs.
viewports A logical value indicating whether to list viewports.
fullNames A logical value indicating whether to embellish object names with information
about the object type.
recursive A logical value indicating whether recursive structures should also list their children.
print A logical indicating whether to print the listing or a function that will print the
listing.
flatten A logical value indicating whether to flatten the listing. Otherwise a more complex
hierarchical object is produced.
gindent The indent used to show nesting in the output for grobs.
vpindent The indent used to show nesting in the output for viewports.
gvpSep The string used to separate viewport paths from grob paths.
gAlign Logical indicating whether to align the left hand edge of all grob paths.
... Arguments passed to the print function.
Details

If the argument x is NULL, the current contents of the grid display list are listed (both viewports and
grobs). In other words, all objects representing the current scene are listed.
Otherwise, x should be a grob or a viewport.

The default behaviour of this function is to print information about the grobs in the current scene.
It is also possible to add information about the viewports in the scene. By default, the listing is
recursive, so all children of gTrees and all nested viewports are reported.

The format of the information can be controlled via the print argument, which can be given a
function to perform the formatting. The nestedListing function produces a line per grob or view-
port, with indenting used to show nesting. The pathListing function produces a line per grob or
viewport, with viewport paths and grob paths used to show nesting. The grobPathListing is a
simple derivation that only shows lines for grobs. The user can define new functions.

Value

The result of this function is either a "gridFlatListing" object (if flatten is TRUE) or a
"gridListing" object.
The former is a simple (flat) list of vectors. This is convenient, for example, for working program-
matically with the list of grob and viewport names, or for writing a new display function for the
listing.
The latter is a more complex hierarchical object (list of lists), but it does contain more detailed
information so may be of use for more advanced customisations.

grob viewport

Examples

# A gTree, called "parent", with children gp (vp2 within vp1)
# and child grob, called "child", with vp vpPath (down to vp2)
sampleGTree <- gTree(name="parent",
    children=gList(grob(name="child", vp="vp1::vp2")),
  childrenvp=vpTree(parent=viewport(name="vp"),
    children=vpList(viewport(name="vp2"))))
grid.ls(sampleGTree)
# Show viewports too
grid.ls(sampleGTree, view=TRUE)
# Only show viewports
grid.ls(sampleGTree, view=TRUE, grob=FALSE)
# Alternate displays
# nested listing, custom indent
grid.ls(sampleGTree, view=TRUE, print=nestedListing, gindent="\"")
# path listing
grid.ls(sampleGTree, view=TRUE, print=pathListing)
# path listing, without grobs aligned
grid.ls(sampleGTree, view=TRUE, print=pathListing, gAlign=FALSE)
# grob path listing
grid.ls(sampleGTree, view=TRUE, print=grobPathListing)
grid.move.to

# path listing, grobs only
grid.ls(sampleGTree, print=pathListing)
# path listing, viewports only
grid.ls(sampleGTree, view=TRUE, grob=FALSE, print=pathListing)
# raw flat listing
str(grid.ls(sampleGTree, view=TRUE, print=FALSE))

grid.move.to  Move or Draw to a Specified Position

Description

Grid has the notion of a current location. These functions sets that location.

Usage

grid.move.to(x = 0, y = 0, default.units = "npc", name = NULL,
           draw = TRUE, vp = NULL)

moveToGrob(x = 0, y = 0, default.units = "npc", name = NULL,
           vp = NULL)

grid.line.to(x = 1, y = 1, default.units = "npc",
             arrow = NULL, name = NULL,
             gp = gpar(), draw = TRUE, vp = NULL)

lineToGrob(x = 1, y = 1, default.units = "npc",
            arrow = NULL,
            name = NULL, gp = gpar(), vp = NULL)

Arguments

x  A numeric value or a unit object specifying an x-value.
y  A numeric value or a unit object specifying a y-value.
default.units A string indicating the default units to use if x or y are only given as numeric values.
arow A list describing arrow heads to place at either end of the line, as produced by the arrow function.
name A character identifier.
draw A logical value indicating whether graphics output should be produced.
gp An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
vp A Grid viewport object (or NULL).

Details

Both functions create a move.to/line.to grob (a graphical object describing a move-to/line-to), but only grid.move.to/line.to() draws the move.to/line.to (and then only if draw is TRUE).

Value

A move.to/line.to grob. grid.move.to/line.to() returns the value invisibly.
grid.newpage

Move to a New Page on a Grid Device

Description

This function erases the current device or moves to a new page.

Usage

grid.newpage(recording = TRUE)

Arguments

recording A logical value to indicate whether the new-page operation should be saved onto the Grid display list.

Details

The new page is painted with the fill colour (gpar("fill")), which is often transparent. For devices with a canvas colour (the on-screen devices X11, windows and quartz), the page is first painted with the canvas colour and then the background colour.

There are two hooks called "before.grid.newpage" and "grid.newpage" (see setHook). The latter is used in the testing code to annotate the new page. The hook function(s) are called with no argument. (If the value is a character string, get is called on it from within the grid namespace.)

Value

None.

Author(s)

Paul Murrell
Description

These functions create a NULL graphical object, which has zero width, zero height, and draw nothing. It can be used as a place-holder or as an invisible reference point for other drawing.

Usage

```r
nullGrob(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
  default.units = "npc",
  name = NULL, vp = NULL)
grid.null(...)  
```

Arguments

- `x` A numeric vector or unit object specifying x-location.
- `y` A numeric vector or unit object specifying y-location.
- `default.units` A string indicating the default units to use if `x`, `y`, `width`, or `height` are only given as numeric vectors.
- `name` A character identifier.
- `vp` A Grid viewport object (or NULL).
- `...` Arguments passed to `nullGrob()`.

Value

A null grob.

Author(s)

Paul Murrell

See Also

`Grid`, `viewport`

Examples

```r
grid.newpage()
grid.null(name="ref")
grid.rect(height=grobHeight("ref"))
grid.segments(0, 0, grobX("ref", 0), grobY("ref", 0))
```
grid.pack *Pack an Object within a Frame*

**Description**

This functions, together with `grid.frame` and `frameGrob` are part of a GUI-builder-like interface to constructing graphical images. The idea is that you create a frame with `grid.frame` or `frameGrob` then use this functions to pack objects into the frame.

**Usage**

```r
grid.pack(gPath, grob, redraw = TRUE, side = NULL,
          row = NULL, row.before = NULL, row.after = NULL,
          col = NULL, col.before = NULL, col.after = NULL,
          width = NULL, height = NULL,
          force.width = FALSE, force.height = FALSE, border = NULL,
          dynamic = FALSE)
```

```r
packGrob(frame, grob, side = NULL,
          row = NULL, row.before = NULL, row.after = NULL,
          col = NULL, col.before = NULL, col.after = NULL,
          width = NULL, height = NULL,
          force.width = FALSE, force.height = FALSE, border = NULL,
          dynamic = FALSE)
```

**Arguments**

- **gPath**: A `gPath` object, which specifies a frame on the display list.
- **frame**: An object of class `frame`, typically the output from a call to `grid.frame`.
- **grob**: An object of class `grob`. The object to be packed.
- **redraw**: A boolean indicating whether the output should be updated.
- **side**: One of “left”, “top”, “right”, “bottom” to indicate which side to pack the object on.
- **row**: Which row to add the object to. Must be between 1 and the-number-of-rows-currently-in-the-frame + 1, or `NULL` in which case the object occupies all rows.
- **row.before**: Add the object to a new row just before this row.
- **row.after**: Add the object to a new row just after this row.
- **col**: Which col to add the object to. Must be between 1 and the-number-of-cols-currently-in-the-frame + 1, or `NULL` in which case the object occupies all cols.
- **col.before**: Add the object to a new col just before this col.
- **col.after**: Add the object to a new col just after this col.
- **width**: Specifies the width of the column that the object is added to (rather than allowing the width to be taken from the object).
- **height**: Specifies the height of the row that the object is added to (rather than allowing the height to be taken from the object).
- **force.width**: A logical value indicating whether the width of the column that the grob is being packed into should be EITHER the width specified in the call to `grid.pack` OR the maximum of that width and the pre-existing width.
force.height A logical value indicating whether the height of the column that the grob is being packed into should be EITHER the height specified in the call to grid.pack OR the maximum of that height and the pre-existing height.

border A unit object of length 4 indicating the borders around the object.

dynamic If the width/height is taken from the grob being packed, this boolean flag indicates whether the grobwidth/height unit refers directly to the grob, or uses a gPath to the grob. In the latter case, changes to the grob will trigger a recalculation of the width/height.

Details

packGrob modifies the given frame grob and returns the modified frame grob.

grid.pack destructively modifies a frame grob on the display list (and redraws the display list if redraw is TRUE).

These are (meant to be) very flexible functions. There are many different ways to specify where the new object is to be added relative to the objects already in the frame. The function checks that the specification is not self-contradictory.

NOTE that the width/height of the row/col that the object is added to is taken from the object itself unless the width/height is specified.

Value

packGrob returns a frame grob, but grid.pack returns NULL.

Author(s)

Paul Murrell

See Also

grid.frame, grid.place, grid.edit, and gPath.

grid.path Draw a Path

Description

These functions create and draw a path. The final point will automatically be connected to the initial point.

Usage

pathGrob(x, y,
           id=NULL, id.lengths=NULL,
           rule="winding",
           default.units="npc",
           name=NULL, gp=gpar(), vp=NULL)
grid.path(...)
Arguments

x       A numeric vector or unit object specifying x-locations.
y       A numeric vector or unit object specifying y-locations.
id       A numeric vector used to separate locations in x and y into sub-paths. All locations
    with the same id belong to the same sub-path.
id.lengths       A numeric vector used to separate locations in x and y into sub-paths. Specifies
    consecutive blocks of locations which make up separate sub-paths.
rule       A character value specifying the fill rule: either "winding" or "evenodd".
default.units       A string indicating the default units to use if x or y are only given as numeric
    vectors.
nname       A character identifier.
gp       An object of class gpar, typically the output from a call to the function gpar.
    This is basically a list of graphical parameter settings.
vp       A Grid viewport object (or NULL).
...       Arguments passed to pathGrobi() under.

Details

Both functions create a path grob (a graphical object describing a path), but only grid.path draws
the path (and then only if draw is TRUE).
A path is like a polygon except that the former can contain holes, as interpreted by the fill rule;
these fill a region if the path border encircles it an odd or non-zero number of times, respectively.
Not all graphics devices support this function: for example xfig and pictex do not.

Value

A grob object.

Paul Murrell

See Also

Grid, viewport

Examples

pathSample <- function(x, y, rule, gp = gpar()) {
  if (is.na(rule))
    grid.path(x, y, id = rep(1:2, each = 4), gp = gp)
  else
    if (!is.na(rule))
      grid.text(paste("Rule:", rule), y = 0, just = "bottom")
}

pathTriplet <- function(x, y, title) {
  pushViewport(viewport(height = 0.9, layout = grid.layout(1, 3),
                        gp = gpar(cex = .7)))
  grid.rect(y = 1, height = unit(1, "char"), just = "top",
                        ...
grid.place

Place an Object within a Frame

Description

These functions provide a simpler (and faster) alternative to the grid.pack() and packGroeb functions. They can be used to place objects within the existing rows and columns of a frame layout.
They do not provide the ability to add new rows and columns nor do they affect the heights and widths of the rows and columns.

Usage

grid.place(gPath, grob, row = 1, col = 1, redraw = TRUE)
placeGrob(frame, grob, row = NULL, col = NULL)

Arguments

- **gPath**: A gPath object, which specifies a frame on the display list.
- **frame**: An object of class frame, typically the output from a call to grid.frame.
- **grob**: An object of class grob. The object to be placed.
- **row**: Which row to add the object to. Must be between 1 and the-number-of-rows-currently-in-the-frame.
- **col**: Which col to add the object to. Must be between 1 and the-number-of-cols-currently-in-the-frame.
- **redraw**: A boolean indicating whether the output should be updated.

Details

placeGrob modifies the given frame grob and returns the modified frame grob.

grid.place destructively modifies a frame grob on the display list (and redraws the display list if redraw is TRUE).

Value

placeGrob returns a frame grob, but grid.place returns NULL.

grid.frame, grid.pack, grid.edit, and gPath.

Description

This function is just a wrapper for a simple demonstration of how a basic plot and legend can be drawn from scratch using grid.

Usage

grid.plot.and.legend()
grid.points

Author(s)
Paul Murrell

Examples

grid.plot.and.legend()

grid.points          Draw Data Symbols

Description

These functions create and draw data symbols.

Usage

grid.points(x = stats::runif(10),
    y = stats::runif(10),
    pch = 1, size = unit(1, "char"),
    default.units = "native", name = NULL,
    gp = gpar(), draw = TRUE, vp = NULL)
pointsGrob(x = stats::runif(10),
    y = stats::runif(10),
    pch = 1, size = unit(1, "char"),
    default.units = "native", name = NULL,
    gp = gpar(), vp = NULL)

Arguments

x A numeric vector or unit object specifying x-values.
y A numeric vector or unit object specifying y-values.
pch A numeric or character vector indicating what sort of plotting symbol to use. See points for the interpretation of these values.
size A unit object specifying the size of the plotting symbols.
default.units A string indicating the default units to use if x or y are only given as numeric vectors.
name A character identifier.
gp An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
draw A logical value indicating whether graphics output should be produced.
vp A Grid viewport object (or NULL).

Details

Both functions create a points grob (a graphical object describing points), but only grid.points draws the points (and then only if draw is TRUE).
grid.polygon

Value

A points grob. grid.points returns the value invisibly.

Author(s)

Paul Murrell

Grid, viewport

grid.polygon

Draw a Polygon

Description

These functions create and draw a polygon. The final point will automatically be connected to the initial point.

Usage

grid.polygon(x=c(0, 0.5, 1, 0.5), y=c(0.5, 1, 0.5, 0),
          id=NULL, id.lengths=NULL,
          default.units="npc", name=NULL,
          gp=gpar(), draw=TRUE, vp=NULL)
polygonGrob(x=c(0, 0.5, 1, 0.5), y=c(0.5, 1, 0.5, 0),
           id=NULL, id.lengths=NULL,
           default.units="npc", name=NULL,
           gp=gpar(), vp=NULL)

Arguments

x  A numeric vector or unit object specifying x-locations.

y  A numeric vector or unit object specifying y-locations.

id  A numeric vector used to separate locations in x and y into multiple polygons. All locations with the same id belong to the same polygon.

id.lengths  A numeric vector used to separate locations in x and y into multiple polygons. Specifies consecutive blocks of locations which make up separate polygons.

default.units  A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.

name  A character identifier.

gp  An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.

draw  A logical value indicating whether graphics output should be produced.

vp  A Grid viewport object (or NULL).

Details

Both functions create a polygon grob (a graphical object describing a polygon), but only grid.polygon draws the polygon (and then only if draw is TRUE).
**grid.pretty**

**Generate a Sensible Set of Breakpoints**

**Description**

Produces a pretty set of breakpoints within the range given.

**Usage**

```r
grid.pretty(range)
```

**Arguments**

- `range` A numeric vector

**Value**

A numeric vector of breakpoints.

**Author(s)**

Paul Murrell
grid.raster

Render a raster object

Description

Render a raster object (bitmap image) at the given location, size, and orientation.

Usage

grid.raster(image,
            x = unit(0.5, "npc"), y = unit(0.5, "npc"),
            width = NULL, height = NULL,
            just = "centre", hjust = NULL, vjust = NULL,
            interpolate = TRUE, default.units = "npc",
            name = NULL, gp = gpar(), vp = NULL)

rasterGrob(image,
            x = unit(0.5, "npc"), y = unit(0.5, "npc"),
            width = NULL, height = NULL,
            just = "centre", hjust = NULL, vjust = NULL,
            interpolate = TRUE, default.units = "npc",
            name = NULL, gp = gpar(), vp = NULL)

Arguments

image Any R object that can be coerced to a raster object.
x A numeric vector or unit object specifying x-location.
y A numeric vector or unit object specifying y-location.
width A numeric vector or unit object specifying width.
height A numeric vector or unit object specifying height.
just The justification of the rectangle relative to its (x, y) location. If there are two
      values, the first value specifies horizontal justification and the second value
      specifies vertical justification. Possible string values are: "left", "right",
      "centre", "center", "bottom", and "top". For numeric values, 0 means left
      alignment and 1 means right alignment.
hjust A numeric vector specifying horizontal justification. If specified, overrides the
      just setting.
vjust A numeric vector specifying vertical justification. If specified, overrides the
      just setting.
default.units A string indicating the default units to use if x, y, width, or height are only
given as numeric vectors.
name A character identifier.
gp An object of class gpar, typically the output from a call to the function gpar.
    This is basically a list of graphical parameter settings.
vp A Grid viewport object (or NULL).
interpolate A logical value indicating whether to linearly interpolate the image (the alterna-
tive is to use nearest-neighbour interpolation, which gives a more blocky result).
Details

Neither width nor height needs to be specified, in which case, the aspect ratio of the image is preserved. If both width and height are specified, it is likely that the image will be distorted.

Not all graphics devices are capable of rendering raster images and some may not be able to produce rotated images (i.e., if a raster object is rendered within a rotated viewport). See also the comments under rasterImage.

All graphical parameter settings in gp will be ignored, including alpha.

Value

A rastergrob grob.

Author(s)

Paul Murrell

See Also

as.raster.

dev.capabilities to see if it is supported.

Examples

redGradient <- matrix(hcl(0, 80, seq(50, 80, 10)),
                     nrow=4, ncol=5)
# interpolated
grid.newpage()
grid.raster(redGradient)
# blocky
grid.newpage()
grid.raster(redGradient, interpolate=FALSE)
# blocky and stretched
grid.newpage()
grid.raster(redGradient, interpolate=FALSE, height=unit(1, "npc"))
# The same raster drawn several times
grid.newpage()
grid.raster(0, x=1:3/4, y=1:3/4, w=.1, interp=FALSE)

grid.record

Encapsulate calculations and drawing

Description

Evaluates an expression that includes both calculations and drawing that depends on the calculations so that both the calculations and the drawing will be rerun when the scene is redrawn (e.g., device resize or editing).

Intended only for expert use.
Usage

recordGrob(expr, list, name=NULL, gp=NULL, vp=NULL)
grid.record(expr, list, name=NULL, gp=NULL, vp=NULL)

Arguments

expr object of mode expression or call or an unevaluated expression.
list a list defining the environment in which expr is to be evaluated.
name A character identifier.
gp An object of class gpars, typically the output from a call to the function gpars. This is basically a list of graphical parameter settings.
vp A Grid viewport object (or NULL).

Details

A grob is created of special class "recordedGrob" (and drawn, in the case of grid.record). The drawDetails method for this class evaluates the expression with the list as the evaluation environment (and the grid Namespace as the parent of that environment).

Note

This function must be used instead of the function recordGraphics; all of the dire warnings about using recordGraphics responsibly also apply here.

Author(s)

Paul Murrell

recordGraphics

Examples

grid.record({
  w <- convertWidth(unit(1, "inches"), "npc")
  grid.rect(width=w)
},
list())
Usage

```r
grid.rect(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
       width = unit(1, "npc"), height = unit(1, "npc"),
       just = "centre", hjust = NULL, vjust = NULL,
       default.units = "npc", name = NULL,
       gp = gpar(), draw = TRUE, vp = NULL)
```

```r
rectGrob(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
        width = unit(1, "npc"), height = unit(1, "npc"),
        just = "centre", hjust = NULL, vjust = NULL,
        default.units = "npc", name = NULL,
        gp = gpar(), vp = NULL)
```

Arguments

- **x**: A numeric vector or unit object specifying x-location.
- **y**: A numeric vector or unit object specifying y-location.
- **width**: A numeric vector or unit object specifying width.
- **height**: A numeric vector or unit object specifying height.
- **just**: The justification of the rectangle relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment.
- **hjust**: A numeric vector specifying horizontal justification. If specified, overrides the just setting.
- **vjust**: A numeric vector specifying vertical justification. If specified, overrides the just setting.
- **default.units**: A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
- **name**: A character identifier.
- **gp**: An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
- **draw**: A logical value indicating whether graphics output should be produced.
- **vp**: A Grid viewport object (or NULL).

Details

Both functions create a rect grob (a graphical object describing rectangles), but only `grid.rect` draws the rectangles (and then only if `draw` is TRUE).

Value

A rect grob. `grid.rect` returns the value invisibly.

- `Grid`, `viewport`
grid.remove

Remove a Grid Graphical Object

Description
Remove a grob from a gTree or a descendant of a gTree.

Usage
grid.remove(gTree, gPath, warn = TRUE, strict = FALSE, grep = FALSE, global = FALSE, allDevices = FALSE, redraw = TRUE)
ggrid.remove(..., grep = TRUE, global = TRUE)
removeGrob(gTree, gPath, strict = FALSE, grep = FALSE, global = FALSE, warn = TRUE)

Arguments
- gTree A gTree object.
- gPath A gPath object. For grid.remove this specifies a gTree on the display list. For removeGrob this specifies a descendant of the specified gTree.
- strict A boolean indicating whether the gPath must be matched exactly.
- grep A boolean indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE) means that every odd element of the gPath will be treated as a regular expression).
- global A boolean indicating whether the function should affect just the first match of the gPath, or whether all matches should be affected.
- allDevices A boolean indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.
- warn A logical to indicate whether failing to find the specified grob should trigger an error.
- redraw A logical value to indicate whether to redraw the grob.
- ... Arguments that are passed to grid.get.
Details

removeGrob copies the specified grob and returns a modified grob.

grid.remove destructively modifies a grob on the display list. If redraw is TRUE it then redraws everything to reflect the change.

grid.gremove (g for global) is just a convenience wrapper for grid.remove with different defaults.

Value

removeGrob returns a grob object; grid.remove returns NULL.

Author(s)

Paul Murrell

grob, getGrob, removeGrob, removeGrob.

grid.reorder

Reorder the children of a gTree

Description

Change the order in which the children of a gTree get drawn.

Usage

grid.reorder(gPath, order, back=TRUE, grep=FALSE, redraw=TRUE)
reorderGrob(x, order, back=TRUE)

Arguments

gPath  A gPath object specifying a gTree within the current scene.
x      A gTree object to be modified.
order  A character vector or a numeric vector that specifies the new drawing order for the children of the gTree. May not refer to all children of the gTree (see Details).
back   Controls what happens when the order does not specify all children of the gTree (see Details).
grep   Should the gPath be treated as a regular expression?
redraw Should the modified scene be redrawn?
Details

In the simplest case, order specifies a new ordering for all of the children of the gTree. The children may be specified either by name or by existing numerical order.

If the order does not specify all children of the gTree then, by default, the children specified by order are drawn first and then all remaining children are drawn. If back=FALSE then the children not specified in order are drawn first, followed by the specified children. This makes it easy to specify a send-to-back or bring-to-front reordering. The order argument is always in back-to-front order.

It is not possible to reorder the grid display list (the top-level grobs in the current scene) because the display list is a mixture of grobs and viewports (so it is not clear what reordering even means and it would be too easy to end up with a scene that would not draw). If you want to reorder the grid display list, try grid.grab() to create a gTree and then reorder (and redraw) that gTree.

Value

grid.reorder() is called for its side-effect of modifying the current scene. reorderGrob() returns the modified gTree.

Warning

This function may return a gTree that will not draw. For example, a gTree has two children, A and B (in that order), and the width of child B depends on the width of child A (e.g., a box around a piece of text). Switching the order so that B is drawn before A will not allow B to be drawn. If this happens with grid.reorder(), the modification will not be performed. If this happens with reorderGrob() it should be possible simply to restore the original order.

Author(s)

Paul Murrell

Examples

# gTree with two children, "red-rect" and "blue-rect" (in that order)
gt <- gTree(children=glist(  
  rectGrob(gp=gpar(col=NA, fill="red"),  
  width=.8, height=.2, name="red-rect"),  
  rectGrob(gp=gpar(col=NA, fill="blue"),  
  width=.2, height=.8, name="blue-rect")),  
  name="gt")
grid.newpage()
grid.draw(gt)
# Spec entire order as numeric (blue-rect, red-rect)
grid.reorder("gt", 2:1)
# Spec entire order as character
grid.reorder("gt", c("red-rect", "blue-rect"))
# Only spec the one I want behind as character
grid.reorder("gt", "blue-rect")
# Only spec the one I want in front as character
grid.reorder("gt", "blue-rect", back=FALSE)
grid.segments **Draw Line Segments**

Description

These functions create and draw line segments.

Usage

```r
grid.segments(x0 = unit(0, "npc"), y0 = unit(0, "npc"),
              x1 = unit(1, "npc"), y1 = unit(1, "npc"),
              default.units = "npc",
              arrow = NULL,
              name = NULL, gp = gpar(), draw = TRUE, vp = NULL)
segmentsGrob(x0 = unit(0, "npc"), y0 = unit(0, "npc"),
             x1 = unit(1, "npc"), y1 = unit(1, "npc"),
             default.units = "npc",
             arrow = NULL, name = NULL, gp = gpar(), vp = NULL)
```

Arguments

- `x0` Numeric indicating the starting x-values of the line segments.
- `y0` Numeric indicating the starting y-values of the line segments.
- `x1` Numeric indicating the stopping x-values of the line segments.
- `y1` Numeric indicating the stopping y-values of the line segments.
- `default.units` A string.
- `arrow` A list describing arrow heads to place at either end of the line segments, as produced by the `arrow` function.
- `name` A character identifier.
- `gp` An object of class `gpar`.
- `draw` A logical value indicating whether graphics output should be produced.
- `vp` A Grid viewport object (or NULL).

Details

Both functions create a segments grob (a graphical object describing segments), but only `grid.segments` draws the segments (and then only if `draw` is `TRUE`).

Value

A segments grob. `grid.segments` returns the value invisibly.

grid.set  

Set a Grid Graphical Object

Description

Replace a grob or a descendant of a grob.

Usage

grid.set(gPath, newGrob, strict = FALSE, grep = FALSE, redraw = TRUE)

setGrob(gTree, gPath, newGrob, strict = FALSE, grep = FALSE)

Arguments

gTree  
A gTree object.

gPath  
A gPath object. For grid.set this specifies a grob on the display list. For setGrob this specifies a descendant of the specified gTree.

newGrob  
A grob object.

strict  
A boolean indicating whether the gPath must be matched exactly.

grep  
A boolean indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE) means that every odd element of the gPath will be treated as a regular expression).

redraw  
A logical value to indicate whether to redraw the grob.

Details

setGrob copies the specified grob and returns a modified grob.

grid.set destructively replaces a grob on the display list. If redraw is TRUE it then redraws everything to reflect the change.

These functions should not normally be called by the user.

Value

setGrob returns a grob object; grid.set returns NULL.

grid.grob.
grid.show.layout  

**Draw a Diagram of a Grid Layout**

**Description**

This function uses Grid graphics to draw a diagram of a Grid layout.

**Usage**

```r
grid.show.layout(l, newpage=TRUE, bg = "light grey",
    cell.border = "blue", cell.fill = "light blue",
    cell.label = TRUE, label.col = "blue",
    unit.col = "red", vp = NULL)
```

**Arguments**

- `l`  
  A Grid layout object.

- `newpage`  
  A logical value indicating whether to move on to a new page before drawing the diagram.

- `bg`  
  The colour used for the background.

- `cell.border`  
  The colour used to draw the borders of the cells in the layout.

- `cell.fill`  
  The colour used to fill the cells in the layout.

- `cell.label`  
  A logical indicating whether the layout cells should be labelled.

- `label.col`  
  The colour used for layout cell labels.

- `unit.col`  
  The colour used for labelling the widths/heights of columns/rows.

- `vp`  
  A Grid viewport object (or NULL).

**Details**

A viewport is created within `vp` to provide a margin for annotation, and the layout is drawn within that new viewport. The margin is filled with light grey, the new viewport is filled with white and framed with a black border, and the layout regions are filled with light blue and framed with a blue border. The diagram is annotated with the widths and heights (including units) of the columns and rows of the layout using red text. (All colours are defaults and may be customised via function arguments.)

**Value**

None.

**Author(s)**

Paul Murrell

**See Also**

`Grid`, `viewport`, `grid.layout`
Examples

```r
## Diagram of a simple layout
grid.show.layout(grid.layout(4,2,
    heights=unit(rep(1, 4),
        c("lines", "lines", "lines", "null")),
    widths=unit(c(1, 1), "inches")))
```

Description

This function uses Grid graphics to draw a diagram of a Grid viewport.

Usage

```r
grid.show.viewport(v, parent.layout = NULL, newpage = TRUE,
    border.fill="light grey",
    vp.col="blue", vp.fill="light blue",
    scale.col="red",
    vp = NULL)
```

Arguments

- **v**: A Grid viewport object.
- **parent.layout**: A grid layout object. If this is not NULL and the viewport given in `v` has its location specified relative to the layout, then the diagram shows the layout and which cells `v` occupies within the layout.
- **newpage**: A logical value to indicate whether to move to a new page before drawing the diagram.
- **border.fill**: Colour to fill the border margin.
- **vp.col**: Colour for the border of the viewport region.
- **vp.fill**: Colour to fill the viewport region.
- **scale.col**: Colour to draw the viewport axes.
- **vp**: A Grid viewport object (or NULL).

Details

A viewport is created within `vp` to provide a margin for annotation, and the diagram is drawn within that new viewport. By default, the margin is filled with light grey, the new viewport is filled with white and framed with a black border, and the viewport region is filled with light blue and framed with a blue border. The diagram is annotated with the width and height (including units) of the viewport, the (x, y) location of the viewport, and the x- and y-scales of the viewport, using red lines and text.

Value

None.
grid.text

   grid.layout(3, 4))

grid.text

Draw Text

Description
These functions create and draw text and plotmath expressions.

Usage
grid.text(label, x = unit(0.5, "npc"), y = unit(0.5, "npc"),
   just = "centre", hjust = NULL, vjust = NULL, rot = 0,
   check.overlap = FALSE, default.units = "npc",
   name = NULL, gp = gpar(), draw = TRUE, vp = NULL)
textGrob(label, x = unit(0.5, "npc"), y = unit(0.5, "npc"),
   just = "centre", hjust = NULL, vjust = NULL, rot = 0,
   check.overlap = FALSE, default.units = "npc",
   name = NULL, gp = gpar(), vp = NULL)

Arguments
- **label** A character or expression vector. Other objects are coerced by
  as.graphicsAnnot.
- **x** A numeric vector or unit object specifying x-values.
- **y** A numeric vector or unit object specifying y-values.
- **just** The justification of the text relative to its (x, y) location. If there are two values,
  the first value specifies horizontal justification and the second value specifies
  vertical justification. Possible string values are: "left", "right", "centre",
  "center", "bottom", and "top". For numeric values, 0 means left alignment
  and 1 means right alignment.
- **hjust** A numeric vector specifying horizontal justification. If specified, overrides the
  just setting.
- **vjust** A numeric vector specifying vertical justification. If specified, overrides the
  just setting.
- **rot** The angle to rotate the text.
check.overlap
A logical value to indicate whether to check for and omit overlapping text.
default.units
A string indicating the default units to use if x or y are only given as numeric vectors.
name
A character identifier.
gp
An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
draw
A logical value indicating whether graphics output should be produced.
vp
A Grid viewport object (or NULL).

Details
Both functions create a text grob (a graphical object describing text), but only `grid.text` draws the text (and then only if `draw` is TRUE).

If the `label` argument is an expression, the output is formatted as a mathematical annotation, as for base graphics `text`.

Value
A text grob. `grid.text` returns the value invisibly.

Examples
```r
grid.newpage()
x <- stats::runif(20)
y <- stats::runif(20)
rot <- stats::runif(20, 0, 360)
grid.text("SOMETHING NICE AND BIG", x=x, y=y, rot=rot,
          gp=gpar(fontsize=20, col="grey"))
grid.text("SOMETHING NICE AND BIG", x=x, y=y, rot=rot,
          gp=gpar(fontsize=20), check=TRUE)
grid.newpage()
draw.text <- function(just, i, j) {
grid.text("ABCD", x=x[j], y=y[i], just=just)
grid.text(deparse(substitute(just)), x=x[j], y=y[i] + unit(2, "lines"),
          gp=gpar(col="grey", fontsize=8))
}
x <- unit(1:4/5, "npc")
y <- unit(1:4/5, "npc")
grid.grill(h=y, v=x, gp=gpar(col="grey"))
draw.text(c("bottom"), 1, 1)
draw.text(c("left", "bottom"), 2, 1)
draw.text(c("right", "bottom"), 3, 1)
draw.text(c("centre", "bottom"), 4, 1)
draw.text(c("centre"), 1, 2)
draw.text(c("left", "centre"), 2, 2)
draw.text(c("right", "centre"), 3, 2)
```
grid.xaxis

Draw an X-Axis

Description

These functions create and draw an x-axis.

Usage

\[
\text{grid.xaxis(at = NULL, label = TRUE, main = TRUE,}
\]
\[
edits = \text{NULL, name = NULL,}
\]
\[
gp = \text{gpar()}, \text{draw = TRUE, vp = NULL)}
\]
\[
\text{xaxisGrob(at = NULL, label = TRUE, main = TRUE,}
\]
\[
edits = \text{NULL, name = NULL,}
\]
\[
gp = \text{gpar()}, \text{vp = NULL)}
\]

Arguments

- \texttt{at} \quad \text{A numeric vector of x-value locations for the tick marks.}
- \texttt{label} \quad \text{A logical value indicating whether to draw the labels on the tick marks, or an expression or character vector which specify the labels to use. If not logical, must be the same length as the at argument.}
- \texttt{main} \quad \text{A logical value indicating whether to draw the axis at the bottom (TRUE) or at the top (FALSE) of the viewport.}
- \texttt{edits} \quad \text{A gEdit or gEditList containing edit operations to apply (to the children of the axis) when the axis is first created and during redrawing whenever at is NULL.}
- \texttt{name} \quad \text{A character identifier.}
- \texttt{gp} \quad \text{An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.}
- \texttt{draw} \quad \text{A logical value indicating whether graphics output should be produced.}
- \texttt{vp} \quad \text{A Grid viewport object (or NULL).}

Details

Both functions create an xaxis grob (a graphical object describing an xaxis), but only \texttt{grid.xaxis} draws the xaxis (and then only if \texttt{draw} is TRUE).

Value

An xaxis grob. \texttt{grid.xaxis} returns the value invisibly.
grid.xspline

Children

If the at slot of an xaxis grob is not NULL then the xaxis will have the following children:

- **major**: representing the line at the base of the tick marks.
- **ticks**: representing the tick marks.
- **labels**: representing the tick labels.

If the at slot is NULL then there are no children and ticks are drawn based on the current viewport scale.

grid.xspline

**Draw an Xspline**

Description

These functions create and draw an xspline, a curve drawn relative to control points.

Usage

```r
grid.xspline(...)
xsplineGrob(x = c(0, 0.5, 1, 0.5), y = c(0.5, 1, 0.5, 0),
            id = NULL, id.lengths = NULL,
            default.units = "npc",
            shape = 0, open = TRUE, arrow = NULL, repEnds = TRUE,
            name = NULL, gp = gpar(), vp = NULL)
```

Arguments

- **x**: A numeric vector or unit object specifying x-locations of spline control points.
- **y**: A numeric vector or unit object specifying y-locations of spline control points.
- **id**: A numeric vector used to separate locations in x and y into multiple xsplines. All locations with the same id belong to the same xspline.
- **id.lengths**: A numeric vector used to separate locations in x and y into multiple xspline. Specifies consecutive blocks of locations which make up separate xsplines.
- **default.units**: A string indicating the default units to use if x or y are only given as numeric vectors.
- **shape**: A numeric vector of values between -1 and 1, which control the shape of the spline relative to the control points.
- **open**: A logical value indicating whether the spline is a line or a closed shape.
- **arrow**: A list describing arrow heads to place at either end of the xspline, as produced by the `arrow` function.
repEnds  A logical value indicating whether the first and last control points should be replicated for drawing the curve (see Details below).

name    A character identifier.

gp      An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.

vp      A Grid viewport object (or NULL).

...    Arguments to be passed to xsplineGrob.

Details

Both functions create an xspline grob (a graphical object describing an xspline), but only grid.xspline draws the xspline.

An xspline is a line drawn relative to control points. For each control point, the line may pass through (interpolate) the control point or it may only approach (approximate) the control point; the behaviour is determined by a shape parameter for each control point.

If the shape parameter is greater than zero, the spline approximates the control points (and is very similar to a cubic B-spline when the shape is 1). If the shape parameter is less than zero, the spline interpolates the control points (and is very similar to a Catmull-Rom spline when the shape is -1). If the shape parameter is 0, the spline forms a sharp corner at that control point.

For open xsplines, the start and end control points must have a shape of 0 (and non-zero values are silently converted to zero without warning).

For open xsplines, by default the start and end control points are actually replicated before the curve is drawn. A curve is drawn between (interpolating or approximating) the second and third of each set of four control points, so this default behaviour ensures that the resulting curve starts at the first control point you have specified and ends at the last control point. The default behaviour can be turned off via the repEnds argument, in which case the curve that is drawn starts (approximately) at the second control point and ends (approximately) at the first and second-to-last control point.

The repEnds argument is ignored for closed xsplines.

Missing values are not allowed for x and y (i.e., it is not valid for a control point to be missing).

For closed xsplines, a curve is automatically drawn between the final control point and the initial control point.

Value

A grob object.

**grid.yaxis**

**Draw a Y-Axis**

**Description**

These functions create and draw a y-axis.
grid.yaxis

Usage

grid.yaxis(at = NULL, label = TRUE, main = TRUE,
            edits = NULL, name = NULL,
            gp = gpar(), draw = TRUE, vp = NULL)

yaxisGrob(at = NULL, label = TRUE, main = TRUE,
           edits = NULL, name = NULL,
           gp = gpar(), vp = NULL)

Arguments

at                  A numeric vector of y-value locations for the tick marks.
label               A logical value indicating whether to draw the labels on the tick marks, or an expression or character vector which specify the labels to use. If not logical, must be the same length as the at argument.
main                A logical value indicating whether to draw the axis at the left (TRUE) or at the right (FALSE) of the viewport.
edits               A gEdit or gEditList containing edit operations to apply (to the children of the axis) when the axis is first created and during redrawing whenever at is NULL.
name                A character identifier.
gp                  An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
draw                A logical value indicating whether graphics output should be produced.
vp                   A Grid viewport object (or NULL).

Details

Both functions create a yaxis grob (a graphical object describing a yaxis), but only grid.yaxis draws the yaxis (and then only if draw is TRUE).

Value

A yaxis grob. grid.yaxis returns the value invisibly.

Children

If the at slot of an xaxis grob is not NULL then the xaxis will have the following children:

major  representing the line at the base of the tick marks.
ticks  representing the tick marks.
labels representing the tick labels.

If the at slot is NULL then there are no children and ticks are drawn based on the current viewport scale.

grobName  Generate a Name for a Grob

Description
This function generates a unique (within-session) name for a grob, based on the grob’s class.

Usage
\texttt{grobName(grob = NULL, prefix = "GRID")}

Arguments
\begin{itemize}
  \item \texttt{grob} A grob object or NULL.
  \item \texttt{prefix} The prefix part of the name.
\end{itemize}

Value
A character string of the form \texttt{prefix.class(grob).index}

Author(s)
Paul Murrell

---

grobWidth  Create a Unit Describing the Width of a Grob

Description
These functions create a unit object describing the width or height of a grob. They are generic.

Usage
\texttt{grobWidth(x)}
\texttt{grobHeight(x)}
\texttt{grobAscent(x)}
\texttt{grobDescent(x)}

Arguments
\begin{itemize}
  \item \texttt{x} A grob object.
\end{itemize}

Value
A unit object.

unit and stringWidth

---

Create a Unit Describing a Grob Boundary Location

Description

These functions create a unit object describing a location somewhere on the boundary of a grob. They are generic.

Usage

grobX(x, theta)
grobY(x, theta)

Arguments

- **x**: A grob, or gList, or gTree, or gPath.
- **theta**: An angle indicating where the location is on the grob boundary. Can be one of "east", "north", "west", or "south", which correspond to angles 0, 90, 180, and 270, respectively.

Details

The angle is anti-clockwise with zero corresponding to a line with an origin centred between the extreme points of the shape, and pointing at 3 o’clock.

If the grob describes a single shape, the boundary value should correspond to the exact edge of the shape.

If the grob describes multiple shapes, the boundary value will either correspond to the edge of a bounding box around all of the shapes described by the grob (for multiple rectangles, circles, xsplines, or text), or to a convex hull around all vertices of all shapes described by the grob (for multiple polygons, points, lines, polylines, and segments).

Points grobs are currently a special case because the convex hull is based on the data symbol locations and does not take into account the extent of the data symbols themselves.

The extents of any arrow heads are currently *not* taken into account.

Value

A unit object.

Author(s)

Paul Murrell

See Also

unit and grobWidth
Description

These generic hook functions are called whenever a grid grob is drawn. They provide an opportunity for customising the drawing context and drawing content of a new class derived from grob (or gTree).

Usage

makeContext(x)
makeContent(x)

Arguments

x A grid grob.

Details

These functions are called by the grid::draw methods for grobs and gTrees.

makeContext is called first during the drawing of a grob. This function should be used to modify the vp slot of x (and/or the childrenvp slot if x is a gTree). The function must return the modified x. Note that the default behaviour for grobs is to push any viewports in the vp slot, and for gTrees is to also push and up any viewports in the childrenvp slot, so this function is used to customise the drawing context for a grob or gTree.

makeContent is called next and is where any additional calculations should occur and graphical content should be generated (see, for example, grid::makeContent::xaxis. This function should be used to modify the children of a gTree. The function must return the modified x. Note that the default behaviour for gTrees is to draw all grobs in the children slot, so this function is used to customise the drawing content for a gTree. It is also possible to customise the drawing content for a simple grob, but more care needs to be taken; for example, the function should return a standard grid primitive with a drawDetails() method in this case.

Note that these functions should be cumulative in their effects, so that the x returned by makeContent() includes any changes made by makeContext().

Note that makeContext is also called in the calculation of "grobwidth" and "grobheight" units.

Value

Both functions are expected to return a grob or gTree (a modified version of x).

grid::draw
plotViewport  Create a Viewport with a Standard Plot Layout

Description
This is a convenience function for producing a viewport with the common S-style plot layout – i.e., a central plot region surrounded by margins given in terms of a number of lines of text.

Usage
plotViewport(margins=c(5.1, 4.1, 4.1, 2.1), ...)

Arguments
margins       A numeric vector interpreted in the same way as par(mar) in base graphics.
...           All other arguments will be passed to a call to the viewport() function.

Value
A grid viewport object.

Author(s)
Paul Murrell

See Also
viewport and dataViewport.

pop.viewport  Pop a Viewport off the Grid Viewport Stack

Description
Grid maintains a viewport stack — a list of nested drawing contexts. This function makes the parent of the specified viewport the new default viewport.

Usage
pop.viewport(n=1, recording=TRUE)

Arguments
n          An integer giving the number of viewports to pop. Defaults to 1.
recording  A logical value to indicate whether the set-viewport operation should be recorded on the Grid display list.

Value
None.
push.viewport

Warning

This function has been deprecated. Please use `push.viewport` instead.

Author(s)

Paul Murrell

See Also

`push.viewport`.

---

push.viewport  Push a Viewport onto the Grid Viewport Stack

Description

Grid maintains a viewport stack — a list of nested drawing contexts.

This function makes the specified viewport the default viewport and makes its parent the previous default viewport (i.e., nests the specified context within the previous default context).

Usage

`push.viewport(..., recording=TRUE)`

Arguments

- `...` One or more objects of class "viewport", or NULL.
- `recording` A logical value to indicate whether the set-viewport operation should be recorded on the Grid display list.

Value

None.

Warning

This function has been deprecated. Please use `pushViewport` instead.

Author(s)

Paul Murrell

`pop.viewport`. 
Querying the Viewport Tree

Get the Current Grid Viewport (Tree)

Description

current.viewport() returns the viewport that Grid is going to draw into.
current.vpTree returns the entire Grid viewport tree.
current.vpPath returns the viewport path to the current viewport.
current.transform returns the transformation matrix for the current viewport.

Usage

current.viewport(vp=NULL)
current.vpTree(all=TRUE)
current.vpPath()
current.transform()

Arguments

vp A Grid viewport object. Use of this argument has been deprecated.
all A logical value indicating whether the entire viewport tree should be returned.

Details

If all is FALSE then current.vpTree only returns the subtree below the current viewport.

Value

A Grid viewport object from current.viewport or current.vpTree.
current.transform returns a 4x4 transformation matrix.
The viewport path returned by current.vpPath is NULL if the current viewport is the ROOT viewport.

viewport

Examples

grid.newpage()
pushViewport(viewport(width=0.8, height=0.8, name="A"))
pushViewport(viewport(x=0.1, width=0.3, height=0.6,
    just="left", name="B"))
upViewport()  
pushViewport(viewport(x=0.5, width=0.4, height=0.8,
    just="left", name="C"))
pushViewport(viewport(width=0.8, height=0.8, name="D"))
### roundrect

**Description**

Draw a single rectangle with rounded corners.

**Usage**

```r
drawrectGrob(x=0.5, y=0.5, width=1, height=1, 
default.units="npc", 
r=unit(0.1, "npc"), 
just="centre", 
name=NULL, gp=NULL, vp=NULL)
grid.roundrect(...)```

**Arguments**

- `x`, `y`, `width`, `height`
  - The location and size of the rectangle.
- `default.units`
  - A string indicating the default units to use if `x`, `y`, `width`, or `height` are only given as numeric vectors.
- `r`
  - The radius of the rounded corners.
- `just`
  - The justification of the rectangle relative to its location.
- `name`
  - A name to identify the grob.
- `gp`
  - Graphical parameters to apply to the grob.
- `vp`
  - A viewport object or `NULL`.
- `...`
  - Arguments to be passed to `roundrectGrob()`.

**Details**

At present, this function can only be used to draw one rounded rectangle.

**Examples**

```r
grid.roundrect(width=.5, height=.5, name="rr")
theta <- seq(0, 360, length=50)
for (i in 1:50)
  grid.circle(x=grobX("rr", theta[i]),
              y=grobY("rr", theta[i]),
              r=unit(1, "mm"),
              gp=gpar(fill="black"))```
**showGrob**

Label grid grobs.

**Description**

Produces a graphical display of (by default) the current grid scene, with labels showing the names of each grob in the scene. It is also possible to label only specific grobs in the scene.

**Usage**

```
showGrob(x = NULL,
          gPath = NULL, strict = FALSE, grep = FALSE,
          recurse = TRUE, depth = NULL,
          labelfun = grobLabel, ...)
```

**Arguments**

- **x**  
  If NULL, the current grid scene is labelled. Otherwise, a grob (or gTree) to draw and then label.

- **gPath**  
  A path identifying a subset of the current scene or grob to be labelled.

- **strict**  
  Logical indicating whether the gPath is strict.

- **grep**  
  Logical indicating whether the gPath is a regular expression.

- **recurse**  
  Should the children of gTrees also be labelled?

- **depth**  
  Only display grobs at the specified depth (may be a vector of depths).

- **labelfun**  
  Function used to generate a label from each grob.

- **...**  
  Arguments passed to labelfun to control fine details of the generated label.

**Details**

None of the labelling is recorded on the grid display list so the original scene can be reproduced by calling `grid.refresh`.

**See Also**

`grob` and `gTree`

**Examples**

```
grid.newpage()

gt <- gTree(children=vpStack(
    viewport(x=0, width=.5, just="left", name="vp"),
    viewport(y=.5, height=.5, just="bottom", name="vp2")),
    children=gList(rectGrob(vp="vp::vp2", name="child")),
    name="parent")

grid.draw(gt)
showGrob()
showGrob(gPath="child")
showGrob(recurse=FALSE)
showGrob(depth=1)
showGrob(depth=2)
```
showGrob(depth=1:2)
showGrob(gt)
showGrob(gt, gPath="child")
showGrob(just="left", gp=gpar(col="red", cex=.5, rot=45)
showGrob(labelfun=function(grob, ...) {
  x <- grobX(grob, "west")
  y <- grobY(grob, "north")
gTree(children=gList(rectGrob(x=y, y=y, width=stringWidth(grob$name) + unit(2, "mm"),
  height=stringHeight(grob$name) + unit(2, "mm"),
  gp=gpar(col=NA, fill=rgb(1, 0, 0, .5)),
  just=c("left", "top")),
  textGrob(grob$name, x=x + unit(1, "mm"), y=y - unit(1, "mm"),
  just=c("left", "top")))
})

showGrob(gPath="panel-3-3")
showGrob(gPath="axis.title", grep=TRUE)
showGrob(depth=2)

## End(Not run)

---

**showViewport**

*Display grid viewports.*

**Description**

Produces a graphical display of (by default) the current grid viewport tree. It is also possible to display only specific viewports. Each viewport is drawn as a rectangle and the leaf viewports are labelled with the viewport name.

**Usage**

```r
showViewport(vp = NULL, recurse = TRUE, depth = NULL,
  newpage = FALSE, leaves = FALSE,
  col = rgb(0, 0, 1, 0.2), fill = rgb(0, 0, 1, 0.1),
  label = TRUE, nrow = 3, ncol = nrow)
```
Arguments

vp
If NULL, the current viewport tree is displayed. Otherwise, a viewport (or vpList, or vpStack, or vpTree) or a vpPath that specifies which viewport to display.

recurse
Should the children of the specified viewport also be displayed?

depth
Only display viewports at the specified depth (may be a vector of depths).

newpage
Start a new page for the display? Otherwise, the viewports are displayed on top of the current plot.

leaves
Produce a matrix of smaller displays, with each leaf viewport in its own display.

col
The colour used to draw the border of the rectangle for each viewport and to draw the label for each viewport. If a vector, then the first colour is used for the top-level viewport, the second colour is used for its children, the third colour for their children, and so on.

fill
The colour used to fill each viewport. May be a vector as per col.

label
Should the viewports be labelled (with the viewport name)?

nrow, ncol
The number of rows and columns when leaves is TRUE. Otherwise ignored.

showViewport(vpStack(viewport(width=.5, height=.5, name="vp1"),
    viewport(width=.5, height=.5, name="vp2")),
    newpage=TRUE)

showViewport(vpStack(viewport(width=.5, height=.5, name="vp1"),
    viewport(width=.5, height=.5, name="vp2"),
    fill=rgb(1:0, 0:1, 0, .1),
    newpage=TRUE)

stringWidth
Create a Unit Describing the Width and Height of a String or Math Expression

Description

These functions create a unit object describing the width or height of a string.

Usage

stringWidth(string)
stringHeight(string)
stringAscent(string)
stringDescent(string)
Arguments

string A character vector or a language object (as used for 'plotmath' calls.

Value

A unit object.

Author(s)

Paul Murrell

See Also

unit and grobWidth
strwidth in the graphics package for more details of the typographic concepts behind the computations.

unit Function to Create a Unit Object

Description

This function creates a unit object — a vector of unit values. A unit value is typically just a single numeric value with an associated unit.

Usage

unit(x, units, data=NULL)

Arguments

x A numeric vector.
units A character vector specifying the units for the corresponding numeric values.
data This argument is used to supply extra information for special unit types.

Details

Unit objects allow the user to specify locations and dimensions in a large number of different coordinate systems. All drawing occurs relative to a viewport and the units specifies what coordinate system to use within that viewport.

Possible units (coordinate systems) are:

"npc" Normalised Parent Coordinates (the default). The origin of the viewport is (0, 0) and the viewport has a width and height of 1 unit. For example, (0.5, 0.5) is the centre of the viewport.
"cm" Centimetres.
"inches" Inches. 1 in = 2.54 cm.
"mm" Millimetres. 10 mm = 1 cm.
"points" Points. 72.27 pt = 1 in.
"picas" Picas. 1 pc = 12 pt.
"bigpts"  Big Points. 72 bp = 1 in.
"dida"  Dida. 1157 dd = 1238 pt.
"cicero"  Cicero. 1 cc = 12 dd.
"scaledpts"  Scaled Points. 65536 sp = 1 pt.
"lines"  Lines of text. Locations and dimensions are in terms of multiples of the default text size of the viewport (as specified by the viewport's fontsize and lineheight).
"char"  Multiples of nominal font height of the viewport (as specified by the viewport's fontsize).
"native"  Locations and dimensions are relative to the viewport's xscale andyscale.
"snpc"  Square Normalised Parent Coordinates. Same as Normalised Parent Coordinates, except gives the same answer for horizontal and vertical locations/dimensions. It uses the lesser of npc-width and npc-height. This is useful for making things which are a proportion of the viewport, but have to be square (or have a fixed aspect ratio).
"strwidth"  Multiples of the width of the string specified in the data argument. The font size is determined by the pointsize of the viewport.
"strheight"  Multiples of the height of the string specified in the data argument. The font size is determined by the pointsize of the viewport.
"grobwidth"  Multiples of the width of the grob specified in the data argument.
"grobheight"  Multiples of the height of the grob specified in the data argument.

A number of variations are also allowed for the most common units. For example, it is possible to use "in" or "inch" instead of "inches" and "centimetre" or "centimeter" instead of "cm".

A special units value of "null" is also allowed, but only makes sense when used in specifying widths of columns or heights of rows in grid layouts (see grid.layout).

The data argument must be a list when the unit.length() is greater than 1. For example,

```r
unit(rep(1, 3), c("npc", "strwidth", "inches"),
data = list(NULL, "my string", NULL))
```

It is possible to subset unit objects in the normal way (e.g., unit(1:5, "npc")[2:4]), but a special function unit.c is provided for combining unit objects.

Certain arithmetic and summary operations are defined for unit objects. In particular, it is possible to add and subtract unit objects (e.g., unit(1, "npc") - unit(1, "inches")), and to specify the minimum or maximum of a list of unit objects (e.g., min(unit(0.5, "npc"), unit(1, "inches"))).

Value

An object of class "unit".

WARNING

There is a special function unit.c for concatenating several unit objects.

The c function will not give the right answer.

There used to be "mynlines", "mychar", "mystrwidth", "mystrheight" units. These will still be accepted, but work exactly the same as "lines", "char", "strwidth", "strheight".
Author(s)

Paul Murrell

See Also

unit

Examples

unit(1, "npc")
unit(1:3/4, "npc")
unit(1:3/4, "npc") + unit(1, "inches")
min(unit(0.5, "npc"), unit(1, "inches"))
unit.c(unit(0.5, "npc"), unit(2, "inches") + unit(1:3/4, "npc"),
       unit(1, "strwidth", "hi there"))

Description

This function produces a new unit object by combining the unit objects specified as arguments.

Usage

unit.c(...)  

Arguments

...  

An arbitrary number of unit objects.

Value

An object of class unit.

Author(s)

Paul Murrell

See Also

unit.
unit.length  

Length of a Unit Object

Description
The length of a unit object is defined as the number of unit values in the unit object.
This function has been deprecated in favour of a unit method for the generic length function.

Usage
unit.length(unit)

Arguments
unit  A unit object.

Value
An integer value.

Author(s)
Paul Murrell

See Also
unit

Examples

length(unit(1:3, "npc"))
length(unit(1:3, "npc") + unit(1, "inches"))
length(max(unit(1:3, "npc") + unit(1, "inches")))
length(max(unit(1:3, "npc") + unit(1, "strwidth", "a")*4))
length(unit(1:3, "npc") + unit(1, "strwidth", "a")*4)

unit.pmin  

Parallel Unit Minima and Maxima

Description
Returns a unit object whose i’th value is the minimum (or maximum) of the i’th values of the arguments.

Usage
unit.pmin(...)  
unit.pmax(...)
Arguments

... One or more unit objects.

Details

The length of the result is the maximum of the lengths of the arguments; shorter arguments are recycled in the usual manner.

Value

A unit object.

Author(s)

Paul Murrell

Examples

max(unit(1:3, "cm"), unit(0.5, "npc"))
unit.pmax(unit(1:3, "cm"), unit(0.5, "npc"))

Description

Replicates the units according to the values given in `times` and `length.out`.
This function has been deprecated in favour of a unit method for the generic `rep` function.

Usage

unit.rep(x, ...)

Arguments

x An object of class "unit".
... arguments to be passed to `rep` such as `times` and `length.out`.

Value

An object of class "unit".

Author(s)

Paul Murrell

See Also

rep
Examples

```r
rep(unit(1:3, "npc"), 3)
rep(unit(1:3, "npc"), 1:3)
rep(unit(1:3, "npc") + unit(1, "inches"), 3)
rep(max(unit(1:3, "npc") + unit(1, "inches")), 3)
rep(max(unit(1:3, "npc") + unit(1, "strwidth", "a")*4, 3)
rep(unit(1:3, "npc") + unit(1, "strwidth", "a")*4, 3)
```

---

**valid.just**  
*Validate a Justification*

**Description**

This utility function is useful for determining whether a justification specification is valid. An error is given if the justification is not valid.

**Usage**

```r
valid.just(just)
```

**Arguments**

- `just`  
  A justification either as a character value, e.g., "left", or as a numeric value, e.g., 0.

**Details**

This function is useful within a `validDetails` method when writing a new grob class.

**Value**

A numeric representation of the justification (e.g., "left" becomes 0, "right" becomes 1, etc,...).

**Author(s)**

Paul Murrell

---

**validDetails**  
*Customising grid grob Validation*

**Description**

This generic hook function is called whenever a grid grob is created or edited via `grob`, `gTree`, `grid.edit` or `editGrob`. This provides an opportunity for customising the validation of a new class derived from grob (or gTree).

**Usage**

```r
validDetails(x)
```
Arguments

x A grid grob.

Details

This function is called by `grob`, `gTree`, `grid.edit` and `editGrob`. A method should be written for classes derived from `grob` or `gTree` to validate the values of slots specific to the new class. (e.g., see `grid::validDetails.axis`).

Note that the standard slots for grobs and gTrees are automatically validated (e.g., `vp`, `gp` slots for grobs and, in addition, `children`, and `childrenvp` slots for gTrees) so only slots specific to a new class need to be addressed.

Value

The function MUST return the validated grob.

Author(s)

Paul Murrell

See Also

`grid.edit`

---

**vpPath**

顺应 Viewport Names

Description

This function can be used to generate a viewport path for use in `downViewport` or `seekViewport`. A viewport path is a list of nested viewport names.

Usage

`vpPath(...)`

Arguments

... Character values which are viewport names.

Details

Viewport names must only be unique amongst viewports which share the same parent in the viewport tree.

This function can be used to generate a specification for a viewport that includes the viewport’s parent’s name (and the name of its parent and so on).

For interactive use, it is possible to directly specify a path, but it is strongly recommended that this function is used otherwise in case the path separator is changed in future versions of grid.
widthDetails

Value
A \texttt{vpPath} object.

See Also
\texttt{viewport.pushViewport.popViewport.downViewport.seekViewport.upViewport}

Examples
\texttt{vpPath("vp1", "vp2")}

widthDetails \hspace{1cm} Width and Height of a grid grob

Description
These generic functions are used to determine the size of grid grobs.

Usage
\begin{verbatim}
  widthDetails(x)
  heightDetails(x)
  ascentDetails(x)
  descentDetails(x)
\end{verbatim}

Arguments
\begin{itemize}
  \item \texttt{x} \hspace{1cm} A grid grob.
\end{itemize}

Details
These functions are called in the calculation of "grobwidth" and "grobheight" units. Methods should be written for classes derived from grob or gTree where the size of the grob can be determined (see, for example \texttt{grid::widthDetails.frame}).

The ascent of a grob is the height of the grob by default and the descent of a grob is zero by default, except for text grobs where the label is a single character value or expression.

Value
A unit object.

Author(s)
Paul Murrell

See Also
\texttt{absolute.size}. 
Maintaining and Navigating the Grid Viewport Tree

Description

Grid maintains a tree of viewports — nested drawing contexts. These functions provide ways to add or remove viewports and to navigate amongst viewports in the tree.

Usage

- `pushViewport(..., recording=TRUE)`
- `popViewport(n, recording=TRUE)`
- `downViewport(name, strict=FALSE, recording=TRUE)`
- `seekViewport(name, recording=TRUE)`
- `upViewport(n, recording=TRUE)`

Arguments

- `...`: One or more objects of class "viewport".
- `n`: An integer value indicating how many viewports to pop or navigate up. The special value 0 indicates to pop or navigate viewports right up to the root viewport.
- `name`: A character value to identify a viewport in the tree.
- `strict`: A boolean indicating whether the vpPath must be matched exactly.
- `recording`: A logical value to indicate whether the viewport operation should be recorded on the Grid display list.

Details

Objects created by the `viewport()` function are only descriptions of a drawing context. A viewport object must be pushed onto the viewport tree before it has any effect on drawing.

The viewport tree always has a single root viewport (created by the system) which corresponds to the entire device (and default graphical parameter settings). Viewports may be added to the tree using `pushViewport()` and removed from the tree using `popViewport()`.

There is only ever one current viewport, which is the current position within the viewport tree. All drawing and viewport operations are relative to the current viewport. When a viewport is pushed it becomes the current viewport. When a viewport is popped, the parent viewport becomes the current viewport. Use `upViewport` to navigate to the parent of the current viewport, without removing the current viewport from the viewport tree. Use `downViewport` to navigate to a viewport further down the viewport tree and `seekViewport` to navigate to a viewport anywhere else in the tree.

If a viewport is pushed and it has the same name as a viewport at the same level in the tree, then it replaces the existing viewport in the tree.

Value

- `downViewport` returns the number of viewports it went down.
- This can be useful for returning to your starting point by doing something like `depth <- downViewport()` then `upViewport(depth)`.

y=unit(1, "npc") - unit(2, "lines"), gp=gpar(col="grey"))
xDetails

Boundary of a grid grob

Description

These generic functions are used to determine a location on the boundary of a grid grob.

Usage

```r
xDetails(x, theta)
yDetails(x, theta)
```

Arguments

- `x` A grid grob.
- `theta` A numeric angle, in degrees, measured anti-clockwise from the 3 o'clock or one of the following character strings: "north", "east", "west", "south".

Details

The location on the grob boundary is determined by taking a line from the centre of the grob at the angle `theta` and intersecting it with the convex hull of the grob (for the basic grob primitives, the centre is determined as half way between the minimum and maximum values in x and y directions).

These functions are called in the calculation of "grobx" and "groby" units as produced by the `grobx` and `groby` functions. Methods should be written for classes derived from grob or gTree where the boundary of the grob can be determined.

Value

A unit object.
xsplinePoints

Author(s)
Paul Murrell

See Also

grobX, grobY.

xsplinePoints  

Return the points that would be used to draw an Xspline (or a Bezier curve).

Description
Rather than drawing an Xspline (or Bezier curve), this function returns the points that would be used to draw the series of line segments for the Xspline. This may be useful to post-process the Xspline curve, for example, to clip the curve.

Usage

xsplinePoints(x)  
bezierPoints(x)

Arguments

x  An Xspline grob, as produced by the xsplineGrob() function (or a beziergrob, as produced by the bezierGrob() function).

Details
The points returned by this function will only be relevant for the drawing context in force when this function was called.

Value
Depends on how many Xsplines would be drawn. If only one, then a list with two components, named x and y, both of which are unit objects (in inches). If several Xsplines would be drawn then the result of this function is a list of lists.

The methods package

Formal Methods and Classes

Description

Formally defined methods and classes for R objects, plus other programming tools, as described in the references.

Details

This package provides the ‘S4’ or ‘S version 4’ approach to methods and classes in a functional language.

See the documentation entries Classes, Methods, and GenericFunctions for general discussion of these topics, at a fairly technical level. Links from those pages, and the documentation of setClass and setMethod cover the main programming tools needed.

For a complete list of functions and classes, use library(help="methods").

.BasicFunsList

List of Builtin and Special Functions

Description

A named list providing instructions for turning builtin and special functions into generic functions. Functions in R that are defined as .Primitive(<name>) are not suitable for formal methods, because they lack the basic reflectance property. You can’t find the argument list for these functions by examining the function object itself.

Future versions of R may fix this by attaching a formal argument list to the corresponding function. While generally the names of arguments are not checked by the internal code implementing the function, the number of arguments frequently is.

In any case, some definition of a formal argument list is needed if users are to define methods for these functions. In particular, if methods are to be merged from multiple packages, the different sets of methods need to agree on the formal arguments.

In the absence of reflectance, this list provides the relevant information via a dummy function associated with each of the known specials for which methods are allowed.

At the same time, the list flags those specials for which methods are meaningless (e.g., for) or just a very bad idea (e.g., .Primitive).

A generic function created via setMethod, for example, for one of these special functions will have the argument list from .BasicFunsList. If no entry exists, the argument list (x, ...) is assumed.

as

Force an Object to Belong to a Class

Description

These functions manage the relations that allow coercing an object to a given class.

Usage

as(object, Class, strict=TRUE, ext)

as(object, Class) <- value

setAs(from, to, def, replace, where = topenv(parent.frame()))

Arguments

  object any R object.
  Class the name of the class to which object should be coerced.
  strict logical flag. If TRUE, the returned object must be strictly from the target class (unless that class is a virtual class, in which case the object will be from the closest actual class, in particular the original object, if that class extends the virtual class directly).
If `strict = FALSE`, any simple extension of the target class will be returned, without further change. A simple extension is, roughly, one that just adds slots to an existing class.

**value**  The value to use to modify object (see the discussion below). You should supply an object with class `Class`; some coercion is done, but you’re unwise to rely on it.

**from, to**  The classes between which the coerce methods `def` and `replace` perform coercion.

**def**  function of one argument. It will get an object from class `from` and had better return an object of class `to`. The convention is that the name of the argument is `from`; if another argument name is used, `setAs` will attempt to substitute `from`.

**replace**  if supplied, the function to use as a replacement method, when `as` is used on the left of an assignment. Should be a function of two arguments, `from, value`, although `setAs` will attempt to substitute if the arguments differ.

**where**  the position or environment in which to store the resulting methods. For most applications, it is recommended to omit this argument and to include the call to `setAs` in source code that is evaluated at the top level; that is, either in an R session by something equivalent to a call to `source`, or as part of the R source code for a package.

**ext**  the optional object defining how `Class` is extended by the class of the object (as returned by `possibleExtends`). This argument is used internally (to provide essential information for non-public classes), but you are unlikely to want to use it directly.

### Summary of Functions

**as:**  Returns the version of this object coerced to be the given `Class`. When used in the replacement form on the left of an assignment, the portion of the object corresponding to `Class` is replaced by `value`.

The operation of `as()` in either form depends on the definition of coerce methods. Methods are defined automatically when the two classes are related by inheritance; that is, when one of the classes is a subclass of the other. See the section on inheritance below for details.

Coerce methods are also predefined for basic classes (including all the types of vectors, functions and a few others). See `showMethods(coerce)` for a list of these.

Beyond these two sources of methods, further methods are defined by calls to the `setAs` function.

**setAs:**  Define methods for coercing an object of class `from` to be of class `to`; the `def` argument provides for direct coercing and the `replace` argument, if included, provides for replacement.

See the “How” section below for details.

**coerce, coerce<->:**  Coerce `from` to be of the same class as `to`.

These functions should not be called explicitly. The function `setAs` creates methods for them for the as function to use.

### Inheritance and Coercion

Objects from one class can turn into objects from another class either automatically or by an explicit call to the `as` function. Automatic conversion is special, and comes from the designer of one class of objects asserting that this class extends another class. The most common case is that one or more class names are supplied in the `contains=` argument to `setClass`, in which case the new class
extends each of the earlier classes (in the usual terminology, the earlier classes are superclasses of the new class and it is a subclass of each of them).

This form of inheritance is called simple inheritance in R. See setClass for details. Inheritance can also be defined explicitly by a call to setIs. The two versions have slightly different implications for coerce methods. Simple inheritance implies that inherited slots behave identically in the subclass and the superclass. Whenever two classes are related by simple inheritance, corresponding coerce methods are defined for both direct and replacement use of as. In the case of simple inheritance, these methods do the obvious computation: they extract or replace the slots in the object that correspond to those in the superclass definition.

The implicitly defined coerce methods may be overridden by a call to setAs; note, however, that the implicit methods are defined for each subclass-superclass pair, so that you must override each of these explicitly, not rely on inheritance.

When inheritance is defined by a call to setIs, the coerce methods are provided explicitly, not generated automatically. Inheritance will apply (to the from argument, as described in the section below). You could also supply methods via setAs for non-inherited relationships, and now these also can be inherited.

For further on the distinction between simple and explicit inheritance, see setIs.

How Functions 'as' and 'setAs' Work

The function as turns object into an object of class Class. In doing so, it applies a “coerce method”, using S4 classes and methods, but in a somewhat special way. Coerce methods are methods for the function coerce or, in the replacement case the function `coerce<-`. These functions have two arguments in method signatures, from and to, corresponding to the class of the object and the desired coerce class. These functions must not be called directly, but are used to store tables of methods for the use of as, directly and for replacements. In this section we will describe the direct case, but except where noted the replacement case works the same way, using `coerce<-` and the replace argument to setAs, rather than coerce and the def argument.

Assuming the object is not already of the desired class, as first looks for a method in the table of methods for the function coerce for the signature c(from = class(object), to = Class), in the same way method selection would do its initial lookup. To be precise, this means the table of both direct and inherited methods, but inheritance is used specially in this case (see below).

If no method is found, as looks for one. First, if either Class or class(object) is a superclass of the other, the class definition will contain the information needed to construct a coerce method. In the usual case that the subclass contains the superclass (i.e., has all its slots), the method is constructed either by extracting or replacing the inherited slots. Non-simple extensions (the result of a call to setIs) will usually contain explicit methods, though possibly not for replacement.

If no subclass/superclass relationship provides a method, as looks for an inherited method, but applying, inheritance for the argument from only, not for the argument to (if you think about it, you’ll probably agree that you wouldn’t want the result to be from some class other than the Class specified). Thus, selectMethod("coerce", sig, useInherited = c(from=TRUE, to= FALSE)) replicates the method selection used by as().

In nearly all cases the method found in this way will be cached in the table of coerce methods (the exception being subclass relationships with a test, which are legal but discouraged). So the detailed calculations should be done only on the first occurrence of a coerce from class(object) to Class.

Note that coerce is not a standard generic function. It is not intended to be called directly. To prevent accidentally caching an invalid inherited method, calls are routed to an equivalent call to as, and a warning is issued. Also, calls to selectMethod for this function may not represent the method that as will choose. You can only trust the result if the corresponding call to as has occurred previously in this session.
With this explanation as background, the function setAs does a fairly obvious computation: It constructs and sets a method for the function coerce with signature c(from, to), using the def argument to define the body of the method. The function supplied as def can have one argument (interpreted as an object to be coerced) or two arguments (the from object and the to class). Either way, setAs constructs a function of two arguments, with the second defaulting to the name of the to class. The method will be called from as with the object as the from argument and no to argument, with the default for this argument being the name of the intended to class, so the method can use this information in messages.

The direct version of the as function also has a strict= argument that defaults to TRUE. Calls during the evaluation of methods for other functions will set this argument to FALSE. The distinction is relevant when the object being coerced is from a simple subclass of the to class; if strict=FALSE in this case, nothing need be done. For most user-written coerce methods, when the two classes have no subclass/superclass, the strict= argument is irrelevant.

The replace argument to setAs provides a method for `coerce<-`. As with all replacement methods, the last argument of the method must have the name value for the object on the right of the assignment. As with the coerce method, the first two arguments are from, to; there is no strict= option for the replace case.

The function coerce exists as a repository for such methods, to be selected as described above by the as function. Actually dispatching the methods using standardGeneric could produce incorrect inherited methods, by using inheritance on the to argument; as mentioned, this is not the logic used for as. To prevent selecting and caching invalid methods, calls to coerce are currently mapped into calls to as, with a warning message.

**Basic Coercion Methods**

Methods are pre-defined for coercing any object to one of the basic datatypes. For example, as(x, "numeric") uses the existing as.numeric function. These built-in methods can be listed by showMethods("coerce").

**References**

Chambers, John M. (1998) *Programming with Data* Springer (For the original S4 version.)

**See Also**

If you think of using try(as(x, c1)), consider canCoerce(x, c1) instead.

**Examples**

```r
## using the definition of class "track" from \link{setClass}

setAs("track", "numeric", function(from) from@y)

t1 <- new("track", x=1:20, y=(1:20)^2)

as(t1, "numeric")

## The next example shows:
## 1. A virtual class to define setAs for several classes at once.
```
### 2. as() using inherited information

```r
defineClass("ca", representation(a = "character", id = "numeric"))
defineClass("cb", representation(b = "character", id = "numeric"))
defineClass("id")
define("ca", "id")
define("cb", "id")

defineAs("id", "numeric", function(from) from@id)
```

```r
CA <- define("ca", a = "A", id = 1)
CB <- define("cb", b = "B", id = 2)
defineAs("cb", "ca", function(from, to) new(to, a=from@b, id = from@id))
```

```r
as(CB, "numeric")
```

---

**Basic Classes**

**Classes Corresponding to Basic Data Types**

**Description**

Formal classes exist corresponding to the basic R object types, allowing these types to be used in method signatures, as slots in class definitions, and to be extended by new classes.

**Usage**

```r
### The following are all basic vector classes.
### They can appear as class names in method signatures, 
### in calls to as(), is(), and new().
"character"
"complex"
"double"
"expression"
"integer"
"list"
"logical"
"numeric"
"single"
"raw"

### the class
"vector"
### is a virtual class, extended by all the above

### the class
"S4"
### is an object type for S4 objects that do not extend
### Basic Classes

#### Objects from the Classes

If a class is not virtual (see section in [Classes](#)), objects can be created by calls of the form `new(Class, ...)`, where `Class` is the quoted class name, and the remaining arguments if any are objects to be interpreted as vectors of this class. Multiple arguments will be concatenated.

The class "expression" is slightly odd, in that the ... arguments will *not* be evaluated; therefore, don’t enclose them in a call to `quote()`.

Note that class "list" is a pure vector. Although lists with names go back to the earliest versions of S, they are an extension of the vector concept in that they have an attribute (which can now be a slot) and which is either NULL or a character vector of the same length as the vector. If you want to guarantee that list names are preserved, use class "namedList", rather than "list". Objects from this class must have a names attribute, corresponding to slot "names", of type "character". Internally, R treats names for lists specially, which makes it impractical to have the corresponding slot in class "namedList" be a union of character names and NULL.

#### Classes and Types

The basic classes include classes for the basic R types. Note that objects of these types will not usually be S4 objects (`isS4` will return `FALSE`), although objects from classes that contain the basic class will be S4 objects, still with the same type. The type as returned by `typeof` will sometimes differ from the class, either just from a choice of terminology (type "symbol" and class "name", for example) or because there is not a one-to-one correspondence between class and type (most of the classes that inherit from class "language" have type "language", for example).

#### Extends

The vector classes extend "vector", directly.

#### Methods

*coerce* Methods are defined to coerce arbitrary objects to the vector classes, by calling the corresponding basic function, for example, `as(x, "numeric")` calls `as.numeric(x)`.
callGeneric  

Call the Current Generic Function from a Method

Description

A call to callGeneric can only appear inside a method definition. It then results in a call to the current generic function. The value of that call is the value of callGeneric. While it can be called from any method, it is useful and typically used in methods for group generic functions.

Usage

callGeneric(...)

Arguments

...  

Optionally, the arguments to the function in its next call.

If no arguments are included in the call to callGeneric, the effect is to call the function with the current arguments. See the detailed description for what this really means.

Details

The name and package of the current generic function is stored in the environment of the method definition object. This name is looked up and the corresponding function called.

The statement that passing no arguments to callGeneric causes the generic function to be called with the current arguments is more precisely as follows. Arguments that were missing in the current call are still missing (remember that "missing" is a valid class in a method signature). For a formal argument, say x, that appears in the original call, there is a corresponding argument in the generated call equivalent to x = x. In effect, this means that the generic function sees the same actual arguments, but arguments are evaluated only once.

Using callGeneric with no arguments is prone to creating infinite recursion, unless one of the arguments in the signature has been modified in the current method so that a different method is selected.

Value

The value returned by the new call.

callNextMethod

**Examples**

```r
## the method for group generic function Ops
## for signature(e1="structure", e2="vector")
function (e1, e2)
{
  value <- callGeneric(e1@Data, e2)
  if (length(value) == length(e1)) {
    e1@Data <- value
    e1
  }
  else value
}
```

```r
## For more examples
## Not run:
showMethods("Ops", includeDefs = TRUE)
```

**callNextMethod**  
*Call an Inherited Method*

**Description**

A call to `callNextMethod` can only appear inside a method definition. It then results in a call to the first inherited method after the current method, with the arguments to the current method passed down to the next method. The value of that method call is the value of `callNextMethod`.

**Usage**

`callNextMethod(...)`

**Arguments**

`...`  
Optionally, the arguments to the function in its next call (but note that the dispatch is as in the detailed description below; the arguments have no effect on selecting the next method.)

If no arguments are included in the call to `callNextMethod`, the effect is to call the method with the current arguments. See the detailed description for what this really means.

Calling with no arguments is often the natural way to use `callNextMethod`; see the examples.

**Details**

The ‘next’ method (i.e., the first inherited method) is defined to be that method which *would* have been called if the current method did not exist. This is more-or-less literally what happens: The current method (to be precise, the method with signature given by the defined slot of the method from which `callNextMethod` is called) is deleted from a copy of the methods for the current generic, and `selectMethod` is called to find the next method (the result is cached in a special object, so the search only typically happens once per session per combination of argument classes).
Note that the preceding definition means that the next method is defined uniquely when `setMethod` inserts the method containing the `callNextMethod` call, given the definitions of the classes in the signature. The choice does not depend on the path that gets us to that method (for example, through inheritance or from another `callNextMethod` call). This definition was not enforced in versions of R prior to 2.3.0, where the method was selected based on the target signature, and so could vary depending on the actual arguments.

It is also legal, and often useful, for the method called by `callNextMethod` to itself have a call to `callNextMethod`. This generally works as you would expect, but for completeness be aware that it is possible to have ambiguous inheritance in the S structure, in the sense that the same two classes can appear as superclasses in the opposite order in two other class definitions. In this case the effect of a nested instance of `callNextMethod` is not well defined. Such inconsistent class hierarchies are both rare and nearly always the result of bad design, but they are possible, and currently undetected.

The statement that the method is called with the current arguments is more precisely as follows. Arguments that were missing in the current call are still missing (remember that "missing" is a valid class in a method signature). For a formal argument, say `x`, that appears in the original call, there is a corresponding argument in the next method call equivalent to `x = x`. In effect, this means that the next method sees the same actual arguments, but arguments are evaluated only once.

**Value**

The value returned by the selected method.

Chambers, John M. (1998) *Programming with Data* Springer (For the original S4 version.)

**See Also**

`callGeneric` to call the generic function with the current dispatch rules (typically for a group generic function); *Methods* for the general behavior of method dispatch.

**Examples**

```r
## some class definitions with simple inheritance
setClass("B0", representation(b0 = "numeric"))

setClass("B1", representation(b1 = "character"), contains = "B0")

setClass("B2", representation(b2 = "logical"), contains = "B1")

## and a rather silly function to illustrate callNextMethod
f <- function(x) class(x)

setMethod("f", "B0", function(x) c(x@b0*2, callNextMethod()))
setMethod("f", "B1", function(x) c(paste(x@b1,":"), callNextMethod()))
setMethod("f", "B2", function(x) c(x@b2, callNextMethod()))

b1 <- new("B1", b0 = 2, b1 = "Testing")

b2 <- new("B2", b2 = FALSE, b1 = "More testing", b0 = 10)
```
canCoerce

f(b2)
stopifnot(identical(f(b2), c(b2@b2, paste(b2@b1,""), b2@b0^2, "B2")))
f(b1)

## a sneakier method: the *changed* x is used:
setMethod("f", "B2",
    function(x) {x@b0 <- 111; c(x@b2, callNextMethod())})
f(b2)
stopifnot(identical(f(b2), c(b2@b2, paste(b2@b1,""), 111^2, "B2")))

---

canCoerce  Can an Object be Coerced to a Certain S4 Class?

Description

Test if an object can be coerced to a given S4 class. Maybe useful inside if() to ensure that calling as(object, Class) will find a method.

Usage

canCoerce(object, Class)

Arguments

object any R object, typically of a formal S4 class.
Class an S4 class (see isClass).

Value

a scalar logical, TRUE if there is a coerce method (as defined by setAs, e.g.) for the signature (from = class(object), to = Class).

See Also

as, setAs, selectMethod, setClass,

Examples

m <- matrix(pi, 2,3)
canCoerce(m, "numeric") # TRUE
canCoerce(m, "array")  # TRUE
cbind2 Combine two Objects by Columns or Rows

Description

Combine two matrix-like R objects by columns (cbind2) or rows (rbind2). These are (S4) generic functions with default methods.

Usage

cbind2(x, y, ...)  
rbind2(x, y, ...)

Arguments

x any R object, typically matrix-like.
y any R object, typically similar to x, or missing completely.
... optional arguments for methods.

Details

The main use of cbind2 (rbind2) is to be called by cbind() (rbind()) if these are activated. This allows cbind (rbind) to work for formally classed (aka 'S4') objects by providing S4 methods for these objects. Currently, a call  
methods::bind_activation(TRUE)  
is needed to install a cbind2-calling version of cbind (into the base namespace) and the same for rbind.  
methods::bind_activation(FALSE) reverts to the previous internal version of cbind which does not build on cbind2, see the examples.

Value

A matrix (or matrix like object) combining the columns (or rows) of x and y.

Methods

signature(x = "ANY", y = "ANY") the default method using R's internal code.
signature(x = "ANY", y = "missing") the default method for one argument using R's internal code.

See Also

cbind, rbind; further, cBind, rBind in the Matrix package.

Examples

cbind2(1:3, 4)  
m <- matrix(3:8, 2, 3, dimnames=list(c("a","b"), LETTERS[1:3]))  
cbind2(1:2, m) # keeps dimnames from m

### Note: Use the following activation if you want cbind() to work
### ---- on S4 objects -- be careful otherwise!
Description

Class definitions are objects that contain the formal definition of a class of R objects, usually referred to as an S4 class, to distinguish them from the informal S3 classes. This document gives an overview of S4 classes; for details of the class representation objects, see help for the class `classRepresentation`.

Metadata Information

When a class is defined, an object is stored that contains the information about that class. The object, known as the `metadata` defining the class, is not stored under the name of the class (to allow programmers to write generating functions of that name), but under a specially constructed name. To examine the class definition, call `getClass`. The information in the metadata object includes:

Slots: The data contained in an object from an S4 class is defined by the `slots` in the class definition. Each slot in an object is a component of the object; like components (that is, elements) of a list, these may be extracted and set, using the function `slot()` or more often the operator `@`. However, they differ from list components in important ways. First, slots can only be referred to by name, not by position, and there is no partial matching of names as with list elements.

All the objects from a particular class have the same set of slot names; specifically, the slot names that are contained in the class definition. Each slot in each object always is an object of the class specified for this slot in the definition of the current class. The word "is" corresponds to the R function of the same name (`is`), meaning that the class of the object in the slot must be the same as the class specified in the definition, or some class that extends the one in the definition (a subclass).

A special slot name, `.Data`, stands for the ‘data part’ of the object. An object from a class with a data part is defined by specifying that the class contains one of the R object types or one of the special pseudo-classes, `matrix` or `array`, usually because the definition of the class, or of one of its superclasses, has included the type or pseudo-class in its `contains` argument. A second special slot name, `.xData`, is used to enable inheritance from abnormal types such as "environment." See the section on inheriting from non-S4 classes for details on the representation and for the behavior of S3 methods with objects from these classes.

Some slot names correspond to attributes used in old-style S3 objects and in R objects without an explicit class, for example, the `names` attribute. If you define a class for which that attribute
Classes will be set, such as a subclass of named vectors, you should include "names" as a slot. See the definition of class "namedlist" for an example. Using the names() assignment to set such names will generate a warning if there is no names slot and an error if the object in question is not a vector type. A slot called "names" can be used anywhere, but only if it is assigned as a slot, not via the default names() assignment.

**Superclasses:** The definition of a class includes the superclasses—the classes that this class extends. A class Fancy, say, extends a class Simple if an object from the Fancy class has all the capabilities of the Simple class (and probably some more as well). In particular, and very usefully, any method defined to work for a Simple object can be applied to a Fancy object as well.

This relationship is expressed equivalently by saying that Simple is a superclass of Fancy, or that Fancy is a subclass of Simple.

The direct superclasses of a class are those superclasses explicitly defined. Direct superclasses can be defined in three ways. Most commonly, the superclasses are listed in the contains= argument in the call to setClass that creates the subclass. In this case the subclass will contain all the slots of the superclass, and the relation between the class is called simple, as it in fact is. Superclasses can also be defined explicitly by a call to setIs; in this case, the relation requires methods to be specified to go from subclass to superclass. Thirdly, a class union is a superclass of all the members of the union. In this case the relation is simple, but notice that the relation is defined when the superclass is created, not when the subclass is created as with the contains= mechanism.

The definition of a superclass will also potentially contain its own direct superclasses. These are considered (and shown) as superclasses at distance 2 from the original class; their direct superclasses are at distance 3, and so on. All these are legitimate superclasses for purposes such as method selection.

When superclasses are defined by including the names of superclasses in the contains= argument to setClass, an object from the class will have all the slots defined for its own class and all the slots defined for all its superclasses as well.

The information about the relation between a class and a particular superclass is encoded as an object of class SClassExtension. A list of such objects for the superclasses (and sometimes for the subclasses) is included in the metadata object defining the class. If you need to compute with these objects (for example, to compare the distances), call the function extends with argument fullInfo=TRUE.

**Prototype:** The objects from a class created by a call to new are defined by the prototype object for the class and by additional arguments in the call to new, which are passed to a method for that class for the function initialize.

Each class representation object contains a prototype object for the class (although for a virtual class the prototype may be NULL). The prototype object must have values for all the slots of the class. By default, these are the prototypes of the corresponding slot classes. However, the definition of the class can specify any valid object for any of the slots.

**Virtual classes; Basic classes**

Classes exist for which no actual objects can be created by a call to new, the virtual classes, in fact a very important programming tool. They are used to group together ordinary classes that want to share some programming behavior, without necessarily restricting how the behavior is implemented. Virtual class definitions may if you want include slots (to provide some common behavior without fully defining the object—see the class traceable for an example).

A simple and useful form of virtual class is the class union, a virtual class that is defined in a call to setClassUnion by listing one or more of subclasses (classes that extend the class union). Class unions can include as subclasses basic object types (whose definition is otherwise sealed).
Classes

There are a number of ‘basic’ classes, corresponding to the ordinary kinds of data occurring in \( \mathbb{R} \). For example, "numeric" is a class corresponding to numeric vectors. The other vector basic classes are "logical", "integer", "complex", "character", "raw", "list" and "expression". The prototypes for the vector classes are vectors of length 0 of the corresponding type. Notice that basic classes are unusual in that the prototype object is from the class itself.

In addition to the vector classes there are also basic classes corresponding to objects in the language, such as "function" and "call". These classes are subclasses of the virtual class "language". Finally, there are object types and corresponding basic classes for “abnormal” objects, such as "environment" and "externalptr". These objects do not follow the functional behavior of the language; in particular, they are not copied and so cannot have attributes or slots defined locally.

All these classes can be used as slots or as superclasses for any other class definitions, although they do not themselves come with an explicit class. For the abnormal object types, a special mechanism is used to enable inheritance as described below.

Inheriting from non-S4 Classes

A class definition can extend classes other than regular S4 classes, usually by specifying them in the contains argument to \( \text{setClass} \). Three groups of such classes behave distinctly:

1. S3 classes, which must have been registered by a previous call to \( \text{setOldClass} \) (you can check that this has been done by calling \( \text{getClass} \), which should return a class that extends oldClass);
2. One of the \( \mathbb{R} \) object types, typically a vector type, which then defines the type of the S4 objects, but also a type such as environment that can not be used directly as a type for an S4 object. See below.
3. One of the pseudo-classes matrix and array, implying objects with arbitrary vector types plus the dim and dimnames attributes.

This section describes the approach to combining S4 computations with older S3 computations by using such classes as superclasses. The design goal is to allow the S4 class to inherit S3 methods and default computations in as consistent a form as possible.

As part of a general effort to make the S4 and S3 code in R more consistent, when objects from an S4 class are used as the first argument to a non-default S3 method, either for an S3 generic function (one that calls \( \text{UseMethod} \)) or for one of the primitive functions that dispatches S3 methods, an effort is made to provide a valid object for that method. In particular, if the S4 class extends an S3 class or matrix or array, and there is an S3 method matching one of these classes, the S4 object will be coerced to a valid S3 object, to the extent that is possible given that there is no formal definition of an S3 class.

For example, suppose "myFrame" is an S4 class that includes the S3 class "data.frame" in the contains argument to \( \text{setClass} \). If an object from this S4 class is passed to a function, say as.matrix, that has an S3 method for "data.frame", the internal code for \( \text{UseMethod} \) will convert the object to a data frame; in particular, to an S3 object whose class attribute will be the vector corresponding to the S3 class (possibly containing multiple class names). Similarly for an S4 object inheriting from "matrix" or "array", the S4 object will be converted to a valid S3 matrix or array.

Note that the conversion is not applied when an S4 object is passed to the default S3 method. Some S3 generics attempt to deal with general objects, including S4 objects. Also, no transformation is applied to S4 objects that do not correspond to a selected S3 method; in particular, to objects from a class that does not contain either an S3 class or one of the basic types. See \( \text{asS4} \) for the transformation details.

In addition to explicit S3 generic functions, S3 methods are defined for a variety of operators and functions implemented as primitives. These methods are dispatched by some internal C code that
operates partly through the same code as real S3 generic functions and partly via special consider-
ations (for example, both arguments to a binary operator are examined when looking for methods).
The same mechanism for adapting S4 objects to S3 methods has been applied to these computations
as well, with a few exceptions such as generating an error if an S4 object that does not extend an
appropriate S3 class or type is passed to a binary operator.

The remainder of this section discusses the mechanisms for inheriting from basic object types. See
matrix or array for inhering from the matrix and array pseudo-classes, or from time-series. For
the corresponding details for inheritance from S3 classes, see setOldClass.

An object from a class that directly and simply contains one of the basic object types in R, has
implicitly a corresponding .Data slot of that type, allowing computations to extract or replace the
data part while leaving other slots unchanged. If the type is one that can accept attributes and is
duplicated normally, the inheritance also determines the type of the object; if the class definition
has a .Data slot corresponding to a normal type, the class of the slot determines the type of the
object (that is, the value of typeof(x)). For such classes, .Data is a pseudo-slot; that is, extracting
or setting it modifies the non-slot data in the object. The functions getDataPart and setDataPart
are a cleaner, but essentially equivalent way to deal with the data part.

Extending a basic type this way allows objects to use old-style code for the corresponding type as
well as S4 methods. Any basic type can be used for .Data, but a few types are treated differently
because they do not behave like ordinary objects; for example, "NULL", environments, and external
pointers. Classes extend these types by having a slot, .xData, itself inherited from an internally
defined S4 class. This slot actually contains an object of the inherited type, to protect computations
from the reference semantics of the type. Coercing to the nonstandard object type then requires an
actual computation, rather than the "simple" inclusion for other types and classes. The intent is
that programmers will not need to take account of the mechanism, but one implication is that you
should not explicitly use the type of an S4 object to detect inheritance from an arbitrary object type.
Use is and similar functions instead.

classesToAM  Compute an Adjacency Matrix for Superclasses of Class Definitions
Description

Given a vector of class names or a list of class definitions, the function returns an adjacency matrix of the superclasses of these classes; that is, a matrix with class names as the row and column names and with element \([i, j]\) being 1 if the class in column \(j\) is a direct superclass of the class in row \(i\), and 0 otherwise.

The matrix has the information implied by the `contains` slot of the class definitions, but in a form that is often more convenient for further analysis; for example, an adjacency matrix is used in packages and other software to construct graph representations of relationships.

Usage

```r
classesToAM(classes, includeSubclasses = FALSE, abbreviate = 2)
```

Arguments

- `classes`: Either a character vector of class names or a list, whose elements can be either class names or class definitions. The list is convenient, for example, to include the package slot for the class name. See the examples.
- `includeSubclasses`: A logical flag; if `TRUE`, then the matrix will include all the known subclasses of the specified classes as well as the superclasses. The argument can also be a logical vector of the same length as `classes`, to include subclasses for some but not all the classes.
- `abbreviate`: Control of the abbreviation of the row and/or column labels of the matrix returned: values 0, 1, 2, or 3 abbreviate neither, rows, columns or both. The default, 2, is useful for printing the matrix, since class names tend to be more than one character long, making for spread-out printing. Values of 0 or 3 would be appropriate for making a graph (3 avoids the tendency of some graph plotting software to produce labels in minuscule font size).

Details

For each of the classes, the calculation gets all the superclass names from the class definition, and finds the edges in those classes’ definitions; that is, all the superclasses at distance 1. The corresponding elements of the adjacency matrix are set to 1.

The adjacency matrices for the individual class definitions are merged. Note two possible kinds of inconsistency, neither of which should cause problems except possibly with identically named classes from different packages. Edges are computed from each superclass definition, so that information overrides a possible inference from extension elements with distance > 1 (and it should). When matrices from successive classes in the argument are merged, the computations do not currently check for inconsistencies—this is the area where possible multiple classes with the same name could cause confusion. A later revision may include consistency checks.

Value

As described, a matrix with entries 0 or 1, non-zero values indicating that the class corresponding to the column is a direct superclass of the class corresponding to the row. The row and column names are the class names (without package slot).

`extends` and `classRepresentation` for the underlying information from the class definition.

Examples

```r
## the super- and subclasses of "standardGeneric"
## and "derivedDefaultMethod"
am <- classesToAM(list(class(show), class(getMethod(show))), TRUE)
am

## Not run:
## the following function depends on the Bioconductor package Rgraphviz
plotInheritance <- function(classes, subclasses = FALSE, ...) {
  if(!require("Rgraphviz", quietly=TRUE))
    stop("Only implemented if Rgraphviz is available")
mM <- classesToAM(classes, subclasses)
classes <- rownames(mM); rownames(mM) <- colnames(mM)
graph <- new("graphAM", mm, "directed", ...)
plot(graph)
cat("Key:\n", paste(abbreviate(classes), " = ", classes, " ",
               sep = ""), sep = """, fill = TRUE)
invisible(graph)
}

## The plot of the class inheritance of the package "graph"
require(graph)
plotInheritance(getClasses("package:graph"))

## End(Not run)
```

<table>
<thead>
<tr>
<th>className</th>
<th>Class names including the corresponding package</th>
</tr>
</thead>
</table>

Description

The function `className()` generates a valid references to a class, including the name of the package containing the class definition. The object returned, from class "className", is the unambiguous way to refer to a class, for example when calling `setMethod`, just in case multiple definitions of the class exist.

Function "multipleClasses" returns information about multiple definitions of classes with the same name from different packages.

Usage

```r
className(class, package)
multipleClasses(details = FALSE)
```
Arguments

class, package  The character string name of a class and, optionally, of the package to which it belongs. If argument package is missing and the class argument has a package slot, that is used (in particular, passing in an object from class "className" returns itself in this case, but changes the package slot if the second argument is supplied).

If there is no package argument or slot, a definition for the class must exist and will be used to define the package. If there are multiple definitions, one will be chosen and a warning printed giving the other possibilities.

details  If FALSE, the default, multipleClasses() returns a character vector of those classes currently known with multiple definitions.

If TRUE, a named list of those class definitions is returned. Each element of the list is itself a list of the corresponding class definitions, with the package names as the names of the list. Note that identical class definitions will not be considered “multiple” definitions (see the discussion of the details below).

Details

The table of class definitions used internally can maintain multiple definitions for classes with the same name but coming from different packages. If identical class definitions are encountered, only one class definition is kept; this occurs most often with S3 classes that have been specified in calls to setOldClass. For true classes, multiple class definitions are unavoidable in general if two packages happen to have used the same name, independently.

Overriding a class definition in another package with the same name deliberately is usually a bad idea. Although R attempts to keep and use the two definitions (as of version 2.14.0), ambiguities are always possible. It is more sensible to define a new class that extends an existing class but has a different name.

Value

A call to className() returns an object from class "className".

A call to multipleClasses() returns either a character vector or a named list of class definitions. In either case, testing the length of the returned value for being greater than 0 is a check for the existence of multiply defined classes.

Objects from the Class

The class "className" extends "character" and has a slot "package", also of class "character".

Examples

## Not run:

className("vector")  # will be found, from package "methods"
className("vector", "magic")  # OK, even though the class doesn't exist

className("An unknown class")  # Will cause an error

## End(Not run)
Description

These are the objects that hold the definition of classes of objects. They are constructed and stored as meta-data by calls to the function `setClass`. Don’t manipulate them directly, except perhaps to look at individual slots.

Details

Class definitions are stored as metadata in various packages. Additional metadata supplies information on inheritance (the result of calls to `setIs`). Inheritance information implied by the class definition itself (because the class contains one or more other classes) is also constructed automatically.

When a class is to be used in an R session, this information is assembled to complete the class definition. The completion is a second object of class "classRepresentation", cached for the session or until something happens to change the information. A call to `getClass` returns the completed definition of a class; a call to `getClassDef` returns the stored definition (uncompleted). In particular, completion fills in the upward- and downward-pointing inheritance information for the class, in slots `contains` and `subclasses` respectively. It’s in principle important to note that this information can depend on which packages are installed, since these may define additional subclasses or superclasses.

Slots

- **slots**: A named list of the slots in this class; the elements of the list are the classes to which the slots must belong (or extend), and the names of the list gives the corresponding slot names.
- **contains**: A named list of the classes this class ‘contains’: the elements of the list are objects of `SClassExtension`. The list may be only the direct extensions or all the currently known extensions (see the details).
- **virtual**: Logical flag, set to `TRUE` if this is a virtual class.
- **prototype**: The object that represents the standard prototype for this class; i.e., the data and slots returned by a call to `new` for this class with no special arguments. Don’t mess with the prototype object directly.
- **validity**: Optionally, a function to be used to test the validity of objects from this class. See `validObject`.
- **access**: Access control information. Not currently used.
- **className**: The character string name of the class.
- **package**: The character string name of the package to which the class belongs. Nearly always the package on which the metadata for the class is stored, but in operations such as constructing inheritance information, the internal package name rules.
- **subclasses**: A named list of the classes known to extend this class’: the elements of the list are objects of class `SClassExtension`. The list is currently only filled in when completing the class definition (see the details).
- **versionKey**: Object of class "externalPtr"; eventually will perhaps hold some versioning information, but not currently used.
- **sealed**: Object of class "logical"; is this class sealed? If so, no modifications are allowed.

Description

Special documentation can be supplied to describe the classes and methods that are created by the software in the methods package. Techniques to access this documentation and to create it in R help files are described here.

Getting documentation on classes and methods

You can ask for on-line help for class definitions, for specific methods for a generic function, and for general discussion of methods for a generic function. These requests use the `?` operator (see `help` for a general description of the operator). Of course, you are at the mercy of the implementer as to whether there is any documentation on the corresponding topics.

Documentation on a class uses the argument `class` on the left of the `?`, and the name of the class on the right; for example,

```r
class ? genericFunction
```

to ask for documentation on the class "genericFunction".

When you want documentation for the methods defined for a particular function, you can ask either for a general discussion of the methods or for documentation of a particular method (that is, the method that would be selected for a particular set of actual arguments).

Overall methods documentation is requested by calling the `?` operator with `methods` as the left-side argument and the name of the function as the right-side argument. For example,

```r
methods ? initialize
```

asks for documentation on the methods for the `initialize` function.

Asking for documentation on a particular method is done by giving a function call expression as the right-hand argument to the "?" operator. There are two forms, depending on whether you prefer to give the class names for the arguments or expressions that you intend to use in the actual call.

If you planned to evaluate a function call, say `myFun(x, sqrt(wt))` and wanted to find out something about the method that would be used for this call, put the call on the right of the "?" operator:

```r
?myFun(x, sqrt(wt))
```

A method will be selected, as it would be for the call itself, and documentation for that method will be requested. If `myFun` is not a generic function, ordinary documentation for the function will be requested.

If you know the actual classes for which you would like method documentation, you can supply these explicitly in place of the argument expressions. In the example above, if you want method documentation for the first argument having class "maybeNumber" and the second "logical", call the "?" operator, this time with a left-side argument `method` and with a function call on the right using the class names as arguments:

```r
method ? myFun("maybeNumber", "logical")
```
Once again, a method will be selected, this time corresponding to the specified classes, and method
documentation will be requested. This version only works with generic functions.

The two forms each have advantages. The version with actual arguments doesn’t require you to
figure out (or guess at) the classes of the arguments. On the other hand, evaluating the arguments
may take some time, depending on the example. The version with class names does require you to
pick classes, but it’s otherwise unambiguous. It has a subtler advantage, in that the classes supplied
may be virtual classes, in which case no actual argument will have specifically this class. The class
“maybeNumber”, for example, might be a class union (see the example for `setClassUnion`).

In either form, methods will be selected as they would be in actual computation, including use of
inheritance and group generic functions. See `selectMethod` for the details, since it is the function
used to find the appropriate method.

### Writing Documentation for Methods

The on-line documentation for methods and classes uses some extensions to the R documentation
format to implement the requests for class and method documentation described above. See the
document *Writing R Extensions* for the available markup commands (you should have consulted
this document already if you are at the stage of documenting your software).

In addition to the specific markup commands to be described, you can create an initial, overall file
with a skeleton of documentation for the methods defined for a particular generic function:

```r
promptMethods("myFun")
```

will create a file, `myFun-methods.Rd` with a skeleton of documentation for the methods defined
for function `myFun`. The output from `promptMethods` is suitable if you want to describe all or most
of the methods for the function in one file, separate from the documentation of the generic function
itself. Once the file has been filled in and moved to the ‘man’ subdirectory of your source package,
requests for methods documentation will use that file, both for specific methods documentation as
described above, and for overall documentation requested by

```r
methods ? myFun
```

You are not required to use `promptMethods`, and if you do, you may not want to use the entire file
created:

- If you want to document the methods in the file containing the documentation for the generic
  function itself, you can cut-and-paste to move the `alias` lines and the `Methods` section from
  the file created by `promptMethods` to the existing file.
- On the other hand, if these are auxiliary methods, and you only want to document the added
  or modified software, you should strip out all but the relevant `alias` lines for the methods of
  interest, and remove all but the corresponding `item` entries in the `Methods` section. Note that in
  this case you will usually remove the first `alias` line as well, since that is the marker for general
  methods documentation on this function (in the example, `\alias{myfun-methods}`).

If you simply want to direct documentation for one or more methods to a particular R documentation
file, insert the appropriate alias.
**Description**

The “…” argument in R functions is treated specially, in that it matches zero, one or more actual arguments (and so, objects). A mechanism has been added to R to allow “…,” as the signature of a generic function. Methods defined for such functions will be selected and called when all the arguments matching “…,” are from the specified class or from some subclass of that class.

**Using "..." in a Signature**

Beginning with version 2.8.0 of R, S4 methods can be dispatched (selected and called) corresponding to the special argument “…,”. Currently, “…,” cannot be mixed with other formal arguments: either the signature of the generic function is “…,” only, or it does not contain “…,”. (This restriction may be lifted in a future version.)

Given a suitable generic function, methods are specified in the usual way by a call to `setMethod`. The method definition must be written expecting all the arguments corresponding to “…,” to be from the class specified in the method’s signature, or from a class that extends that class (i.e., a subclass of that class).

Typically the methods will pass “…,” down to another function or will create a list of the arguments and iterate over that. See the examples below.

When you have a computation that is suitable for more than one existing class, a convenient approach may be to define a union of these classes by a call to `setClassUnion`. See the example below.

**Method Selection and Dispatch for "..."**

See Methods for a general discussion. The following assumes you have read the “Method Selection and Dispatch” section of that documentation.

A method selecting on “…,” is specified by a single class in the call to `setMethod`. If all the actual arguments corresponding to “…,” have this class, the corresponding method is selected directly.

Otherwise, the class of each argument and that class’ superclasses are computed, beginning with the first “…,” argument. For the first argument, eligible methods are those for any of the classes. For each succeeding argument that introduces a class not considered previously, the eligible methods are further restricted to those matching the argument’s class or superclasses. If no further eligible classes exist, the iteration breaks out and the default method, if any, is selected.

At the end of the iteration, one or more methods may be eligible. If more than one, the selection looks for the method with the least distance to the actual arguments. For each argument, any inherited method corresponds to a distance, available from the `contains` slot of the class definition. Since the same class can arise for more than one argument, there may be several distances associated with it. Combining them is inevitably arbitrary: the current computation uses the minimum distance. Thus, for example, if a method matched one argument directly, one as first generation superclass and another as a second generation superclass, the distances are 0, 1 and 2. The current selection computation would use distance 0 for this method. In particular, this selection criterion tends to use a method that matches exactly one or more of the arguments’ class.

As with ordinary method selection, there may be multiple methods with the same distance. A warning message is issued and one of the methods is chosen (the first encountered, which in this case is rather arbitrary).

Notice that, while the computation examines all arguments, the essential cost of dispatch goes up with the number of distinct classes among the arguments, likely to be much smaller than the number of arguments when the latter is large.
Implementation Details

Methods dispatching on "..." were introduced in version 2.8.0 of R. The initial implementation of the corresponding selection and dispatch is in an R function, for flexibility while the new mechanism is being studied. In this implementation, a local version of `setGeneric` is inserted in the generic function's environment. The local version selects a method according to the criteria above and calls that method, from the environment of the generic function. This is slightly different from the action taken by the C implementation when "..." is not involved. Aside from the extra computing time required, the method is evaluated in a true function call, as opposed to the special context constructed by the C version (which cannot be exactly replicated in R code.) However, situations in which different computational results would be obtained have not been encountered so far, and seem very unlikely.

Methods dispatching on arguments other than "..." are cached by storing the inherited method in the table of all methods, where it will be found on the next selection with the same combination of classes in the actual arguments (but not used for inheritance searches). Methods based on "..." are also cached, but not found quite as immediately. As noted, the selected method depends only on the set of classes that occur in the "..." arguments. Each of these classes can appear one or more times, so many combinations of actual argument classes will give rise to the same effective signature. The selection computation first computes and sorts the distinct classes encountered. This gives a label that will be cached in the table of all methods, avoiding any further search for inherited classes after the first occurrence. A call to `showMethods` will expose such inherited methods.

The intention is that the "..." features will be added to the standard C code when enough experience with them has been obtained. It is possible that at the same time, combinations of "..." with other arguments in signatures may be supported.

Examples

```r
cc <- function(...)c(...)
setGeneric("cc")
setMethod("cc", "character", function(...)paste(...))
setClassUnion("Number", c("numeric", "complex"))
setMethod("cc", "Number", function(...) sum(...))
setClass("cdate", contains = "character", representation(date = "Date"))
setClass("vdate", contains = "vector", representation(date = "Date"))

cd1 <- new("cdate", "abcdef", date = Sys.Date())
cd2 <- new("vdate", "abcdef", date = Sys.Date())
```
**environment-class**

Class "environment"

**Description**

A formal class for R environments.

**Objects from the Class**

Objects can be created by calls of the form `new("environment", ...)`. The arguments in `...`, if any, should be named and will be assigned to the newly created environment.

**Methods**

- **coerce** signature(from = "ANY", to = "environment") calls `as.environment`.
- **initialize** signature(object = "environment"): Implements the assignments in the new environment. Note that the object argument is ignored; a new environment is always created, since environments are not protected by copying.
Description

Support Class to Implement R Objects using Reference Semantics

NOTE:

The software described here is an initial version. The eventual goal is to support reference-style classes with software in R itself or using inter-system interfaces. The current implementation (R version 2.12.0) is preliminary and subject to change, and currently includes only the R-only implementation. Developers are encouraged to experiment with the software, but the description here is more than usually subject to change.

Purpose of the Class

This class implements basic reference-style semantics for R objects. Objects normally do not come directly from this class, but from subclasses defined by a call to setRefClass. The documentation below is technical background describing the implementation, but applications should use the interface documented under setRefClass, in particular the $ operator and field accessor functions as described there.

A Basic Reference Class

The design of reference classes for R divides those classes up according to the mechanism used for implementing references, fields, and class methods. Each version of this mechanism is defined by a basic reference class, which must implement a set of methods and provide some further information used by setRefClass.

The required methods are for operators $ and $<- to get and set a field in an object, and for initialize to initialize objects.

To support these methods, the basic reference class needs to have some implementation mechanism to store and retrieve data from fields in the object. The mechanism needs to be consistent with reference semantics; that is, changes made to the contents of an object are global, seen by any code accessing that object, rather than only local to the function call where the change takes place. As described below, class envRefClass implements reference semantics through specialized use of environment objects. Other basic reference classes may use an interface to a language such as Java or C++ using reference semantics for classes.

Usually, the R user will be able to invoke class methods on the class, using the $ operator. The basic reference class method for $ needs to make this possible. Essentially, the operator must return an R function corresponding to the object and the class method name.

Class methods may include an implementation of data abstraction, in the sense that fields are accessed by “get” and “set” methods. The basic reference class provides this facility by setting the "fieldAccessorGenerator" slot in its definition to a function of one variable. This function will be called by setRefClass with the vector of field names as arguments. The generator function must return a list of defined accessor functions. An element corresponding to a get operation is invoked with no arguments and should extract the corresponding field; an element for a set operation will
be invoked with a single argument, the value to be assigned to the field. The implementation needs
to supply the object, since that is not an argument in the method invocation. The mechanism used
currently by envRefClass is described below.

Support Classes

Two virtual classes are supplied to test for reference objects: is(x, "refClass") tests
whether x comes from a class defined using the reference class mechanism described here; is(x, "refObject") tests whether the object has reference semantics generally, including the
previous classes and also classes inheriting from the R types with reference semantics, such as
"environment".

Installed class methods are "classMethodDefinition" objects, with slots that identify the name
of the function as a class method and the other class methods called from this method. The latter
information is determined heuristically when the class is defined by using the codetools recom-
mended package. This package must be installed when reference classes are defined, but is not
needed in order to use existing reference classes.

**evalSource**

*Use Function Definitions from a Source File without Reinstalling a Package*

---

**Description**

Definitions of functions and/or methods from a source file are inserted into a package, using the
trace mechanism. Typically, this allows testing or debugging modified versions of a few functions
without reinstalling a large package.

**Usage**

```r
evalSource(source, package = "", lock = TRUE, cache = FALSE)

insertSource(source, package = "", functions = , methods = ,
force = )
```

**Arguments**

- **source**
  
  A file to be parsed and evaluated by evalSource to find the new function and
  method definitions.
  
  The argument to insertSource can be an object of class
  "sourceEnvironment" returned from a previous call to evalSource If a
  file name is passed to insertSource it calls evalSource to obtain the
  corresponding object. See the section on the class for details.

- **package**
  
  Optionally, the name of the package to which the new code corresponds and into
  which it will be inserted. Although the computations will attempt to infer the
  package if it is omitted, the safe approach is to supply it. In the case of a package
  that is not attached to the search list, the package name must be supplied.
functions, methods

Optionally, the character-string names of the functions to be used in the insertion. Names supplied in the `functions` argument are expected to be defined as functions in the source. For names supplied in the `methods` argument, a table of methods is expected (as generated by calls to `setMethod`, see the details section); methods from this table will be inserted by `insertSource`. In both cases, the revised function or method is inserted only if it differs from the version in the corresponding package as loaded.

If what is omitted, the results of evaluating the source file will be compared to the contents of the package (see the details section).

lock, cache

Optional arguments to control the actions taken by `evalSource`. If `lock` is `TRUE`, the environment in the object returned will be locked, and so will all its bindings. If `cache` is `FALSE`, the normal caching of method and class definitions will be suppressed during evaluation of the source file.

The default settings are generally recommended, the `lock` to support the credibility of the object returned as a snapshot of the source file, and the second so that method definitions can be inserted later by `insertSource` using the trace mechanism.

force

If `FALSE`, only functions currently in the environment will be redefined, using `trace`. If `TRUE`, other objects/functions will be simply assigned. By default, `TRUE` if neither the `functions` nor the `methods` argument is supplied.

Details

The source file is parsed and evaluated, suppressing by default the actual caching of method and class definitions contained in it, so that functions and methods can be tested out in a reversible way. The result, if all goes well, is an environment containing the assigned objects and metadata corresponding to method and class definitions in the source file.

From this environment, the objects are inserted into the package, into its namespace if it has one, for use during the current session or until reverting to the original version by a call to `untrace`. The insertion is done by calls to the internal version of `trace`, to make reversion possible.

Because the trace mechanism is used, only function-type objects will be inserted, functions themselves or S4 methods.

When the `functions` and `methods` arguments are both omitted, `insertSource` selects all suitable objects from the result of evaluating the source file.

In all cases, only objects in the source file that differ from the corresponding objects in the package are inserted. The definition of “differ” is that either the argument list (including default expressions) or the body of the function is not identical. Note that in the case of a method, there need be no specific method for the corresponding signature in the package: the comparison is made to the method that would be selected for that signature.

Nothing in the computation requires that the source file supplied be the same file as in the original package source, although that case is both likely and sensible if one is revising the package. Nothing in the computations compares source files: the objects generated by evaluating `source` are compared as objects to the content of the package.

Value

An object from class "sourceEnvironment", a subclass of "environment" (see the section on the class) The environment contains the versions of all object resulting from evaluation of the source file. The class also has slots for the time of creation, the source file and the package name. Future extensions may use these objects for versioning or other code tools.
evalSource

The object returned can be used in debugging (see the section on that topic) or as the source argument in a future call to insertSource. If only some of the revised functions were inserted in the first call, others can be inserted in a later call without re-evaluating the source file, by supplying the environment and optionally suitable functions and/or methods argument.

Debugging

Once a function or method has been inserted into a package by insertSource, it can be studied by the standard debugging tools; for example, debug or the various versions of trace. Calls to trace should take the extra argument edit = env, where env is the value returned by the call to evalSource. The trace mechanism has been used to install the revised version from the source file, and supplying the argument ensures that it is this version, not the original, that will be traced. See the example below.

To turn tracing off, but retain the source version, use trace(x, edit = env) as in the example. To return to the original version from the package, use untrace(x).

Class "sourceEnvironment"

Objects from this class can be treated as environments, to extract the version of functions and methods generated by evalSource. The objects also have the following slots:

packageName: The character-string name of the package to which the source code corresponds.

dateCreated: The date and time that the source file was evaluated (usually from a call to Sys.time).

sourceFile: The character-string name of the source file used.

Note that using the environment does not change the dateCreated.

See Also

trace for the underlying mechanism, and also for the edit= argument that can be used for somewhat similar purposes; that function and also debug and setBreakpoint, for techniques more oriented to traditional debugging styles. The present function is directly intended for the case that one is modifying some of the source for an existing package, although it can be used as well by inserting debugging code in the source (more useful if the debugging involved is non-trivial). As noted in the details section, the source file need not be the same one in the original package source.

Examples

```r
## Not run:
## Suppose package P0 has a source file "all.R"
## First, evaluate the source, and from it
## insert the revised version of methods for summary()
env <- insertSource("./P0/R/all.R", package = "P0",
                   methods = "summary")
## now test one of the methods, tracing the version from the source
trace("summary", signature = "myMat", browser, edit = env)
## After testing, remove the browser() call but keep the source
trace("summary", signature = "myMat", edit = env)
## Now insert all the (other) revised functions and methods
## without re-evaluating the source file.
## The package name is included in the object env.
insertSource(env)

## End(Not run)
```
Computations with Classes

Description

Functions to find and manipulate class definitions.

Usage

removeClass(Class, where)

isClass(Class, formal=TRUE, where)

classDef

getClasses(where, inherits = missing(where))

findClass(Class, where, unique = "")

resetClass(Class, classDef, where)

sealClass(Class, where)

Arguments

Class character string name for the class. The functions will usually take a class definition instead of the string. To restrict the class to those defined in a particular package, set the packageSlot of the character string.

where the environment in which to modify or remove the definition. Defaults to the top-level environment of the calling function (the global environment for ordinary computations, but the environment or namespace of a package in the source for a package).

When searching for class definitions, where defines where to do the search, and the default is to search from the top-level environment or namespace of the caller to this function.

unique if findClass expects a unique location for the class, unique is a character string explaining the purpose of the search (and is used in warning and error messages). By default, multiple locations are possible and the function always returns a list.

inherits in a call to getClasses, should the value returned include all parent environments of where, or that environment only? Defaults to TRUE if where is omitted, and to FALSE otherwise.

formal Should a formal definition be required?

classDef For removeClass, the optional class definition (but usually it’s better for Class to be the class definition, and to omit classDef).

Details

These are the functions that test and manipulate formal class definitions. Brief documentation is provided below. See the references for an introduction and for more details.
**findMethods**

**removeClass**: Remove the definition of this class, from the environment where if this argument is supplied; if not, removeClass will search for a definition, starting in the top-level environment of the call to removeClass, and remove the (first) definition found.

**isClass**: Is this the name of a formally defined class? (Argument formal is for compatibility and is ignored.)

**getClasses**: The names of all the classes formally defined on where. If called with no argument, all the classes visible from the calling function (if called from the top-level, all the classes in any of the environments on the search list). The inherits argument can be used to search a particular environment and all its parents, but usually the default setting is what you want.

**findClass**: The list of environments or positions on the search list in which a class definition of Class is found. If where is supplied, this is an environment (or namespace) from which the search takes place; otherwise the top-level environment of the caller is used. If unique is supplied as a character string, findClass returns a single environment or position. By default, it always returns a list. The calling function should select, say, the first element as a position or environment for functions such as get.

If unique is supplied as a character string, findClass will warn if there is more than one definition visible (using the string to identify the purpose of the call), and will generate an error if no definition can be found.

**resetClass**: Reset the internal definition of a class. Causes the complete definition of the class to be re-computed, from the representation and superclasses specified in the original call to setClass.

This function is called when aspects of the class definition are changed. You would need to call it explicitly if you changed the definition of a class that this class extends (but doing that in the middle of a session is living dangerously, since it may invalidate existing objects).

**sealClass**: Seal the current definition of the specified class, to prevent further changes. It is possible to seal a class in the call to setClass, but sometimes further changes have to be made (e.g., by calls to setIs). If so, call sealClass after all the relevant changes have been made.

`setClassUnion, Methods, makeClassRepresentation`

---

**Description**

The function `findMethods` converts the methods defined in a table for a generic function (as used for selection of methods) into a list, for study or display. The list is actually from the class `listOfMethods` (see the section describing the class, below).
The list will be limited to the methods defined in environment where if that argument is supplied and limited to those including one or more of the specified classes in the method signature if that argument is supplied.

To see the actual table (an environment) used for methods dispatch, call `getMethodsForDispatch`. The names of the list returned by `findMethods` are the names of the objects in the table.

The function `findMethodSignatures` returns a character matrix whose rows are the class names from the signature of the corresponding methods; it operates either from a list returned by `findMethods`, or by computing such a list itself, given the same arguments as `findMethods`.

The function `hasMethods` returns TRUE or FALSE according to whether there is a non-empty table of methods for function f in the environment or search position `where` (or for the generic function generally if `where` is missing).

The deprecated function `getMethod` is an older alternative to `findMethods`, returning information in the form of an object of class `MethodsList`, previously used for method dispatch. It is not recommended, since this class of objects is deprecated generally and will disappear in a future version of R.

**Usage**

```r
findMethods(f, where, classes = character(), inherited = FALSE, package = "")
findMethodSignatures(..., target = TRUE, methods = )
hasMethods(f, where, package)
```

### DEPRECATED

```r
getMethods(f, where, table = FALSE)
```

**Arguments**

- **f**
  - A generic function or the character-string name of one.

- **where**
  - Optionally, an environment or position on the search list to look for methods metadata.
  - If `where` is missing, `findMethods` uses the current table of methods in the generic function itself, and `hasMethods` looks for metadata anywhere in the search list.

- **table**
  - If TRUE in a call to `getMethods` the returned value is the table used for dispatch, including inherited methods discovered to date. Used internally, but since the default result is the now unused `mList` object, the default will likely be changed at some point.

- **classes**
  - If supplied, only methods whose signatures contain at least one of the supplied classes will be included in the value returned.

- **inherited**
  - Logical flag; if TRUE, the table of all methods, inherited or defined directly, will be used; otherwise, only the methods explicitly defined. Option TRUE is meaningful only if `where` is missing.

- **...**
  - In the call to `findMethodSignatures`, any arguments that might be given to `findMethods`.

- **target**
  - Optional flag to `findMethodSignatures`; if TRUE, the signatures used are the target signatures (the classes for which the method will be selected); if FALSE, they will be the signatures are defined. The difference is only meaningful if `inherited` is TRUE.
methods
In the call to `findMethodSignatures`, an optional list of methods, presumably returned by a previous call to `findMethods`. If missing, that function will be call with the ... arguments.

package
In a call to `hasMethods`, the package name for the generic function (e.g., “base” for primitives). If missing this will be inferred either from the “package” attribute of the function name, if any, or from the package slot of the generic function. See ‘Details’.

Details
The functions obtain a table of the defined methods, either from the generic function or from the stored metadata object in the environment specified by `where`. In a call to `getMethod`, the information in the table is converted as described above to produce the returned value, except with the table argument.

Note that `hasMethods`, but not the other functions, can be used even if no generic function of this name is currently found. In this case package must either be supplied as an argument or included as an attribute of `f`, since the package name is part of the identification of the methods tables.

The Class for lists of methods
The class “listOfMethods” returns the methods as a named list of method definitions (or a primitive function, see the slot documentation below). The names are the strings used to store the corresponding objects in the environment from which method dispatch is computed. The current implementation uses the names of the corresponding classes in the method signature, separated by “#” if more than one argument is involved in the signature.

Slots

.Data: Object of class "list" The method definitions.
   Note that these may include the primitive function itself as default method, when the generic corresponds to a primitive. (Basically, because primitive functions are abnormal R objects, which cannot currently be extended as method definitions.) Computations that use the returned list to derive other information need to take account of this possibility. See the implementation of `findMethodSignatures` for an example.

arguments: Object of class "character". The names of the formal arguments in the signature of the generic function.

signatures: Object of class "list". A list of the signatures of the individual methods. This is currently the result of splitting the names according to the “#” separator.
   If the object has been constructed from a table, as when returned by `findMethods`, the signatures will all have the same length. However, a list rather than a character matrix is used for generality. Calling `findMethodSignatures` as in the example below will always convert to the matrix form.

generic: Object of class "genericFunction". The generic function corresponding to these methods. There are plans to generalize this slot to allow reference to the function.

names: Object of class "character". The names as noted are the class names separated by “#”.

Extends
Class "namedList", directly.
Class "list", by class "namedList", distance 2.
Class "vector", by class "namedList", distance 3.
Fix Objects Saved from R Versions Previous to 1.8

Description
Beginning with R version 1.8.0, the class of an object contains the identification of the package in which the class is defined. The function fixPre1.8 fixes and re-assigns objects missing that information (typically because they were loaded from a file saved with a previous version of R.)

Usage
fixPre1.8(names, where)

Arguments
names Character vector of the names of all the objects to be fixed and re-assigned.
where The environment from which to look for the objects, and for class definitions. Defaults to the top environment of the call to fixPre1.8, the global environment if the function is used interactively.

Details
The named object will be saved where it was found. Its class attribute will be changed to the full form required by R 1.8; otherwise, the contents of the object should be unchanged.

Objects will be fixed and re-assigned only if all the following conditions hold:
1. The named object exists.
2. It is from a defined class (not a basic datatype which has no actual class attribute).
3. The object appears to be from an earlier version of R.
4. The class is currently defined.
5. The object is consistent with the current class definition.

If any condition except the second fails, a warning message is generated.

Note that fixPre1.8 currently fixes only the change in class attributes. In particular, it will not fix binary versions of packages installed with earlier versions of R if these use incompatible features. Such packages must be re-installed from source, which is the wise approach always when major version changes occur in R.

Value
The names of all the objects that were in fact re-assigned.
Generic Function Objects

Description

Generic functions (objects from or extending class genericFunction) are extended function objects, containing information used in creating and dispatching methods for this function. They also identify the package associated with the function and its methods.

Objects from the Class

Generic functions are created and assigned by setGeneric or setGroupGeneric and, indirectly, by setMethod.

As you might expect setGeneric and setGroupGeneric create objects of class "genericFunction" and "groupGenericFunction" respectively.

Slots

- .Data: Object of class "function", the function definition of the generic, usually created automatically as a call to standardGeneric.
- generic: Object of class "character", the name of the generic function.
- package: Object of class "character", the name of the package to which the function definition belongs (and not necessarily where the generic function is stored). If the package is not specified explicitly in the call to setGeneric, it is usually the package on which the corresponding non-generic function exists.
- group: Object of class "list", the group or groups to which this generic function belongs. Empty by default.
- valueClass: Object of class "character"; if not an empty character vector, identifies one or more classes. It is asserted that all methods for this function return objects from these class (or from classes that extend them).
- signature: Object of class "character", the vector of formal argument names that can appear in the signature of methods for this generic function. By default, it is all the formal arguments, except for .... Order matters for efficiency: the most commonly used arguments in specifying methods should come first.
- default: Object of class "optionalMethod" (a union of classes "function" and "NULL"), containing the default method for this function if any. Generated automatically and used to initialize method dispatch.
- skeleton: Object of class "call", a slot used internally in method dispatch. Don’t expect to use it directly.

Extends

Class "function", from data part.
Class "OptionalMethods", by class "function".
Class "PossibleMethod", by class "function".
Generic function objects are used in the creation and dispatch of formal methods; information from the object is used to create methods list objects and to merge or update the existing methods for this generic.

### Tools for Managing Generic Functions

The functions documented here manage collections of methods associated with a generic function, as well as providing information about the generic functions themselves.

#### Usage

- `isGeneric(f, where, fdef, getName = FALSE)`
- `isGroup(f, where, fdef)`
- `removeGeneric(f, where)`

- `dumpMethod(f, signature, file, where, def)`
- `findFunction(f, generic = TRUE, where = topenv(parent.frame()))`
- `dumpMethods(f, file, signature, methods, where)`
- `signature(...)`

- `removeMethods(f, where = topenv(parent.frame()), all = missing(where))`

- `setReplaceMethod(f, ..., where = topenv(parent.frame()))`

- `getGenerics(where, searchForm = FALSE)`

#### Arguments

- **f**: The character string naming the function.
- **where**: The environment, namespace, or search-list position from which to search for objects. By default, start at the top-level environment of the calling function, typically the global environment (i.e., use the search list), or the namespace of a package from which the call came. It is important to supply this argument when calling any of these functions indirectly. With package namespaces, the default is likely to be wrong in such calls.
- **signature**: The class signature of the relevant method. A signature is a named or unnamed vector of character strings. If named, the names must be formal argument names for the generic function. Signatures are matched to the arguments specified in the signature slot of the generic function (see the Details section of the `setMethod` documentation).

  The signature argument to `dumpMethods` is ignored (it was used internally in previous implementations).

- **file**: The file or connection on which to dump method definitions.
- **def**: The function object defining the method; if omitted, the current method definition corresponding to the signature.
... Named or unnamed arguments to form a signature.

generic In testing or finding functions, should generic functions be included. Supply as
FALSE to get only non-generic functions.

fdef Optional, the generic function definition.
Usually omitted in calls to isGeneric

getName If TRUE, isGeneric returns the name of the generic. By default, it returns TRUE.

methods The methods object containing the methods to be dumped. By default, the meth-
ods defined for this generic (optionally on the specified where location).

all in removeMethods, logical indicating if all (default) or only the first method
found should be removed.

searchForm In getGenerics, if TRUE, the package slot of the returned result is in
the form used by search(), otherwise as the simple package name (e.g.
"package:base" vs "base").

Summary of Functions

isGeneric: Is there a function named f, and if so, is it a generic?
The getName argument allows a function to find the name from a function definition. If it
is TRUE then the name of the generic is returned, or FALSE if this is not a generic function
definition.
The behavior of isGeneric and getGeneric for primitive functions is slightly different.
These functions don’t exist as formal function objects (for efficiency and historical reasons),
regardless of whether methods have been defined for them. A call to isGeneric tells you
whether methods have been defined for this primitive function, anywhere in the current search
list, or in the specified position where. In contrast, a call to getGeneric will return what the
generic for that function would be, even if no methods have been currently defined for it.

removeGeneric, removeMethods: Remove all the methods for the generic function of this name.
In addition, removeGeneric removes the function itself, removeMethods restores the
non-generic function which was the default method. If there was no default method,
removeMethods leaves a generic function with no methods.

standardGeneric: Dispatches a method from the current function call for the generic function
f. It is an error to call standardGeneric anywhere except in the body of the corresponding
generic function.
Note that standardGeneric is a primitive function in the base package for efficiency reasons,
but rather documented here where it belongs naturally.

dumpMethod: Dump the method for this generic function and signature.

findFirst: return a list of either the positions on the search list, or the current top-level envi-
ronment, on which a function object for name exists. The returned value is always a list, use
the first element to access the first visible version of the function. See the example.
NOTE: Use this rather than find with mode="function", which is not as meaningful, and has
a few subtle bugs from its use of regular expressions. Also, findFunction works correctly in
the code for a package when attaching the package via a call to library.

dumpMethods: Dump all the methods for this generic.

signature: Returns a named list of classes to be matched to arguments of a generic function.

getGenerics: returns the names of the generic functions that have methods defined on where; this
argument can be an environment or an index into the search list. By default, the whole search
list is used.
The methods definitions are stored with package qualifiers; for example, methods for function "initialize" might refer to two different functions of that name, on different packages. The package names corresponding to the method list object are contained in the slot package of the returned object. The form of the returned name can be plain (e.g., "base"), or in the form used in the search list ("package:base") according to the value of searchForm.

Details

setGeneric: If there is already a non-generic function of this name, it will be used to define the generic unless def is supplied, and the current function will become the default method for the generic.

If def is supplied, this defines the generic function, and no default method will exist (often a good feature, if the function should only be available for a meaningful subset of all objects).

Arguments group and valueClass are retained for consistency with S-Plus, but are currently not used.

isGeneric: If the fdef argument is supplied, take this as the definition of the generic, and test whether it is really a generic, with f as the name of the generic. (This argument is not available in S-Plus.)

removeGeneric: If where supplied, just remove the version on this element of the search list; otherwise, removes the first version encountered.

standardGeneric: Generic functions should usually have a call to standardGeneric as their entire body. They can, however, do any other computations as well.

The usual setGeneric (directly or through calling setMethod) creates a function with a call to standardGeneric.

dumpMethod: The resulting source file will recreate the method.

findFirst: If generic is FALSE, ignore generic functions.

dumpMethods: If signature is supplied only the methods matching this initial signature are dumped. (This feature is not found in S-Plus: don’t use it if you want compatibility.)

signature: The advantage of using signature is to provide a check on which arguments you meant, as well as clearer documentation in your method specification. In addition, signature checks that each of the elements is a single character string.

removeMethods: Returns TRUE if f was a generic function, FALSE (silently) otherwise.

If there is a default method, the function will be re-assigned as a simple function with this definition. Otherwise, the generic function remains but with no methods (so any call to it will generate an error). In either case, a following call to setMethod will consistently re-establish the same generic function as before.

setClass("B", contains="A")
setMethod("plot", "B", function(x,y,...){ cat("B ...\n") })
dumpMethods("plot", file=tmp)
stopifnot(removeMethod("plot", "A"),
  removeMethod("plot", "B"))
source(tmp)
stopifnot(is(getMethod("plot", "A"), "MethodDefinition"),
  is(getMethod("plot", "B"), "MethodDefinition"))

---

**getClass**

Get Class Definition
**Description**

Get the definition of a class.

**Usage**

```r
getClass(Class, .Force = FALSE, where)
getClassDef(Class, where, package, inherits = TRUE)
```

**Arguments**

- **Class**
  the character-string name of the class, often with a "package" attribute as noted below under package.

- **.Force**
  if TRUE, return NULL if the class is undefined; otherwise, an undefined class results in an error.

- **where**
  environment from which to begin the search for the definition; by default, start at the top-level (global) environment and proceed through the search list.

- **package**
  the name of the package asserted to hold the definition. If it is a non-empty string it is used instead of `where`, as the first place to look for the class. Note that the package must be loaded but need not be attached. By default, the package attribute of the `Class` argument is used, if any. There will usually be a package attribute if `Class` comes from `class(x)` for some object.

- **inherits**
  Should the class definition be retrieved from any enclosing environment and also from the cache? If FALSE only a definition in the environment `where` will be returned.

**Details**

Class definitions are stored in metadata objects in a package namespace or other environment where they are defined. When packages are loaded, the class definitions in the package are cached in an internal table. Therefore, most calls to `getClassDef` will find the class in the cache or fail to find it at all, unless `inherits` is FALSE, in which case only the environment(s) defined by `package` or `where` are searched.

The class cache allows for multiple definitions of the same class name in separate environments, with of course the limitation that the package attribute or package name must be provided in the call to

**Value**

The object defining the class. If the class definition is not found, `getClassDef` returns NULL, while `getClass`, which calls `getClassDef`, either generates an error or, if `.Force` is TRUE, returns a simple definition for the class. The latter case is used internally, but is not typically sensible in user code.

The non-null returned value is an object of class `classRepresentation`. For all reasonable purposes, use this object only to extract information, rather than trying to modify it: Use functions such as `setClass` and `setIs` to create or modify class definitions.

**References**

Chambers, John M. (1998) *Programming with Data* Springer (For the original S4 version.)
getMethod

Get or Test for the Definition of a Method

Description

Functions to look for a method corresponding to a given generic function and signature. The functions `getMethod` and `selectMethod` return the method; the functions `existsMethod` and `hasMethod` test for its existence. In both cases the first function only gets direct definitions and the second uses inheritance. In all cases, the search is in the generic function itself or in the package/environment specified by argument `where`.

The function `findMethod` returns the package(s) in the search list (or in the packages specified by the `where` argument) that contain a method for this function and signature.

Usage

```r
getMethod(f, signature=character(), where, optional = FALSE, 
  mlist, fdef)

existsMethod(f, signature = character(), where)

findMethod(f, signature, where)

selectMethod(f, signature, optional = FALSE, useInherited =,
  mlist = , fdef = , verbose = , doCache = )

hasMethod(f, signature=character(), where)
```

Arguments

- `f` A generic function or the character-string name of one.
- `signature` the signature of classes to match to the arguments of `f`. See the details below.
- `where` The position or environment in which to look for the method(s): by default, the table of methods defined in the generic function itself is used.

See Also

`Classes`, `setClass`, `isClass`.

Examples

```r
getClass("numeric") ## a built in class

cld <- getClass("thisIsAnUndefinedClass", .Force = TRUE)
cld ## a NULL prototype
## If you are really curious:
utils::str(cld)
## Whereas these generate errors:
try(getClass("thisIsAnUndefinedClass"))
try(getClassDef("thisIsAnUndefinedClass"))
```
optional If the selection in selectMethod does not find a valid method an error is generated, unless this argument is TRUE. In that case, the value returned is NULL if no method matches.

mlist, fdef, useInherited, verbose, doCache Optional arguments togetMethod and selectMethod for internal use. Avoid these: some will work as expected and others will not, and none of them is required for normal use of the functions.

Details

The signature argument specifies classes, corresponding to formal arguments of the generic function; to be precise, to the signature slot of the generic function object. The argument may be a vector of strings identifying classes, and may be named or not. Names, if supplied, match the names of those formal arguments included in the signature of the generic. That signature is normally all the arguments except .... However, generic functions can be specified with only a subset of the arguments permitted, or with the signature taking the arguments in a different order.

It’s a good idea to name the arguments in the signature to avoid confusion, if you’re dealing with a generic that does something special with its signature. In any case, the elements of the signature are matched to the formal signature by the same rules used in matching arguments in function calls (see match.call).

The strings in the signature may be class names, "missing" or "ANY". See Methods for the meaning of these in method selection. Arguments not supplied in the signature implicitly correspond to class "ANY"; in particular, giving an empty signature means to look for the default method.

A call to getMethod returns the method for a particular function and signature. As with other get functions, argument where controls where the function looks (by default anywhere in the search list) and argument optional controls whether the function returns NULL or generates an error if the method is not found. The search for the method makes no use of inheritance.

The function selectMethod also looks for a method given the function and signature, but makes full use of the method dispatch mechanism; i.e., inherited methods and group generics are taken into account just as they would be in dispatching a method for the corresponding signature, with the one exception that conditional inheritance is not used. Like getMethod, selectMethod returns NULL or generates an error if the method is not found, depending on the argument optional.

The functions existsMethod and hasMethod return TRUE or FALSE according to whether a method is found, the first corresponding to getMethod (no inheritance) and the second to selectMethod.

Value

The call to selectMethod or getMethod returns the selected method, if one is found. (This class extends function, so you can use the result directly as a function if that is what you want.) Otherwise an error is thrown if optional is FALSE and NULL is returned if optional is TRUE.

The returned method object is a MethodDefinition object, except that the default method for a primitive function is required to be the primitive itself. Note therefore that the only reliable test that the search failed is is.null().

getPackageName

See Also

Methods for the details of method selection; GenericFunctions for other functions manipulating methods and generic function objects; MethodDefinition for the class that represents method definitions.

Examples

```r
setGeneric("testFun", function(x)standardGeneric("testFun"))
setMethod("testFun", "numeric", function(x)x+x)
hasMethod("testFun", "numeric")
## Not run: [1] TRUE
hasMethod("testFun", "integer") # inherited
## Not run: [1] TRUE
existsMethod("testFun", "integer")
## Not run: [1] FALSE
hasMethod("testFun") # default method
## Not run: [1] FALSE
hasMethod("testFun", "ANY")
## Not run: [1] FALSE
```

getPackageName

The Name associated with a Given Package

Description

The functions below produce the package associated with a particular environment or position on the search list, or of the package containing a particular function. They are primarily used to support computations that need to differentiate objects on multiple packages.

Usage

```r
getPackageName(where, create = TRUE)
setpackageName(pkg, env)

packageSlot(object)
packageSlot(object) <- value
```

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>where</td>
<td>the environment or position on the search list associated with the desired package.</td>
</tr>
<tr>
<td>object</td>
<td>object providing a character string name, plus the package in which this object is to be found.</td>
</tr>
<tr>
<td>value</td>
<td>the name of the package.</td>
</tr>
<tr>
<td>create</td>
<td>flag, should a package name be created if none can be inferred? If TRUE and no non-empty package name is found, the current date and time are used as a package name, and a warning is issued. The created name is stored in the environment if that environment is not locked.</td>
</tr>
<tr>
<td>pkg, env</td>
<td>make the string in pkg the internal package name for all computations that set class and method definitions in environment env.</td>
</tr>
</tbody>
</table>
Details

Package names are normally installed during loading of the package, by the `INSTALL` script or by the `library` function. (Currently, the name is stored as the object `.packageName` but don’t trust this for the future.)

Value

`getPackageName` returns the character-string name of the package (without the extraneous "package:" found in the search list).

`packageSlot` returns or sets the package name slot (currently an attribute, not a formal slot, but this may change someday).

`setPackageName` can be used to establish a package name in an environment that would otherwise not have one. This allows you to create classes and/or methods in an arbitrary environment, but it is usually preferable to create packages by the standard R programming tools (`package.skeleton`, etc.)

See Also

`search`, `packageName`

Examples

```r
## all the following usually return "base"
getPackageName(length(search()))
getPackageName(baseenv())
getPackageName(asNamespace("base"))
getPackageName("package:base")
```

---

hasArg 

Look for an Argument in the Call

Description

Returns TRUE if `name` corresponds to an argument in the call, either a formal argument to the function, or a component of ..., and FALSE otherwise.

Usage

`hasArg(name)`

Arguments

`name` The name of a potential argument, as an unquoted name or character string.

Details

The expression `hasArg(x)`, for example, is similar to `!missing(x)`, with two exceptions. First, `hasArg` will look for an argument named `x` in the call if `x` is not a formal argument to the calling function, but ... is. Second, `hasArg` never generates an error if given a name as an argument, whereas `missing(x)` generates an error if `x` is not a formal argument.
**Value**

Always TRUE or FALSE as described above.

**See Also**

`missing`

**Examples**

```r
define(f1, x) c(hasArg(x), hasArg("y2"))

f1(1)  ## c(TRUE, FALSE)
f1(1, 2)  ## c(TRUE, FALSE)
f1(y = 2)  ## c(FALSE, TRUE) (no partial matching)
f1(y = 2, x = 1)  ## c(TRUE, TRUE) partial match x1
```

---

**Description**

Create or access implicit generic functions, used to enforce consistent generic versions of functions that are not currently generic. Function `implicitGeneric()` returns the implicit generic version, `setGenericImplicit()` turns a generic implicit, `prohibitGeneric()` prevents your function from being made generic, and `registerImplicitGenerics()` saves a set of implicit generic definitions in the cached table of the current session.

**Usage**

```r
implicitGeneric(name, where, generic)
setGenericImplicit(name, where, restore = TRUE)
prohibitGeneric(name, where)
registerImplicitGenerics(what, where)
```

**Arguments**

- `name`: Character string name of the function.
- `where`: Package or environment in which to register the implicit generics. When using the functions from the top level of your own package source, this argument can usually be omitted (and should be).
- `generic`: Optionally, the generic function definition to be cached, but usually omitted. See Details section.
- `restore`: Should the non-generic version of the function be restored after the current.
- `what`: For `registerImplicitGenerics()`. Optional table of the implicit generics to register, but nearly always omitted. See Details section.
Details

Multiple packages may define methods for the same function, using the version of a function stored in one package. All these methods should be marshaled and dispatched consistently when a user calls the function. For consistency, the generic version of the function must have a unique definition (the same arguments allowed in methods signatures, the same values for optional slots such as the value class, and the same standard or non-standard definition of the function itself).

If the original function is already an S4 generic, there is no problem. The implicit generic mechanism enforces consistency when the version in the package owning the function is not generic. If a call to setGeneric() attempts to turn a function in another package into a generic, the mechanism compares the proposed new generic function to the implicit generic version of that function. If the two agree, all is well. If not, and if the function belongs to another package, then the new generic will not be associated with that package. Instead, a warning is issued and a separate generic function is created, with its package slot set to the current package, not the one that owns the non-generic version of the function. The effect is that the new package can still define methods for this function, but it will not share the methods in other packages, since it is forcing a different definition of the generic function.

The right way to proceed in nearly all cases is to call setGeneric("Foo"), giving only the name of the function; this will automatically use the implicit generic version. If you don’t like that version, the best solution is to convince the owner of the other package to agree with you and to insert code to define the non-default properties of the function (even if the owner does not want foo() to be a generic by default).

For any function, the implicit generic form is a standard generic in which all formal arguments, except for ..., are allowed in the signature of methods. If that is the suitable generic for a function, no action is needed. If not, the best mechanism is to set up the generic in the code of the package owning the function, and then call setGenericImplicit() to record the implicit generic and restore the non-generic version. See the example.

Note that the package can define methods for the implicit generic as well; when the implicit generic is made a real generic, those methods will be included.

Other than predefining methods, the usual reason for having a non-default implicit generic is to provide a non-default signature, and the usual reason for that is to allow lazy evaluation of some arguments. See the example. All arguments in the signature of a generic function must be evaluated at the time the function needs to select a method. (But those arguments can be missing, with or without a default expression being defined; you can always examine missing(x) even for arguments in the signature.)

If you want to completely prohibit anyone from turning your function into a generic, call prohibitGeneric().

Value

Function implicitGeneric() returns the implicit generic definition (and caches that definition the first time it has to construct it).

The other functions exist for their side effect and return nothing useful.

### How we would make the function `\link(with)()` into a generic:
inheritedSlotNames

Names of Slots Inherited From a Super Class

Description

For a class (or class definition, see getClass and the description of class classRepresentation), give the names which are inherited from “above”, i.e., super classes, rather than by this class’ definition itself.

Usage

inheritedSlotNames(Class, where = topenv(parent.frame()))

Arguments

Class character string or classRepresentation, i.e., resulting from getClass.
where environment, to be passed further to isClass and getClass.

Value

character vector of slot names, or NULL.

See Also

slotNames, slot, setClass, etc.

Examples

.srcch <- search()
library(stats4)
inheritedSlotNames("mle")

## Not run:
if(require("Matrix")) {
  print( inheritedSlotNames("Matrix") ) # NULL
  ## whereas
  print( inheritedSlotNames("sparseMatrix") ) # -- Dim & Dimnames
  ## i.e. inherited from "Matrix" class
  print( cl <- getClass("dgCMatrix") ) # six slots, etc
  print( inheritedSlotNames(cl) ) # *all* six slots are inherited
}

## detach package we've attached above:
for(n in rev(which(is.na(match(search(), .srch)))))
  try(detach(pos = n))

## End(Not run)

### Methods to Initialize New Objects from a Class

#### Description

The arguments to function new to create an object from a particular class can be interpreted specially for that class, by the definition of a method for function initialize for the class. This documentation describes some existing methods, and also outlines how to write new ones.

#### Methods

**signature(.Object = "ANY")** The default method for initialize takes either named or unnamed arguments. Argument names must be the names of slots in this class definition, and the corresponding arguments must be valid objects for the slot (that is, have the same class as specified for the slot, or some superclass of that class). If the object comes from a superclass, it is not coerced strictly, so normally it will retain its current class (specifically, as(object, Class, strict = FALSE)).

Unnamed arguments must be objects of this class, of one of its superclasses, or one of its subclasses (from the class, from a class this class extends, or from a class that extends this class). If the object is from a superclass, this normally defines some of the slots in the object. If the object is from a subclass, the new object is that argument, coerced to the current class.

Unnamed arguments are processed first, in the order they appear. Then named arguments are processed. Therefore, explicit values for slots always override any values inferred from superclass or subclass arguments.

**signature(.Object = "traceable")** Objects of a class that extends traceable are used to implement debug tracing (see class traceable and trace).

The initialize method for these classes takes special arguments def, tracer, exit, at, print. The first of these is the object to use as the original definition (e.g., a function). The others correspond to the arguments to trace.

**signature(.Object = "environment"), signature(.Object = ".environment")** The initialize method for environments takes a named list of objects to be used to initialize the environment. Subclasses of "environment" inherit an initialize method through ".environment", which has the additional effect of allocating a new environment.
define your own method for such a subclass, be sure either to call the existing method via `callNextMethod` or allocate an environment in your method, since environments are references and are not duplicated automatically.

`signature(.Object = "signature")` This is a method for internal use only. It takes an optional `functionDef` argument to provide a generic function with a `signature` slot to define the argument names. See Methods for details.

### Writing Initialization Methods

Initialization methods provide a general mechanism corresponding to generator functions in other languages.

The arguments to `initialize` are `.Object` and `...`. Nearly always, `initialize` is called from `new`, not directly. The `.Object` argument is then the prototype object from the class.

Two techniques are often appropriate for `initialize` methods: special argument names and `callNextMethod`.

You may want argument names that are more natural to your users than the (default) slot names. These will be the formal arguments to your method definition, in addition to `.Object` (always) and `...` (optionally). For example, the method for class "traceable" documented above would be created by a call to `setMethod` of the form:

```r
setMethod("initialize", "traceable",
  function(.Object, def, tracer, exit, at, print) ...
)
```

In this example, no other arguments are meaningful, and the resulting method will throw an error if other names are supplied.

When your new class extends another class, you may want to call the `initialize` method for this superclass (either a special method or the default). For example, suppose you want to define a method for your class, with special argument `x`, but you also want users to be able to set slots specifically. If you want `x` to override the slot information, the beginning of your method definition might look something like this:

```r
function(.Object, x, ...) {
  Object <- callNextMethod(.Object, ...)
  if(!missing(x)) { # do something with x
    # Override slot information
  }
}
```

You could also choose to have the inherited method override, by first interpreting `x`, and then calling the next method.

---

### Is an Object from a Class?

**Description**

Functions to test inheritance relationships between an object and a class (`is`) or between two classes (`extends`), and to establish such relationships (`setIs`, an explicit alternative to the `contains=` argument to `setClass`).
Usage

is(object, class2)

extends(class1, class2, maybe = TRUE, fullInfo = FALSE)

setIs(class1, class2, test=NULL, coerce=NULL, replace=NULL,
by = character(), where = topenv(parent.frame()), classDef =,
extensionObject = NULL, doComplete = TRUE)

Arguments

object any R object.
class1, class2 the names of the classes between which is relations are to be examined defined, or (more efficiently) the class definition objects for the classes.
maybe, fullInfo
In a call to extends, maybe is the value returned if a relation is conditional. In a call with class2 missing, fullInfo is a flag, which if TRUE causes a list of objects of class classExtension to be returned, rather than just the names of the classes.
coerce, replace
In a call to setIs, functions optionally supplied to coerce the object to class2, and to alter the object so that is(object, class2) is identical to value. See the details section below.
test
In a call to setIs, a conditional relationship is defined by supplying this function. Conditional relations are discouraged and are not included in selecting methods. See the details section below.
The remaining arguments are for internal use and/or usually omitted.
extensionObject alternative to the test, coerce, replace, by arguments; an object from class SClassExtension describing the relation. (Used in internal calls.)
doComplete when TRUE, the class definitions will be augmented with indirect relations as well. (Used in internal calls.)
by
In a call to setIs, the name of an intermediary class. Coercion will proceed by first coercing to this class and from there to the target class. (The intermediate coercions have to be valid.)
where
In a call to setIs, where to store the metadata defining the relationship. Default is the global environment for calls from the top level of the session or a source file evaluated there. When the call occurs in the top level of a file in the source of a package, the default will be the namespace or environment of the package. Other uses are tricky and not usually a good idea, unless you really know what you are doing.
classDef Optional class definition for class, required internally when setIs is called during the initial definition of the class by a call to setClass. Don’t use this argument, unless you really know why you’re doing so.

Summary of Functions

is: With two arguments, tests whether object can be treated as from class2.
   With one argument, returns all the super-classes of this object’s class.
extends: Does the first class extend the second class? The call returns maybe if the extension includes a test.

When called with one argument, the value is a vector of the superclasses of class1. If argument fullInfo is TRUE, the call returns a named list of objects of class SClassExtension; otherwise, just the names of the superclasses.

setIs: Defines class1 to be an extension (subclass) of class2. If class2 is an existing virtual class, such as a class union, then only the two classes need to be supplied in the call, if the implied inherited methods work for class1. See the details section below.

Alternatively, arguments coerce and replace should be supplied, defining methods to coerce to the superclass and to replace the part corresponding to the superclass. As discussed in the details and other sections below, this form is often less recommended than the corresponding call to setAs, to which it is an alternative.

Argument test allows conditional inheritance, in which the is() result is tested for each object rather than being determined by the class definition. This form is discouraged when it can be avoided; in particular, note that conditional inheritance is not used to select methods for dispatch.

Details

Arranging for a class to inherit from another class is a key tool in programming. In R, there are three basic techniques, the first two providing what is called “simple” inheritance, the preferred form:

1. By the contains argument in a call to setClass. This is and should be the most common mechanism. It arranges that the new class contains all the structure of the existing class, and in particular all the slots with the same class specified. The resulting class extension is defined to be simple, with important implications for method definition (see the section on this topic below).

2. Making class1 a subclass of a virtual class either by a call to setClassUnion to make the subclass a member of a new class union, or by a call to setIs to add a class to an existing class union or as a new subclass of an existing virtual class. In either case, the implication should be that methods defined for the class union or other superclass all work correctly for the subclass. This may depend on some similarity in the structure of the subclasses or simply indicate that the superclass methods are defined in terms of generic functions that apply to all the subclasses. These relationships are also generally simple.

3. Supplying coerce and replace arguments to setAs. R allows arbitrary inheritance relationships, using the same mechanism for defining coerce methods by a call to setAs. The difference between the two is simply that setAs will require a call to as for a conversion to take place, whereas after the call to setIs, objects will be automatically converted to the superclass.

The automatic feature is the dangerous part, mainly because it results in the subclass potentially inheriting methods that do not work. See the section on inheritance below. If the two classes involved do not actually inherit a large collection of methods, as in the first example below, the danger may be relatively slight.

If the superclass inherits methods where the subclass has only a default or remotely inherited method, problems are more likely. In this case, a general recommendation is to use the setAs mechanism instead, unless there is a strong counter reason. Otherwise, be prepared to override some of the methods inherited.

With this caution given, the rest of this section describes what happens when coerce= and replace= arguments are supplied to setIs.
The coerce and replace arguments are functions that define how to coerce a class1 object to class2, and how to replace the part of the subclass object that corresponds to class2. The first of these is a function of one argument which should be from, and the second of two arguments (from, value). For details, see the section on coerce functions below.

When by is specified, the coerce process first coerces to this class and then to class2. It’s unlikely you would use the by argument directly, but it is used in defining cached information about classes. The value returned (invisibly) by setIs is the revised class definition of class1.

**Coerce, replace, and test functions**

The coerce argument is a function that turns a class1 object into a class2 object. The replace argument is a function of two arguments that modifies a class1 object (the first argument) to replace the part of it that corresponds to class2 (supplied as value, the second argument). It then returns the modified object as the value of the call. In other words, it acts as a replacement method to implement the expression as(object, class2) <- value.

The easiest way to think of the coerce and replace functions is by thinking of the case that class1 contains class2 in the usual sense, by including the slots of the second class. (To repeat, in this situation you would not call setIs, but the analogy shows what happens when you do.)

The coerce function in this case would just make a class2 object by extracting the corresponding slots from the class1 object. The replace function would replace in the class1 object the slots corresponding to class2, and return the modified object as its value.

For additional discussion of these functions, see the documentation of the setIs function. (Unfortunately, argument def to that function corresponds to argument coerce here.)

The inheritance relationship can also be conditional, if a function is supplied as the test argument. This should be a function of one argument that returns TRUE or FALSE according to whether the object supplied satisfies the relation is(object, class2). Conditional relations between classes are discouraged in general because they require a per-object calculation to determine their validity. They cannot be applied as efficiently as ordinary relations and tend to make the code that uses them harder to interpret. *NOTE: conditional inheritance is not used to dispatch methods.* Methods for conditional superclasses will not be inherited. Instead, a method for the subclass should be defined that tests the conditional relationship.

**Inherited methods**

A method written for a particular signature (classes matched to one or more formal arguments to the function) naturally assumes that the objects corresponding to the arguments can be treated as coming from the corresponding classes. The objects will have all the slots and available methods for the classes.

The code that selects and dispatches the methods ensures that this assumption is correct. If the inheritance was “simple”, that is, defined by one or more uses of the contains= argument in a call to setClass, no extra work is generally needed. Classes are inherited from the superclass, with the same definition.

When inheritance is defined by a general call to setIs, extra computations are required. This form of inheritance implies that the subclass does not just contain the slots of the superclass, but instead requires the explicit call to the coerce and/or replace method. To ensure correct computation, the inherited method is supplemented by calls to as before the body of the method is evaluated.

The calls to as generated in this case have the argument strict = FALSE, meaning that extra information can be left in the converted object, so long as it has all the appropriate slots. (It’s this option that allows simple subclass objects to be used without any change.) When you are writing your coerce method, you may want to take advantage of that option.
Methods inherited through non-simple extensions can result in ambiguities or unexpected selections. If `class2` is a specialized class with just a few applicable methods, creating the inheritance relation may have little effect on the behavior of `class1`. But if `class2` is a class with many methods, you may find that you now inherit some undesirable methods for `class1`, in some cases, fail to inherit expected methods. In the second example below, the non-simple inheritance from class "factor" might be assumed to inherit S3 methods via that class. But the S3 class is ambiguous, and in fact is "character" rather than "factor".

For some generic functions, methods inherited by non-simple extensions are either known to be invalid or sufficiently likely to be so that the generic function has been defined to exclude such inheritance. For example `initialize` methods must return an object of the target class; this is straightforward if the extension is simple, because no change is made to the argument object, but is essentially impossible. For this reason, the generic function insists on only simple extensions for inheritance. See the `simpleInheritanceOnly` argument to `setGeneric` for the mechanism. You can use this mechanism when defining new generic functions.

If you get into problems with functions that do allow non-simple inheritance, there are two basic choices. Either back off from the `setIs` call and settle for explicit coercing defined by a call to `setAs`; or, define explicit methods involving `class1` to override the bad inherited methods. The first choice is the safer, when there are serious problems.

References

Chambers, John M. (1998) Programming with Data Springer (For the original S4 version.)

See Also

`inherits` is nearly always equivalent to `is`, both for S4 and non-S4 objects, and is somewhat faster. The non-equivalence applies to classes that have conditional superclasses, with a non-trivial test in the relation (not common and discouraged): for these, `is` tests for the relation but `inherits` by definition ignores conditional inheritance for S4 objects.

`selectSuperClasses`(`cl`) has similar semantics as `extends`(`cl`), typically returning subsets of the latter.

Examples

```r
## Two examples of setIs() with coerce= and replace= arguments
## The first one works fairly well, because neither class has many
## inherited methods do be disturbed by the new inheritance

## The second example does NOT work well, because the new superclass,
## "factor", causes methods to be inherited that should not be.

## First example:
## a class definition (see \link{setClass} for class "track")
setClass("trackCurve", contains = "track",
  representation(smooth = "numeric"))
## A class similar to "trackCurve", but with different structure
## allowing matrices for the "y" and "smooth" slots
setClass("trackMultiCurve",
  representation(x="numeric", y="matrix", smooth="matrix"),
  prototype = structure(list(x=numeric(), y=matrix(0,0,0),
```
smooth = matrix(0, 0, 0))

## Automatically convert an object from class "trackCurve" into
## "trackMultiCurve", by making the y, smooth slots into 1-column matrices
setIs("trackCurve",
  "trackMultiCurve",
  coerce = function(obj) {
    new("trackMultiCurve",
        x = obj$x,
        y = as.matrix(obj$y),
        smooth = as.matrix(obj$smooth))
  },
  replace = function(obj, value) {
    obj$y <- as.matrix(value$y)
    obj$x <- value$x
    obj$smooth <- as.matrix(value$smooth)
    obj})

## Second Example:
## A class that adds a slot to "character"
setClass("stringsDated", contains = "character",
  representation(stamp="POSIXt"))

## Convert automatically to a factor by explicit coerce
setIs("stringsDated", "factor",
  coerce = function(from) factor(from@.Data),
  replace= function(from, value) {
    from@.Data <- as.character(value); from })

ll <- sample(letters, 10, replace = TRUE)
l0 <- new("stringsDated", ll, stamp = Sys.time())

levels(as(l0, "factor"))
levels(l0) # will be NULL---see comment in section on inheritance above.

## In contrast, a class that simply extends "factor"
## has no such ambiguities
setClass("factorDated", contains = "factor",
  representation(stamp="POSIXt"))
fd <- new("factorDated", factor(ll), stamp = Sys.time())
identical(levels(fd), levels(as(fd, "factor")))

### isSealedMethod
#### Check for a Sealed Method or Class

**Description**

These functions check for either a method or a class that has been *sealed* when it was defined, and which therefore cannot be re-defined.

**Usage**

isSealedMethod(f, signature, fdef, where)
isSealedClass(Class, where)
isSealedMethod

Arguments

f                      The quoted name of the generic function.
signature             The class names in the method’s signature, as they would be supplied to `setMethod`
fdef                   Optional, and usually omitted: the generic function definition for f.
Class                   The quoted name of the class.
where                   where to search for the method or class definition. By default, searches from the top environment of the call to isSealedMethod or isSealedClass, typically the global environment or the namespace of a package containing a call to one of the functions.

Details

In the R implementation of classes and methods, it is possible to seal the definition of either a class or a method. The basic classes (numeric and other types of vectors, matrix and array data) are sealed. So also are the methods for the primitive functions on those data types. The effect is that programmers cannot re-define the meaning of these basic data types and computations. More precisely, for primitive functions that depend on only one data argument, methods cannot be specified for basic classes. For functions (such as the arithmetic operators) that depend on two arguments, methods can be specified if one of those arguments is a basic class, but not if both are.

Programmers can seal other class and method definitions by using the sealed argument to `setClass` or `setMethod`.

Value

The functions return FALSE if the method or class is not sealed (including the case that it is not defined); TRUE if it is.

References

Examples

```r
## these are both TRUE
isSealedMethod("+", c("numeric", "character"))
isSealedClass("matrix")

setClass("track",
    representation(x="numeric", y="numeric"))
## but this is FALSE
isSealedClass("track")
## and so is this
isSealedClass("A Name for an undefined Class")
## and so are these, because only one of the two arguments is basic
isSealedMethod("+", c("track", "numeric"))
isSealedMethod("+", c("numeric", "track"))
```
language-class  Classes to Represent Unevaluated Language Objects

Description

The virtual class "language" and the specific classes that extend it represent unevaluated objects, as produced for example by the parser or by functions such as `quote`.

Usage

### each of these classes corresponds to an unevaluated object
### in the S language.
### The class name can appear in method signatures,
### and in a few other contexts (such as some calls to `as()`).

`"(`
`"<-`
`"call"
`"for"
`"if"
`"repeat"
`"while"
`"name"
`""`

### Each of the classes above extends the virtual class
"language"

Objects from the Class

"language" is a virtual class; no objects may be created from it.

Objects from the other classes can be generated by a call to `new(Class, ...),` where `Class` is the quoted class name, and the ...arguments are either empty or a `single` object that is from this class (or an extension).

Methods

`coerce` signature(`from = "ANY", to = "call"`). A method exists for `as(object, "call"),` calling `as.call()`.

LinearMethodsList-class

Class "LinearMethodsList"

Description

A version of methods lists that has been ‘linearized’ for producing summary information. The actual objects from class "MethodsList" used for method dispatch are defined recursively over the arguments involved.
Objects from the Class

The function `linearizeMlist` converts an ordinary methods list object into the linearized form.

Slots

- `methods`: Object of class "list", the method definitions.
- `arguments`: Object of class "list", the corresponding formal arguments, namely as many of the arguments in the signature of the generic function as are active in the relevant method table.
- `classes`: Object of class "list", the corresponding classes in the signatures.
- `generic`: Object of class "genericFunction": the generic function to which the methods correspond.

Future Note

The current version of `linearizeMlist` does not take advantage of the `MethodDefinition` class, and therefore does more work for less effect than it could. In particular, we may move to redefine both the function and the class to take advantage of the stored signatures. Don't write code depending precisely on the present form, although all the current information will be obtainable in the future.

See Also

Function `linearizeMlist` for the computation, and class `MethodsList` for the original, recursive form.

LocalReferenceClasses  Localized Objects based on Reference Classes

Description

Local reference classes are modified `ReferenceClasses` that isolate the objects to the local frame. Therefore, they do not propagate changes back to the calling environment. At the same time, they use the reference field semantics locally, avoiding the automatic duplication applied to standard R objects.

The current implementation has no special construction. To create a local reference class, call `setRefClass()` with a `contains=` argument that includes "localRefClass". See the example below.

Local reference classes operate essentially as do regular, functional classes in R; that is, changes are made by assignment and take place in the local frame. The essential difference is that replacement operations (like the change to the `twiddle` field in the example) do not cause duplication of the entire object, as would be the case for a formal class or for data with attributes or in a named list. The purpose is to allow large objects in some fields that are not changed along with potentially frequent changes to other fields, but without copying the large fields.

Usage

```r
setRefClass(Class, fields = , contains = c("localRefClass",....),
            methods = , where =, ...)
```
Details

Localization of objects is only partially automated in the current implementation. Replacement expressions using the $<-$ operator are safe.

However, if reference methods for the class themselves modify fields, using $<-$, for example, then one must ensure that the object is local to the relevant frame before any such method is called. Otherwise, standard reference class behavior still prevails.

There are two ways to ensure locality. The direct way is to invoke the special method ensureLocal() on the object. The other way is to modify a field explicitly by x$Field $<-$ ...

It’s only necessary that one or the other of these happens once for each object, in order to trigger the shallow copy that provides locality for the references. In the example below, we show both mechanisms.

However it’s done, localization must occur before any methods make changes. (Eventually, some use of code tools should at least largely automate this process, although it may be difficult to guarantee success under arbitrary circumstances.)

Author(s)

John Chambers

Examples

```r
## class "myIter" has a BigData field for the real (big) data
## and a "twiddle" field for some parameters that it twiddles
## ( for some reason)

myIter <- setRefClass("myIter", contains = "localRefClass",
  fields = list(BigData = "numeric", twiddle = "numeric"))

tw <- rnorm(3)
x1 <- myIter(BigData = rnorm(1000), twiddle = tw) # OK, not REALLY big

twiddler <- function(x, n) {
  x$ensureLocal() # see the Details. Not really needed in this example
  for(i in seq(length = n)) {
    x$twiddle $<-$ x$twiddle + rnorm(length(x$twiddle))
    ## then do something ....
    ## Snooping in gdb, etc will show that x$BigData is not copied
  }
  return(x)
}

x2 <- twiddler(x1, 10)

stopifnot(identical(x1$twiddle, tw), !identical(x1$twiddle, x2$twiddle))
```

makeClassRepresentation

Create a Class Definition
makeClassRepresentation

Description

Constructs an object of class `classRepresentation` to describe a particular class. Mostly a utility function, but you can call it to create a class definition without assigning it, as `setClass` would do.

Usage

    makeClassRepresentation(name, slots=list(), superClasses=character(),
                            prototype=NULL, package, validity, access,
                            version, sealed, virtual=NA, where)

Arguments

name character string name for the class
slots named list of slot classes as would be supplied to `setClass`, but without the unnamed arguments for `superClasses` if any.
superClasses what classes does this class extend
prototype an object providing the default data for the class, e.g., the result of a call to `prototype`.
package The character string name for the package in which the class will be stored; see `getPackageName`.
validity Optional validity method. See `validObject`, and the discussion of validity methods in the reference.
access Access information. Not currently used.
version Optional version key for version control. Currently generated, but not used.
sealed Is the class sealed? See `setClass`.
virtual Is this known to be a virtual class?
where The environment from which to look for class definitions needed (e.g., for slots or superclasses). See the discussion of this argument under `GenericFunctions`.

`setClass`
Create a Skeleton File for a New Method

Description

This function writes a source file containing a call to `setMethod` to define a method for the generic function and signature supplied. By default the method definition is in line in the call, but can be made an external (previously assigned) function.

Usage

```
method.skeleton(generic, signature, file, external = FALSE, where)
```

Arguments

- `generic`: the character string name of the generic function, or the generic function itself. In the first case, the function need not currently be a generic, as it would not for the resulting call to `setMethod`.
- `signature`: the method signature, as it would be given to `setMethod`.
- `file`: a character string name for the output file, or a writable connection. By default the generic function name and the classes in the signature are concatenated, with separating underscore characters. The file name should normally end in ".R". To write multiple method skeletons to one file, open the file connection first and then pass it to `method.skeleton()` in multiple calls.
- `external`: flag to control whether the function definition for the method should be a separate external object assigned in the source file, or included in line in the call to `setMethod`. If supplied as a character string, this will be used as the name for the external function; by default the name concatenates the generic and signature names, with separating underscores.
- `where`: The environment in which to look for the function; by default, the top-level environment of the call to `method.skeleton`.

Value

The `file` argument, invisibly, but the function is used for its side effect.

See Also

`setMethod`, `package.skeleton`

Examples

```
setClass("track", representation(x ="numeric", y="numeric"))
method.skeleton("show", "track")  ### writes show_track.R
method.skeleton("Ops", c("track", "track"))  ### writes "Ops_track_track.R"

### write multiple method skeletons to one file
con <- file("./Math_track.R", "w")
method.skeleton("Math", "track", con)
method.skeleton("exp", "track", con)
method.skeleton("log", "track", con)
```
Classes to Represent Method Definitions

Description

These classes extend the basic class "function" when functions are to be stored and used as method definitions.

Details

Method definition objects are functions with additional information defining how the function is being used as a method. The target slot is the class signature for which the method will be dispatched, and the defined slot the signature for which the method was originally specified (that is, the one that appeared in some call to setMethod).

Objects from the Class

The action of setting a method by a call to setMethod creates an object of this class. It's unwise to create them directly.

The class "SealedMethodDefinition" is created by a call to setMethod with argument sealed = TRUE. It has the same representation as "MethodDefinition".

Slots

.data: Object of class "function"; the data part of the definition.
target: Object of class "signature"; the signature for which the method was wanted.
defined: Object of class "signature"; the signature for which a method was found. If the method was inherited, this will not be identical to target.
generic: Object of class "character"; the function for which the method was created.

Extends

Class "function", from data part.
Class "PossibleMethod", directly.
Class "OptionalMethods", by class "function".

See Also

class MethodsList for the objects defining sets of methods associated with a particular generic function. The individual method definitions stored in these objects are from class MethodDefinition, or an extension. Class MethodWithNext for an extension used by callNextMethod.
Methods

General Information on Methods

Description

This documentation section covers some general topics on how methods work and how the methods package interacts with the rest of R. The information is usually not needed to get started with methods and classes, but may be helpful for moderately ambitious projects, or when something doesn’t work as expected.

The section “How Methods Work” describes the underlying mechanism; “S3 Methods and Generic Functions” gives the rules applied when S4 classes and methods interact with older S3 methods; “Method Selection and Dispatch” provides more details on how class definitions determine which methods are used; “Generic Functions” discusses generic functions as objects. For additional information specifically about class definitions, see Classes.

How Methods Work

A generic function has associated with it a collection of other functions (the methods), all of which have the same formal arguments as the generic. See the “Generic Functions” section below for more on generic functions themselves.

Each R package will include methods metadata objects corresponding to each generic function for which methods have been defined in that package. When the package is loaded into an R session, the methods for each generic function are cached, that is, stored in the environment of the generic function along with the methods from previously loaded packages. This merged table of methods is used to dispatch or select methods from the generic, using class inheritance and possibly group generic functions (see GroupGenericFunctions) to find an applicable method. See the “Method Selection and Dispatch” section below. The caching computations ensure that only one version of each generic function is visible globally; although different attached packages may contain a copy of the generic function, these behave identically with respect to method selection. In contrast, it is possible for the same function name to refer to more than one generic function, when these have different package slots. In the latter case, R considers the functions unrelated: A generic function is defined by the combination of name and package. See the “Generic Functions” section below.

The methods for a generic are stored according to the corresponding signature in the call to setMethod that defined the method. The signature associates one class name with each of a subset of the formal arguments to the generic function. Which formal arguments are available, and the order in which they appear, are determined by the “signature” slot of the generic function itself. By default, the signature of the generic consists of all the formal arguments except . . . , in the order they appear in the function definition.

Trailing arguments in the signature of the generic will be inactive if no method has yet been specified that included those arguments in its signature. Inactive arguments are not needed or used in labeling the cached methods. (The distinction does not change which methods are dispatched, but ignoring inactive arguments improves the efficiency of dispatch.)

All arguments in the signature of the generic function will be evaluated when the function is called, rather than using the traditional lazy evaluation rules of S. Therefore, it’s important to exclude from the signature any arguments that need to be dealt with symbolically (such as the first argument to function substitute). Note that only actual arguments are evaluated, not default expressions. A missing argument enters into the method selection as class “missing”.

The cached methods are stored in an environment object. The names used for assignment are a concatenation of the class names for the active arguments in the method signature.
Methods

Methods for S3 Generic Functions

S4 methods may be wanted for functions that also have S3 methods, corresponding to classes for the first formal argument of an S3 generic function—either a regular R function in which there is a call to the S3 dispatch function, UseMethod, or one of a fixed set of primitive functions, which are not true functions but go directly to C code. In either case S3 method dispatch looks at the class of the first argument or the class of either argument in a call to one of the primitive binary operators. S3 methods are ordinary functions with the same arguments as the generic function (for primitives the formal arguments are not actually part of the object, but are simulated when the object is printed or viewed by args()). The “signature” of an S3 method is identified by the name to which the method is assigned, composed of the name of the generic function, followed by ".\"", followed by the name of the class. For details, see S3Methods.

To implement a method for one of these functions corresponding to S4 classes, there are two possibilities: either an S4 method or an S3 method with the S4 class name. The S3 method is only possible if the intended signature has the first argument and nothing else. In this case, the recommended approach is to define the S3 method and also supply the identical function as the definition of the S4 method. If the S3 generic function was f3(x, ...) and the S4 class for the new method was "myClass":

f3.myClass <- function(x, ...) { ..... }
setMethod("f3", "myClass", f3.myClass)

The reasons for defining both S3 and S4 methods are as follows:

1. An S4 method alone will not be seen if the S3 generic function is called directly. However, primitive functions and operators are exceptions: The internal C code will look for S4 methods if and only if the object is an S4 object. In the examples, the method for `\[\` for class "myFrame" will always be called for objects of this class.

For the same reason, an S4 method defined for an S3 class will not be called from internal code for a non-S4 object. (See the example for function Math and class "data.frame" in the examples.)

2. An S3 method alone will not be called if there is any eligible non-default S4 method. (See the example for function fS and class "classA" in the examples.)

Details of the selection computations are given below.

When an S4 method is defined for an existing function that is not an S4 generic function (whether or not the existing function is an S3 generic), an S4 generic function will be created corresponding to the existing function and the package in which it is found (more precisely, according to the implicit generic function either specified or inferred from the ordinary function; see implicitGeneric). A message is printed after the initial call to setMethod; this is not an error, just a reminder that you have created the generic. Creating the generic explicitly by the call setGeneric("f3")

avoids the message, but has the same effect. The existing function becomes the default method for the S4 generic function. Primitive functions work the same way, but the S4 generic function is not explicitly created (as discussed below).

S4 and S3 method selection are designed to follow compatible rules of inheritance, as far as possible. S3 classes can be used for any S4 method selection, provided that the S3 classes have been registered by a call to setOldClass, with that call specifying the correct S3 inheritance pattern. S4 classes can be used for any S3 method selection; when an S4 object is detected, S3 method selection uses the contents of extends(class(x)) as the equivalent of the S3 inheritance (the inheritance is cached after the first call).

An existing S3 method may not behave as desired for an S4 subclass, in which case utilities such as asS3 and S3Part may be useful. If the S3 method fails on the S4 object, asS3(x) may be
passed instead; if the object returned by the S3 method needs to be incorporated in the S4 object, the replacement function for S3Part may be useful, as in the method for class "myFrame" in the examples.

Here are details explaining the reasons for defining both S3 and S4 methods. Calls still accessing the S3 generic function directly will not see S4 methods, except in the case of primitive functions. This means that calls to the generic function from namespaces that import the S3 generic but not the S4 version will only see S3 methods. On the other hand, S3 methods will only be selected from the S4 generic function as part of its default ("ANY") method. If there are inherited S4 non-default methods, these will be chosen in preference to any S3 method.

S3 generic functions implemented as primitive functions (including binary operators) are an exception to recognizing only S3 methods. These functions dispatch both S4 and S3 methods from the internal C code. There is no explicit generic function, either S3 or S4. The internal code looks for S4 methods if the first argument, or either of the arguments in the case of a binary operator, is an S4 object. If no S4 method is found, a search is made for an S3 method.

S4 methods can be defined for an S3 generic function and an S3 class, but if the function is a primitive, such methods will not be selected if the object in question is not an S4 object. In the examples below, for instance, an S4 method for signature "data.frame" for function `fSHI` would be called for the S3 object `df1`. A similar S4 method for primitive function `\[\]` would be ignored for that object, but would be called for the S4 object `mydf1` that inherits from "data.frame". Defining both an S3 and S4 method removes this inconsistency.

Method Selection and Dispatch: Details

When a call to a generic function is evaluated, a method is selected corresponding to the classes of the actual arguments in the signature. First, the cached methods table is searched for an exact match; that is, a method stored under the signature defined by the string value of `class(x)` for each non-missing argument, and "missing" for each missing argument. If no method is found directly for the actual arguments in a call to a generic function, an attempt is made to match the available methods to the arguments by using the superclass information about the actual classes.

Each class definition may include a list of one or more superclasses of the new class. The simplest and most common specification is by the contains= argument in the call to `setClass`. Each class named in this argument is a superclass of the new class. Two additional mechanisms for defining superclasses exist. A call to `setClassUnion` creates a union class that is a superclass of each of the members of the union. A call to `setIs` can create an inheritance relationship that is not the simple one of containing the superclass representation in the new class. Arguments coerce and replace supply methods to convert to the superclass and to replace the part corresponding to the superclass. (In addition, a test= argument allows conditional inheritance; conditional inheritance is not recommended and is not used in method selection.) All three mechanisms are treated equivalently for purposes of method selection: they define the direct superclasses of a particular class. For more details on the mechanisms, see Classes.

The direct superclasses themselves may have superclasses, defined by any of the same mechanisms, and similarly through further generations. Putting all this information together produces the full list of superclasses for this class. The superclass list is included in the definition of the class that is cached during the R session. Each element of the list describes the nature of the relationship (see SClassExtension for details). Included in the element is a distance slot containing the path length for the relationship: 1 for direct superclasses (regardless of which mechanism defined them), then 2 for the direct superclasses of those classes, and so on. In addition, any class implicitly has class "ANY" as a superclass. The distance to "ANY" is treated as larger than the distance to any actual class. The special class "missing" corresponding to missing arguments has only "ANY" as a superclass, while "ANY" has no superclasses.
When a class definition is created or modified, the superclasses are ordered, first by a stable sort of the all superclasses by distance. If the set of superclasses has duplicates (that is, if some class is inherited through more than one relationship), these are removed, if possible, so that the list of superclasses is consistent with the superclasses of all direct superclasses. See the reference on inheritance for details.

The information about superclasses is summarized when a class definition is printed.

When a method is to be selected by inheritance, a search is made in the table for all methods directly corresponding to a combination of either the direct class or one of its superclasses, for each argument in the active signature. For an example, suppose there is only one argument in the signature and that the class of the corresponding object was "BdgematrixB" (from the recommended package Matrix). This class has two direct superclasses and through these 4 additional superclasses. Method selection finds all the methods in the table of directly specified methods labeled by one of these classes, or by "ANY".

When there are multiple arguments in the signature, each argument will generate a similar list of inherited classes. The possible matches are now all the combinations of classes from each argument (think of the function outer generating an array of all possible combinations). The search now finds all the methods matching any of this combination of classes. For each argument, the position in the list of superclasses of that argument’s class defines which method or methods (if the same class appears more than once) match best. When there is only one argument, the best match is unambiguous. With more than one argument, there may be zero or one match that is among the best matches for all arguments.

If there is no best match, the selection is ambiguous and a message is printed noting which method was selected (the first method lexicographically in the ordering) and what other methods could have been selected. Since the ambiguity is usually nothing the end user could control, this is not a warning. Package authors should examine their package for possible ambiguous inheritance by calling testInheritedMethods.

When the inherited method has been selected, the selection is cached in the generic function so that future calls with the same class will not require repeating the search. Cached inherited selections are not themselves used in future inheritance searches, since that could result in invalid selections. If you want inheritance computations to be done again (for example, because a newly loaded package has a more direct method than one that has already been used in this session), call resetGeneric. Because classes and methods involving them tend to come from the same package, the current implementation does not reset all generics every time a new package is loaded.

Besides being initiated through calls to the generic function, method selection can be done explicitly by calling the function selectMethod.

Once a method has been selected, the evaluator creates a new context in which a call to the method is evaluated. The context is initialized with the arguments from the call to the generic function. These arguments are not rematched. All the arguments in the signature of the generic will have been evaluated (including any that are currently inactive); arguments that are not in the signature will obey the usual lazy evaluation rules of the language. If an argument was missing in the call, its default expression if any will not have been evaluated, since method dispatch always uses class missing for such arguments.

A call to a generic function therefore has two contexts: one for the function and a second for the method. The argument objects will be copied to the second context, but not any local objects created in a nonstandard generic function. The other important distinction is that the parent (“enclosing”) environment of the second context is the environment of the method as a function, so that all R programming techniques using such environments apply to method definitions as ordinary functions.

For further discussion of method selection and dispatch, see the first reference.
Generic Functions

In principle, a generic function could be any function that evaluates a call to `standardGeneric()`, the internal function that selects a method and evaluates a call to the selected method. In practice, generic functions are special objects that in addition to being from a subclass of class "function" also extend the class `genericFunction`. Such objects have slots to define information needed to deal with their methods. They also have specialized environments, containing the tables used in method selection.

The slots "generic" and "package" in the object are the character string names of the generic function itself and of the package from which the function is defined. As with classes, generic functions are uniquely defined in `{R}` by the combination of the two names. There can be generic functions of the same name associated with different packages (although inevitably keeping such functions cleanly distinguished is not always easy). On the other hand, `{R}` will enforce that only one definition of a generic function can be associated with a particular combination of function and package name, in the current session or other active version of `{R}`.

Tables of methods for a particular generic function, in this sense, will often be spread over several other packages. The total set of methods for a given generic function may change during a session, as additional packages are loaded. Each table must be consistent in the signature assumed for the generic function.

`{R}` distinguishes standard and nonstandard generic functions, with the former having a function body that does nothing but dispatch a method. For the most part, the distinction is just one of simplicity: knowing that a generic function only dispatches a method call allows some efficiencies and also removes some uncertainties.

In most cases, the generic function is the visible function corresponding to that name, in the corresponding package. There are two exceptions, implicit generic functions and the special computations required to deal with `R`'s primitive functions. Packages can contain a table of implicit generic versions of functions in the package, if the package wishes to leave a function non-generic but to constrain what the function would be like if it were generic. Such implicit generic functions are created during the installation of the package, essentially by defining the generic function and possibly methods for it, and then reverting the function to its non-generic form. (See `implicitGeneric` for how this is done.) The mechanism is mainly used for functions in the older packages in `{R}`, which may prefer to ignore S4 methods. Even in this case, the actual mechanism is only needed if something special has to be specified. All functions have a corresponding implicit generic version defined automatically (an implicit, implicit generic function one might say). This function is a standard generic with the same arguments as the non-generic function, with the non-generic version as the default (and only) method, and with the generic signature being all the formal arguments except ....

The implicit generic mechanism is needed only to override some aspect of the default definition. One reason to do so would be to remove some arguments from the signature. Arguments that may need to be interpreted literally, or for which the lazy evaluation mechanism of the language is needed, must not be included in the signature of the generic function, since all arguments in the signature will be evaluated in order to select a method. For example, the argument `expr` to the function `with` is treated literally and must therefore be excluded from the signature.

One would also need to define an implicit generic if the existing non-generic function were not suitable as the default method. Perhaps the function only applies to some classes of objects, and the package designer prefers to have no general default method. In the other direction, the package designer might have some ideas about suitable methods for some classes, if the function were generic. With reasonably modern packages, the simple approach in all these cases is just to define the function as a generic. The implicit generic mechanism is mainly attractive for older packages that do not want to require the methods package to be available.
Generic functions will also be defined but not obviously visible for functions implemented as \textit{primitive} functions in the base package. Primitive functions look like ordinary functions when printed but are in fact not function objects but objects of two types interpreted by the \texttt{R} evaluator to call underlying C code directly. Since their entire justification is efficiency, \texttt{R} refuses to hide primitives behind a generic function object. Methods may be defined for most primitives, and corresponding metadata objects will be created to store them. Calls to the primitive still go directly to the C code, which will sometimes check for applicable methods. The definition of “sometimes” is that methods must have been detected for the function in some package loaded in the session and \texttt{isS4(x)} is \texttt{TRUE} for the first argument (or for the second argument, in the case of binary operators). You can test whether methods have been detected by calling \texttt{isGeneric} for the relevant function and you can examine the generic function by calling \texttt{getGeneric}, whether or not methods have been detected. For more on generic functions, see the first reference and also section 2 of \textit{R Internals}.

\section*{Method Definitions}

All method definitions are stored as objects from the \texttt{MethodDefinition} class. Like the class of generic functions, this class extends ordinary \texttt{R} functions with some additional slots: “generic”, containing the name and package of the generic function, and two signature slots, “defined” and “target”, the first being the signature supplied when the method was defined by a call to \texttt{setMethod}. The “target” slot starts off equal to the “defined” slot. When an inherited method is cached after being selected, as described above, a copy is made with the appropriate “target” signature. Output from \texttt{showMethods}, for example, includes both signatures.

Method definitions are required to have the same formal arguments as the generic function, since the method dispatch mechanism does not rematch arguments, for reasons of both efficiency and consistency.
