\begin{verbatim}
## A class that extends a registered S3 class inherits that class' S3 methods.

setClass("myFrame", contains = "data.frame",
       representation(timestamps = "POSIXt"))

df1 <- data.frame(x = 1:10, y = rnorm(10), z = sample(letters,10))

mydf1 <- new("myFrame", df1, timestamps = Sys.time())

## "myFrame" objects inherit "data.frame" S3 methods; e.g., for `\ fractional
\end{verbatim}
mydf1[1:2, ] # a data frame object (with extra attributes)

## a method explicitly for "myFrame" class

```r
setMethod("[", 
  signature(x = "myFrame"), 
  function(x, i, j, ..., drop = TRUE) 
  { 
    S3Part(x) <- callNextMethod() 
    x@timestamps <- c(Sys.time(), as.POSIXct(x@timestamps)) 
    x 
  })
```

mydf1[1:2, ]

```r
setClass("myDateTime", contains = "POSIXt")

now <- Sys.time() # class(now) is c("POSIXct", "POSIXt")
nowLt <- as.POSIXlt(now)# class(nowLt) is c("POSIXlt", "POSIXt")

mCt <- new("myDateTime", now)
mlt <- new("myDateTime", nowLt)

## S3 methods for an S4 object will be selected using S4 inheritance
## Objects mCt and mLt have different S3class() values, but this is
## not used.

f3 <- function(x)UseMethod("f3") # an S3 generic to illustrate inheritance

f3.POSIXct <- function(x) "The POSIXct result"

f3.POSIXlt <- function(x) "The POSIXlt result"

f3.POSIXt <- function(x) "The POSIXt result"

stopifnot(identical(f3(mCt), f3.POSIXt(mCt)))
stopifnot(identical(f3(mlt), f3.POSIXt(mlt)))

## An S4 object selects S3 methods according to its S4 "inheritance"

```r
setClass("classA", contains = "numeric", 
          representation(realData = "numeric"))

Math.classA <- function(x) {(getFunction(.Generic))(x@realData)}

setMethod("Math", "classA", Math.classA)

x <- new("classA", log(1:10), realData = 1:10)

stopifnot(identical(abs(x), 1:10))

setClass("classB", contains = "classA")

y <- new("classB", x)
stopifnot(identical(abs(y), 1:10)) # (version 2.9.0 or earlier fails here)

## an S3 generic: just for demonstration purposes
f3 <- function(x, ...) UseMethod("f3")

f3.default <- function(x, ...) "Default f3"

## S3 method (only) for classA
f3.classA <- function(x, ...) "Class classA for f3"

## S3 and S4 method for numeric
f3.numeric <- function(x, ...) "Class numeric for f3"
setMethod("f3", "numeric", f3.numeric)

## The S3 method for classA and the closest inherited S3 method for classB
## are not found.

f3(x); f3(y) # both choose "numeric" method

## to obtain the natural inheritance, set identical S3 and S4 methods
setMethod("f3", "classA", f3.classA)

f3(x); f3(y) # now both choose "classA" method

## Need to define an S3 as well as S4 method to use on an S3 object
## or if called from a package without the S4 generic
MathFun <- function(x) { # a smarter "data.frame" method for Math group
  for (i in seq(length = ncol(x)))[sapply(x, is.numeric)]
    x[, i] <- (getFunction(.Generic))(x[, i])
  x
}
setMethod("Math", "data.frame", MathFun)

## S4 method works for an S4 class containing data.frame,
## but not for data.frame objects (not S4 objects)
try(logIris <- log(iris)) #gets an error from the old method

## Define an S3 method with the same computation
Math.data.frame <- MathFun

logIris <- log(iris)
MethodWithNext-class

Description

This class of objects was used in the original implementation of the package to control method dispatch. Its use is now deprecated, but objects appear as the default method slot in generic functions. This and any other remaining uses will be removed in the future.

For the modern alternative, see listMethods.

The details in this documentation are retained to allow analysis of old-style objects.

Details

Suppose a function \( f \) has formal arguments \( x \) and \( y \). The methods list object for that function has the object as \( .names("x") \) as its argument slot. An element of the methods named "track" is selected if the actual argument corresponding to \( x \) is an object of class "track". If there is such an element, it can generally be either a function or another methods list object.

In the first case, the function defines the method to use for any call in which \( x \) is of class "track". In the second case, the new methods list object defines the available methods depending on the remaining formal arguments, in this example, \( y \).

Each method corresponds conceptually to a *signature*; that is a named list of classes, with names corresponding to some or all of the formal arguments. In the previous example, if selecting class "track" for \( x \), finding that the selection was another methods list and then selecting class "numeric" for \( y \) would produce a method associated with the signature \( x = "\text{track}", y = "\text{numeric}".\)

Slots

- **argument**: Object of class "name". The name of the argument being used for dispatch at this level.
- **methods**: A named list of the methods (and method lists) defined *explicitly* for this argument. The names are the names of classes, and the corresponding element defines the method or methods to be used if the corresponding argument has that class. See the details below.
- **allMethods**: A named list, contains all the directly defined methods from the methods slot, plus any inherited methods. Ignored when methods tables are used for dispatch (see Methods

Extends

Class "OptionalMethods", directly.

---

MethodWithNext-class  Class MethodWithNext

Description

Class of method definitions set up for callNextMethod

Objects from the Class

Objects from this class are generated as a side-effect of calls to callNextMethod.
new

Generate an Object from a Class

Description

Given the name or the definition of a class, plus optionally data to be included in the object, new returns an object from that class.

Usage

new(Class, ...) initialize(.Object, ...)

Arguments

Class either the name of a class, a character string, (the usual case) or the object describing the class (e.g., the value returned by getClass).

... data to include in the new object. Named arguments correspond to slots in the class definition. Unnamed arguments must be objects from classes that this class extends.

.Object An object: see the Details section.
Details

The function `new` begins by copying the prototype object from the class definition. Then information is inserted according to the ... arguments, if any. As of version 2.4 of R, the type of the prototype object, and therefore of all objects returned by `new()`, is "S4" except for classes that extend one of the basic types, where the prototype has that basic type. User functions that depend on `typeof(object)` should be careful to handle "S4" as a possible type.

Note that the `name` of the first argument, "Class" entails that "Class" is an undesirable slot name in any formal class: `new("myClass", Class = <value>)` will not work.

The interpretation of the ... arguments can be specialized to particular classes, if an appropriate method has been defined for the generic function "initialize". The new function calls `initialize` with the object generated from the prototype as the .Object argument to `initialize`.

By default, unnamed arguments in the ... are interpreted as objects from a superclass, and named arguments are interpreted as objects to be assigned into the correspondingly named slots. Thus, explicit slots override inherited information for the same slot, regardless of the order in which the arguments appear.

The `initialize` methods do not have to have ... as their second argument (see the examples). Initialize methods are often written when the natural parameters describing the new object are not the names of the slots. If you do define such a method, note the implications for future subclasses of your class. If these have additional slots, and your `initialize` method has ... as a formal argument, then your method should pass such arguments along via `callNextMethod`. If your method does not have this argument, then either a subclass must have its own method or else the added slots must be specified by users in some way other than as arguments to new.

For examples of `initialize` methods, see `initialize-methods` for existing methods for classes "traceable" and "environment", among others. See the comments there on subclasses of "environment"; any `initialize` methods for these should be sure to allocate a new environment.

Methods for `initialize` can be inherited only by simple inheritance, since it is a requirement that the method return an object from the target class. See the `simpleInheritanceOnly` argument to `setGeneric` and the discussion in `setIs` for the general concept.

Note that the basic vector classes, "numeric", etc. are implicitly defined, so one can use `new` for these classes.

References

Chambers, John M. (1998) *Programming with Data* Springer (For the original S4 version.)

See Also

Classes for an overview of defining class, and `setOldClass` for the relation to S3 classes.

Examples

```r
## using the definition of class "track" from \link{setClass}

## a new object with two slots specified
t1 <- new("track", x = seq_along(ydata), y = ydata)

# a new object including an object from a superclass, plus a slot
```
t2 <- new("trackCurve", t1, smooth = ysmooth)

### define a method for initialize, to ensure that new objects have
### equal-length x and y slots.

```
setMethod("initialize", "track",
  function(.Object, x = numeric(0), y = numeric(0)) {
    if(nargs() > 1) {
      if(length(x) != length(y))
        stop("specified x and y of different lengths")
      .Object@x <- x
      .Object@y <- y
    }
    .Object
  })
```

### the next example will cause an error (x will be numeric(0)),
### because we didn’t build in defaults for x,
### although we could with a more elaborate method for initialize

try(new("track", y = sort(stats::rnorm(10))))

## a better way to implement the previous initialize method.
## Why? By using callNextMethod to call the default initialize method
## we don’t inhibit classes that extend "track" from using the general
## form of the new() function. In the previous version, they could only
## use x and y as arguments to new, unless they wrote their own
## initialize method.

```
setMethod("initialize", "track", function(.Object, ...) {
  .Object <- callNextMethod()
  if(length(.Object@x) != length(.Object@y))
    stop("specified x and y of different lengths")
  .Object
})
```

---

**nonStructure-class**  
* A non-structure S4 Class for basic types

### Description

S4 classes that are defined to extend one of the basic vector classes should contain the class
**structure** if they behave like structures; that is, if they should retain their class behavior under
math functions or operators, so long as their length is unchanged. On the other hand, if their class
depends on the values in the object, not just its structure, then they should lose that class under any
such transformations. In the latter case, they should be defined to contain **nonStructure**.

If neither of these strategies applies, the class likely needs some methods of its own for **Ops, Math**,  
and/or other generic functions. What is not usually a good idea is to allow such computations to  
drop down to the default, base code. This is inconsistent with most definitions of such classes.
ObjectsWithPackage-class

Methods

Methods are defined for operators and math functions (groups Ops, Math and Math2. In all cases the result is an ordinary vector of the appropriate type.

xx <- new("NumericNotStructure", 1:10)
xz + 1 # vector
log(xx) # vector
sample(xx) # vector
```

ObjectsWithPackage-class

A Vector of Object Names, with associated Package Names

Description

This class of objects is used to represent ordinary character string object names, extended with a package slot naming the package associated with each object.

Objects from the Class

The function `getGenerics` returns an object of this class.

Slots

- `.Data`: Object of class "character": the object names.
- `package`: Object of class "character" the package names.

Extends

Class "character", from data part.
Class "vector", by class "character".

See Also

Methods for general background.
promptClass

Generate a Shell for Documentation of a Formal Class

Description

Assembles all relevant slot and method information for a class, with minimal markup for Rd processing; no QC facilities at present.

Usage

promptClass(clName, filename = NULL, type = "class",
keywords = "classes", where = topoenv(parent.frame()),
generatorName = clName)

Arguments

clName a character string naming the class to be documented.
filename usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is the topic name for the class documentation, followed by ".Rd". Can also be NA (see below).
type the documentation type to be declared in the output file.
k keywords the keywords to include in the shell of the documentation. The keyword "classes" should be one of them.
where where to look for the definition of the class and of methods that use it.
generatorName the name for a generator function for this class; only required if a generator function was created and saved under a name different from the class name.

Details

The class definition is found on the search list. Using that definition, information about classes extended and slots is determined.

In addition, the currently available generics with methods for this class are found (using getGenerics). Note that these methods need not be in the same environment as the class definition; in particular, this part of the output may depend on which packages are currently in the search list.

As with other prompt-style functions, unless filename is NA, the documentation shell is written to a file, and a message about this is given. The file will need editing to give information about the meaning of the class. The output of promptClass can only contain information from the metadata about the formal definition and how it is used.

If filename is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to cat(unlist(x), file = filename, sep = "\n"), where x is the list-style representation.

If a generator function is found assigned under the class name or the optional generatorName, skeleton documentation for that function is added to the file.

Value

If filename is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.
promptMethods

Author(s)
VJ Carey <stvjc@channing.harvard.edu> and John Chambers

References
Chambers, John M. (1998) *Programming with Data* Springer (For the original S4 version.)

See Also
`prompt` for documentation of functions, `promptMethods` for documentation of method definitions.

For processing of the edited documentation, either use R CMD Rdconv, or include the edited file in the ‘man’ subdirectory of a package.

Examples
```r
## Not run: > promptClass("track")
A shell of class documentation has been written to the file "track-class.Rd".

## End(Not run)
```

```
promptMethods Generate a Shell for Documentation of Formal Methods

Description
Generates a shell of documentation for the methods of a generic function.

Usage
`promptMethods(f, filename = NULL, methods)`

Arguments

- **f**
a character string naming the generic function whose methods are to be documented.

- **filename**
usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to the coded topic name for these methods (currently, `f` followed by "-methods.Rd"). Can also be FALSE or NA (see below).

- **methods**
Optional methods list object giving the methods to be documented. By default, the first methods object for this generic is used (for example, if the current global environment has some methods for `f`, these would be documented). If this argument is supplied, it is likely to be `getMethods(f, where)`, with `where` some package containing methods for `f`.```
Details

If `filename` is `FALSE`, the text created is returned, presumably to be inserted some other documentation file, such as the documentation of the generic function itself (see `prompt`).

If `filename` is `NA`, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n"), where x is the list-style representation.

Otherwise, the documentation shell is written to the file specified by `filename`.

Value

If `filename` is `FALSE`, the text generated; if `filename` is `NA`, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

`prompt` and `promptClass`

---

**Description**

The software described here supports reference classes whose objects have fields accessed by reference in the style of “OOP” languages such as Java and C++. Computations with these objects invoke methods on them and extract or set their fields. The field and method computations potentially modify the object. All computations referring to the objects see the modifications, in contrast to the usual functional programming model in R. Reference classes can be used to program in R directly or in combination with an interface to an OOP-style language, allowing R-written methods to extend the interface.

**Usage**

```r
setRefClass(Class, fields = , contains = , methods =,
             where =, ...)  
getRefClass(Class, where =)
```

**Arguments**

- `Class` character string name for the class.
  In the call to `getRefClass()` this argument can also be any object from the relevant class; note also the corresponding reference class methods documented in the section on “Writing Reference Methods”.
fields
either a character vector of field names or a named list of the fields. The resulting fields will be accessed with reference semantics (see the section on “Reference Objects”). If the argument is a list, the elements of the list can be the character string name of a class, in which case the field must be from that class or a subclass.

The element in the list can alternatively be an accessor function, a function of one argument that returns the field if called with no argument or sets it to the value of the argument otherwise. Accessor functions are used internally and for inter-system interface applications. Their definition follows the rules for writing methods for the class: they can refer to other fields and can call other methods for this class or its superclasses. See the section on “Implementation” for the internal mechanism used by accessor functions.

Note that fields are distinct from the slots, if any, in the object. Slots are, as always, handled by standard R object management. It is not generally a good idea to mix slots and fields in the same class; this confuses the distinction in behavior between reference classes and regular S4 classes. See the comments in the “Implementation” section.

contains
optional vector of superclasses for this class. If a superclass is also a reference class, the fields and class-based methods will be inherited.

methods
a named list of function definitions that can be invoked on objects from this class. These can also be created by invoking the $methods method on the generator object returned. See the section on “Writing Reference Methods” for details.

Two optional method names are interpreted specially, initialize and finalize. If an initialize method is defined, it will be invoked when an object is generated from the class. See the discussion of method $new(...) in the section “Reference Object Generators”.

If a finalize method is defined, a function will be registered to invoke it before the environment in the object is discarded by the garbage collector. See the matrix viewer example for both initialize and finalize methods.

where
the environment in which to store the class definition (or to begin the search for it, in the case of getClass()). Defaults to the package namespace or environment for code that is part of an R package, and to the global environment for code sourced directly at the session top level.

... other arguments to be passed to getClass.

Value

setRefClass() returns a generator function suitable for creating objects from the class, invisibly. A call to this function takes any number of arguments, which will be passed on to the initialize method. If no initialize method is defined for the class or one of its superclasses, the default method expects named arguments with the name of one of the fields and unnamed arguments, if any, that are objects from one of the superclasses of this class (but only superclasses that are themselves reference classes have any effect).

The generator function is similar to the S4 generator function returned by getClass. In addition to being a generator function, however, it is also a reference class generator object, with reference class methods for various utilities. See the section on reference class generator objects below.

If the class has a method defined for $initialize(), this method will be called once the reference object has been created. You should write such a method for a class that needs to do some special initialization. In particular, a reference method is recommended rather than a method for the S4 generic function initialize(), because some special initialization is required for reference objects
**Reference Classes**

Before the initialization of fields. As with S4 classes, methods are written for \$initialize() and not for \$new(), both for the previous reason and also because \$new() is invoked on the generator object and would be a method for that class.

The default method for \$initialize() is equivalent to invoking the method \$initFields(...). Named arguments assign initial values to the corresponding fields. Unnamed arguments must be objects from this class or a reference superclass of this class. Fields will be initialized to the contents of the fields in such objects, but named arguments override the corresponding inherited fields. Note that fields are simply assigned. If the field is itself a reference object, that object is not copied. The new and previous object will share the reference. Also, a field assigned from an unnamed argument counts as an assignment for locked fields. To override an inherited value for a locked field, the new value must be one of the named arguments in the initializing call. A later assignment of the field will result in an error.

For technical reasons, the default method does not currently appear explicitly, but can be invoked by \$callSuper(...) from a method for \$initialize(). Initialization methods need some care in design, as they do for S4 classes. In particular, remember that others may subclass your class and pass through field assignments or other arguments. Therefore, your method should normally include … as an argument, all other arguments should have defaults or check for missingness, and your method should pass all initialized values on via \$callSuper() or \$initFields() if you know that your superclasses have no initialization methods.

\texttt{getRefClass()} also returns the generator function for the class. Note that the package slot in the value is the correct package from the class definition, regardless of the \texttt{where} argument, which is used only to find the class if necessary.

**Reference Objects**

Normal objects in \texttt{R} are passed as arguments in function calls consistently with functional programming semantics; that is, changes made to an object passed as an argument are local to the function call. The object that supplied the argument is unchanged.

The functional model (sometimes called pass-by-value, although this is inaccurate for \texttt{R}) is suitable for many statistical computations and is implicit, for example, in the basic \texttt{R} software for fitting statistical models. In some other situations, one would like all the code dealing with an object to see the exact same content, so that changes made in any computation would be reflected everywhere. This is often suitable if the object has some “objective” reality, such as a window in a user interface.

In addition, commonly used languages, including Java, C++ and many others, support a version of classes and methods assuming reference semantics. The corresponding programming mechanism is to invoke a method on an object. In the \texttt{R} syntax we use \texttt{\$} for this operation; one invokes a method, \texttt{m1} say, on an object \texttt{x} by the expression \texttt{x\$m1(...)}.

Methods in this paradigm are associated with the object, or more precisely with the class of the object, as opposed to methods in a function-based class/method system, which are fundamentally associated with the function (in \texttt{R}, for example, a generic function in an \texttt{R} session has a table of all its currently known methods). In this document “methods for a class” as opposed to “methods for a function” will make the distinction.

Objects in this paradigm usually have named fields on which the methods operate. In the \texttt{R} implementation, the fields are defined when the class is created. The field itself can optionally have a specified class, meaning that only objects from this class or one of its subclasses can be assigned to the field. By default, fields have class "ANY". Fields may also be defined by supplying an accessor function which will be called to get or set the field. Accessor functions are likely when reference classes are part of an inter-system interface. The interface will usually supply the accessor functions automatically based on the definition of the corresponding class in the other language.

Fields are accessed by reference. In particular, invoking a method may modify the content of the fields.
Programming for such classes involves writing new methods for a particular class. In the \texttt{R} implementation, these methods are \texttt{R} functions, with zero or more formal arguments. The object on which the methods are invoked is not an explicit argument to the method. Instead, fields and methods for the class can be referred to by name in the method definition. The implementation uses \texttt{R} environments to make fields and methods available by name. Additional special fields allow reference to the complete object and to the definition of the class. See the section on “Writing Reference Methods”.

The goal of the software described here is to provide a uniform programming style in \texttt{R} for software dealing with reference classes, whether implemented directly in \texttt{R} or through an interface to one of the OOP languages.

\textbf{Writing Reference Methods}

Reference methods are functions supplied as elements of a named list, either when invoking \texttt{g$methods()} on a generator object \texttt{g} or as the argument \texttt{methods} in a call to \texttt{setRefClass}. They are written as ordinary \texttt{R} functions but have some special features and restrictions. The body of the function can contain calls to any other reference method, including those inherited from other reference classes and may refer to fields in the object by name.

Fields may be modified in a method by using the non-local assignment operator, \texttt{<-}, as in the \texttt{edit} and \texttt{undo} methods in the example below. Note that non-local assignment is required: a local assignment with the \texttt{<-} operator just creates a local object in the function call, as it would in any \texttt{R} function. When methods are installed, a heuristic check is made for local assignments to field names and a warning issued if any are detected.

Reference methods should be kept simple; if they need to do some specialized \texttt{R} computation, that computation should use a separate \texttt{R} function that is called from the reference method. Specifically, methods can not use special features of the enclosing environment mechanism, since the method’s environment is used to access fields and other methods. In particular, methods should not use non-exported entries in the package’s namespace, because the methods may be inherited by a reference class in another package.

Reference methods can not themselves be generic functions; if you want additional function-based method dispatch, write a separate generic function and call that from the method.

The entire object can be referred to in a method by the reserved name \texttt{.self}, as shown in the \texttt{save} method of the example. The special object \texttt{.refClassDef} contains the definition of the class of the object. These fields are read-only (it makes no sense to modify these references), with one exception. In principal, the \texttt{.self} field can be modified in the \texttt{$initialize} method, because the object is still being created at this stage. This is definitely not recommended, unless to set some non-reference properties of the object defined for this class, which is itself not recommended if it mixes slots and fields.

The methods available include methods inherited from superclasses, as discussed in the next section. Only methods actually used will be included in the environment corresponding to an individual object. To declare that a method requires a particular other method, the first method should include a call to \texttt{usingMethods()} with the name of the other method as an argument. Declaring the methods this way is essential if the other method is used indirectly (e.g., via \texttt{sapply()} or \texttt{do.call()}). If it is called directly, code analysis will find it. Declaring the method is harmless in any case, however, and may aid readability of the source code.

Documentation for the methods can be obtained by the \texttt{?help} method for the generator object. Methods for classes are not documented in the \texttt{.Rd} format used for \texttt{R} functions. Instead, the \texttt{?help} method prints the calling sequence of the method, followed by self-documentation from the method definition, in the style of Python. If the first element of the body of the method is a literal character string (possibly multi-line), that string is interpreted as documentation. See the method definitions in the example.
Inheritance

Reference classes inherit from other reference classes by using the standard R inheritance; that is, by including the superclasses in the `contains=` argument when creating the new class. The names of the reference superclasses are in slot `refSuperClasses` of the class definition. Reference classes can inherit from ordinary S4 classes also, but this is usually a bad idea if it mixes reference fields and non-reference slots. See the comments in the section on “Implementation”.

Class fields are inherited. A class definition can override a field of the same name in a superclass only if the overriding class is a subclass of the class of the inherited field. This ensures that a valid object in the field remains valid for the superclass as well.

Inherited methods are installed in the same way as directly specified methods. The code in a method can refer to inherited methods in the same way as directly specified methods.

A method may override a method of the same name in a superclass. The overriding method can call the superclass method by `callSuper(...)`, as described below.

All reference classes inherit from the class "envRefClass", which provides the following methods.

- `callSuper(...)` Calls the method inherited from a reference superclass. The call is meaningful only from within another method, and will be resolved to call the inherited method of the same name. The arguments to `callSuper` are passed to the superclass version. See the matrix viewer class in the example.

  Note that the intended arguments for the superclass method must be supplied explicitly; there is no convention for supplying the arguments automatically, in contrast to the similar mechanism for functional methods.

- `copy(shallow = FALSE)` Creates a copy of the object. With reference classes, unlike ordinary R objects, merely assigning the object with a different name does not create an independent copy. If `shallow` is `FALSE`, any field that is itself a reference object will also be copied, and similarly recursively for its fields. Otherwise, while reassigning a field to a new reference object will have no side effect, modifying such a field will still be reflected in both copies of the object. The argument has no effect on non-reference objects in fields. When there are reference objects in some fields but it is asserted that they will not be modified, using `shallow = TRUE` will save some memory and time.

- `field(name, value)` With one argument, returns the field of the object with character string `name`. With two arguments, the corresponding field is assigned `value`. Assignment checks that `name` specifies a valid field, but the single-argument version will attempt to get anything of that name from the object’s environment.

  The `field()` method replaces the direct use of a field name, when the name of the field must be calculated, or for looping over several fields.

- `export(Class)` Returns the result of coercing the object to `Class` (typically one of the superclasses of the object’s class). Calling the method has no side effect on the object itself.

- `getRefClass(); getClass()` These return respectively the generator object and the formal class definition for the reference class of this object, efficiently.

- `import(value, Class = class(value))` Import the object `value` into the current object, replacing the corresponding fields in the current object. Object `value` must come from one of the superclasses of the current object’s class. If argument `Class` is supplied, `value` is first coerced to that class.

- `initFields(...)` Initialize the fields of the object from the supplied arguments. This method is usually only called from a class with a `initialize()` method. It corresponds to the default initialization for reference classes. If there are slots and non-reference superclasses, these may be supplied in the ... argument as well.
Typically, a specialized \$initialize() method carries out its own computations, then invokes \$initializeFields() to perform standard initialization, as shown in the matrixViewer class in the example below.

\$show() This method is called when the object is printed automatically, analogously to the show function. A general method is defined for class "envRefClass". User-defined reference classes will often define their own method: see the Example below.

Note two points in the example. As with any show() method, it is a good idea to print the class explicitly to allow for subclasses using the method. Second, to call the function show() from the method, as opposed to the \$show() method itself, refer to methods::show() explicitly.

\$trace(what, ...), \$untrace(what) Apply the tracing and debugging facilities of the trace function to the reference method what.

All the arguments of the trace function can be supplied, except for signature, which is not meaningful.

The reference method can be invoked on either an object or the generator for the class. See the section on Debugging below for details.

\$usingMethods(...) Reference methods used by this method are named as the arguments either quoted or unquoted. In the code analysis phase of installing the the present method, the declared methods will be included. It is essential to declare any methods used in a nonstandard way (e.g., via an apply function). Methods called directly do not need to be declared, but it is harmless to do so. \$usingMethods() does nothing at run time.

Objects also inherit two reserved fields:

```
.self a reference to the entire object;
.refClassDef the class definition.
```

The defined fields should not override these, and in general it is unwise to define a field whose name begins with ".", since the implementation may use such names for special purposes.

Reference Class Generators

The call to setRefClass defines the specified class and returns a "generator function" object for that class. This object has class "refObjectGenerator"; it inherits from "function" via "classGeneratorFunction" and can be called to generate new objects from the reference class.

The returned object is also a reference class object, although not of the standard construction. It can be used to invoke reference methods and access fields in the usual way, but instead of being implemented directly as an environment it has a subsidiary generator object as a slot, a standard reference object (of class "refGeneratorSlot"). Note that if one wanted to extend the reference class generator capability with a subclass, this should be done by subclassing "refGeneratorSlot", not "refObjectGenerator".

The fields are def, the class definition, and className, the character string name of the class. Methods generate objects from the class, to access help on reference methods, and to define new reference methods for the class. The currently available methods are:

\$new(...) This method is equivalent to calling the generator function returned by setRefClass.

\$help(topic) Prints brief help on the topic. The topics recognized are reference method names, quoted or not.

The information printed is the calling sequence for the method, plus self-documentation if any. Reference methods can have an initial character string or vector as the first element in the body of the function defining the method. If so, this string is taken as self-documentation for the method (see the section on "Writing Reference Methods" for details).

If no topic is given or if the topic is not a method name, the definition of the class is printed.
$methods(...) With no arguments, returns a list of the reference methods for this class.

Named arguments are method definitions, which will be installed in the class, as if they had been supplied in the methods argument to setRefClass(). Supplying methods in this way, rather than in the call to setRefClass(), is largely for the sake of clearer source code when many or large methods are being defined. All methods for a class should be defined in the source code that defines the class, typically as part of a package. In particular, methods can not be redefined in a class in an attached package with a namespace: The class method checks for a locked binding of the class definition.

The new methods can refer to any currently defined method by name (including other methods supplied in this call to $methods()). Note though that previously defined methods are not reanalyzed meaning that they will not call the new method (unless it redefines an existing method of the same name).

To remove a method, supply NULL as its new definition.

$fields() Returns a list of the fields, each with its corresponding class. Fields for which an accessor function was supplied in the definition have class "activeBindingFunction".

$lock(...) The fields named in the arguments are locked; specifically, after the lock method is called, the field may be set once. Any further attempt to set it will generate an error.

If called with no arguments, the method returns the names of the locked fields.

Fields that are defined by an explicit accessor function can not be locked (on the other hand, the accessor function can be defined to generate an error if called with an argument).

All code to lock fields should normally be part of the definition of a class; that is, the read-only nature of the fields is meant to be part of the class definition, not a dynamic property added later. In particular, fields can not be locked in a class in an attached package with a namespace: The class method checks for a locked binding of the class definition. Locked fields can not be subsequently unlocked.

$trace(what, ... , classMethod = FALSE) Establish a traced version of method what for objects generated from this class. The generator object tracing works like the $trace() method for objects from the class, with two differences. Since it changes the method definition in the class object itself, tracing applies to all objects, not just the one on which the trace method is invoked.

Second, the optional argument classMethod = TRUE allows tracing on the methods of the generator object itself. By default, what is interpreted as the name of a method in the class for which this object is the generator.

$accessors(...) A number of systems using the OOP programming paradigm recommend or enforce getter and setter methods corresponding to each field, rather than direct access by name. If you like this style and want to extract a field named abc by x$getAbc() and assign it by x$setAbc(value), the $accessors method is a convenience function that creates such getter and setter methods for the specified fields. Otherwise there is no reason to use this mechanism. In particular, it has nothing to do with the general ability to define fields by functions as described in the section on "Reference Objects".

Implementation

Reference classes are implemented as S4 classes with a data part of type "environment". Fields correspond to named objects in the environment. A field associated with a function is implemented as an active binding. In particular, fields with a specified class are implemented as a special form of active binding to enforce valid assignment to the field. A field, say data, can be accessed generally by an expression of the form x$data for any object from the relevant class. In a method for this class, the field can be accessed by the name data. A field that is not locked can be set by an expression of the form x$data <- value. Inside a method, a field can be assigned by an expression of the form x $< - value. Note the non-local assignment operator. The standard R interpretation of
this operator works to assign it in the environment of the object. If the field has an accessor function defined, getting and setting will call that function.

When a method is invoked on an object, the function defining the method is installed in the object’s environment, with the same environment as the environment of the function.

Because of the implementation, new reference classes can inherit from non-reference S4 classes as well as reference classes. This is usually a bad idea, if the slots from the non-reference class are thought of as alternatives to fields. Unless there is some special argument in favor, mixing the functional and reference paradigms for properties of the same object is conceptually unclear. In addition, the initialization method for the class will have to sort out fields from slots, with a good chance of creating anomalous behavior for subclasses of this class. Better in general to define fields analogous to the slots in the S4 class, and to initialize those from an S4 object of that class.

Inter-System Interfaces

A number of languages use a similar reference-based programming model with classes and class-based methods. Aside from differences in choice of terminology and other details, many of these languages are compatible with the programming style described here. R interfaces to the languages exist in a number of packages.

The reference class definitions here provide a hook for classes in the foreign language to be exposed in R. Access to fields and/or methods in the class can be implemented by defining an R reference class corresponding to classes made available through the interface. Typically, the inter-system interface will take care of the details of creating the R class, given a description of the foreign class (what fields and methods it has, the classes for the fields, whether any are read-only, etc.) The specifics for the fields and methods can be implemented via reference methods for the R class. In particular, the use of active bindings allows field access for getting and setting, with actual access handled by the inter-system interface.

R methods and/or fields can be included in the class definition as for any reference class. The methods can use or set fields and can call other methods transparently whether the field or method comes from the interface or is defined directly in R.

For an inter-system interface using this approach, see the code for package Rcpp, version 0.8.7 or later.

Debugging

The standard R debugging and tracing facilities can be applied to reference methods. Reference methods can be passed to debug and its relatives from an object to debug further method invocations on that object; for example, debug(xx$edit).

Somewhat more flexible use is available for a reference method version of the trace function. A corresponding $trace() reference method is available for either an object or for the reference class generator (xx$trace() or mEdit$trace() in the example below). Using $trace() on an object sets up a tracing version for future invocations of the specified method for that object. Using $trace() on the generator for the class sets up a tracing version for all future objects from that class (and sometimes for existing objects from the class if the method is not declared or previously invoked).

In either case, all the arguments to the standard trace function are available, except for signature= which is meaningless since reference methods can not be S4 generic functions. This includes the typical style trace(what, browser) for interactive debugging and trace(what, edit = TRUE) to edit the reference method interactively.
Examples

```r
## a simple editor for matrix objects. Method `edit()` changes some
## range of values; method `undo()` undoes the last edit.

mEdit <- setRefClass("mEdit",
  fields = list( data = "matrix",
    edits = "list"),
  methods = list(
    edit = function(i, j, value) {
      ## the following string documents the edit method
      ## Replaces the range [i, j] of the
      ## object by value.
      
      backup <-
        list(i, j, data[i,j])
      data[i,j] <<- value
      edits <<- c(edits, list(backup))
      invisible(value)
    },
    undo = function() {
      ## Undoes the last edit() operation
      ## and update the edits field accordingly.
      
      prev <- edits
      if(length(prev)) prev <<- prev[[length(prev)]]
      else stop("No more edits to undo")
      edit(prev[[1]], prev[[2]], prev[[3]])
      ## trim the edits list
      length(edits) <<- length(edits) - 2
      invisible(prev)
    },
    show = function() {
      ## Method for automatically printing matrix editors'
      cat("Reference matrix editor object of class",
           classLabel(class(.self)), "\n")
      cat("Data: \n")
      methods::show(data)
      cat("Undo list is of length", length(edits), "\n")
    }
  ))

xMat <- matrix(1:12, 4, 3)
x <- mEdit(data = xMat)
x$edit(2, 2, 0)
x
x$undo()
mEdit$help("undo")
stopifnot(all.equal(x$x$data, xMat))

utils::str(x) # show fields and names of non-trivial methods

## add a method to save the object
mEdit$methods(
```
save = function(file) {
  'Save the current object on the file
  in R external object format.
  
  base::save(.self, file = file)
}
}

if (tempfile) {
  xx$save(tf)
}

## Not run:
## Inheriting a reference class: a matrix viewer
mv <- setRefClass("matrixViewer",
  fields = c("viewerDevice", "viewerFile"),
  contains = "mEdit",
  methods = list( view = function() {
    dd <- dev.cur(); dev.set(viewerDevice)
    devAskNewPage(FALSE)
    matplot(data, main = paste("After", length(edits), "edits"))
    dev.set(dd),
    edit = # invoke previous method, then replot
    function(i, j, value) {
      callSuper(i, j, value)
      view()
    })
  })

## initialize and finalize methods
mv$methods( initialize =
  function(file = ".matrixView.pdf", ...) {
    viewerFile <<- file
    pdf(viewerFile)
    viewerDevice <<- dev.cur()
    dev.set(dev.prev())
    callSuper(...) 
  },
  finalize = function() {
    dev.off(viewerDevice)
  })

## debugging an object: call browser() in method $edit()
x$x$trace(edit, browser)

## debugging all objects from class mEdit in method $undo()
mEdit$trace(undo, browser)

## End(Not run)
Description

These are old utility functions to construct, respectively a list designed to represent the slots and superclasses and a list of prototype specifications. The `representation()` function is no longer useful, since the arguments `slots` and `contains` to `setClass` are now recommended.

The `prototype()` function may still be used for the corresponding argument, but a simple list of the same arguments works as well.

Usage

```r
representation(...)
prototype(...)
```

Arguments

... The call to `representation` takes arguments that are single character strings. Unnamed arguments are classes that a newly defined class extends; named arguments name the explicit slots in the new class, and specify what class each slot should have.

In the call to `prototype`, if an unnamed argument is supplied, it unconditionally forms the basis for the prototype object. Remaining arguments are taken to correspond to slots of this object. It is an error to supply more than one unnamed argument.

Details

The `representation` function applies tests for the validity of the arguments. Each must specify the name of a class.

The classes named don’t have to exist when `representation` is called, but if they do, then the function will check for any duplicate slot names introduced by each of the inherited classes.

The arguments to `prototype` are usually named initial values for slots, plus an optional first argument that gives the object itself. The unnamed argument is typically useful if there is a data part to the definition (see the examples below).

Value

The value of `representation` is just the list of arguments, after these have been checked for validity.

The value of `prototype` is the object to be used as the prototype. Slots will have been set consistently with the arguments, but the construction does not use the class definition to test validity of the contents (it hardly can, since the prototype object is usually supplied to create the definition).

`setClass`
Examples

```r
## representation for a new class with a directly define slot "smooth"
## which should be a "numeric" object, and extending class "track"
representation("track", smooth = "numeric")

setClass("Character", representation("character"))
setClass("TypedCharacter", representation("Character", type = "character"),
  prototype(character(0), type = "plain"))

ttt <- new("TypedCharacter", "foo", type = "character")

setClass("num1", representation(comment = "character"),
  contains = "numeric",
  prototype = prototype(pi, comment = "Start with pi"))
```

---

**S3Part**  
*S3-style Objects and S4-class Objects*

**Description**

Old-style (S3) classes may be registered as S4 classes (by calling `setOldClass`, and many have been. These classes can then be contained in (that is, superclasses of) regular S4 classes, allowing formal methods and slots to be added to the S3 behavior. The function `S3Part` extracts or replaces the S3 part of such an object. `S3Class` extracts or replaces the S3-style class. `S3Class` also applies to object from an S4 class with `S3methods=TRUE` in the call to `setClass`.

See the details below. Also discussed are S3 <-> S4 coercion; see the section “S3 and S4 objects”

**Usage**

```r
S3Part(object, strictS3 = FALSE, S3Class)
S3Part(object, strictS3 = TRUE, needClass = ) <- value
S3Class(object)
S3Class(object) <- value
isS3S3Class(classDef)
slotsFromS3(object)
```

**Arguments**

- **object**  
  An object from some class that extends a registered S3 class, usually because the class has as one of its superclasses an S3 class registered by a call to `setOldClass`, or from a class that extends a basic vector, matrix or array object type. See the details.
For most of the functions, an S3 object can also be supplied, with the interpretation that it is its own S3 part.

**strictS3**

If TRUE, the value returned by `S3Part` will be an S3 object, with all the S4 slots removed. Otherwise, an S4 object will always be returned; for example, from the S4 class created by `setOldClass` as a proxy for an S3 class, rather than the underlying S3 object.

**S3Class**

The character vector to be stored as the S3 class slot in the object. Usually, and by default, retains the slot from object.

**needClass**

Require that the replacement value be this class or a subclass of it.

**value**

For `S3Part<-`, the replacement value for the S3 part of the object. This does not need to be an S4 object; in fact, the usual way to create objects from these classes is by giving an S3 object of the right class as an argument to `new`. For `S3Class<-`, the character vector that will be used as a proxy for `class(x)` in S3 method dispatch. This replacement function can be used to control S3 per-object method selection.

**classDef**

A class definition object, as returned by `getClass`.

### Details

Classes that register S3 classes by a call to `setOldClass` have slot `".S3Class"` to hold the corresponding S3 vector of class strings. The prototype of such a class has the value for this slot determined by the argument to `setOldClass`. Other S4 classes will have the same slot if the argument `S3methods = TRUE` is supplied to `setClass`; in this case, the slot is set to the S4 inheritance of the class.

New S4 classes that extend (contain) such classes also have the same slot, and by default the prototype has the value determined by the `contains=` argument to `setClass`. Individual objects from the S4 class may have an S3 class corresponding to the value in the prototype or to an (S3) subclass of that value. See the examples below.

`S3Part()` with `strictS3 = TRUE` constructs the underlying S3 object by eliminating all the formally defined slots and turning off the S4 bit of the object. With `strictS3 = FALSE` the object returned is from the corresponding S4 class. For consistency and generality, `S3Part()` works also for classes that extend the basic vector, matrix and array classes. Since R is somewhat arbitrary about what it treats as an S3 class ("ts" is, but "matrix" is not), `S3Part()` tries to return an S3 (that is, non-S4) object whenever the S4 class has a suitable superclass, of either S3 or basic object type.

One general application that relies on this generality is to use `S3Part()` to get a superclass object that is guaranteed not to be an S4 object. If you are calling some function that checks for S4 objects, you need to be careful not to end up in a closed loop (fooS4 calls fooS3, which checks for an S4 object and calls fooS4 again, maybe indirectly). Using `S3Part()` with `strictS3 = TRUE` is a mechanism to avoid such loops.

Because the contents of S3 class objects have no definition or guarantee, the computations involving S3 parts do not check for slot validity. Slots are implemented internally in R as attributes, which are copied when present in the S3 part. Grave problems can occur if an S4 class extending an S3 class uses the name of an S3 attribute as the name of an S4 slot, and S3 code sets the attribute to an object from an invalid class according to the S4 definition.

Frequently, `S3Part` can and should be avoided by simply coercing objects to the desired class; methods are automatically defined to deal correctly with the slots when `as` is called to extract or replace superclass objects.

The function `slotsFromS3()` is a generic function used internally to access the slots associated with the S3 part of the object. Methods for this function are created automatically when `setOldClass` is
called with the S4Class argument. Usually, there is only one S3 slot, containing the S3 class, but the S4Class argument may provide additional slots, in the case that the S3 class has some guaranteed attributes that can be used as formal S4 slots. See the corresponding section in the documentation of `setOldClass`.

**Value**

S3Part: Returns or sets the S3 information (and possibly some S4 slots as well, depending on arguments S3Class and keepSlots). See the discussion of argument strict above. If it is TRUE the value returned is an S3 object.

S3Class: Returns or sets the character vector of S3 class(es) stored in the object, if the class has the corresponding .S3Class slot. Currently, the function defaults to `class` otherwise.

isXS3Class: Returns TRUE or FALSE according to whether the class defined by `ClassDef` extends S3 classes (specifically, whether it has the slot for holding the S3 class).

slotsFromS3: returns a list of the relevant slot classes, or an empty list for any other object.

**S3 and S4 Objects: Conversion Mechanisms**

Objects in R have an internal bit that indicates whether or not to treat the object as coming from an S4 class. This bit is tested by `isS4` and can be set on or off by `asS4`. The latter function, however, does no checking or interpretation; you should only use it if you are very certain every detail has been handled correctly.

As a friendlier alternative, methods have been defined for coercing to the virtual classes "S3" and "S4". The expressions `as(object, "S3")` and `as(object, "S4")` return S3 and S4 objects, respectively. In addition, they attempt to do conversions in a valid way, and also check validity when coercing to S4.

The expression `as(object, "S3")` can be used in two ways. For objects from one of the registered S3 classes, the expression will ensure that the class attribute is the full multi-string S3 class implied by `class(object)`. If the registered class has known attribute/slots, these will also be provided.

Another use of `as(object, "S3")` is to take an S4 object and turn it into an S3 object with corresponding attributes. This is only meaningful with S4 classes that have a data part. If you want to operate on the object without invoking S4 methods, this conversion is usually the safest way.

The expression `as(object, "S4")` will use the attributes in the object to create an object from the S4 definition of `class(object)`. This is a general mechanism to create partially defined version of S4 objects via S3 computations (not much different from invoking `new` with corresponding arguments, but usable in this form even if the S4 object has an initialize method with different arguments).

## two examples extending S3 class "lm", class "xlm" directly
## and "ylm" indirectly
setClass("xlm", representation(eps = "numeric"), contains = "lm")
setClass("ylm", representation(header = "character"), contains = "xlm")

## lm.D9 is as computed in the example for stats::lm
y1 = new("ylm", lm.D9, header = "test", eps = .1)
x = new("xlm", lm.D9, eps = .1)
y2 = new("ylm", x, header = "test")
stopifnot(inherits(y2, "lm"))
stopifnot(identical(y1, y2))

## note that these classes can insert an S3 subclass of "lm" as the S3 part:
mydata <- data.frame(time = 1:10, y = (1:10)^.5)
myLm <- lm(cbind(y, y^3) ~ time, myData) # S3 class: c("mlm", "lm")
ym1 = new("ylm", myLm, header = "Example", eps = 0.)

## similar classes to "xlm" and "ylm", but extending S3 class c("mlm", "lm")
setClass("xmm", representation(eps = "numeric"), contains = "mlm")
setClass("ymm", representation(header="character"), contains = "xmm")

ym2 <- new("ymm", myLm, header = "Example2", eps = .001)

## but for class "ymm", an S3 part of class "lm" is an error:
try(new("ymm", lm.D9, header = "Example2", eps = .001))

setClass("dataFrameD", representation(date = "Date"), contains = "data.frame")
myDD <- new("dataFrameD", myData, date = Sys.Date())

## S3Part() applied to classes with a data part (.Data slot)
setClass("NumX", contains="numeric", representation(id="character"))
nn = new("NumX", 1:10, id="test")
stopifnot(identical(1:10, S3Part(nn, strict = TRUE)))

m1 = cbind(group, weight)
setClass("MatX", contains = "matrix", representation(date = "Date"))
mx1 = new("MatX", m1, date = Sys.Date())
stopifnot(identical(mx1, S3Part(mx1, strict = TRUE)))

---

Description

Methods can be defined for *group generic functions*. Each group generic function has a number of *member* generic functions associated with it.
Methods defined for a group generic function cause the same method to be defined for each member of the group, but a method explicitly defined for a member of the group takes precedence over a method defined, with the same signature, for the group generic.

The functions shown in this documentation page all reside in the methods package, but the mechanism is available to any programmer, by calling setGroupGeneric (provided package methods is attached).

Usage

```r
## S4 group generics:
Arith(e1, e2)
Compare(e1, e2)
Ops(e1, e2)
Logic(e1, e2)
Math(x)
Math2(x, digits)
Summary(x, ..., na.rm = FALSE)
Complex(z)
```

Arguments

- `x, z, e1, e2` objects.
- `digits` number of digits to be used in round or signif.
- `...` further arguments passed to or from methods.
- `na.rm` logical: should missing values be removed?

Details

Methods can be defined for the group generic functions by calls to `setMethod` in the usual way. Note that the group generic functions should never be called directly – a suitable error message will result if they are. When metadata for a group generic is loaded, the methods defined become methods for the members of the group, but only if no method has been specified directly for the member function for the same signature. The effect is that group generic definitions are selected before inherited methods but after directly specified methods. For more on method selection, see `methods`.

There are also S3 groups Math, Ops, Summary and Complex, see ?S3groupGeneric, with no corresponding R objects, but these are irrelevant for S4 group generic functions.

The members of the group defined by a particular generic can be obtained by calling `getGroupMembers`. For the group generic functions currently defined in this package the members are as follows:

```r
Arith "+", "+", "/", "/", "/", "/", "/", "/,
Compare "+", "+", "+", "+", "+", "+", "+,
Logic "&", "|",
Ops "Arith", "Compare", "Logic"
Math2 "round", "signif"
```
An object from this class represents a single 'is' relationship; lists of these objects are used to represent all the extensions (superclasses) and subclasses for a given class. The object contains information about how the relation is defined and methods to coerce, test, and replace correspondingly.
Objects from the Class

Objects from this class are generated by `setIs`, from direct calls and from the `contains` information in a call to `setClass`, and from class unions created by `setClassUnion`. In the last case, the information is stored in defining the subclasses of the union class (allowing unions to contain sealed classes).

Slots

- `subClass`, `superClass`: The classes being extended: corresponding to the `from` and to arguments to `setIs`.
- `package`: The package to which that class belongs.
- `coerce`: A function to carry out the `as()` computation implied by the relation. Note that these functions should not be used directly. They only deal with the `strict=`TRUE calls to the `as` function, with the full method constructed from this mechanically.
- `test`: The function that would test whether the relation holds. Except for explicitly specified `test` arguments to `setIs`, this function is trivial.
- `replace`: The method used to implement `as(x, Class) <= value`.
- `simple`: A "logical" flag, TRUE if this is a simple relation, either because one class is contained in the definition of another, or because a class has been explicitly stated to extend a virtual class. For simple extensions, the three methods are generated automatically.
- `by`: If this relation has been constructed transitively, the first intermediate class from the subclass.
- `dataPart`: A "logical" flag, TRUE if the extended class is in fact the data part of the subclass. In this case the extended class is a basic class (i.e., a type).
- `distance`: The distance between the two classes, 1 for directly contained classes, plus the number of generations between otherwise.

Methods

No methods defined with class "SClassExtension" in the signature.

See Also

`is`, `as`, and the `classRepresentation` class.

**selectSuperClasses**

Super Classes (of Specific Kinds) of a Class

Description

Return superclasses of `TypeDef`, possibly only non-virtual or direct or simple ones.

These functions are designed to be fast, and consequently only work with the `contains` slot of the corresponding class definitions.

Usage

```r
selectSuperClasses(Class, dropVirtual = FALSE, namesOnly = TRUE,
                   directOnly = TRUE, simpleOnly = directOnly,
                   where = topenv(parent.frame()))

selectSuperClasses(ext, dropVirtual = FALSE, namesOnly = TRUE,
                   directOnly = TRUE, simpleOnly = directOnly)
```
setClass

Create a Class Definition

Description

Create a class definition, specifying the representation (the slots) and/or the classes contained in this one (the superclasses), plus other optional details. As a side effect, the class definition is stored in the specified environment. A generator function is returned as the value of setClass(), suitable for creating objects from the class if the class is not virtual. Of the many arguments to the function only Class, slots= and contains= are usually needed.

Arguments

- **Class**: name of the class or (more efficiently) the class definition object (see getClass).
- **dropVirtual**: logical indicating if only non-virtual superclasses should be returned.
- **namesOnly**: logical indicating if only a vector names instead of a named list class-extensions should be returned.
- **directOnly**: logical indicating if only a direct super classes should be returned.
- **simpleOnly**: logical indicating if only simple class extensions should be returned.
- **where**: (only used when Class is not a class definition) environment where the class definition of Class is found.
- **ext**: for .selectSuperClasses() only, a list of class extensions, typically getClassDef(...)$contains.

Value

a character vector (if namesOnly is true, as per default) or a list of class extensions (as the contains slot in the result of getClass).

Note

The typical user level function is selectSuperClasses() which calls .selectSuperClasses(); i.e., the latter should only be used for efficiency reasons by experienced useRs.

See Also

is, getClass; further, the more technical class classRepresentation documentation.

Examples

```r
setClass("Root")
setClass("Base", contains = "Root", representation(length = "integer"))
setClass("A", contains = "Base", representation(x = "numeric"))
setClass("B", contains = "Base", representation(y = "character"))
setClass("C", contains = c("A", "B"))
extends("C")  #--> "C" "A" "B" "Base" "Root"
selectSuperClasses("C") # "A" "B"
selectSuperClasses("C", direct=FALSE) # "A" "B" "Base" "Root"
selectSuperClasses("C", dropVirt = TRUE, direct=FALSE)# ditto w/o "Root"
```
setClass

Usage

setClass(Class, representation, prototype, contains=character(),
validity, access, where, version, sealed, package,
S3methods = FALSE, slots)

Arguments

Class character string name for the class.
slots a named list or named character vector. The names are the names of the slots in the new class and the elements are the character string names of the corresponding classes.
In rare cases where there is ambiguity about the class of a slot, because two classes of the same name are imported from different packages, the corresponding element of the argument must have a "package" attribute to disambiguate the choice.
It is allowed to provide an unnamed character vector as a limiting case, with the elements taken as slot names and all slots having the unrestricted class "ANY".
contains the names (and optionally package slots) for the superclasses of this class. The special superclass "VIRTUAL" causes the new class to be created as a virtual class; see the section on virtual classes in Classes.
prototype an object providing the default data for the slots in this class. By default, each will be the prototype object for the superclass. If provided, using a call to prototype will carry out some checks.
where the environment in which to store the definition. Should not be supplied in standard use. For calls to setClass() appearing in the source code for a package, will default to the namespace of the package. For calls typed or sourced at the top level in a session, will default to the global environment.
validity if supplied, should be a validity-checking method for objects from this class (a function that returns TRUE if its argument is a valid object of this class and one or more strings describing the failures otherwise). See validObject for details.
S3methods, representation, access, version
All these arguments are deprecated from version 3.0.0 of R and should be avoided.
S3methods is a flag indicating that old-style methods will be written involving this class. Modern versions of R attempt to match formal and old-style methods consistently, so this argument is largely irrelevant.
representation is an argument inherited from S that included both slots and contains, but the use of the latter two arguments is clearer and recommended.
access and version are included for historical compatibility with S-Plus, but ignored.
sealed if TRUE, the class definition will be sealed, so that another call to setClass will fail on this class name.
package an optional package name for the class. Should very rarely be used. By default the name of the package in which the class definition is assigned.

Value

A generator function suitable for creating objects from the class is returned, invisibly. A call to this function generates a call to new for the class. The call takes any number of arguments, which will
be passed on to the initialize method. If no initialize method is defined for the class or one of its superclasses, the default method expects named arguments with the name of one of the slots.

Typically the generator function is assigned the name of the class, for programming clarity. This is not a requirement and objects from the class can also be generated directly from `new`. The advantages of the generator function are a slightly simpler and clearer call, and that the call will contain the package name of the class (eliminating any ambiguity if two classes from different packages have the same name).

If the class is virtual, an attempt to generate an object from either the generator or `new()` will result in an error.

**Basic Use: Slots and Inheritance**

The two essential arguments other than the class name are `slots` and `contains`, defining the explicit slots and the inheritance (superclasses). Together, these arguments define all the information in an object from this class; that is, the names of all the slots and the classes required for each of them.

The name of the class determines which methods apply directly to objects from this class. The inheritance information specifies which methods apply indirectly, through inheritance. See Methods.

The slots in a class definition will be the union of all the slots specified directly by `slots` and all the slots in all the contained classes. There can only be one slot with a given name; specifically, the direct and inherited slot names must be unique. That does not, however, prevent the same class from being inherited via more than one path.

One kind of element in the `contains` argument is special, specifying one of the R object types or one of a few other special R types (matrix and array). See the section on inheriting from object types, below.

Slot names "class" and "Class" are not allowed. There are other slot names with a special meaning; these names start with the "." character. To be safe, you should define all of your own slots with names starting with an alphabetic character.

**Inheriting from Object Types**

In addition to containing other S4 classes, a class definition can contain either an S3 class (see the next section) or a built-in R pseudo-class—one of the R object types or one of the special R pseudo-classes "matrix" and "array". A class can contain at most one of the object types, directly or indirectly. When it does, that contained class determines the "data part" of the class.

Objects from the new class try to inherit the built in behavior of the contained type. In the case of normal R data types, including vectors, functions and expressions, the implementation is relatively straightforward. For any object x from the class, `typeof(x)` will be the contained basic type; and a special pseudo-slot, `.Data`, will be shown with the corresponding class. See the "numWithId" example below.

Classes may also inherit from "vector", "matrix" or "array". The data part of these objects can be any vector data type.

For an object from any class that does not contain one of these types or classes, `typeof(x)` will be "S4".

Some R data types do not behave normally, in the sense that they are non-local references or other objects that are not duplicated. Examples include those corresponding to classes "environment", "externalptr", and "name". These can not be the types for objects with user-defined classes (either S4 or S3) because setting an attribute overwrites the object in all contexts. It is possible to define a class that inherits from such types, through an indirect mechanism that stores the inherited object in a reserved slot. See the example for class "stampedEnv" below. S3 method dispatch and
the relevant as \texttt{type()} functions should behave correctly, but code that uses the type of the object directly will not.

Also, keep in mind that the object passed to low-level computations will be the underlying object type, \textit{without} any of the slots defined in the class. To return the full information, you will usually have to define a method that sets the data part.

\section*{Inheriting from S3 Classes}

Old-style S3 classes have no formal definition. Objects are “from” the class when their class attribute contains the character string considered to be the class name.

Using such classes with formal classes and methods is necessarily a risky business, since there are no guarantees about the content of the objects or about consistency of inherited methods. Given that, it is still possible to define a class that inherits from an S3 class, providing that class has been registered as an old class (see \texttt{setOldClass}).

Broadly speaking, both S3 and S4 method dispatch try to behave sensibly with respect to inheritance in either system. Given an S4 object, S3 method dispatch and the \texttt{inherits} function should use the S4 inheritance information. Given an S3 object, an S4 generic function will dispatch S4 methods using the S3 inheritance, provided that inheritance has been declared via \texttt{setOldClass}.

\section*{Classes and Packages}

Class definitions normally belong to packages (but can be defined in the global environment as well, by evaluating the expression on the command line or in a file sourced from the command line). The corresponding package name is part of the class definition; that is, part of the \texttt{classRepresentation} object holding that definition. Thus, two classes with the same name can exist in different packages, for most purposes.

When a class name is supplied for a slot or a superclass in a call to \texttt{setClass}, a corresponding class definition will be found, looking from the namespace of the current package, assuming the call in question appears directly in the source for the package, as it should to avoid ambiguity. The class definition must be found in the namespace of the current package, in the imports for that namespace or in the basic classes defined by the methods package. (The methods package must be included in the \texttt{depends} directive of the package’s \texttt{DESCRIPTION} file in order for the \texttt{CMD check} utility to find these classes.)

When this rule does not identify a class uniquely (because it appears in more than one imported package) then the \texttt{packageSlot} of the character string name needs to be supplied with the name. This should be a rare occurrence.

setClassUnion

Examples

```r
## A simple class with two slots
track <- setClass("track",
   slots = c(x="numeric", y="numeric"))
## an object from the class
t1 <- track(x = 1:10, y = 1:10 + rnorm(10))

## A class extending the previous, adding one more slot
trackCurve <- setClass("trackCurve",
   slots = c(smal = "numeric"),
   contains = "track")

## an object containing a superclass object
t1s <- trackCurve(t1, smooth = 1:10)

## A class similar to "trackCurve", but with different structure
## allowing matrices for the "y" and "smooth" slots
setClass("trackMultiCurve",
   slots = c(x="numeric", y="matrix", smal="matrix"),
   prototype = list(x=numeric(), y=matrix(0,0,0),
      smal = matrix(0,0,0)))

## See ?setIs for further examples using these classes

## A class that extends the built-in data type "numeric"
numWithid <- setClass("numWithid", slots = c(id = "character"),
   contains = "numeric")

numWithid(1:3, id = "An Example")

## inherit from reference object of type "environment"
stampedEnv <- setClass("stampedEnv", contains = "environment",
   slots = c(update = "POSIXct"))
setMethod("<-", c("stampedEnv", "character", "missing"),
   function(x, i, j, ..., value) {
      ev <- as(x, "environment")
      ev[[i]] <- value  #update the object in the environment
      x$update <- Sys.time()  #and the update time
   })

e1 <- stampedEnv(update = Sys.time())
e1[["noise"]] <- rnorm(10)
```

setClassUnion

Classes Defined as the Union of Other Classes

Description

A class may be defined as the union of other classes; that is, as a virtual class defined as a superclass of several other classes. Class unions are useful in method signatures or as slots in other classes, when we want to allow one of several classes to be supplied.
Usage

setClassUnion(name, members, where)
isClassUnion(Class)

Arguments

name the name for the new union class.
members the classes that should be members of this union.
where where to save the new class definition; by default, the environment of the package in which the setClassUnion call appears, or the global environment if called outside of the source of a package.

Class the name or definition of a class.

Details

The classes in members must be defined before creating the union. However, members can be added later on to an existing union, as shown in the example below. Class unions can be members of other class unions.

The prototype object in the class union definition will be NULL if class "NULL" is a member of the union and the prototype object of the first member class otherwise (as of version 2.15.0 of R; earlier versions had a NULL prototype even if that was not valid).

Class unions are the only way to create a class that is extended by a class whose definition is sealed (for example, the basic datatypes or other classes defined in the base or methods package in R are sealed). You cannot say setIs("function", "other") unless "other" is a class union. In general, a setIs call of this form changes the definition of the first class mentioned (adding "other" to the list of superclasses contained in the definition of "function").

Class unions get around this by not modifying the first class definition, relying instead on storing information in the subclasses slot of the class union. In order for this technique to work, the internal computations for expressions such as extends(class1, class2) work differently for class unions than for regular classes; specifically, they test whether any class is in common between the superclasses of class1 and the subclasses of class2.

The different behavior for class unions is made possible because the class definition object for class unions has itself a special class, "ClassUnionRepresentation", an extension of class classRepresentation.

References

Chambers, John M. (1998) Programming with Data Springer (For the original S4 version.)

Examples

```r
## a class for either numeric or logical data
setClassUnion("maybeNumber", c("numeric", "logical"))

## use the union as the data part of another class
setClass("withId", representation("maybeNumber", id = "character"))

w1 <- new("withId", 1:10, id = "test 1")
w2 <- new("withId", sqrt(w1)%%< .01, id = "Perfect squares")
```
## setGeneric

### Define a New Generic Function

**Description**

Create a new generic function of the given name, that is, a function that dispatches methods according to the classes of the arguments, from among the formal methods defined for this function.

**Usage**

```r
setGeneric(name, def=, group=list(), valueClass=character(),
    where=, package=, signature=, useAsDefault=,
    genericFunction=, simpleInheritanceOnly = )
```

```r
setGroupGeneric(name, def=, group=list(), valueClass=character(),
    knownMembers=list(), package=, where= )
```

**Arguments**

- **name**: The character string name of the generic function. The simplest (and recommended) call, `setGeneric(name)`, looks for a function with this name and creates a corresponding generic function, if the function found was not generic. In the latter case, the existing function becomes the default method.

- **def**: An optional function object, defining the generic. Don’t supply this argument if you want to turn an existing non-generic function into a generic. In this case, you usually want to use the simple call with one argument.

  Do supply `def` if there is no current function of this name or for some reason you do not want to use that function to define the generic. In that case, the formal arguments and default values for the generic are taken from `def`. In most cases, the body of `def` will then define the default method, as the existing function did in the one-argument call.

  If you want to create a new generic function with *no* default method, then `def` should be only a call to `standardGeneric` with the same character string as name.

- **group**: Optionally, a character string giving the name of the group generic function to which this function belongs. See Methods for details of group generic functions in method selection.
setGeneric

valueClass
   An optional character vector of one or more class names. The value returned
   by the generic function must have (or extend) this class, or one of the classes;
   otherwise, an error is generated.

package
   The name of the package with which this function is associated. Usually deter-
   mined automatically (as the package containing the non-generic version if there
   is one, or else the package where this generic is to be saved).

where
   Where to store the resulting initial methods definition, and possibly the generic
   function; by default, stored into the top-level environment.

signature
   Optionally, the vector of names, from among the formal arguments to the func-
   tion, that can appear in the signature of methods for this function, in calls to
   setMethod. If . . . is one of the formal arguments, it is treated specially. Starting
   with version 2.8.0 of R, . . . may be signature of the generic function. Methods
   will then be selected if their signature matches all the . . . arguments. See the
documentation for topic dotsMethods for details. In the present version, it is not
possible to mix . . . and other arguments in the signature (this restriction may be
lifted in later versions).

   By default, the signature is inferred from the implicit generic function corre-
   sponding to a non-generic function. If no implicit generic function has been
defined, the default is all the formal arguments except . . ., in the order they ap-
pear in the function definition. In the case that . . . is the only formal argument,
that is also the default signature. To use . . . as the signature in a function that has
any other arguments, you must supply the signature argument explicitly. See the
"Implicit Generic" section below for more details.

useAsDefault
   Override the usual choice of default argument. Argument useAsDefault can be
   supplied, either as a function to use for the default, or as a logical value. This
   argument is now rarely needed. See the section on details.

simpleInheritanceOnly
   Supply this argument as TRUE to require that methods selected be inherited
   through simple inheritance only; that is, from superclasses specified in the
   contains= argument to setClass, or by simple inheritance to a class union
   or other virtual class. Generic functions should require simple inheritance if
   they need to be assured that they get the complete original object, not one that
   has been transformed. Examples of functions requiring simple inheritance are
   initialize, because by definition it must return an object from the same class
   as its argument, and show, because it claims to give a full description of the
   object provided as its argument.

genericFunction
   Don’t use; for (possible) internal use only.

knownMembers
   (For setGroupGeneric only.) The names of functions that are known to be
   members of this group. This information is used to reset cached definitions of
   the member generics when information about the group generic is changed.

Value

   The setGeneric function exists for its side effect: saving the generic function to allow methods to
   be specified later. It returns name.

Basic Use

   The setGeneric function is called to initialize a generic function as preparation for defining some
   methods for that function.
The simplest and most common situation is that `name` is already an ordinary non-generic non-primitive function, and you now want to turn this function into a generic. In this case you will most often supply only `name`, for example:

```
setGeneric("colSums")
```

There must be an existing function of this name, on some attached package (in this case package "base"). A generic version of this function will be created in the current package (or in the global environment if the call to `setGeneric()` is from an ordinary source file or is entered on the command line). The existing function becomes the default method, and the package slot of the new generic function is set to the location of the original function ("base" in the example). It's an important feature that the same generic function definition is created each time, depending in the example only on the definition of `print` and where it is found. The signature of the generic function, defining which of the formal arguments can be used in specifying methods, is set by default to all the formal arguments except ....

Note that calling `setGeneric()` in this form is not strictly necessary before calling `setMethod()` for the same function. If the function specified in the call to `setMethod` is not generic, `setMethod` will execute the call to `setGeneric` itself. Declaring explicitly that you want the function to be generic can be considered better programming style; the only difference in the result, however, is that not doing so produces a message noting the creation of the generic function.

You cannot (and never need to) create an explicit generic version of the primitive functions in the base package. Those which can be treated as generic functions have methods selected and dispatched from the internal C code, to satisfy concerns for efficiency, and the others cannot be made generic. See the section on Primitive Functions below.

The description above is the effect when the package that owns the non-generic function has not created an implicit generic version. Otherwise, it is this implicit generic function that is used. See the section on Implicit Generic Functions below. Either way, the essential result is that the same version of the generic function will be created each time.

The second common use of `setGeneric()` is to create a new generic function, unrelated to any existing function, and frequently having no default method. In this case, you need to supply a skeleton of the function definition, to define the arguments for the function. The body of a generic function is usually a standard form, `standardGeneric(name)` where `name` is the quoted name of the generic function. When calling `setGeneric` in this form, you would normally supply the `def` argument as a function of this form. See the second and third examples below.

The `useAsDefault` argument controls the default method for the new generic. If not told otherwise, `setGeneric` will try to find a non-generic version of the function to use as a default. So, if you do have a suitable default method, it is often simpler to first set this up as a non-generic function, and then use the one-argument call to `setGeneric` at the beginning of this section. See the first example in the Examples section below.

If you don't want the existing function to be taken as default, supply the argument `useAsDefault`. That argument can be the function you want to be the default method, or `FALSE` to force no default (i.e., to cause an error if there is no direct or inherited method selected for a call to the function).

**Details**

The great majority of calls to `setGeneric()` should either have one argument to ensure that an existing function can have methods, or arguments `name` and `def` to create a new generic function and optionally a default method. If that's not what you plan to do, read on.

If you want to change the behavior of an existing function (typically, one in another package) when you create a generic version, you must supply arguments to `setGeneric` correspondingly. Whatever changes are made, the new generic function will be assigned with a package slot set to the current package, not the one in which the non-generic version of the function is found. This step is required
because the version you are creating is no longer the same as that implied by the function in the
other package. A message will be printed to indicate that this has taken place and noting one of the
differences between the two functions. It tends to be a bad idea, because the two versions are now
competing for methods, with many chances for mistakes in programming.

The body of a generic function usually does nothing except for dispatching methods by a call to
\texttt{standardGeneric}. Under some circumstances you might just want to do some additional computa-
tion in the generic function itself. As long as your function eventually calls \texttt{standardGeneric}
that is permissible (though perhaps not a good idea, in that it may make the behavior of your
function less easy to understand). If your explicit definition of the generic function does \textit{not} call
\texttt{standardGeneric} you are in trouble, because none of the methods for the function will ever be
dispatched.

By default, the generic function can return any object. If \texttt{valueClass} is supplied, it should be a vec-
tor of class names; the value returned by a method is then required to satisfy \texttt{is(object, Class)}
for one of the specified classes. An empty (i.e., zero length) vector of classes means anything is
allowed. Note that more complicated requirements on the result can be specified explicitly, by
defining a non-standard generic function.

The \texttt{setGroupGeneric} function behaves like \texttt{setGeneric} except that it constructs a group generic
function, differing in two ways from an ordinary generic function. First, this function cannot be
called directly, and the body of the function created will contain a \texttt{stop} call with this information.
Second, the group generic function contains information about the known members of the group,
used to keep the members up to date when the group definition changes, through changes in the
search list or direct specification of methods, etc.

\textbf{Implicit Generic Functions}

Saying that a non-generic function “is converted to a generic” is more precisely state that the func-
tion is converted to the corresponding \textit{implicit} generic function. If no special action has been taken,
any function corresponds implicitly to a generic function with the same arguments, in which all
arguments other than 
odot
dot can be used. The signature of this generic function is the vector of formal
arguments, in order, except for \nodot
dot.

The source code for a package can define an implicit generic function version of any function in
that package (see \texttt{implicitGeneric} for the mechanism). You can not, generally, define an implicit
generic function in someone else’s package. The usual reason for defining an implicit generic is
to prevent certain arguments from appearing in the signature, which you must do if you want the
arguments to be used literally or if you want to enforce lazy evaluation for any reason. An implicit
generic can also contain some methods that you want to be predefined; in fact, the implicit generic
can be any generic version of the non-generic function. The implicit generic mechanism can also
be used to prohibit a generic version (see \texttt{prohibitGeneric}).

Whether defined or inferred automatically, the implicit generic will be compared with the generic
function that \texttt{setGeneric} creates, when the implicit generic is in another package. If the two
functions are identical, then the package slot of the created generic will have the name of the
package containing the implicit generic. Otherwise, the slot will be the name of the package in
which the generic is assigned.

The purpose of this rule is to ensure that all methods defined for a particular combination of generic
function and package names correspond to a single, consistent version of the generic function. Calling
\texttt{setGeneric} with only \texttt{name} and possibly \texttt{package} as arguments guarantees getting the
implicit generic version, if one exists.

Including any of the other arguments can force a new, local version of the generic function. If you
don’t want to create a new version, don’t use the extra arguments.
Generic Functions and Primitive Functions

A number of the basic \texttt{R} functions are specially implemented as primitive functions, to be evaluated directly in the underlying C code rather than by evaluating an \texttt{R} language definition. Most have implicit generics (see \texttt{implicitGeneric}), and become generic as soon as methods (including group methods) are defined on them. Others cannot be made generic.

Even when methods are defined for such functions, the generic version is not visible on the search list, in order that the C version continues to be called. Method selection will be initiated in the C code. Note, however, that the result is to restrict methods for primitive functions to signatures in which at least one of the classes in the signature is a formal S4 class.

To see the generic version of a primitive function, use \texttt{getGeneric(name)}. The function \texttt{isGeneric} will tell you whether methods are defined for the function in the current session.

Note that S4 methods can only be set on those primitives which are ‘internal generic’, plus \%\%.

Examples

```r
## create a new generic function, with a default method
setGeneric("props", function(object) attributes(object))

## A new generic function with no default method
setGeneric("increment", function(object, step, ...) standardGeneric("increment")

## A non-standard generic function. It insists that the methods
## return a non-empty character vector (a stronger requirement than
## valueClass = "character" in the call to setGeneric)
setGeneric("authorNames",
  function(text) {
    value <- standardGeneric("authorNames")
    if(!is(value, "character") & any(nchar(value)>0))
      stop("authorNames methods must return non-empty strings")
    value
  })

## An example of group generic methods, using the class
## "track"; see the documentation of \link{setClass} for its definition
```
setLoadActions

Description

These functions provide a mechanism for packages to specify computations to be done during the loading of the package namespace. Such actions are a flexible way to provide information only available at load time (such as locations in a dynamically linked library).

A call to `setLoadAction()` or `setLoadActions()` specifies one or more functions to be called when the corresponding package is loaded, with the . . . argument names being used as identifying names for the actions.

`getLoadActions()` reports the currently defined load actions, given a package’s namespace as its argument.

`hasLoadAction()` returns TRUE if a load action corresponding to the given name has previously been set for the where namespace.

`evalOnLoad()` and `evalQOnLoad()` schedule a specific expression for evaluation at load time.

Usage

```r
setLoadAction(action, aname=, where=)
setLoadActions(..., .where=)
getLoadActions(where=)
hasLoadAction(aname, where=)
evalOnLoad(expr, where=, aname=)
```
setLoadActions

`evalqOnLoad(expr, where=, aname=)`

**Arguments**

- **action, ...** functions of one or more arguments, to be called when this package is loaded. The functions will be called with one argument (the package namespace) so all following arguments must have default values. If the elements of ... are named, these names will be used for the corresponding load metadata.

- **where, .where** the namespace of the package for which the list of load actions are defined. This argument is normally omitted if the call comes from the source code for the package itself, but will be needed if a package supplies load actions for another package.

- **aname** the name for the action. If an action is set without supplying a name, the default uses the position in the sequence of actions specified (".1", etc.).

- **expr** an expression to be evaluated in a load action in environment where. In the case of `evalqOnLoad()`, the expression is interpreted literally, in that of `evalqOnLoad()` it must be precomputed, typically as an object of type "language".

**Details**

The `evalqOnLoad()` and `evalqOnLoad()` functions are for convenience. They construct a function to evaluate the expression and call `setLoadAction()` to schedule a call to that function. Each of the functions supplied as an argument to `setLoadAction()` or `setLoadActions()` is saved as metadata in the namespace, typically that of the package containing the call to `setLoadActions()`. When this package's namespace is loaded, each of these functions will be called. Action functions are called in the order they are supplied to `setLoadActions()`. The objects assigned have metadata names constructed from the names supplied in the call; unnamed arguments are taken to be named by their position in the list of actions (".1", etc.).

Multiple calls to `setLoadAction()` or `setLoadActions()` can be used in a package's code; the actions will be scheduled after any previously specified, except if the name given to `setLoadAction()` is that of an existing action. In typical applications, `setLoadActions()` is more convenient when calling from the package's own code to set several actions. Calls to `setLoadAction()` are more convenient if the action name is to be constructed, which is more typical when one package constructs load actions for another package.

Actions can be revised by assigning with the same name, actual or constructed, in a subsequent call. The replacement must still be a valid function, but can of course do nothing if the intention was to remove a previously specified action.

The functions must have at least one argument. They will be called with one argument, the namespace of the package. The functions will be called at the end of processing of S4 metadata, after dynamically linking any libraries, the call to `.onLoad()`, if any, and caching method and class definitions, but before the namespace is sealed.

Functions may therefore assign or modify objects in the namespace supplied as the argument in the call. The mechanism allows packages to save information not available until load time, such as values obtained from a dynamically linked library.

Load actions should be contrasted with user load hooks supplied by `setHook()`. User hooks are generally provided from outside the package and are run after the namespace has been sealed. Load
actions are part of the package code, and the list of actions is normally established when the package is installed.

Load actions can be supplied directly in the source code for a package. It is also possible and useful to provide facilities in one package to create load actions in another package. The software needs to be careful to assign the action functions in the correct environment, namely the namespace of the target package.

Value

setLoadAction() and setLoadActions() are called for their side effect and return no useful value.

getLoadActions() returns a named list of the actions in the supplied namespace.

hasLoadAction() returns TRUE if the specified action name appears in the actions for this package.

Examples

## Not run:
## in the code for some package

## ... somewhere else
setLoadActions(function(attach)
  cat(c("Loaded", "Unloaded") [attach], "at", Sys.time(), "\n"),
setCount = function(ns) assign("myCount", 1, envir = ns),
function(ns) assign("myPointer", getMyExternalPointer(), envir = ns))
... somewhere later
if(countShouldBe0)
  setLoadAction(function(ns) assign("myCount", 0, envir = ns), "setCount")

## End(Not run)

---

**setMethod**

Create and Save a Method

Description

Create and save a formal method for a given function and list of classes.

Usage

setMethod(f, signature=character(), definition,
  where = toppenv(parent.frame()),
  valueClass = NULL, sealed = FALSE)

removeMethod(f, signature, where)

Arguments

- **f**
  A generic function or the character-string name of the function.

- **signature**
  A match of formal argument names for f with the character-string names of corresponding classes. See the details below; however, if the signature is not trivial, you should use method.skeleton to generate a valid call to setMethod.
**setMethod**

<table>
<thead>
<tr>
<th>argument</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>definition</td>
<td>A function definition, which will become the method called when the arguments in a call to <code>f</code> match the classes in signature, directly or through inheritance.</td>
</tr>
<tr>
<td>where</td>
<td>the environment in which to store the definition of the method. For <code>setMethod</code>, it is recommended to omit this argument and to include the call in source code that is evaluated at the top level; that is, either in an R session by something equivalent to a call to <code>source</code>, or as part of the R source code for a package. For <code>removeMethod</code>, the default is the location of the (first) instance of the method for this signature.</td>
</tr>
<tr>
<td>valueClass</td>
<td>Obsolete and unused, but see the same argument for <code>setGeneric</code>.</td>
</tr>
<tr>
<td>sealed</td>
<td>If <code>TRUE</code>, the method so defined cannot be redefined by another call to <code>setMethod</code> (although it can be removed and then re-assigned).</td>
</tr>
</tbody>
</table>

**Details**

The call to `setMethod` stores the supplied method definition in the metadata table for this generic function in the environment, typically the global environment or the namespace of a package. In the case of a package, the table object becomes part of the namespace or environment of the package. When the package is loaded into a later session, the methods will be merged into the table of methods in the corresponding generic function object.

Generic functions are referenced by the combination of the function name and the package name; for example, the function "show" from the package "methods". Metadata for methods is identified by the two strings; in particular, the generic function object itself has slots containing its name and its package name. The package name of a generic is set according to the package from which it originally comes; in particular, and frequently, the package where a non-generic version of the function originated. For example, generic functions for all the functions in package `base` will have "base" as the package name, although none of them is an S4 generic on that package. These include most of the base functions that are primitives, rather than true functions; see the section on primitive functions in the documentation for `setGeneric` for details.

Multiple packages can have methods for the same generic function; that is, for the same combination of generic function name and package name. Even though the methods are stored in separate tables in separate environments, loading the corresponding packages adds the methods to the table in the generic function itself, for the duration of the session.

The class names in the signature can be any formal class, including basic classes such as "numeric", "character", and "matrix". Two additional special class names can appear: "ANY", meaning that this argument can have any class at all; and "missing", meaning that this argument must not appear in the call in order to match this signature. Don’t confuse these two: if an argument isn’t mentioned in a signature, it corresponds implicitly to class "ANY", not to "missing". See the example below. Old-style ("S3") classes can also be used, if you need compatibility with these, but you should definitely declare these classes by calling `setOldClass` if you want S3-style inheritance to work.

Method definitions can have default expressions for arguments, but a current limitation is that the generic function must have some default expression for the same argument in order for the method’s defaults to be used. If so, and if the corresponding argument is missing in the call to the generic function, the default expression in the method is used. If the method definition has no default for the argument, then the expression supplied in the definition of the generic function itself is used, but note that this expression will be evaluated using the enclosing environment of the method, not of the generic function. Note also that specifying class "missing" in the signature does not require any default expressions, and method selection does not evaluate default expressions. All actual (non-missing) arguments in the signature of the generic function will be evaluated when a method is selected—when the call to `standardGeneric(f)` occurs.

It is possible to have some differences between the formal arguments to a method supplied to `setMethod` and those of the generic. Roughly, if the generic has ... as one of its arguments, then
the method may have extra formal arguments, which will be matched from the arguments matching … in the call to f. (What actually happens is that a local function is created inside the method, with the modified formal arguments, and the method is re-defined to call that local function.)

Method dispatch tries to match the class of the actual arguments in a call to the available methods collected for f. If there is a method defined for the exact same classes as in this call, that method is used. Otherwise, all possible signatures are considered corresponding to the actual classes or to superclasses of the actual classes (including "ANY"). The method having the least distance from the actual classes is chosen; if more than one method has minimal distance, one is chosen (the lexicographically first in terms of superclasses) but a warning is issued. All inherited methods chosen are stored in another table, so that the inheritance calculations only need to be done once per session per sequence of actual classes. See Methods for more details.

The function `removeMethod` removes the specified method from the metadata table in the corresponding environment. It’s not a function that is used much, since one normally wants to redefine a method rather than leave no definition.

**Value**

These functions exist for their side-effect, in setting or removing a method in the object defining methods for the specified generic.

The value returned by `removeMethod` is TRUE if a method was found to be removed.

**Examples**

```r
require(graphics)
## methods for plotting track objects (see the example for \link{setClass})
##
## First, with only one object as argument:
setMethod("plot", signature(x="track", y="missing"),
  function(x, y, ...) plot(slot(x, "x"), slot(x, "y"), ...)
)
## Second, plot the data from the track on the y-axis against anything
## as the x data.
setMethod("plot", signature(y = "track"),
  function(x, y, ...) plot(x, slot(y, "y"), ...)
)
## and similarly with the track on the x-axis (using the short form of
## specification for signatures)
setMethod("plot", "track",
  function(x, y, ...) plot(slot(x, "y"), y, ...)
)```
setOldClass

)  
t1 <- new("track", x=1:20, y=(1:20)^2)  
tcl <- new("trackCurve", t1)  
slot(tcl, "smooth") <- smooth.spline(slot(tcl, "x"), slot(tcl, "y"))
plot(t1)  
plot(qnorm(ppoints(20)), t1)  
## An example of inherited methods, and of conforming method arguments  
## (note the dotCurve argument in the method, which will be pulled out  
## of ... in the generic.  
setMethod("plot", c("trackCurve", "missing"),  
function(x, y, dotCurve = FALSE, ...) {  
  plot(as(x, "track"))  
  if(length(slot(x, "smooth") > 0))  
    lines(slot(x, "x"), slot(x, "smooth"),  
      lty = if(dotCurve) 2 else 1)  
})  
## the plot of tcl alone has an added curve; other uses of tcl  ## are treated as if it were a "track" object.  
plot(tcl, dotCurve = TRUE)  
plot(qnorm(ppoints(20)), tcl)  

## defining methods for a special function.  
## Although "[" and "length" are not ordinary functions  
## methods can be defined for them.  
setMethod("[", "track",  
  function(x, i, j, ..., drop) {  
    x@x <- x@x[i]; x@y <- x@y[i]  
    x  
  })  
plot(t1[1:15])  

setMethod("length", "track", function(x)length(x@y))  
length(t1)  

## methods can be defined for missing arguments as well  
setGeneric("summary")  
## make the function into a generic  

## A method for summary()  
## The method definition can include the arguments, but  
## if they're omitted, class "missing" is assumed.  
setMethod("summary", "missing", function() "<No Object>")

setOldClass

Register Old-Style (S3) Classes and Inheritance

Description

Register an old-style (a.k.a. 'S3') class as a formally defined class. The Classes argument is the character vector used as the class attribute; in particular, if there is more than one string, old-style class inheritance is mimicked. Registering via setOldClass allows S3 classes to appear in method signatures, as a slot in an S4 class, or as a superclass of an S4 class.
setOldClass

**Usage**

```r
setOldClass(Classes, prototype, where = NULL, test = FALSE, S4Class)
```

**Arguments**

- **Classes**: A character vector, giving the names for S3 classes, as they would appear on the right side of an assignment of the `class` attribute in S3 computations. In addition to S3 classes, an object type or other valid data part can be specified, if the S3 class is known to require its data to be of that form.
- **prototype**: An optional object to use as the prototype. This should be provided as the default S3 object for the class. If omitted, the S4 class created to register the S3 class is `VIRTUAL`. See the details.
- **where**: Where to store the class definitions, the global or top-level environment by default. (When either function is called in the source for a package, the class definitions will be included in the package’s environment by default.)
- **test**: Flag, if `TRUE`, arrange to test inheritance explicitly for each object, needed if the S3 class can have a different set of class strings, with the same first string. This is a different mechanism in implementation and should be specified separately for each pair of classes that have an optional inheritance. See the ‘Details’.
- **S4Class**: Optionally, the class definition or the class name of an S4 class. The new class will have all the slots and other properties of this class, plus its S3 inheritance as defined by the `Classes` argument. Arguments `prototype` and `test` must not be supplied in this case. See the section on “S3 classes with known attributes” below.

**Details**

Each of the names will be defined as an S4 class, extending the remaining classes in `Classes`, and the class `oldClass`, which is the ‘root’ of all old-style classes. S3 classes have no formal definition, and therefore no formally defined slots. If a `prototype` argument is supplied in the call to `setOldClass()`, objects from the class can be generated, by a call to `new`; however, this usually not as relevant as generating objects from subclasses (see the section on extending S3 classes below). If a prototype is not provided, the class will be created as a virtual S4 class. The main disadvantage is that the prototype object in an S4 class that uses this class as a slot will have a `NULL` object in that slot, which can sometimes lead to confusion.

Beginning with version 2.8.0 of R, support is provided for using a (registered) S3 class as a superclass of a new S4 class. See the section on extending S3 classes below, and the examples.

See **Methods** for the details of method dispatch and inheritance.

Some S3 classes cannot be represented as an ordinary combination of S4 classes and superclasses, because objects from the S3 class can have a variable set of strings in the class. It is still possible to register such classes as S4 classes, but now the inheritance has to be verified for each object, and you must call `setOldClass` with argument `test=TRUE` once for each superclass.

For example, ordered factors *always* have the S3 class `c("ordered", "factor")`. This is proper behavior, and maps simply into two S4 classes, with “ordered” extending “factor”.

But objects whose class attribute has "POSIXt" as the first string may have either (or neither) of "POSIXct" or "POSIXt1" as the second string. This behavior can be mapped into S4 classes but now to evaluate `is(x, "POSIXt1")`, for example, requires checking the S3 class attribute on each object. Supplying the `test=TRUE` argument to `setOldClass` causes an explicit test to be included in the class definitions. It’s never wrong to have this test, but since it adds significant overhead to
methods defined for the inherited classes, you should only supply this argument if it's known that object-specific tests are needed.

The list \texttt{.OldClassesList} contains the old-style classes that are defined by the methods package. Each element of the list is a character vector, with multiple strings if inheritance is included. Each element of the list was passed to \texttt{setOldClass} when creating the \texttt{methods} package; therefore, these classes can be used in \texttt{setMethod} calls, with the inheritance as implied by the list.

\section*{Extending S3 classes}

A call to \texttt{setOldClass} creates formal classes corresponding to S3 classes, allows these to be used as slots in other classes or in a signature in \texttt{setMethod}, and mimics the S3 inheritance.

In documentation for the initial implementation of S4 classes in \texttt{R}, users were warned against defining S4 classes that contained S3 classes, even if those had been registered. The warning was based mainly on two points. 1: The S3 behavior of the objects would fail because the S3 class would not be visible, for example, when S3 methods are dispatched. 2: Because S3 classes have no formal definition, nothing can be asserted in general about the S3 part of an object from such a class. (The warning was repeated as recently as the first reference below.) Nevertheless, defining S4 classes to contain an S3 class and extend its behavior is attractive in many applications. The alternative is to be stuck with S3 programming, without the flexibility and security of formal class and method definitions.

Beginning with version 2.8.0, \texttt{R} provides support for extending registered S3 classes; that is, for new classes defined by a call to \texttt{setClass} in which the \texttt{contains=} argument includes an S3 class. See the examples below. The support is aimed primarily at providing the S3 class information for all classes that extend class \texttt{oldClass}, in particular by ensuring that all objects from such classes contain the S3 class in a special slot.

There are three different ways to indicate an extension to an existing S3 class: \texttt{setOldClass()}, \texttt{setClass()} and \texttt{setIs()}. In most cases, calling \texttt{setOldClass} is the best approach, but the alternatives may be preferred in the special circumstances described below.

Suppose "A" is any class extending "oldClass". then

\begin{verbatim}
setOldClass(c("B", "A"))
\end{verbatim}

creates a new class "B" whose S3 class concatenates "B" with \texttt{S3Class("A")}. The new class is a virtual class. If "A" was defined with known attribute/slots, then "B" has these slots also; therefore, you must believe that the corresponding S3 objects from class "B" do indeed have the claimed attributes. Notice that you can supply an S4 definition for the new class to specify additional attributes (as described in the next section.) The first alternative call produces a non-virtual class.

\begin{verbatim}
setClass("B", contains = "A")
\end{verbatim}

This creates a non-virtual class with the same slots and superclasses as class "A". However, class "B" is not included in the S3 class slot of the new class, unless you provide it explicitly in the prototype.

\begin{verbatim}
setClass("B"); setIs("B", "A", ....)
\end{verbatim}

This creates a virtual class that extends "A", but does not contain the slots of "A". The additional arguments to \texttt{setIs} should provide a coerce and replacement method. In order for the new class to inherit S3 methods, the coerce method must ensure that the class "A" object produced has a suitable S3 class. The only likely reason to prefer this third approach is that class "B" is not consistent with known attributes in class "A".

Beginning with version 2.9.0 of \texttt{R}, objects from a class extending an S3 class will be converted to the corresponding S3 class when being passed to an S3 method defined for that class (that is, for one of the strings in the S3 class attribute). This is intended to ensure, as far as possible, that such methods will work if they work for ordinary S3 objects. See \texttt{Classes} for details.
S3 Classes with known attributes

A further specification of an S3 class can be made if the class is guaranteed to have some attributes of known class (where as with slots, “known” means that the attribute is an object of a specified class, or a subclass of that class).

In this case, the call to `setOldClass()` can supply an S4 class definition representing the known structure. Since S4 slots are implemented as attributes (largely for just this reason), the known attributes can be specified in the representation of the S4 class. The usual technique will be to create an S4 class with the desired structure, and then supply the class name or definition as the argument `S4Class` to `setOldClass()`.

See the definition of class "ts" in the examples below. The call to `setClass` to create the S4 class can use the same class name, as here, so long as the class definition is not sealed. In the example, we define "ts" as a vector structure with a numeric slot for "tsp". The validity of this definition relies on an assertion that all the S3 code for this class is consistent with that definition; specifically, that all "ts" objects will behave as vector structures and will have a numeric "tsp" attribute. We believe this to be true of all the base code in R, but as always with S3 classes, no guarantee is possible.

The S4 class definition can have virtual superclasses (as in the "ts" case) if the S3 class is asserted to behave consistently with these (in the example, time-series objects are asserted to be consistent with the `structure` class).

For another example, look at the S4 class definition for "data.frame".

Be warned that failures of the S3 class to live up to its asserted behavior will usually go uncorrected, since S3 classes inherently have no definition, and the resulting invalid S4 objects can cause all sorts of grief. Many S3 classes are not candidates for known slots, either because the presence or class of the attributes are not guaranteed (e.g., `dimnames` in arrays, although these are not even S3 classes), or because the class uses named components of a list rather than attributes (e.g., "lm"). An attribute that is sometimes missing cannot be represented as a slot, not even by pretending that it is present with class "NULL", because attributes unlike slots can not have value `NULL`.

One irregularity that is usually tolerated, however, is to optionally add other attributes to those guaranteed to exist (for example, "terms" in "data.frame" objects returned by `model.frame`). As of version 2.8.0, validity checks by `validObject` ignore extra attributes; even if this check is tightened in the future, classes extending S3 classes would likely be exempted because extra attributes are so common.

`setClass`, `setMethod`

Examples

```r
require(stats)
setOldClass(c("mlm", "lm"))
setGeneric("dfResidual", function(model) standardGeneric("dfResidual"))
setMethod("dfResidual", "lm", function(model) model$df.residual)

## dfResidual will work on mlm objects as well as lm objects
```
myData <- data.frame(time = 1:10, y = (1:10)^.5)
myLm <- lm(cbind(y, y^3) ~ time, myData)

showClass("data.frame") # to see the predefined S4 "oldClass"

## two examples extending S3 class "lm", class "xlm" directly
## and "ylm" indirectly
setClass("xlm", representation(eps = "numeric"), contains = "lm")
setClass("ylm", representation(header = "character"), contains = "xlm")
yml <- new("ylm", myLm, header = "Example", eps = 0.)
## for more examples, see ?\link[S3Class]{utils::str(.OldClassesList)}

## Examples of S3 classes with guaranteed attributes
## an S3 class "stamped" with a vector and a "date" attribute
## Here is a generator function and an S3 print method.
## NOTE: it’s essential that the generator checks the attribute classes
stamped <- function(x, date = Sys.time()) {
  if(!inherits(date, "POSIXt"))
    stop("bad date argument")
  if(!is.vector(x))
    stop("x must be a vector")
  attr(x, "date") <- date
  class(x) <- "stamped"
  x
}

print.stamped <- function(x, ...) {
  print(as.vector(x))
  cat("Date: ", format(attr(x,"date")), "\n")
}

## Now, an S4 class with the same structure:
setClass("stamped4", contains = "vector", representation(date = "POSIXt"))

## We can use the S4 class to register "stamped", with its attributes:
setOldClass("stamped", S4Class = "stamped4")
selectMethod("show", "stamped")
## and then remove "stamped4" to clean up
removeClass("stamped4")

someLetters <- stamped(sample(letters, 10),
  ISOdatetime(2008, 10, 15, 12, 0, 0))

st <- new("stamped", someLetters)
st
# show() method prints the object's class, then calls the S3 print method.
stopifnot(identical(S3Part(st, TRUE), someLetters))

# creating the S4 object directly from its data part and slots
new("stamped", 1:10, date = ISOdatetime(1976, 5, 5, 15, 10, 0))

## Not run:
## show

**Show an Object**

### Description

Display the object, by printing, plotting or whatever suits its class. This function exists to be specialized by methods. The default method calls `showDefault`.

Formal methods for `show` will usually be invoked for automatic printing (see the details).

### Usage

```r
show(object)
```

### Arguments

- **object**: Any R object

### Details

Objects from an S4 class (a class defined by a call to `setClass`) will be displayed automatically if by a call to `show`. S4 objects that occur as attributes of S3 objects will also be displayed in this form; conversely, S3 objects encountered as slots in S4 objects will be printed using the S3 convention, as if by a call to `print`.

Methods defined for `show` will only be inherited by simple inheritance, since otherwise the method would not receive the complete, original object, with misleading results. See the `simpleInheritanceOnly` argument to `setGeneric` and the discussion in `setIs` for the general concept.

### Value

`show` returns an invisible NULL.

### See Also

- `showMethods` prints all the methods for one or more functions.
showMethods

Examples

## following the example shown in the setMethod documentation ...

```r
setClass("track",
    representation(x="numeric", y="numeric"))
setClass("trackCurve",
    representation("track", smooth = "numeric"))

t1 <- new("track", x=1:20, y=(1:20)^2)
tcl <- new("trackCurve", t1)

setMethod("show", "track",
    function(object)print(rbind(x = object@x, y=object@y)))
)
## The method will now be used for automatic printing of t1

t1
```

## Not run: 
```
 x 1  2  3  4  5  6  7  8  9 10 11 12
 y 1  4  9 16 25 36 49 64 81 100 121 144
```
```
 x 13 14 15 16 17 18 19 20
 y 169 196 225 256 289 324 361 400
```

## End(Not run)

## and also for tcl, an object of a class that extends "track"

tcl

## Not run: 
```
 x 1  2  3  4  5  6  7  8  9 10 11 12
 y 1  4  9 16 25 36 49 64 81 100 121 144
```
```
 x 13 14 15 16 17 18 19 20
 y 169 196 225 256 289 324 361 400
```

## End(Not run)

---

showMethods

Show all the methods for the specified function(s)

Description

Show a summary of the methods for one or more generic functions, possibly restricted to those involving specified classes.

Usage

```r
showMethods(f = character(), where = toplevel(parent.frame()),
    classes = NULL, includeDefs = FALSE,
    inherited = !includeDefs,
    showEmpty, printTo = stdout(), fdef)
```
Arguments

\( f \)

one or more function names. If omitted, all functions will be shown that match the other arguments.

The argument can also be an expression that evaluates to a single generic function, in which case argument \( f\text{def} \) is ignored. Providing an expression for the function allows examination of hidden or anonymous functions; see the example for \texttt{isDiagonal()}. 

\( \text{where} \)

Where to find the generic function, if not supplied as an argument. When \( f \) is missing, or length 0, this also determines which generic functions to examine. If \( \text{where} \) is supplied, only the generic functions returned by \texttt{getGenerics(\text{where})} are eligible for printing. If \( \text{where} \) is also missing, all the cached generic functions are considered.

\( \text{classes} \)

If argument \( \text{classes} \) is supplied, it is a vector of class names that restricts the displayed results to those methods whose signatures include one or more of those classes.

\( \text{includeDefs} \)

If \( \text{includeDefs} \) is \( \text{TRUE} \), include the definitions of the individual methods in the printout.

\( \text{inherited} \)

logical indicating if methods that have been found by inheritance, so far in the session, will be included and marked as inherited. Note that an inherited method will not usually appear until it has been used in this session. See \texttt{selectMethod} if you want to know what method would be dispatched for particular classes of arguments.

\( \text{showEmpty} \)

logical indicating whether methods with no defined methods matching the other criteria should be shown at all. By default, \( \text{TRUE} \) if and only if argument \( f \) is not missing.

\( \text{printTo} \)

The connection on which the information will be shown; by default, on standard output.

\( \text{fdef} \)

Optionally, the generic function definition to use; if missing, one is found, looking in \( \text{where} \) if that is specified. See also comment in ‘Details’.

Details

The name and package of the generic are followed by the list of signatures for which methods are currently defined, according to the criteria determined by the various arguments. Note that the package refers to the source of the generic function. Individual methods for that generic can come from other packages as well.

When more than one generic function is involved, either as specified or because \( f \) was missing, the functions are found and \texttt{showMethods} is recalled for each, including the generic as the argument \( f\text{def} \). In complicated situations, this can avoid some anomalous results.

Value

If \( \text{printTo} \) is \( \text{FALSE} \), the character vector that would have been printed is returned; otherwise the value is the connection or filename, via \texttt{invisible}.

Examples

```r
require(graphics)

## Assuming the methods for plot
## are set up as in the example of help(setMethod),
## print (without definitions) the methods that involve class "track":
showMethods("plot", classes = "track")
## Not run:
# Function "plot":
# x = ANY, y = track
# x = track, y = missing
# x = track, y = ANY

require("Matrix")
showMethods("%*%")# many!
    methods(class = "Matrix")# nothing
showMethods(class = "Matrix")# everything
showMethods(Matrix:::isDiagonal) # a non-exported generic

## End(Not run)

not.there <- !any("package:stats4" == search())
if(not.there) library(stats4)
showMethods(classes = "mle")
if(not.there) detach("package:stats4")
```

---

signature-class  

*Class "signature" For Method Definitions*

Description

This class represents the mapping of some of the formal arguments of a function onto the corresponding classes. It is used for two slots in the `MethodDefinition` class.

Objects from the Class

Objects can be created by calls of the form `new("signature", functionDef, ...)`. The `functionDef` argument, if it is supplied as a function object, defines the formal names. The other arguments define the classes. More typically, the objects are created as side effects of defining methods. Either way, note that the classes are expected to be well defined, usually because the corresponding class definitions exist. See the comment on the `package` slot.
Slots

.Data: Object of class "character" the class names.
names: Object of class "character" the corresponding argument names.
package: Object of class "character" the names of the packages corresponding to the class
names. The combination of class name and package uniquely defines the class. In princi-
ple, the same class name could appear in more than one package, in which case the package
information is required for the signature to be well defined.

Extends

Class "character", from data part. Class "vector", by class "character".

Methods

initialize signature(object = "signature"): see the discussion of objects from the class,
above.

See Also

class MethodDefinition for the use of this class.

---

slot

The Slots in an Object from a Formal Class

Description

These functions return or set information about the individual slots in an object.

Usage

object@name
object@name <- value

slot(object, name)
slot(object, name, check = TRUE) <- value
.hasSlot(object, name)

slotNames(x)
getSlots(x)

Arguments

<table>
<thead>
<tr>
<th>object</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>An object from a formally defined class.</td>
<td>The name of the slot. The operator takes a fixed name, which can be unquoted if it is syntactically a name in the language. A slot name can be any non-empty string, but if the name is not made up of letters, numbers, and ., it needs to be quoted (by backticks or single or double quotes). In the case of the slot function, name can be any expression that evaluates to a valid slot in the class definition. Generally, the only reason to use the functional form rather than the simpler operator is because the slot name has to be computed.</td>
</tr>
</tbody>
</table>
value A new value for the named slot. The value must be valid for this slot in this object’s class.

check In the replacement version of slot, a flag. If TRUE, check the assigned value for validity as the value of this slot. User’s coded should not set this to FALSE in normal use, since the resulting object can be invalid.

x either the name of a class (as character string), or a class definition. If given an argument that is neither a character string nor a class definition, slotNames (only) uses class(x) instead.

Details

The definition of the class specifies all slots directly and indirectly defined for that class. Each slot has a name and an associated class. Extracting a slot returns an object from that class. Setting a slot first coerces the value to the specified slot and then stores it.

Unlike general attributes, slots are not partially matched, and asking for (or trying to set) a slot with an invalid name for that class generates an error.

The @ extraction operator and slot function themselves do no checking against the class definition, simply matching the name in the object itself. The replacement forms do check (except for slot in the case check=FALSE). So long as slots are set without cheating, the extracted slots will be valid.

Be aware that there are two ways to cheat, both to be avoided but with no guarantees. The obvious way is to assign a slot with check=FALSE. Also, slots in R are implemented as attributes, for the sake of some back compatibility. The current implementation does not prevent attributes being assigned, via attr<-, and such assignments are not checked for legitimate slot names.

Note that the "@" operators for extraction and (since R 3.0.0) replacement are primitive and actually reside in the base package.

The replacement versions of "@" and slot() differ in the computations done to coerce the right side of the assignment to the declared class of the slot. Both verify that the value provided is from a subclass of the declared slot class. The slot() version will go on to call the coerce method if there is one, in effect doing the computation as(value, slotClass, strict = FALSE). The "@" version just verifies the relation, leaving any coerce to be done later (e.g., when a relevant method is dispatched).

In most uses the result is equivalent, and the "@" version saves an extra function call, but if empirical evidence shows that a conversion is needed, either call as() before the replacement or use the replacement version of slot().

Value

The "@" operator and the slot function extract or replace the formally defined slots for the object. Functions slotNames and getSlots return respectively the names of the slots and the classes associated with the slots in the specified class definition. Except for its extended interpretation of x (above), slotNames(x) is just names(getSlots(x)).

Examples

```r
setClass("track", representation(x="numeric", y="numeric"))
myTrack <- new("track", x = -4:4, y = exp(-4:4))
slot(myTrack, "x")
slot(myTrack, "y") <- log(slot(myTrack, "y"))
utils::str(myTrack)

getSlots("track") # or
getSlots(getClass("track"))
slotNames(class(myTrack)) # is the same as
slotNames(myTrack)
```

Description

The virtual class `structure` and classes that extend it are formal classes analogous to S language structures such as arrays and time-series.

Usage

```r
## The following class names can appear in method signatures,
## as the class in as() and is() expressions, and, except for
## the classes commented as VIRTUAL, in calls to new()

"matrix"
"array"
"ts"

"structure" ## VIRTUAL
```

Objects from the Classes

Objects can be created by calls of the form `new(Class, ...)`, where `Class` is the quoted name of the specific class (e.g., "matrix"), and the other arguments, if any, are interpreted as arguments to the corresponding function, e.g., to function `matrix()`. There is no particular advantage over calling those functions directly, unless you are writing software designed to work for multiple classes, perhaps with the class name and the arguments passed in.

Objects created from the classes "matrix" and "array" are unusual, to put it mildly, and have been for some time. Although they may appear to be objects from these classes, they do not have the internal structure of either an S3 or S4 class object. In particular, they have no "class" attribute and are not recognized as objects with classes (that is, both `is.object` and `isS4` will return `FALSE` for such objects). However, methods (both S4 and S3) can be defined for these pseudo-classes and new classes (both S4 and S3) can inherit from them.

That the objects still behave as if they came from the corresponding class (most of the time, anyway) results from special code recognizing such objects being built into the base code of R. For most purposes, treating the classes in the usual way will work, fortunately. One consequence of the
special treatment is that these two classes may be used as the data part of an S4 class; for example, you can get away with contains = "matrix" in a call to setGeneric to create an S4 class that is a subclass of "matrix". There is no guarantee that everything will work perfectly, but a number of classes have been written in this form successfully.

Note that a class containing "matrix" or "array" will have a .Data slot with that class. This is the only use of .Data other than as a pseudo-class indicating the type of the object. In this case the type of the object will be the type of the contained matrix or array. See Classes for a general discussion.

The class "ts" is basically an S3 class that has been registered with S4, using the setOldClass mechanism. Versions of R through 2.7.0 treated this class as a pure S4 class, which was in principal a good idea, but in practice did not allow subclasses to be defined and had other intrinsic problems. (For example, setting the "tsp" parameters as a slot often fails because the built-in implementation does not allow the slot to be temporarily inconsistent with the length of the data. Also, the S4 class prevented the correct specification of the S3 inheritance for class "mts".)

Time-series objects, in contrast to matrices and arrays, have a valid S3 class, "ts", registered using an S4-style definition (see the documentation for setOldClass in the examples section for an abbreviated listing of how this is done. The S3 inheritance of "mts" in package stats is also registered. These classes, as well as "matrix" and "array" should be valid in most examples as superclasses for new S4 class definitions.

All of these classes have special S4 methods for initialize that accept the same arguments as the basic generator functions, matrix, array, and ts, in so far as possible. The limitation is that a class that has more than one non-virtual superclass must accept objects from that superclass in the call to new; therefore, a such a class (what is called a “mixin” in some languages) uses the default method for initialize, with no special arguments.

Extends

The specific classes all extend class "structure", directly, and class "vector", by class "structure".

Methods

coerce Methods are defined to coerce arbitrary objects to these classes, by calling the corresponding basic function, for example, as(x, "matrix") calls as.matrix(x). If strict = TRUE in the call to as(), the method goes on to delete all other slots and attributes other than the dim and dimnames.

Ops Group methods (see, e.g., S4groupGeneric) are defined for combinations of structures and vectors (including special cases for array and matrix), implementing the concept of vector structures as in the reference. Essentially, structures combined with vectors retain the structure as long as the resulting object has the same length. Structures combined with other structures remove the structure, since there is no automatic way to determine what should happen to the slots defining the structure.

Note that these methods will be activated when a package is loaded containing a class that inherits from any of the structure classes or class "vector".

See Also

Class `nonStructure`, which enforces the alternative model, in which all slots are dropped if any math transformation or operation is applied to an object from a class extending one of the basic classes.

Examples

```
showClass("structure")

## explore a bit:
showClass("ts")
(ts0 <- new("ts"))
str(ts0)

showMethods("Ops") # six methods from these classes, but maybe many more
```

testInheritedMethods  Test for and Report about Selection of Inherited Methods

Description

A set of distinct inherited signatures is generated to test inheritance for all the methods of a specified generic function. If method selection is ambiguous for some of these, a summary of the ambiguities is attached to the returned object. This test should be performed by package authors before releasing a package.

Usage

```
testInheritedMethods(f, signatures, test = TRUE, virtual = FALSE, 
    groupMethods = TRUE, where = .GlobalEnv)
```

Arguments

- `f` a generic function or the character string name of one. By default, all currently defined subclasses of all the method signatures for this generic will be examined. The other arguments are mainly options to modify which inheritance patterns will be examined.

- `signatures` An optional set of subclass signatures to use instead of the relevant subclasses computed by `testInheritedMethods`. See the Details for how this is done. This argument might be supplied after a call with `test = FALSE`, to test selection in batches.

- `test` optional flag to control whether method selection is actually tested. If `FALSE`, returns just the list of relevant signatures for subclasses, without calling `selectMethod` for each signature. If there are a very large number of signatures, you may want to collect the full list and then test them in batches.

- `virtual` should virtual classes be included in the relevant subclasses. Normally not, since only the classes of actual arguments will trigger the inheritance calculation in a call to the generic function. Including virtual classes may be useful if the class has no current non-virtual subclasses but you anticipate your users may define such classes in the future.
should methods for the group generic function be included?
the environment in which to look for class definitions. Nearly always, use the
default global environment after attaching all the packages with relevant meth-
ods and/or class definitions.

Details
The following description applies when the optional arguments are omitted, the usual case. First,
the defining signatures for all methods are computed by calls to findMethodSignatures. From
these all the known non-virtual subclasses are found for each class that appears in the signature of
some method. These subclasses are split into groups according to which class they inherit from,
and only one subclass from each group is retained (for each argument in the generic signature). So
if a method was defined with class "vector" for some argument, one actual vector class is
chosen arbitrarily. The case of "ANY" is dealt with specially, since all classes extend it. A dummy,
nonvirtual class, "Other", is used to correspond to all classes that have no superclasses among
those being tested.
All combinations of retained subclasses for the arguments in the generic signature are then com-
puted. Each row of the resulting matrix is a signature to be tested by a call to selectMethod. To
collect information on ambiguous selections, testInheritedMethods establishes a calling handler
for the special signal "ambiguousMethodSelection", by setting the corresponding option.

Value
An object of class "methodSelectionReport". The details of this class are currently subject to
change. It has slots "target", "selected", "candidates", and "note", all referring to the am-
biguous cases (and so of length 0 if there were none). These slots are intended to be examined
by the programmer to detect and preferably fix ambiguous method selections. The object contains
in addition slots "generic", the name of the generic function, and "allSelections", giving the
vector of labels for all the signatures tested.

References
10.6 for basics of method selection.)
classInheritance.pdf (to be submitted to the R Journal).

Examples
## if no other attached packages have methods for `+` or its group
## generic functions, this returns a 16 by 2 matrix of selection
## patterns (in R 2.9.0)
testInheritedMethods("+")

Description
The classes described here are used by the R function trace to create versions of functions and
methods including browser calls, etc., and also to untrace the same objects.
**Usage**

### Objects from the following classes are generated
### by calling `trace()` on an object from the corresponding
### class without the "WithTrace" in the name.

"functionWithTrace"
"MethodDefinitionWithTrace"
"MethodWithNextWithTrace"
"genericFunctionWithTrace"
"groupGenericFunctionWithTrace"

### the following is a virtual class extended by each of the
### classes above

"traceable"

**Objects from the Class**

Objects will be created from these classes by calls to `trace()`. (There is an `initialize` method for class "traceable", but you are unlikely to need it directly.)

**Slots**

.data: The data part, which will be "function" for class "functionWithTrace", and similarly for the other classes.

original: Object of the original class; e.g., "function" for class "functionWithTrace".

**Extends**

Each of the classes extends the corresponding untraced class, from the data part; e.g., "functionWithTrace" extends "function". Each of the specific classes extends "traceable", directly, and class "VIRTUAL", by class "traceable".

**Methods**

The point of the specific classes is that objects generated from them, by function `trace()`, remain callable or dispatchable, in addition to their new trace information.

**See Also**

function `trace`

---

`validObject`  
*Test the Validity of an Object*
validObject

Description
The validity of object related to its class definition is tested. If the object is valid, TRUE is returned; otherwise, either a vector of strings describing validity failures is returned, or an error is generated (according to whether test is TRUE). Optionally, all slots in the object can also be validated.

The function setValidity sets the validity method of a class (but more normally, this method will be supplied as the validity argument to setClass). The method should be a function of one object that returns TRUE or a description of the non-validity.

Usage
validObject(object, test = FALSE, complete = FALSE)
setValidity(Class, method, where = topenv(parent.frame()))
getValidity(ClassDef)

Arguments
object any object, but not much will happen unless the object’s class has a formal definition.
test logical; if TRUE and validity fails, the function returns a vector of strings describing the problems. If test is FALSE (the default) validity failure generates an error.
complete logical; if TRUE, validity methods will be applied recursively to any of the slots that have such methods.
Class the name or class definition of the class whose validity method is to be set.
ClassDef a class definition object, as from getClassDef.
method a validity method; that is, either NULL or a function of one argument (object). Like validObject, the function should return TRUE if the object is valid, and one or more descriptive strings if any problems are found. Unlike validObject, it should never generate an error.
where the modified class definition will be stored in this environment.

Note that validity methods do not have to check validity of superclasses: the logic of validObject ensures these tests are done once only. As a consequence, if one validity method wants to use another, it should extract and call the method from the other definition of the other class by calling getValidity(); it should not call validObject.

Details
Validity testing takes place ‘bottom up’: Optionally, if complete=TRUE, the validity of the object’s slots, if any, is tested. Then, in all cases, for each of the classes that this class extends (the ‘superclasses’), the explicit validity method of that class is called, if one exists. Finally, the validity method of object’s class is called, if there is one.

Testing generally stops at the first stage of finding an error, except that all the slots will be examined even if a slot has failed its validity test.

The standard validity test (with complete=FALSE) is applied when an object is created via new with any optional arguments (without the extra arguments the result is just the class prototype object). An attempt is made to fix up the definition of a validity method if its argument is not object.
validObject returns TRUE if the object is valid. Otherwise a vector of strings describing problems found, except that if test is FALSE, validity failure generates an error, with the corresponding strings in the error message.

setClass; class classRepresentation.

Examples

```
setClass("track",
  representation(x="numeric", y = "numeric"))
t1 <- new("track", x=1:10, y=sort(stats::rnorm(10)))
## A valid "track" object has the same number of x, y values
validTrackObject <- function(object) {
  if(length(object@x) == length(object@y)) TRUE
  else paste("Unequal x, y lengths: ", length(object@x), ", ",
           length(object@y), sep="")
}
## assign the function as the validity method for the class
setValidity("track", validTrackObject)
## t1 should be a valid "track" object
validObject(t1)
## Now we do something bad
t2 <- t1
t2@x <- 1:20
## This should generate an error
## Not run: try(validObject(t2))

setClass("trackCurve",
  representation("track", smooth = "numeric"))
## all superclass validity methods are used when validObject
## is called from initialize() with arguments, so this fails
## Not run: trynew("trackCurve", t2)

setClass("twoTrack", representation(tr1 = "track", tr2 ="track"))
## validity tests are not applied recursively by default,
## so this object is created (invalidly)
tT <- new("twoTrack", tr2 = t2)
## A stricter test detects the problem
## Not run: try(validObject(tT, complete = TRUE))
```
Chapter 8

The parallel package

parallel-package Support for Parallel Computation

Description

Support for parallel computation, including random-number generation.

Details

This package is under development: a first version was released with R 2.14.0.

There is support for multiple RNG streams with the ‘"L’Ecuyer-CMRG"’ RNG: see
nextRNGStream.

It contains functionality derived from and pretty much equivalent to that contained in packages
multicore (with some low-level functions renamed and not exported) and snow (for socket clusters
only, but MPI and NWS clusters generated by snow are also supported). This package also provides
makeForkCluster.

For a complete list of exported functions, use library(help = "parallel").

Author(s)

Brian Ripley, Luke Tierney and Simon Urbanek

Maintainer: R Core Team <R-core@r-project.org>

See Also

Parallel computation involves launching worker processes: functions psnice and pskill in pack-
age tools provide means to manage such processes.
clusterApply  

Apply Operations using Clusters

Description

These functions provide several ways to parallelize computations using a cluster.

Usage

- `clusterCall(cl = NULL, fun, ...)`
- `clusterApply(cl = NULL, x, fun, ...)`
- `clusterApplyLB(cl = NULL, x, fun, ...)`
- `clusterEvalQ(cl = NULL, expr)`
- `clusterExport(cl = NULL, varlist, envir = .GlobalEnv)`
- `clusterMap(cl = NULL, fun, ..., MoreArgs = NULL, RECYCLE = TRUE, SIMPLIFY = FALSE, USE.NAMES = TRUE, .scheduling = c("static", "dynamic"))`
- `clusterSplit(cl = NULL, seq)`
- `parLapply(cl = NULL, X, fun, ...)`
- `parSapply(cl = NULL, X, FUN, ..., simplify = TRUE, USE.NAMES = TRUE)`
- `parApply(cl = NULL, X, MARGIN, FUN, ...)`
- `parRapply(cl = NULL, x, FUN, ...)`
- `parCapply(cl = NULL, x, FUN, ...)`
- `parLapplyLB(cl = NULL, X, fun, ...)`
- `parSapplyLB(cl = NULL, X, FUN, ..., simplify = TRUE, USE.NAMES = TRUE)`

Arguments

- `cl`: a cluster object, created by this package or by package snow. If NULL, use the registered default cluster.
- `fun, FUN`: function or character string naming a function.
- `expr`: expression to evaluate.
- `seq`: vector to split.
- `varlist`: character vector of names of objects to export.
- `envir`: environment from which to export variables.
- `x`: a vector for clusterApply and clusterApplyLB, a matrix for parRapply and parCapply.
- `...`: additional arguments to pass to fun or FUN: beware of partial matching to earlier arguments.
- `MoreArgs`: additional arguments for fun.
- `RECYCLE`: logical; if true shorter arguments are recycled.
- `X`: A vector (atomic or list) for parLapply and parSapply, an array for parApply.
- `MARGIN`: vector specifying the dimensions to use.
simplify, USE.NAMES
   logical; see sapply.
SIMPLIFY logical; see mapply.

.scheduling should tasks be statically allocated to nodes or dynamic load-balancing used?

Details

clusterCall calls a function fun with identical arguments ... on each node.
clusterEvalQ evaluates a literal expression on each cluster node. It is a parallel version of evalq,
and is a convenience function invoking clusterCall.
clusterApply calls fun on the first node with arguments seq[[1]] and ..., on the second node
with seq[[2]] and ..., and so on, recycling nodes as needed.
clusterApplyLB is a load balancing version of clusterApply. If the length p of seq is not greater
than the number of nodes n, then a job is sent to p nodes. Otherwise the first n jobs are placed
in order on the n nodes. When the first job completes, the next job is placed on the node that has
become free; this continues until all jobs are complete. Using clusterApplyLB can result in better
cluster utilization than using clusterApply, but increased communication can reduce performance.
Furthermore, the node that executes a particular job is non-deterministic.
clusterMap is a multi-argument version of clusterApply, analogous to mapply and Map. If
RECYCLE is true shorter arguments are recycled (and either none or all must be of length zero);
otherwise, the result length is the length of the shortest argument. Nodes are recycled if the length
of the result is greater than the number of nodes. (mapply always uses RECYCLE = TRUE, and has
argument SIMPLIFY = TRUE. Map always uses RECYCLE = TRUE.)
clusterExport assigns the values on the master R process of the variables named in varlist
to variables of the same names in the global environment (aka ‘workspace’) of each node. The
environment on the master from which variables are exported defaults to the global environment.
clusterSplit splits seq into a consecutive piece for each cluster and returns the result as a list
with length equal to the number of nodes. Currently the pieces are chosen to be close to equal in
length: the computation is done on the master.
parLapply, parSapply, and parApply are parallel versions of lapply, sapply and apply.
parLapplyLB, parSapplyLB are load-balancing versions, intended for use when applying FUN to
different elements of X takes quite variable amounts of time, and either the function is deterministic
or reproducible results are not required.
parRapply and parCapply are parallel row and column apply functions for a matrix x; they may
be slightly more efficient than parApply but do less post-processing of the result.

Value

For clusterCall, clusterEvalQ and clusterSplit, a list with one element per node.
For clusterApply and clusterApplyLB, a list the same length as seq.
clusterMap follows mapply.
clusterExport returns nothing.
parLapply returns a list the length of X.
parSapply and parApply follow sapply and apply respectively.
parRapply and parCapply always return a vector. If FUN always returns a scalar result this will
be of length the number of rows or columns: otherwise it will be the concatenation of the returned
values.
An error is signalled on the master if any of the workers produces an error.
Note

These functions are almost identical to those in package snow.
Two exceptions: parLapply has argument X not x for consistency with lapply, and parSapply has been updated to match sapply.

Author(s)

Luke Tierney and R Core.
Derived from the snow package.

Examples

```r
## Use option cl.cores to choose an appropriate cluster size.
cl <- makeCluster(getOption("cl.cores", 2))

cclusterApply(cl, 1:2, get("+"), 3)
xx <- 1
cclusterExport(cl, "xx")
cclusterCall(cl, function(y) xx + y, 2)

## Use clusterMap like an mapply example
clusterMap(cl, function(x, y) seq_len(x) + y,
           c(a = 1, b = 2, c = 3), c(A = 10, B = 0, C = -10))

parsapply(cl, 1:20, get("+"), 3)

## A bootstrapping example, which can be done in many ways:
clusterEvalQ(cl, {
    ## set up each worker. Could also use clusterExport()
    library(boot)
    cd4.rg <- function(data, mle) MASS::mvrnorm(nrow(data), mle$m, mle$v)
    cd4.mle <- list(m = colMeans(cd4), v = var(cd4))
    NULL
  })
res <- clusterEvalQ(cl, boot(cd4, corr, R = 100,
                           sim = "parametric", ran.gen = cd4.rg, mle = cd4.mle))
library(boot)
cd4.boot <- do.call(c, res)
boot.ci(cd4.boot, type = c("norm", "basic", "perc"),
       conf = 0.9, h = atanh, hinv = tanh)
stopCluster(cl)

## or
library(boot)
run1 <- function(...) {
    library(boot)
    cd4.rg <- function(data, mle) MASS::mvrnorm(nrow(data), mle$m, mle$v)
    cd4.mle <- list(m = colMeans(cd4), v = var(cd4))
    boot(cd4, corr, R = 500, sim = "parametric",
         ran.gen = cd4.rg, mle = cd4.mle)
}
cl <- makeCluster(mc <- getOption("cl.cores", 2))
## to make this reproducible
clusterSetRNGStream(cl, 123)
```
detectCores <- do.call(c, parLapply(cl, seq_len(mc), runl))
boot.ci(cd4.boot, type = c("norm", "basic", "perc"),
       conf = 0.9, h = atanh, hinv = tanh)
stopCluster(cl)

detectCores

Detect the Number of CPU Cores

Description

Attempt to detect the number of CPU cores on the current host.

Usage

detectCores(all.tests = FALSE, logical = FALSE)

Arguments

all.tests Logical: if true apply all known tests.
logical Logical: if possible, use the number of physical CPUs/cores (if FALSE) or logical CPUs (if TRUE).

Details

This attempts to detect the number of CPU cores in the current machine.
It has methods to do so for Linux, OS X, FreeBSD, Solaris, Irix and Windows. detectCores(TRUE) could be tried on other Unix-alike systems.

Value

An integer, NA if the answer is unknown.
Exactly what this represents is OS-dependent: where possible by default it represents physical cores and not logical (e.g. hyperthreaded) CPUs.
On Windows the default is the number of logical CPUs.
Currently logical makes a difference on Sparc Solaris: there logical = FALSE returns the number of physical cores and logical = TRUE returns the number of available hardware threads. (Some Sparc CPUs which do have multiple cores per CPU, others have multiple threads per core and some have both.) For example, the UltraSparc T2 CPU in the CRAN check server is a single physical CPU with 8 cores, and each core supports 8 hardware threads. So detectCores(logical = FALSE) returns 8, and detectCores(logical = TRUE) returns 64.
Where virtual machines are in use, one would hope that the result represents the number of CPUs available (or potentially available) to that particular VM.

Examples

detectCores()
detectCores(logical = TRUE)
makeCluster

Create a Parallel Socket Cluster

Description

Creates a set of copies of R running in parallel and communicating over sockets.

Usage

makeCluster(spec, type, ...)  
makePSOCKcluster(names, ...)  
makeForkCluster(nnodes = getOption("mc.cores", 2L), ...)  
stopCluster(cl = NULL)  
setDefaultCluster(cl = NULL)

Arguments

spec  A specification appropriate to the type of cluster.  
names  Either a character vector of host names on which to run the worker copies of R,  
or a positive integer (in which case that number of copies is run on 'localhost').  
nnodes  The number of nodes to be forked.  
type  One of the supported types: see ‘Details’.  
...  Options to be passed to the function spawning the workers. See ‘Details’.  
cl  an object of class "cluster".

Details

makeCluster creates a cluster of one of the supported types. The default type, "PSOCK", calls  
makePSOCKcluster. Type "FORK" calls makeForkCluster. Other types are passed to package  
snow.

makePSOCKcluster is very similar to makeSOCKcluster in package snow. It runs Rscript on the  
specified host(s) to set up a worker process which listens on a socket for expressions to evaluate,  
and returns the results (as serialized objects).

makeForkCluster is merely a stub on Windows. On Unix-alike platforms it creates the worker  
process by forking.

The workers are most often running on the same host as the master, when no options need be set.  
Several options are supported (mainly for makePSOCKcluster):

master  The host name of the master, as known to the workers. This may not be the same as it is  
known to the master, and on private subnets it may be necessary to specify this as a numeric  
IP address. For example, OS X is likely to detect a machine as 'somename.local', a name  
known only to itself.

port  The port number for the socket connection, default taken from the environment variable  
R_PARALLEL_PORT, then a randomly chosen port in the range 11000:11999.

timeout  The timeout in seconds for that port. Default 30 days (and the POSIX standard only  
requires values up to 31 days to be supported).
outfile Where to direct the stdout and stderr connection output from the workers. "" indicates no redirection (which may only be useful for workers on the local machines). Defaults to '/dev/null' ('null;' on Windows). The other possibility is a file path on the worker's host. Files will be opened in append mode, as all workers log to the same file.

homogeneous Logical. Are all the hosts running identical setups, so Rscript can be launched using its full path on the master? Otherwise it has to be in the default path on the other hosts.

rscript The path to Rscript on the workers. Defaults to the full path on the master.

renice A numerical 'niceness' to set for the worker processes, e.g. 15 for a low priority. OS-dependent: see psonice for details.

rshcmd The command to be run on the master to launch a process on another host. Defaults to ssh.

user The user name to be used when communicating with another host.

manual Logical. If true the workers will need to be run manually.

methods Logical. If true (default) the workers will load the methods package: not loading it saves ca 30% of the startup time of the cluster.

useXDR Logical. If true (default) serialization will use XDR: where large amounts of data are to be transferred and all the nodes are little-endian, communication may be substantially fast if this is set to false.

Function makeForkCluster creates a socket cluster by forking (and hence is not available on Windows). It supports options port, timeout and outfile, and always uses useXDR = FALSE.

It is good practice to shut down the workers by calling stopCluster: however the workers will terminate themselves once the socket on which they are listening for commands becomes unavailable, which it should if the master R session is completed (or its process dies).

Function setDefaultCluster registers a cluster as the default one for the current session. Using setDefaultCluster(NULL) removes the registered cluster, as does stopping that cluster.

Value

An object of class c("SOCKcluster", "cluster").

Luke Tierney and R Core.

Derived from the snow package.

mcaffinity Get or Set CPU Affinity Mask of the Current Process

Description

mcaffinity retrieves or sets the CPU affinity mask of the current process, i.e., the set of CPUs the process is allowed to be run on. (CPU here means logical CPU which can be CPU, core or hyperthread unit.)

Usage

mcaffinity(affinity = NULL)
Arguments

affinity specification of the CPUs to lock this process to (numeric vector) or NULL if no change is requested

Details

mcaffinity can be used to obtain (affinity = NULL) or set the CPU affinity mask of the current process. The affinity mask is a list of integer CPU identifiers (starting from 1) that this process is allowed to run on. Not all systems provide user access to the process CPU affinity, in cases where no support is present at all mcaffinity() will return NULL. Some systems may take into account only the number of CPUs present in the mask.

Typically, it is legal to specify larger set than the number of logical CPUs (but at most as many as the OS can handle) and the system will return back the actually present set.

Value

NULL if CPU affinity is not supported by the system or an integer vector with the set of CPUs in the active affinity mask for this process (this may be different than affinity).

mcparallel

mcchildren

Description

These are low-level support functions for the forking approach.

They are not available on Windows, and not exported from the namespace.

Usage

children(select)
readChild(child)
readChildren(timeout = 0)
selectChildren(children = NULL, timeout = 0)
sendChildStdin(child, what)
sendMaster(what)
mckill(process, signal = 2L)
mcchildren

Arguments

select if omitted, all active children are returned, otherwise select should be a list of processes and only those from the list that are active will be returned.

child child process (object of the class "childProcess") or a process ID (pid). See also ‘Details’.

timeout timeout (in seconds, fractions supported) to wait for a response before giving up.

children list of child processes or a single child process object or a vector of process IDs or NULL. If NULL behaves as if all currently known children were supplied.

what For sendChildStdin: Character or raw vector. In the former case elements are collapsed using the newline character. (But no trailing newline is added at the end!) For sendMaster: Data to send to the master process. If what is not a raw vector, it will be serialized into a raw vector. Do NOT send an empty raw vector – that is reserved for internal use.

process process (object of the class process) or a process ID (pid)

signal integer: signal to send. Values of 2 (SIGINT), 9 (SIGKILL) and 15 (SIGTERM) are pretty much portable, but for maximal portability use tools::SIGTERM and so on.

Details

children returns currently active children.
readChild reads data from a given child process.
selectChildren checks children for available data.
readChildren checks all children for available data and reads from the first child that has available data.

sendChildStdin sends a string (or data) to one or more child’s standard input. Note that if the master session was interactive, it will also be echoed on the standard output of the master process (unless disabled). The function is vector-compatible, so you can specify child as a list or a vector of process IDs.

sendMaster sends data from the child to the master process.
mckill sends a signal to a child process: it is equivalent to pskill in package tools.

Value

children returns a (possibly empty) list of objects of class "process", the process ID.
readChild and readChildren return a raw vector with a "pid" attribute if data were available, an integer vector of length one with the process ID if a child terminated or NULL if the child no longer exists (no children at all for readChildren).

selectChildren returns TRUE is the timeout was reached, FALSE if an error occurred (e.g. if the master process was interrupted) or an integer vector of process IDs with children that have data available, or NULL if there are no children.

sendChildStdin returns a vector of TRUE values (one for each member of child) or throws an error.

sendMaster returns TRUE or throws an error.
mckill returns TRUE.

**mcfork**

Fork a Copy of the Current R Process

**Description**

These are low-level functions, not available on Windows, and not exported from the namespace.

`mcfork` creates a new child process as a copy of the current R process.

`mcexit` closes the current child process, informing the master process as necessary.

**Usage**

```r
mcfork()
mcfork()
mcfork()
```

**Arguments**

- `exit.code` process exit code. By convention 0L signifies a clean exit, 1L an error.
- `send` if not NULL send this data before exiting (equivalent to using `sendMaster`).

**Details**

The `mcfork` function provides an interface to the `fork` system call. In addition it sets up a pipe between the master and child process that can be used to send data from the child process to the master (see `sendMaster`) and child’s `stdin` is re-mapped to another pipe held by the master process (see `sendChildStdin`).

If you are not familiar with the `fork` system call, do not use this function directly as it leads to very complex inter-process interactions amongst the R processes involved.
In a nutshell fork spawns a copy (child) of the current process, that can work in parallel to the master (parent) process. At the point of forking both processes share exactly the same state including the workspace, global options, loaded packages etc. Forking is relatively cheap in modern operating systems and no real copy of the used memory is created, instead both processes share the same memory and only modified parts are copied. This makes mcfork an ideal tool for parallel processing since there is no need to setup the parallel working environment, data and code is shared automatically from the start.

mcexit is to be run in the child process. It sends send to the master (unless NULL) and then shuts down the child process. The child can also be shut down by sending it the signal SIGUSR1, as is done by the unexported function parallel::rmChild.

Value

mcfork returns an object of the class "childProcess" to the master and of class "masterProcess" to the child: both the classes inherit from class "process". These are lists with components pid (the process id of the other process) and a vector fd of the two file descriptor numbers for ends in the current process of the inter-process pipes.

mcexit never returns.

GUI/embedded environments

It is strongly discouraged to use mcfork and the higher-level functions which rely on it (e.g., mcparallel, mclapply and pvec) in GUI or embedded environments, because it leads to several processes sharing the same GUI which will likely cause chaos (and possibly crashes). Child processes should never use on-screen graphics devices. Some precautions have been taken to make this usable in R.app on OS X, but users of third-party front-ends should consult their documentation.

This can also apply to other connections, e.g. to an X server, created before forking.

Note that tcltk counts as a GUI for these purposes since Tcl runs an event loop. That event loop is inhibited in a child process but there could still be problems with Tk graphical connections.

Warning

This is a very low-level API for expert use only.

mclapply

Parallel Versions of lapply and mapply using Forking

Description

mclapply is a parallelized version of lapply, it returns a list of the same length as X, each element of which is the result of applying FUN to the corresponding element of X.

It relies on forking and hence is not available on Windows unless mc.cores = 1.

mcmapply is a parallelized version of mapply, and mcMap corresponds to Map.

Usage

mclapply(X, FUN, ..., 
  mc.preschedule = TRUE, mc.set.seed = TRUE, 
  mc.silent = FALSE, mc.cores = getOption("mc.cores", 2L), 
  mc.cleanup = TRUE, mc.allow.recursive = TRUE)

mcmapply(FUN, ..., 
  MoreArgs = NULL, SIMPLIFY = TRUE, USE.NAMES = TRUE, 
  mc.preschedule = TRUE, mc.set.seed = TRUE, 
  mc.silent = FALSE, mc.cores = getOption("mc.cores", 2L), 
  mc.cleanup = TRUE)

mcMap(f, ...)

Arguments

X a vector (atomic or list) or an expressions vector. Other objects (including classed objects) will be coerced by as.list.

FUN the function to be applied to (mclapply) each element of X or (mcmapply) in parallel to ....

f the function to be applied in parallel to ....

... For mclapply, optional arguments to FUN. For mcmapply and mcMap, vector or list inputs: see mapply.

MoreArgs, SIMPLIFY, USE.NAMES see mapply.

mc.preschedule if set to TRUE then the computation is first divided to (at most) as many jobs are there are cores and then the jobs are started, each job possibly covering more than one value. If set to FALSE then one job is forked for each value of X. The former is better for short computations or large number of values in X, the latter is better for jobs that have high variance of completion time and not too many values of X compared to mc.cores.

mc.set.seed See mCparallel.

mc.silent if set to TRUE then all output on ‘stdout’ will be suppressed for all parallel processes forked (‘stderr’ is not affected).

mc.cores The number of cores to use, i.e. at most how many child processes will be run simultaneously. The option is initialized from environment variable MC_CORES if set. Must be at least one, and parallelization requires at least two cores.
mc.clnlup

if set to TRUE then all children that have been forked by this function will be killed (by sending SIGTERM) before this function returns. Under normal circumstances mclapply waits for the children to deliver results, so this option usually has only effect when mclapply is interrupted. If set to FALSE then child processes are collected, but not forcefully terminated. As a special case this argument can be set to the number of the signal that should be used to kill the children instead of SIGTERM.

mc.allow.recursive

Unless true, calling mclapply in a child process will use the child and not fork again.

Details

mclapply is a parallelized version of lapply, provided mc.cores > 1: for mc.cores == 1 it simply calls lapply.

By default (mc.preschedule = TRUE) the input x is split into as many parts as there are cores (currently the values are spread across the cores sequentially, i.e. first value to core 1, second to core 2, ... (core + 1)-th value to core 1 etc.) and then one process is forked to each core and the results are collected.

Without prescheduling, a separate job is forked for each value of x. To ensure that no more than mc.cores jobs are running at once, once that number has been forked the master process waits for a child to complete before the next fork.

Due to the parallel nature of the execution random numbers are not sequential (in the random number sequence) as they would be when using lapply. They are sequential for each forked process, but not all jobs as a whole. See mcparallel or the package’s vignette for ways to make the results reproducible with mc.preschedule = TRUE.

Note: the number of file descriptors (and processes) is usually limited by the operating system, so you may have trouble using more than 100 cores or so (see ulimit -n or similar in your OS documentation) unless you raise the limit of permissible open file descriptors (fork will fail with error "unable to create a pipe").

Value

For mclapply, a list of the same length as x and named by x.

For mcmapply, a list, vector or array: see mapply.

For mclMap, a list.

Each forked process runs its job inside try(..., silent = TRUE) so if errors occur they will be stored as class "try-error" objects in the return value and a warning will be given. Note that the job will typically involve more than one value of x and hence a "try-error" object will be returned for all the values involved in the failure, even if not all of them failed.

Warning

It is strongly discouraged to use these functions in GUI or embedded environments, because it leads to several processes sharing the same GUI which will likely cause chaos (and possibly crashes). Child processes should never use on-screen graphics devices.

Some precautions have been taken to make this usable in R.app on OS X, but users of third-party front-ends should consult their documentation.

Note that tcltk counts as a GUI for these purposes since Tcl runs an event loop. That event loop is inhibited in a child process but there could still be problems with Tk graphical connections.
mcparallel

Evaluate an R Expression Asynchronously in a Separate Process

Description

These functions are based on forking and so are not available on Windows.

mcparallel starts a parallel R process which evaluates the given expression.

mccollect collects results from one or more parallel processes.

Usage

mcparallel(expr, name, mc.set.seed = TRUE, silent = FALSE, mc.affinity = NULL, mc.interactive = FALSE)

mccollect(jobs, wait = TRUE, timeout = 0, intermediate = FALSE)
mcparallel

Arguments

expr  expression to evaluate (do not use any on-screen devices or GUI elements in this code).
name  an optional name (character vector of length one) that can be associated with the job.
mc.set.seed  logical: see section ‘Random numbers’.
silent  if set to TRUE then all output on stdout will be suppressed (stderr is not affected).
mc.affinity  either a numeric vector specifying CPUs to restrict the child process to (1-based) or NULL to not modify the CPU affinity
mc.interactive  logical, if TRUE or FALSE then the child process will be set as interactive or non-interactive respectively. If NA then the child process will inherit the interactive flag from the parent.
jobs  list of jobs (or a single job) to collect results for. Alternatively jobs can also be an integer vector of process IDs. If omitted collect will wait for all currently existing children.
wait  if set to FALSE it checks for any results that are available within timeout seconds from now, otherwise it waits for all specified jobs to finish.
timeout  timeout (in seconds) to check for job results – applies only if wait is FALSE.
intermediate  FALSE or a function which will be called while collect waits for results. The function will be called with one parameter which is the list of results received so far.

Details

mcparallel evaluates the expr expression in parallel to the current R process. Everything is shared read-only (or in fact copy-on-write) between the parallel process and the current process, i.e. no side-effects of the expression affect the main process. The result of the parallel execution can be collected using mccollect function.

mccollect function collects any available results from parallel jobs (or in fact any child process). If wait is TRUE then collect waits for all specified jobs to finish before returning a list containing the last reported result for each job. If wait is FALSE then mccollect merely checks for any results available at the moment and will not wait for jobs to finish. If jobs is specified, jobs not listed there will not be affected or acted upon.

Note: If expr uses low-level multicore functions such as sendMaster a single job can deliver results multiple times and it is the responsibility of the user to interpret them correctly. mccollect will return NULL for a terminating job that has sent its results already after which the job is no longer available.

The mc.affinity parameter can be used to try to restrict the child process to specific CPUs. The availability and the extent of this feature is system-dependent (e.g., some systems will only consider the CPU count, others will ignore it completely).

Value

mcparallel returns an object of the class "parallelJob" which inherits from "childProcess" (see the ‘Value’ section of the help for mcfork). If argument name was supplied this will have an additional component name.

mccollect returns any results that are available in a list. The results will have the same order as the specified jobs. If there are multiple jobs and a job has a name it will be used to name the result, otherwise its process ID will be used. If none of the specified children are still running, it returns NULL.
Random numbers

If `mc.set.seed = FALSE`, the child process has the same initial random number generator (RNG) state as the current R session. If the RNG has been used (or `.Random.seed` was restored from a saved workspace), the child will start drawing random numbers at the same point as the current session. If the RNG has not yet been used, the child will set a seed based on the time and process ID when it first uses the RNG: this is pretty much guaranteed to give a different random-number stream from the current session and any other child process.

The behaviour with `mc.set.seed = TRUE` is different only if `RNGkind("L'Ecuyer-CMRG")` has been selected. Then each time a child is forked it is given the next stream (see `nextRNGStream`). So if you select that generator, set a seed and call `mc.reset.stream` just before the first use of `mcparallel` the results of simulations will be reproducible provided the same tasks are given to the first, second, ... forked process.

Note

Package `multicore` also exported functions `collect` and `parallel`. These names are easily masked (for example package `lattice` also has a function `parallel`) and they are not supplied in this package.

Author(s)

Simon Urbanek and R Core.

Derived from the `multicore` package (but with different handling of the RNG stream).

See Also

`pvec`, `mclapply`

Examples

```r
p <- mcparallel(1:10)
q <- mcparallel(1:20)
# wait for both jobs to finish and collect all results
res <- mccollect(list(p, q))

p <- mcparallel(1:10)
mccollect(p, wait = FALSE, 10) # will retrieve the result (since it's fast)
mccollect(p, wait = FALSE)    # will signal the job as terminating
mccollect(p, wait = FALSE)    # there is no longer such a job

# a naive parallel lapply can be created using mcparallel alone:
jobs <- lapply(1:10, function(x) mcparallel(rnorm(x), name = x))
mccollect(jobs)
```
**Description**

pvec parallelizes the execution of a function on vector elements by splitting the vector and submitting each part to one core. The function must be a vectorized map, i.e. it takes a vector input and creates a vector output of exactly the same length as the input which doesn’t depend on the partition of the vector.

It relies on forking and hence is not available on Windows unless mc.cores = 1.

**Usage**

```r
pvec(v, FUN, ..., mc.set.seed = TRUE, mc.silent = FALSE,
     mc.cores = getOption("mc.cores", 2L), mc.cleanup = TRUE)
```

**Arguments**

- `v` vector to operate on
- `FUN` function to call on each part of the vector
- `...` any further arguments passed to `FUN` after the vector
- `mc.set.seed` See `mparallel`.
- `mc.silent` if set to TRUE then all output on ‘stdout’ will be suppressed for all parallel processes forked (‘stderr’ is not affected).
- `mc.cores` The number of cores to use, i.e. at most how many child processes will be run simultaneously. Must be at least one, and at least two for parallel operation. The option is initialized from environment variable `MC_CORES` if set.
- `mc.cleanup` See the description of this argument in `mclapply`.

**Details**

pvec parallelizes `FUN(x, ...)` where `FUN` is a function that returns a vector of the same length as `x`. `FUN` must also be pure (i.e., without side-effects) since side-effects are not collected from the parallel processes. The vector is split into nearly identically sized subvectors on which `FUN` is run. Although it is in principle possible to use functions that are not necessarily maps, the interpretation would be case-specific as the splitting is in theory arbitrary (a warning is given in such cases).

The major difference between pvec and `mclapply` is that `mclapply` will run `FUN` on each element separately whereas pvec assumes that `c(FUN(x[1]), FUN(x[2]))` is equivalent to `FUN(x[1:2])` and thus will split into as many calls to `FUN` as there are cores (or elements, if fewer), each handling a subset vector. This makes it more efficient than `mclapply` but requires the above assumption on `FUN`.

If `mc.cores == 1` this evaluates `FUN(v, ...)` in the current process.

**Value**

The result of the computation – in a successful case it should be of the same length as `v`. If an error occurred or the function was not a map the result may be shorter or longer, and a warning is given.

**Note**

Due to the nature of the parallelization, error handling does not follow the usual rules since errors will be returned as strings and results from killed child processes will show up simply as nonexistent data. Therefore it is the responsibility of the user to check the length of the result to make
sure it is of the correct size. pvec raises a warning if that is the case since it does not know whether such an outcome is intentional or not.

See mcfork for the inadvisability of using this with GUI front-ends.

Examples

x <- pvec(1:1000, sqrt)
stopifnot(all(x == sqrt(1:1000)))

# One use is to convert date strings to unix time in large datasets
# as that is a relatively slow operation.
# So let's get some random dates first
# (A small test only with 2 cores: set options("mc.cores")
# and increase N for a larger-scale test.)
N <- 1e4
dates <- sprintf('%d-%02d-%02d', as.integer(2000+rnorm(N)),
                     as.integer(runif(N, 1, 12)), as.integer(runif(N, 1, 28)))

system.time(a <- as.POSIXct(dates))
# This ought to be faster, but system overhead can be high
# - and is on OS X Lion
system.time(b <- pvec(dates, as.POSIXct))
stopifnot(all(a == b))

# using mclapply for this would much slower because each value
# will require a separate call to as.POSIXct()
# as lapply(dates, as.POSIXct) does
system.time(c <- unlist(mclapply(dates, as.POSIXct))

RNGstreams

Implementation of Pierre L’Ecuyer’s RngStreams

Description

This is an R re-implementation of Pierre L’Ecuyer’s ‘RngStreams’ multiple streams of pseudo-random numbers.

Usage

nextRNGStream(seed)
nextRNGSubStream(seed)

clusterSetRNGStream(cl = NULL, iseed)
mc.reset.stream()
Arguments

- **seed**: An integer vector of length 7 as given by `.Random.seed` when the "L'Ecuyer-CMRG" RNG is in use. See `RNG` for the valid values.
- **cl**: A cluster from this package or package `snow`, or (if `NULL`) the registered cluster.
- **isSeed**: An integer to be supplied to `set.seed`, or `NULL` not to set reproducible seeds.

Details

The ‘RngStream’ interface works with (potentially) multiple streams of pseudo-random numbers: this is particularly suitable for working with parallel computations since each task can be assigned a separate RNG stream.

This uses as its underlying generator `RNGkind("L'Ecuyer-CMRG")`, of L’Ecuyer (1999), which has a seed vector of 6 (signed) integers and a period of around $2^{193}$. Each ‘stream’ is a subsequence of the period of length $2^{127}$ which is in turn divided into ‘substreams’ of length $2^{76}$.

The idea of L’Ecuyer *et al* (2002) is to use a separate stream for each of the parallel computations (which ensures that the random numbers generated never get into to sync) and the parallel computations can themselves use substreams if required. The original interface stores the original seed of the first stream, the original seed of the current stream and the current seed: this could be implemented in R, but it is as easy to work by saving the relevant values of `.Random.seed`: see the examples.

`clusterSetRNGStream` selects the "L'Ecuyer-CMRG" RNG and then distributes streams to the members of a cluster, optionally setting the seed of the streams by `set.seed(isSeed)` (otherwise they are set from the current seed of the master process: after selecting the L’Ecuyer generator).

Calling `mc.reset.stream()` after setting the L’Ecuyer random number generator and seed makes runs from `mcparallel(mc.set.seed = TRUE)` reproducible. This is done internally in `mclapply` and `pvec`. (Note that it does not set the seed in the master process, so does not affect the fallback-to-serial versions of these functions.)

Value

For `nextRNGStream` and `nextRNGSubStream`, a value which can be assigned to `.Random.seed`.

Note

Interfaces to L’Ecuyer’s C code are available in CRAN packages `rlecuyer` and `rstream`.

Author(s)

Brian Ripley

References

- `RNG` for fuller details of R’s built-in random number generators.

The vignette for package `parallel`.
Examples

```r
RNGkind("L\'Ecuyer-CMRG")
set.seed(123)
(s <- .Random.seed)
## do some work involving random numbers.
nextRNGStream(s)
nextRNGSubStream(s)
```

Description

This divides up `1: nx` into `ncl` lists of approximately equal size, as a way to allocate tasks to nodes in a cluster.

It is mainly for internal use, but some package authors have found it useful.

Usage

```r
splitIndices(nx, ncl)
```

Arguments

- `nx`: Number of tasks.
- `ncl`: Number of cluster nodes.

Value

A list of length `ncl`, each element being an integer vector.

Examples

```r
splitIndices(20, 3)
```
Chapter 9

The splines package

splines-package Regression Spline Functions and Classes

Description
Regression spline functions and classes.

Details
This package provides functions for working with regression splines using the B-spline basis, bs, and the natural cubic spline basis, ns.
For a complete list of functions, use library(help = "splines").

asVector Coerce an Object to a Vector

Description
This is a generic function. Methods for this function coerce objects of given classes to vectors.

Usage
asVector(object)

Arguments
object An object.
Methods for vector coercion in new classes must be created for the \texttt{asVector} generic instead of \texttt{as.vector}. The \texttt{as.vector} function is internal and not easily extended. Currently the only class with an \texttt{asVector} method is the \texttt{xyVector} class.

\textbf{Value}

a vector

\textbf{Author(s)}

Douglas Bates and Bill Venables

\textbf{See Also}

\texttt{xVector}

\textbf{Examples}

```r
require(stats)
isp1 <- interpSpline( weight ~ height, women )
pred <- predict(isp1)
class(pred)
utils::str(pred)
asVector(pred)
```

\section*{Description}

Create a monotone inverse of a monotone natural spline.

\section*{Usage}

\texttt{backSpline(object)}

\section*{Arguments}

\begin{itemize}
  \item \texttt{object} an object that inherits from class \texttt{nbSpline} or \texttt{npolySpline}. That is, the object must represent a natural interpolation spline but it can be either in the B-spline representation or the piecewise polynomial one. The spline is checked to see if it represents a monotone function.
\end{itemize}

\section*{Value}

An object of class \texttt{polySpline} that contains the piecewise polynomial representation of a function that has the appropriate values and derivatives at the knot positions to be an inverse of the spline represented by \texttt{object}. Technically this object is not a spline because the second derivative is not constrained to be continuous at the knot positions. However, it is often a much better approximation to the inverse than fitting an interpolation spline to the y/x pairs.

Examples

require(graphics)
isp1 <- interpSpline( women$height, women$weight )
bspl <- backSpline( ispl )
plot( bspl )  # plots over the range of the knots
points( women$weight, women$height )

---

bs  

B-Spline Basis for Polynomial Splines

Description

Generate the B-spline basis matrix for a polynomial spline.

Usage

bs(x, df = NULL, knots = NULL, degree = 3, intercept = FALSE, 
    Boundary.knots = range(x))

Arguments

- x  
  the predictor variable. Missing values are allowed.

- df  
  degrees of freedom; one can specify df rather than knots: bs() then chooses
df−degree (minus one if there is an intercept) knots at suitable quantiles of x
(which will ignore missing values). The default, NULL, corresponds to no
inner knots, i.e., degree − intercept.

- knots  
  the internal breakpoints that define the spline. The default is NULL, which results
in a basis for ordinary polynomial regression. Typical values are the mean or
median for one knot, quantiles for more knots. See also Boundary.knots.

- degree  
  degree of the piecewise polynomial—default is 3 for cubic splines.

- intercept  
  if TRUE, an intercept is included in the basis; default is FALSE.

- Boundary.knots  
  boundary points at which to anchor the B-spline basis (default the range of the
data). If both knots and Boundary.knots are supplied, the basis parameters do
not depend on x. Data can extend beyond Boundary.knots.

Details

bs is based on the function spline.des. It generates a basis matrix for representing the family
of piecewise polynomials with the specified interior knots and degree, evaluated at the values of x. A
primary use is in modeling formulas to directly specify a piecewise polynomial term in a model.
Value

A matrix of dimension c(length(x), df), where either df was supplied or if knots were supplied, df = length(knots) + degree plus one if there is an intercept. Attributes are returned that correspond to the arguments to bs, and explicitly give the knots, Boundary.knots etc for use by predict.bs().

References

See Also
	ns, poly.smooth.spline, predict.bs, SafePrediction

Examples

```r
require(stats); require(graphics)
bs(women$height, df = 5)
summary(fm1 <- lm(weight ~ bs(height, df = 5), data = women))

## example of safe prediction
plot(women, xlab = "Height (in)", ylab = "Weight (lb)")
ht <- seq(57, 73, length.out = 200)
lines(ht, predict(fm1, data.frame(height = ht)))
```

interpSpline

Create an Interpolation Spline

Description

Create an interpolation spline, either from x and y vectors, or from a formula/data.frame combination.

Usage

```r
interpSpline(obj1, obj2, bSpline = FALSE, period = NULL,
na.action = na.fail)
```

Arguments

- `obj1`: Either a numeric vector of x values or a formula.
- `obj2`: If obj1 is numeric this should be a numeric vector of the same length. If obj1 is a formula this can be an optional data frame in which to evaluate the names in the formula.
- `bSpline`: If TRUE the b-spline representation is returned, otherwise the piecewise polynomial representation is returned. Defaults to FALSE.
- `period`: An optional positive numeric value giving a period for a periodic interpolation spline.
- `na.action`: a optional function which indicates what should happen when the data contain NAs. The default action (na.omit) is to omit any incomplete observations. The alternative action na.fail causes interpSpline to print an error message and terminate if there are any incomplete observations.
An object that inherits from class `spline`. The object can be in the B-spline representation, in which case it will be of class `nbSpline` for natural B-spline, or in the piecewise polynomial representation, in which case it will be of class `npolySpline`.

**Author(s)**

Douglas Bates and Bill Venables

**See Also**

`splineKnots`, `splineOrder`, `periodicSpline`.

**Examples**

```r
require(graphics); require(stats)
ispl1 <- interpSpline( women$height, women$weight )
ispl2 <- interpSpline( weight ~ height, women )
# ispl and ispl2 should be the same
plot( predict( ispl1, seq( 55, 75, length.out = 51 ) ), type = "l" )
points( women$height, women$weight )
plot( ispl1 ) # plots over the range of the knots
points( women$height, women$weight )
splineKnots( ispl )
```

**Description**

Generate the B-spline basis matrix for a natural cubic spline.

**Usage**

```r
ns(x, df = NULL, knots = NULL, intercept = FALSE,
   Boundary.knots = range(x))
```

**Arguments**

- **x**: the predictor variable. Missing values are allowed.
- **df**: degrees of freedom. One can supply `df` rather than `knots`; `ns()` then chooses `df - 1 - intercept` knots at suitably chosen quantiles of `x` (which will ignore missing values). The default, `df = 1`, corresponds to no knots.
- **knots**: breakpoints that define the spline. The default is no knots; together with the natural boundary conditions this results in a basis for linear regression on `x`. Typical values are the mean or median for one knot, quantiles for more knots. See also `Boundary.knots`.
- **intercept**: if TRUE, an intercept is included in the basis; default is FALSE.
- **Boundary.knots**: boundary points at which to impose the natural boundary conditions and anchor the B-spline basis (default the range of the data). If both `knots` and `Boundary.knots` are supplied, the basis parameters do not depend on `x`. Data can extend beyond `Boundary.knots`.
Details

`ns` is based on the function `spline.des`. It generates a basis matrix for representing the family of piecewise-cubic splines with the specified sequence of interior knots, and the natural boundary conditions. These enforce the constraint that the function is linear beyond the boundary knots, which can either be supplied or default to the extremes of the data.

A primary use is in modeling formula to directly specify a natural spline term in a model: see the examples.

Value

A matrix of dimension `length(x) * df` where either `df` was supplied or if `knots` were supplied, `df = length(knots) + 1 + intercept`. Attributes are returned that correspond to the arguments to `ns`, and explicitly give the `knots`, `Boundary.knots` etc for use by `predict.ns()`.

`bs`, `predict.ns`, `SafePrediction`

Examples

```r
require(stats); require(graphics)
ns(women$height, df = 5)
summary(fm1 <- lm(weight ~ ns(height, df = 5), data = women))

## To see what knots were selected
attr(terms(fm1), "predvars")

## example of safe prediction
plot(women, xlab = "Height (in)", ylab = "Weight (lb)")
ht <- seq(57, 73, length.out = 200)
lines(ht, predict(fm1, data.frame(height = ht)))
```

periodicSpline

Create a Periodic Interpolation Spline

Description

Create a periodic interpolation spline, either from `x` and `y` vectors, or from a formula/data.frame combination.

Usage

`periodicSpline(obj1, obj2, knots, period = 2*pi, ord = 4)`
Arguments

- **obj1**: either a numeric vector of x values or a formula.
- **obj2**: if obj1 is numeric this should be a numeric vector of the same length. If obj1 is a formula this can be an optional data frame in which to evaluate the names in the formula.
- **knots**: optional numeric vector of knot positions.
- **period**: positive numeric value giving the period for the periodic spline. Defaults to \( \pi \).
- **ord**: integer giving the order of the spline, at least 2. Defaults to 4. See `splineOrder` for a definition of the order of a spline.

Value

An object that inherits from class `spline`. The object can be in the B-spline representation, in which case it will be a `pbSpline` object, or in the piecewise polynomial representation (a `ppolySpline` object).

Author(s)

Douglas Bates and Bill Venables

See Also

`splineKnots`, `interpSpline`  

Examples

```r
require(graphics); require(stats)
xx <- seq(-pi, pi, length.out = 16)[-1]
yy <- sin(xx)
frm <- data.frame(xx, yy)
pisp1 <- periodicSpline(xx, yy, period = 2 * pi)
pisp1
pisp2 <- periodicSpline(yy ~ xx, frm, period = 2 * pi)
stopifnot(all.equal(pisp1, pisp2))  # pisp1 and pisp2 are the same

plot(pisp1)  # displays over one period
points(y ~ xx, col = "brown")
plot(predict(pisp1, seq(-3*pi, 3*pi, length.out = 101)), type = "l")
```

---

**Description**

Create the piecewise polynomial representation of a spline object.

**Usage**

```r
polySpline(object, ...)
as.polySpline(object, ...)
```
predict.bs

Evaluate a Spline Basis

Evaluate a predefined spline basis at given values.

## Usage

```r
## S3 method for class 'bs'
predict(object, newx, ...)

## S3 method for class 'ns'
predict(object, newx, ...)
```

### Arguments

- `object`: the result of a call to `bs` or `ns` having attributes describing knots, degree, etc.
- `newx`: the x values at which evaluations are required.
- `...`: Optional additional arguments. At present no additional arguments are used.

### Value

An object that inherits from class `polySpline`. This is the piecewise polynomial representation of a univariate spline function. It is defined by a set of distinct numeric values called knots. The spline function is a polynomial function between each successive pair of knots. At each interior knot the polynomial segments on each side are constrained to have the same value of the function and some of its derivatives.

### Examples

```r
require(graphics)
ispl <- polySpline(interpSpline( weight ~ height, women, bSpline = TRUE))
print( ispl )  # print the piecewise polynomial representation
plot( ispl )  # plots over the range of the knots
points( women$height, women$weight )
```
Value

An object just like object, except evaluated at the new values of x.

These are methods for the generic function predict for objects inheriting from classes "bs" or "ns". See predict for the general behavior of this function.

See Also

bs, ns, poly.

Examples

```r
require(stats)
basis <- ns(women$height, df = 5)
newx <- seq(58, 72, length.out = 51)
# evaluate the basis at the new data
predict(basis, newx)
```

predict.bSpline  Evaluate a Spline at New Values of x

Description

The predict methods for the classes that inherit from the virtual classes bSpline and polySpline are used to evaluate the spline or its derivatives. The plot method for a spline object first evaluates predict with the x argument missing, then plots the resulting xyVector with type = "l".

Usage

```r
## S3 method for class 'bSpline'
predict(object, x, nseg = 50, deriv = 0, ...) ## S3 method for class 'nbSpline'
predict(object, x, nseg = 50, deriv = 0, ...) ## S3 method for class 'pbSpline'
predict(object, x, nseg = 50, deriv = 0, ...) ## S3 method for class 'npolySpline'
predict(object, x, nseg = 50, deriv = 0, ...) ## S3 method for class 'ppolySpline'
predict(object, x, nseg = 50, deriv = 0, ...)
```

Arguments

- **object** An object that inherits from the bSpline or the polySpline class.
- **x** A numeric vector of x values at which to evaluate the spline. If this argument is missing a suitable set of x values is generated as a sequence of nseg segments spanning the range of the knots.
- **nseg** A positive integer giving the number of segments in a set of equally-spaced x values spanning the range of the knots in object. This value is only used if x is missing.
- **deriv** An integer between 0 and splineOrder(object) - 1 specifying the derivative to evaluate.
- **...** further arguments passed to or from other methods.
**splineDesign**

**Description**

Evaluate the design matrix for the B-splines defined by knots at the values in x.

**Usage**

splineDesign(knots, x, ord = 4, derivs, outer.ok = FALSE, sparse = FALSE)

spline.des (knots, x, ord = 4, derivs, outer.ok = FALSE, sparse = FALSE)
Arguments

- **knots**: a numeric vector of knot positions with non-decreasing values.
- **x**: a numeric vector of values at which to evaluate the B-spline functions or derivatives. Unless `outer.ok` is true, the values in `x` must be between `knots[ord]` and `knots[ length(knots) + 1 - ord ]`.
- **ord**: a positive integer giving the order of the spline function. This is the number of coefficients in each piecewise polynomial segment, thus a cubic spline has order 4. Defaults to 4.
- **derivs**: an integer vector of the same length as `x` and with values between 0 and `ord - 1`. The derivative of the given order is evaluated at the `x` positions. Defaults to a vector of zeroes of the same length as `x`.
- **outer.ok**: logical indicating if `x` should be allowed outside the `inner` knots, see the `x` argument.
- **sparse**: logical indicating if the result should inherit from class `sparseMatrix` (package `Matrix`).

Value

A matrix with `length(x)` rows and `length(knots) - ord` columns. The i'th row of the matrix contains the coefficients of the B-splines (or the indicated derivative of the B-splines) defined by the knot vector and evaluated at the i'th value of `x`. Each B-spline is defined by a set of `ord` successive knots so the total number of B-splines is `length(knots) - ord`.

Note

The older `spine.des` function takes the same arguments but returns a list with several components including `knots`, `ord`, `derivs`, and `design`. The `design` component is the same as the value of the `splineDesign` function.

Author(s)

Douglas Bates and Bill Venables

Examples

```r
require(graphics)
spineDesign(knots = 1:10, x = 4:7)
## visualize band structure
Matrix::drop0(zapsmall(6*spineDesign(knots = 1:40, x = 4:37, sparse = TRUE)))

knots <- c(1,1.8,3:5.6,5.7,8.1,9.2,10)  # 10 => 10-4 = 6 Basis splines
x <- seq(min(knots)-1, max(knots)+1, length.out = 50)
bb <- spineDesign(knots, x = x, outer.ok = TRUE)

plot(range(x), c(0,1), type = "n", xlab = "x", ylab = "",
     main = "B-splines - sum to 1 inside inner knots")
mtext(expression(B[j](x) *" and "* sum(B[j](x), j == 1, 6)), adj = 0)
abline(v = knots, lty = 3, col = "light gray")
abline(v = knots[2:length(knots)-3], lty = 3, col = "gray10")
lines(x, rowSums(bb), col = "gray", lwd = 2)
matlines(x, bb, ylim = c(0,1), lty = 1)
```
splineKnots  Knot Vector from a Spline

Description
Return the knot vector corresponding to a spline object.

Usage
splineKnots(object)

Arguments
object  an object that inherits from class "spline".

Value
A non-decreasing numeric vector of knot positions.

Author(s)
Douglas Bates and Bill Venables

Examples
ispl <- interpSpline( weight ~ height, women )
splineKnots( ispl )

splineOrder  Determine the Order of a Spline

Description
Return the order of a spline object.

Usage
splineOrder(object)

Arguments
object  An object that inherits from class "spline".

Details
The order of a spline is the number of coefficients in each piece of the piecewise polynomial representation. Thus a cubic spline has order 4.

Value
A positive integer.
Author(s)
Douglas Bates and Bill Venables

See Also
splineKnots, interpSpline, periodicSpline

Examples
splineOrder( interpSpline( weight ~ height, women ) )

Construct an xyVector Object

Description
Create an object to represent a set of x-y pairs. The resulting object can be treated as a matrix or as a data frame or as a vector. When treated as a vector it reduces to the y component only.

The result of functions such as predict.spline is returned as an xyVector object so the x-values used to generate the y-positions are retained, say for purposes of generating plots.

Usage
xyVector(x, y)

Arguments
x
a numeric vector
y
a numeric vector of the same length as x

Value
An object of class xyVector with components
x
a numeric vector
y
a numeric vector of the same length as x

Author(s)
Douglas Bates and Bill Venables

Examples
require(stats); require(graphics)
ispl <- interpSpline( weight ~ height, women )
weights <- predict( ispl, seq( 55, 75, length.out = 51 ) )
class( weights )
plot( weights, type = "l", xlab = "height", ylab = "weight" )
points( women$height, women$weight )
weights
Chapter 10

The stats package

\section{stats-package \textit{The R Stats Package}}

\subsection{Description}
R statistical functions

\subsection{Details}
This package contains functions for statistical calculations and random number generation. For a complete list of functions, use \texttt{library(help = \textasciitilde stats\textasciitilde)}.

\subsection{Author(s)}

Maintainer: R Core Team \texttt{\textless R-core@r-project.org\textgreater}

\section{checkMFClasses \textit{Functions to Check the Type of Variables passed to Model Frames}}

\subsection{Description}
\texttt{.checkMFClasses} checks if the variables used in a predict method agree in type with those used for fitting.
\texttt{.MFClass} categorizes variables for this purpose.

\subsection{Usage}
\texttt{.checkMFClasses(cl, m, ordNotOK = FALSE)}
\texttt{.MFClass(x)}
\texttt{.getXlevels(Terms, m)}
Arguments

c1       a character vector of class descriptions to match.
m       a model frame.
x       any R object.
ordNotOK logical: are ordered factors different?
Terms       a terms object.

Details

For applications involving model.matrix such as linear models we do not need to differentiate between ordered factors and factors as although these affect the coding, the coding used in the fit is already recorded and imposed during prediction. However, other applications may treat ordered factors differently: rpart does, for example.

Value

acf returns a character string, one of "logical", "ordered", "factor", "numeric", "nmatrix.*" (a numeric matrix with a number of columns appended) or "other".

getxlevels returns a named character vector, or NULL.

---

acf

Auto- and Cross- Covariance and -Correlation Function Estimation

Description

The function acf computes (and by default plots) estimates of the autocovariance or autocorrelation function. Function pacf is the function used for the partial autocorrelations. Function ccf computes the cross-correlation or cross-covariance of two univariate series.

Usage

acf(x, lag.max = NULL,
    type = c("correlation", "covariance", "partial"),
    plot = TRUE, na.action = na.fail, demean = TRUE, ...)

pacf(x, lag.max, plot, na.action, ...)

## Default S3 method:
pacf(x, lag.max = NULL, plot = TRUE, na.action = na.fail,
    ...)  

ccf(x, y, lag.max = NULL, type = c("correlation", "covariance"),
    plot = TRUE, na.action = na.fail, ...)

## S3 method for class 'acf'
x[i, j]
\textbf{acf}

\textbf{Arguments}

\texttt{x, y} \hspace{1em} \text{a univariate or multivariate (not \texttt{ccf}) numeric time series object or a numeric vector or matrix, or an "acf" object.}

\texttt{lag.max} \hspace{1em} \text{maximum lag at which to calculate the acf. Default is } 10 \log_{10}(N/m) \text{ where } N \text{ is the number of observations and } m \text{ the number of series. Will be automatically limited to one less than the number of observations in the series.}

\texttt{type} \hspace{1em} \text{character string giving the type of acf to be computed. Allowed values are "correlation" (the default), "covariance" or "partial".}

\texttt{plot} \hspace{1em} \text{logical. If TRUE (the default) the acf is plotted.}

\texttt{na.action} \hspace{1em} \text{function to be called to handle missing values. \texttt{na.pass} can be used.}

\texttt{demean} \hspace{1em} \text{logical. Should the covariances be about the sample means?}

\texttt{...} \hspace{1em} \text{further arguments to be passed to \texttt{plot.acf}.}

\texttt{i} \hspace{1em} \text{a set of lags (time differences) to retain.}

\texttt{j} \hspace{1em} \text{a set of series (names or numbers) to retain.}

\textbf{Details}

For \texttt{type} = "correlation" and "covariance", the estimates are based on the sample covariance. (The lag 0 autocorrelation is fixed at 1 by convention.)

By default, no missing values are allowed. If the \texttt{na.action} function passes through missing values (as \texttt{na.pass} does), the covariances are computed from the complete cases. This means that the estimate computed may well not be a valid autocorrelation sequence, and may contain missing values. Missing values are not allowed when computing the PACF of a multivariate time series.

The partial correlation coefficient is estimated by fitting autoregressive models of successively higher orders up to \texttt{lag.max}.

The generic function \texttt{plot} has a method for objects of class "acf".

The lag is returned and plotted in units of time, and not numbers of observations.

There are print and subsetting methods for objects of class "acf".

\textbf{Value}

An object of class "acf", which is a list with the following elements:

\texttt{lag} \hspace{1em} A three dimensional array containing the lags at which the acf is estimated.

\texttt{acf} \hspace{1em} An array with the same dimensions as \texttt{lag} containing the estimated acf.

\texttt{type} \hspace{1em} The type of correlation (same as the \texttt{type} argument).

\texttt{n.used} \hspace{1em} The number of observations in the time series.

\texttt{series} \hspace{1em} The name of the series \texttt{x}.

\texttt{snames} \hspace{1em} The series names for a multivariate time series.

The lag \texttt{k} value returned by \texttt{ccf(x, y)} estimates the correlation between \texttt{x[t+k]} and \texttt{y[t]}.

The result is returned invisibly if \texttt{plot} is TRUE.

\textbf{Author(s)}

Original: Paul Gilbert, Martyn Plummer. Extensive modifications and univariate case of \texttt{pacf} by B. D. Ripley.

`plot.acf`, `ARMAacf` for the exact autocorrelations of a given ARMA process.

Examples

```r
require(graphics)

## Examples from Venables & Ripley
acf(lh)
acf(lh, type = "covariance")
pacf(lh)

acf(ldeaths)
acf(ldeaths, ci.type = "ma")
acf(ts.union(mdeaths, fdeaths))
ccf(mdeaths, fdeaths, ylab = "cross-correlation")
# (just the cross-correlations)

presidents # contains missing values
acf(presidents, na.action = na.pass)
pacf(presidents, na.action = na.pass)
```

acf2AR

*Compute an AR Process Exactly Fitting an ACF*

**Description**

Compute an AR process exactly fitting an autocorrelation function.

**Usage**

```r
acf2AR(acf)
```

**Arguments**

- `acf` An autocorrelation or autocovariance sequence.

**Value**

A matrix, with one row for the computed $AR(p)$ coefficients for $1 \leq p \leq \text{length}(acf)$.

**See Also**

`ARMAacf`, `ar.yw` which does this from an empirical ACF.
Examples

```r
(Acf <- ARMAcf(c(0.6, 0.3, -0.2)))
acf2AR(Acf)
```

---

**add1**

### Add or Drop All Possible Single Terms to a Model

**Description**

Compute all the single terms in the scope argument that can be added to or dropped from the model, fit those models and compute a table of the changes in fit.

**Usage**

```r
add1(object, scope, ...) # Default S3 method:
add1(object, scope, scale = 0, test = c("none", "Chisq"),
      k = 2, trace = FALSE, ...)

# S3 method for class 'lm'
add1(object, scope, scale = 0, test = c("none", "Chisq", "F"),
      x = NULL, k = 2, ...)

# S3 method for class 'glm'
add1(object, scope, scale = 0, test = c("none", "Rao", "LRT", "Chisq", "F"),
      x = NULL, k = 2, ...)

# S3 method for class 'glm'
drop1(object, scope, ...) # Default S3 method:
drop1(object, scope, scale = 0, test = c("none", "Chisq"),
      k = 2, trace = FALSE, ...)

# S3 method for class 'lm'
drop1(object, scope, scale = 0, all.cols = TRUE,
      test = c("none", "Chisq", "F"), k = 2, ...)

# S3 method for class 'glm'
drop1(object, scope, scale = 0,
      test = c("none", "Rao", "LRT", "Chisq", "F"),
      k = 2, ...)```

**Arguments**

- `object` a fitted model object.
- `scope` a formula giving the terms to be considered for adding or dropping.
- `scale` an estimate of the residual mean square to be used in computing $C_p$. Ignored if 0 or NULL.
test should the results include a test statistic relative to the original model? The F test is only appropriate for \texttt{lrm} and \texttt{aov} models or perhaps for \texttt{glm} fits with estimated dispersion. The $\chi^2$ test can be an exact test (\texttt{lrm} models with known scale) or a likelihood-ratio test or a test of the reduction in scaled deviance depending on the method. For \texttt{glm} fits, you can also choose "LRT" and "Rao" for likelihood ratio tests and Rao's efficient score test. The former is synonymous with "Chisq" (although both have an asymptotic chi-square distribution).

\texttt{k} the penalty constant in AIC / $C_p$.

\texttt{trace} if TRUE, print out progress reports.

\texttt{x} a model matrix containing columns for the fitted model and all terms in the upper scope. Useful if \texttt{add1} is to be called repeatedly. \textbf{Warning}: no checks are done on its validity.

\texttt{all.cols} (Provided for compatibility with S.) Logical to specify whether all columns of the design matrix should be used. If FALSE then non-estimable columns are dropped, but the result is not usually statistically meaningful.

\texttt{...} further arguments passed to or from other methods.

\textbf{Details}

For \texttt{drop1} methods, a missing scope is taken to be all terms in the model. The hierarchy is respected when considering terms to be added or dropped: all main effects contained in a second-order interaction must remain, and so on.

In a scope formula . means ‘what is already there’.

The methods for \texttt{lrm} and \texttt{glm} are more efficient in that they do not recompute the model matrix and call the \texttt{fit} methods directly.

The default output table gives AIC, defined as minus twice log likelihood plus $2p$ where $p$ is the rank of the model (the number of effective parameters). This is only defined up to an additive constant (like log-likelihoods). For linear Gaussian models with fixed scale, the constant is chosen to give Mallows’ $C_p$, \textit{RSS/scale} + 2$p$ − $n$. Where $C_p$ is used, the column is labelled as $C_p$ rather than AIC.

The F tests for the "\texttt{glm}" methods are based on analysis of deviance tests, so if the dispersion is estimated it is based on the residual deviance, unlike the F tests of \texttt{anova.glm}.

\textbf{Value}

An object of class "\texttt{anova}" summarizing the differences in fit between the models.

\textbf{Warning}

The model fitting must apply the models to the same dataset. Most methods will attempt to use a subset of the data with no missing values for any of the variables if \texttt{na.action} = \texttt{na.omit}, but this may give biased results. Only use these functions with data containing missing values with great care.

The default methods make calls to the function \texttt{nobs} to check that the number of observations involved in the fitting process remained unchanged.
addmargins

Note

These are not fully equivalent to the functions in S. There is no keep argument, and the methods used are not quite so computationally efficient.

Their authors’ definitions of Mallows’ $C_p$ and Akaike’s AIC are used, not those of the authors of the models chapter of S.

Author(s)

The design was inspired by the S functions of the same names described in Chambers (1992).

step, aov, lm, extractAIC, anova

Examples

```r
require(graphics); require(utils)
## following example(swiss)
lm1 <- lm(Fertility ~ ., data = swiss)
add1(lm1, ~ I(Education^2) + .^2)
drop1(lm1, test = "F") # So called 'type II' anova

## following example(glm)
drop1(glm.093, test = "Chisq")
drop1(glm.093, test = "F")
add1(glm.093, scope = ~outcome*treatment, test = "Rao") # # Pearson Chi-square
```

Description

For a given table one can specify which of the classifying factors to expand by one or more levels to hold margins to be calculated. One may for example form sums and means over the first dimension and medians over the second. The resulting table will then have two extra levels for the first dimension and one extra level for the second. The default is to sum over all margins in the table. Other possibilities may give results that depend on the order in which the margins are computed. This is flagged in the printed output from the function.

Usage

```r
addmargins(A, margin = seq_along(dim(A)), FUN = sum, quiet = FALSE)
```
Arguments

**A**
A table or array. The function uses the presence of the "dim" and "dimnames" attributes of A.

**margin**
vector of dimensions over which to form margins. Margins are formed in the order in which dimensions are specified in margin.

**FUN**
list of the same length as margin, each element of the list being either a function or a list of functions. Names of the list elements will appear as levels in dimnames of the result. Unnamed list elements will have names constructed: the name of a function or a constructed name based on the position in the table.

**quiet**
logical which suppresses the message telling the order in which the margins were computed.

Details

If the functions used to form margins are not commutative the result depends on the order in which margins are computed. Annotation of margins is done via naming the FUN list.

Value

A table or array with the same number of dimensions as A, but with extra levels of the dimensions mentioned in margin. The number of levels added to each dimension is the length of the entries in FUN. A message with the order of computation of margins is printed.

Aye <- sample(c("Yes", "Si", "Oui"), 177, replace = TRUE)
Bee <- sample(c("Hum", "Buzz"), 177, replace = TRUE)
Sea <- sample(c("White", "Black", "Red", "Dead"), 177, replace = TRUE)
(A <- table(Aye, Bee, Sea))
addmargins(A)

ftable(A)
ftable(addmargins(A))

# Non-commutative functions - note differences between resulting tables:
ftable(addmargins(A, c(1, 3),
   FUN = list(Sum = sum, list(Min = min, Max = max))))
ftable(addmargins(A, c(3, 1),
   FUN = list(Min = min, Max = max), Sum = sum))

# Weird function needed to return the N when computing percentages
sqsm <- function(x) sum(x)^2/100
B <- table(Sea, Bee)
round(sweep(addmargins(B, 1, list(list(All = sum, N = sqsm)))), 2)
```
Compute Summary Statistics of Data Subsets

Description

Splits the data into subsets, computes summary statistics for each, and returns the result in a convenient form.

Usage

aggregate(x, ...)

## Default S3 method:
aggregate(x, ...)

## S3 method for class 'data.frame'
aggregate(x, by, FUN, ..., simplify = TRUE)

## S3 method for class 'formula'
aggregate(formula, data, FUN, ..., subset, na.action = na.omit)

## S3 method for class 'ts'
aggregate(x, nfrequency = 1, FUN = sum, ndeltat = 1,
         ts.eps = getOption("ts.eps"), ...)

Arguments

x      an R object.
by      a list of grouping elements, each as long as the variables in the data frame x. The elements are coerced to factors before use.
FUN     a function to compute the summary statistics which can be applied to all data subsets.
simplify a logical indicating whether results should be simplified to a vector or matrix if possible.
aggregate

formula a formula, such as \( y \sim x \) or cbind(y1, y2) ~ x1 + x2, where the y variables are numeric data to be split into groups according to the grouping x variables (usually factors).

data a data frame (or list) from which the variables in formula should be taken.

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NA values. The default is to ignore missing values in the given variables.

nfrequency new number of observations per unit of time; must be a divisor of the frequency of x.

ndeltat new fraction of the sampling period between successive observations; must be a divisor of the sampling interval of x.

ts.epst tolerance used to decide if nfrequency is a sub-multiple of the original frequency.

... further arguments passed to or used by methods.

Details

aggregate is a generic function with methods for data frames and time series.

The default method, aggregate.default, uses the time series method if x is a time series, and otherwise coerces x to a data frame and calls the data frame method.

aggregate.data.frame is the data frame method. If x is not a data frame, it is coerced to one, which must have a non-zero number of rows. Then, each of the variables (columns) in x is split into subsets of cases (rows) of identical combinations of the components of by, and FUN is applied to each such subset with further arguments in ... passed to it. The result is reformatted into a data frame containing the variables in by and x. The ones arising from by contain the unique combinations of grouping values used for determining the subsets, and the ones arising from x the corresponding summaries for the subset of the respective variables in x. If simplify is true, summaries are simplified to vectors or matrices if they have a common length of one or greater than one, respectively; otherwise, lists of summary results according to subsets are obtained. Rows with missing values in any of the by variables will be omitted from the result. (Note that versions of R prior to 2.11.0 required FUN to be a scalar function.)

aggregate.formula is a standard formula interface to aggregate.data.frame.

aggregate.ts is the time series method, and requires FUN to be a scalar function. If x is not a time series, it is coerced to one. Then, the variables in x are split into appropriate blocks of length frequency(x) / nfrequency, and FUN is applied to each such block, with further (named) arguments in ... passed to it. The result returned is a time series with frequency nfrequency holding the aggregated values. Note that this make most sense for a quarterly or yearly result when the original series covers a whole number of quarters or years: in particular aggregating a monthly series to quarters starting in February does not give a conventional quarterly series.

FUN is passed to match.fun, and hence it can be a function or a symbol or character string naming a function.

Value

For the time series method, a time series of class "ts" or class c("mts", "ts").

For the data frame method, a data frame with columns corresponding to the grouping variables in by followed by aggregated columns from x. If the by has names, the non-empty times are used to label the columns in the results, with unnamed grouping variables being named Group. i for by[[i]].
aggregate

aggregate(cbind(ncases, ncontrols) ~ alcgp + tobgp, data = esoph, sum)

## Dot notation:
aggregate(. ~ Species, data = iris, mean)
aggregate(len ~ ., data = ToothGrowth, mean)

## Often followed by xtabs():
ag <- aggregate(len ~ ., data = ToothGrowth, mean)
xtabs(len ~ ., data = ag)
```
## AIC

### Description

Generic function calculating Akaike’s ‘An Information Criterion’ for one or several fitted model objects for which a log-likelihood value can be obtained, according to the formula

\[-2 \text{log-likelihood} + kn_{\text{par}},\]

where \(n_{\text{par}}\) represents the number of parameters in the fitted model, and \(k = 2\) for the usual AIC, or \(k = \log(n)\) (\(n\) being the number of observations) for the so-called BIC or SBC (Schwarz’s Bayesian criterion).

### Usage

- `AIC(object, ...)`
- `BIC(object, ...)`

### Arguments

- **object**: a fitted model object for which there exists a `logLik` method to extract the corresponding log-likelihood, or an object inheriting from class `logLik`.
- **...**: optionally more fitted model objects.
- **k**: numeric, the penalty per parameter to be used; the default \(k = 2\) is the classical AIC.

### Details

When comparing models fitted by maximum likelihood to the same data, the smaller the AIC or BIC, the better the fit.

The theory of AIC requires that the log-likelihood has been maximized: whereas AIC can be computed for models not fitted by maximum likelihood, their AIC values should not be compared.

Examples of models not ‘fitted to the same data’ are where the response is transformed (accelerated-life models are fitted to log-times) and where contingency tables have been used to summarize data.

These are generic functions (with S4 generics defined in package `stats4`): however methods should be defined for the log-likelihood function `logLik` rather than these functions: the action of their default methods is to call `logLik` on all the supplied objects and assemble the results. Note that in several common cases `logLik` does not return the value at the MLE: see its help page.

The log-likelihood and hence the AIC/BIC is only defined up to an additive constant. Different constants have conventionally been used for different purposes and so `extractAIC` and AIC may give different values (and do for models of class "lm": see the help for `extractAIC`). Particular care is needed when comparing fits of different classes (with, for example, a comparison of a Poisson and gamma GLM being meaningless since one has a discrete response, the other continuous).

BIC is defined as \(AIC(object, ..., k = \log(nobs(object)))\). This needs the number of observations to be known: the default method looks first for a "nobs" attribute on the return value from the `logLik` method, then tries the `nobs` generic, and if neither succeed returns BIC as \(NA\).
Value

If just one object is provided, a numeric value with the corresponding AIC (or BIC, or ... , depending on k).

If multiple objects are provided, a data.frame with rows corresponding to the objects and columns representing the number of parameters in the model (df) and the AIC or BIC.

AIC(lm1, lm2)
BIC(lm1, lm2)
```

---

**Description**

Find aliases (linearly dependent terms) in a linear model specified by a formula.

**Usage**

```r
alias(object, ...)
```

## S3 method for class 'formula'
alias(object, data, ...)

## S3 method for class 'lm'
alias(object, complete = TRUE, partial = FALSE, partial.pattern = FALSE, ...)
```
Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object</td>
<td>A fitted model object, for example from <code>lm</code> or <code>aov</code>, or a formula for <code>alias.formula</code>.</td>
</tr>
<tr>
<td>data</td>
<td>Optionally, a data frame to search for the objects in the formula.</td>
</tr>
<tr>
<td>complete</td>
<td>Should information on complete aliasing be included?</td>
</tr>
<tr>
<td>partial</td>
<td>Should information on partial aliasing be included?</td>
</tr>
<tr>
<td>partial.pattern</td>
<td>Should partial aliasing be presented in a schematic way? If this is done, the</td>
</tr>
<tr>
<td></td>
<td>results are presented in a more compact way, usually giving the deciles of the</td>
</tr>
<tr>
<td></td>
<td>coefficients.</td>
</tr>
<tr>
<td>...</td>
<td>further arguments passed to or from other methods.</td>
</tr>
</tbody>
</table>

Details

Although the main method is for class "lm", alias is most useful for experimental designs and so is used with fits from `aov`. Complete aliasing refers to effects in linear models that cannot be estimated independently of the terms which occur earlier in the model and so have their coefficients omitted from the fit. Partial aliasing refers to effects that can be estimated less precisely because of correlations induced by the design.

Some parts of the "lm" method require recommended package `MASS` to be installed.

Value

A list (of class "listof") containing components

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model</td>
<td>Description of the model; usually the formula.</td>
</tr>
<tr>
<td>Complete</td>
<td>A matrix with columns corresponding to effects that are linearly dependent on</td>
</tr>
<tr>
<td></td>
<td>the rows.</td>
</tr>
<tr>
<td>Partial</td>
<td>The correlations of the estimable effects, with a zero diagonal. An object of</td>
</tr>
<tr>
<td></td>
<td>class &quot;mtable&quot; which has its own <code>print</code> method.</td>
</tr>
</tbody>
</table>

Note

The aliasing pattern may depend on the contrasts in use: Helmert contrasts are probably most useful. The defaults are different from those in S.

Author(s)

The design was inspired by the S function of the same name described in Chambers et al. (1992).

References

Examples

```r
op <- options(contrasts = c("contr.helmert", "contr.poly"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
alias(npk.aov)
options(op)  # reset
```
### anova

#### Description

Compute analysis of variance (or deviance) tables for one or more fitted model objects.

#### Usage

```r
anova(object, 
```

#### Arguments

- `object`: an object containing the results returned by a model fitting function (e.g., `lm` or `glm`).
- `...`: additional objects of the same type.

#### Value

This (generic) function returns an object of class `anova`. These objects represent analysis-of-variance and analysis-of-deviance tables. When given a single argument it produces a table which tests whether the model terms are significant.

When given a sequence of objects, `anova` tests the models against one another in the order specified. The print method for `anova` objects prints tables in a 'pretty' form.

#### Warning

The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R’s default of `na.action = na.omit` is used.

#### References

#### See Also

- `coefficients`,
- `effects`,
- `fitted.values`,
- `residuals`,
- `summary`,
- `drop1`,
- `add1`.

---

### anova.glm

#### Description

Compute an analysis of deviance table for one or more generalized linear model fits.

#### Usage

```r
## S3 method for class 'glm'
anova(object, 
```
Arguments

- `object, ...` objects of class `glm`, typically the result of a call to `glm`, or a list of objects for the "glmlist" method.
- `dispersion` the dispersion parameter for the fitting family. By default it is obtained from the object(s).
- `test` a character string, (partially) matching one of "chisq", "LRT", "Rao", "F" or "Cp". See `stat.anova`.

Details

Specifying a single object gives a sequential analysis of deviance table for that fit. That is, the reductions in the residual deviance as each term of the formula is added in turn are given in as the rows of a table, plus the residual deviances themselves.

If more than one object is specified, the table has a row for the residual degrees of freedom and deviance for each model. For all but the first model, the change in degrees of freedom and deviance is also given. (This only makes statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

The table will optionally contain test statistics (and P values) comparing the reduction in deviance for the row to the residuals. For models with known dispersion (e.g., binomial and Poisson fits) the chi-squared test is most appropriate, and for those with dispersion estimated by moments (e.g., gaussian, quasibinomial and quasipoisson fits) the F test is most appropriate. Mallows' $C_p$ statistic is the residual deviance plus twice the estimate of $\sigma^2$ times the residual degrees of freedom, which is closely related to AIC (and a multiple of it if the dispersion is known). You can also choose "LRT" and "Rao" for likelihood ratio tests and Rao's efficient score test. The former is synonymous with "chisq" (although both have an asymptotic chi-square distribution).

The dispersion estimate will be taken from the largest model, using the value returned by `summary.glm`. As this will in most cases use a Chisquared-based estimate, the F tests are not based on the residual deviance in the analysis of deviance table shown.

Value

An object of class "anova" inheriting from class "data.frame".

Warning

The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R's default of `na.action = na.omit` is used, and anova will detect this with an error.

References

See Also

- `glm`, `anova`.
- `drop1` for so-called 'type II' anova where each term is dropped one at a time respecting their hierarchy.
Examples

### Continuing the Example from `?glm`:

```r
anova(glm.D93)
anova(glm.D93, test = "Cp")
anova(glm.D93, test = "Chisq")
glm.D93a <-
  update(glm.D93, ~treatment*outcome) # equivalent to Pearson Chi-square
anova(glm.D93, glm.D93a, test = "Rao")
```

Description

Compute an analysis of variance table for one or more linear model fits.

Usage

```r
## S3 method for class 'lm'
anova(object, ...)

## S3 method for class 'lmList'
anova(object, ..., scale = 0, test = "F")
```

Arguments

- `object, ...` objects of class `lm`, usually, a result of a call to `lm`.
- `test` a character string specifying the test statistic to be used. Can be one of "F", "Chisq" or "Cp", with partial matching allowed, or NULL for no test.
- `scale` numeric. An estimate of the noise variance $\sigma^2$. If zero this will be estimated from the largest model considered.

Details

Specifying a single object gives a sequential analysis of variance table for that fit. That is, the reductions in the residual sum of squares as each term of the formula is added in turn are given in as the rows of a table, plus the residual sum of squares.

The table will contain F statistics (and P values) comparing the mean square for the row to the residual mean square.

If more than one object is specified, the table has a row for the residual degrees of freedom and sum of squares for each model. For all but the first model, the change in degrees of freedom and sum of squares is also given. (This only make statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

Optionally the table can include test statistics. Normally the F statistic is most appropriate, which compares the mean square for a row to the residual sum of squares for the largest model considered. If `scale` is specified chi-squared tests can be used. Mallows’ $C_p$ statistic is the residual sum of squares plus twice the estimate of $\sigma^2$ times the residual degrees of freedom.
### Description

Compute a (generalized) analysis of variance table for one or more multivariate linear models.

### Usage

```r
## S3 method for class 'mlm'
anova(object, ...,
      test = c("Pillai", "Wilks", "Hotelling-Lawley", "Roy",
               "Spherical"),
      Sigma = diag(nrow = p), T = Thin.row(proj(M) - proj(X)),
      M = diag(nrow = p), X = ~0,
      idata = data.frame(index = seq_len(p)), tol = 1e-7)
```
Arguments

object  an object of class "mlm".
...  further objects of class "mlm".
test  choice of test statistic (see below).
Sigma  (only relevant if test == "Spherical"). Covariance matrix assumed proportional to Sigma.
T  transformation matrix. By default computed from M and X.
M  formula or matrix describing the outer projection (see below).
X  formula or matrix describing the inner projection (see below).
idata  data frame describing intra-block design.
tol  tolerance to be used in deciding if the residuals are rank-deficient: see qr.

Details

The `anova.mlm` method uses either a multivariate test statistic for the summary table, or a test based on sphericity assumptions (i.e. that the covariance is proportional to a given matrix).

For the multivariate test, Wilks’ statistic is most popular in the literature, but the default Pillai–Bartlett statistic is recommended by Hand and Taylor (1987). See `summary.manova` for further details.

For the "Spherical" test, proportionality is usually with the identity matrix but a different matrix can be specified using Sigma. Corrections for asphericity known as the Greenhouse–Geisser, respectively Huynh–Feldt, epsilons are given and adjusted F tests are performed.

It is common to transform the observations prior to testing. This typically involves transformation to intra-block differences, but more complicated within-block designs can be encountered, making more elaborate transformations necessary. A transformation matrix T can be given directly or specified as the difference between two projections onto the spaces spanned by M and X, which in turn can be given as matrices or as model formulas with respect to idata (the tests will be invariant to parametrization of the quotient space \( M/X \)).

As with `anova.lm`, all test statistics use the SSD matrix from the largest model considered as the (generalized) denominator.

Contrary to other `anova` methods, the intercept is not excluded from the display in the single-model case. When contrast transformations are involved, it often makes good sense to test for a zero intercept.

Value

An object of class "anova" inheriting from class "data.frame"

Note

The Huynh–Feldt epsilon differs from that calculated by SAS (as of v. 8.2) except when the DF is equal to the number of observations minus one. This is believed to be a bug in SAS, not in R.

**Ansari-Bradley Test**

**Description**

Performs the Ansari-Bradley two-sample test for a difference in scale parameters.

**Usage**

```r
ansari.test(x, y)
```
...)

## S3 method for class 'formula'
ansari.test(formula, data, subset, na.action, ...)

### Arguments

- **x**: numeric vector of data values.
- **y**: numeric vector of data values.
- **alternative**: indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter.
- **exact**: a logical indicating whether an exact p-value should be computed.
- **conf.int**: a logical indicating whether a confidence interval should be computed.
- **conf.level**: confidence level of the interval.
- **formula**: a formula of the form `lhs ~ rhs` where `lhs` is a numeric variable giving the data values and `rhs` a factor with two levels giving the corresponding groups.
- **data**: an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- **...**: further arguments to be passed to or from methods.

### Details

Suppose that `x` and `y` are independent samples from distributions with densities \( f((t - m)/s)/s \) and \( f(t - m) \), respectively, where \( m \) is an unknown nuisance parameter and \( s \), the ratio of scales, is the parameter of interest. The Ansari-Bradley test is used for testing the null that \( s \) equals 1, the two-sided alternative being that \( s \neq 1 \) (the distributions differ only in variance), and the one-sided alternatives being \( s > 1 \) (the distribution underlying `x` has a larger variance, "greater") or \( s < 1 \) ("less").

By default (if `exact` is not specified), an exact p-value is computed if both samples contain less than 50 finite values and there are no ties. Otherwise, a normal approximation is used.

Optionally, a nonparametric confidence interval and an estimator for `s` are computed. If exact p-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations.

Note that mid-ranks are used in the case of ties rather than average scores as employed in Hollander & Wolfe (1973). See, e.g., Hajek, Sidak and Sen (1999), pages 131ff, for more information.

### Value

A list with class "htest" containing the following components:

- **statistic**: the value of the Ansari-Bradley test statistic.
- **p.value**: the p-value of the test.
- **null.value**: the ratio of scales \( s \) under the null, 1.
- **alternative**: a character string describing the alternative hypothesis.
method: the string "Ansari-Bradley test".

data.name: a character string giving the names of the data.

conf.int: a confidence interval for the scale parameter. (Only present if argument conf.int = TRUE.)

estimate: an estimate of the ratio of scales. (Only present if argument conf.int = TRUE.)

Note

To compare results of the Ansari-Bradley test to those of the F test to compare two variances (under the assumption of normality), observe that \( s \) is the ratio of scales and hence \( s^2 \) is the ratio of variances (provided they exist), whereas for the F test the ratio of variances itself is the parameter of interest. In particular, confidence intervals are for \( s \) in the Ansari-Bradley test but for \( s^2 \) in the F test.

Examples

```r
## Hollander & Wolfe (1973, p. 86f):
## Serum iron determination using Hyland control sera
ansari.test(ramsay, jung.parekh)

ansari.test(rnorm(10), rnorm(10, 0, 2), conf.int = TRUE)

## try more points - failed in 2.4.1
ansari.test(rnorm(100), rnorm(100, 0, 2), conf.int = TRUE)
```
**aov**  
Fit an Analysis of Variance Model

**Description**

Fit an analysis of variance model by a call to `lm` for each stratum.

**Usage**

```r
aov(formula, data = NULL, projections = FALSE, qr = TRUE,
    contrasts = NULL, ...
)
```

**Arguments**

- `formula` A formula specifying the model.
- `data` A data frame in which the variables specified in the formula will be found. If missing, the variables are searched for in the standard way.
- `projections` Logical flag: should the projections be returned?
- `qr` Logical flag: should the QR decomposition be returned?
- `contrasts` A list of contrasts to be used for some of the factors in the formula. These are not used for any `Error` term, and supplying contrasts for factors only in the `Error` term will give a warning.
- `...` Arguments to be passed to `lm`, such as `subset` or `na.action`. See ‘Details’ about `weights`.

**Details**

This provides a wrapper to `lm` for fitting linear models to balanced or unbalanced experimental designs.

The main difference from `lm` is in the way `print`, `summary` and so on handle the fit: this is expressed in the traditional language of the analysis of variance rather than that of linear models.

If the formula contains a single `Error` term, this is used to specify error strata, and appropriate models are fitted within each error stratum.

The formula can specify multiple responses.

Weights can be specified by a `weights` argument, but should not be used with an `Error` term, and are incompletely supported (e.g., not by `model.tables`).

**Value**

An object of class `c("aov", "lm")` or for multiple responses of class `c("maov", "aov", "nlm", "lm")` or for multiple error strata of class "aovlist". There are `print` and `summary` methods available for these.
approxfun

**Note**

`aov` is designed for balanced designs, and the results can be hard to interpret without balance: beware that missing values in the response(s) will likely lose the balance. If there are two or more error strata, the methods used are statistically inefficient without balance, and it may be better to use `lme` in package `nlme`.

Balance can be checked with the `replications` function.

The default ‘contrasts’ in R are not orthogonal contrasts, and `aov` and its helper functions will work better with such contrasts: see the examples for how to select these.

**Author(s)**

The design was inspired by the S function of the same name described in Chambers *et al.* (1992).

**References**

**See Also**

`lm`, `summary.aov`, `replications`, `alias`, `proj`, `model.tables`, `TukeyHSD`

**Examples**

```r

## Set orthogonal contrasts.
op <- options(contrasts = c("contr.helmert", "contr.poly"))
  ( npk.aov <- aov(yield ~ block + N*P*K, npk) )
summary(npk.aov)
coefficients(npk.aov)

## to show the effects of re-ordering terms contrast the two fits
aov(yield ~ block + N * P + K, npk)
aov(terms(yield ~ block + N * P + K, keep.order = TRUE), npk)

## as a test, not particularly sensible statistically
npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
npk.aovE
summary(npk.aovE)
options(op)  # reset to previous
```

**approxfun**

**Interpolation Functions**

**Description**

Return a list of points which linearly interpolate given data points, or a function performing the linear (or constant) interpolation.
Usage

```r
approx(x, y = NULL, xout, method = "linear", n = 50,
yleft, yright, rule = 1, f = 0, ties = mean)
apprxfun(x, y = NULL, method = "linear",
yleft, yright, rule = 1, f = 0, ties = mean)
```

Arguments

- `x, y` numeric vectors giving the coordinates of the points to be interpolated. Alternatively a single plotting structure can be specified: see `xy.coords`.
- `xout` an optional set of numeric values specifying where interpolation is to take place.
- `method` specifies the interpolation method to be used. Choices are "linear" or "constant".
- `n` If `xout` is not specified, interpolation takes place at `n` equally spaced points spanning the interval `[min(x), max(x)]`.
- `yleft` the value to be returned when input `x` values are less than `min(x)`. The default is defined by the value of `rule` given below.
- `yright` the value to be returned when input `x` values are greater than `max(x)`. The default is defined by the value of `rule` given below.
- `rule` an integer (of length 1 or 2) describing how interpolation is to take place outside the interval `[min(x), max(x)]`. If `rule` is 1 then NAs are returned for such points and if it is 2, the value at the closest data extreme is used. Use, e.g., `rule = 2:1`, if the left and right side extrapolation should differ.
- `f` for `method = "constant"` a number between 0 and 1 inclusive, indicating a compromise between left- and right-continuous step functions. If `y0` and `y1` are the values to the left and right of the point then the value is `y0*(1-f)+y1*f` so that `f = 0` is right-continuous and `f = 1` is left-continuous.
- `ties` Handling of tied `x` values. Either a function with a single vector argument returning a single number result or the string "ordered".

Details

The inputs can contain missing values which are deleted, so at least two complete `(x, y)` pairs are required (for `method = "linear"`, one otherwise). If there are duplicated (tied) `x` values and `ties` is a function it is applied to the `y` values for each distinct `x` value. Useful functions in this context include `mean`, `min`, and `max`. If `ties = "ordered"` the `x` values are assumed to be already ordered. The first `y` value will be used for interpolation to the left and the last one for interpolation to the right.

Value

`approx` returns a list with components `x` and `y`, containing `n` coordinates which interpolate the given data points according to the `method` (and `rule`) desired.

The function `apprxfun` returns a function performing (linear or constant) interpolation of the given data points. For a given set of `x` values, this function will return the corresponding interpolated values. It uses data stored in its environment when it was created, the details of which are subject to change.
Warning

The value returned by approxfun contains references to the code in the current version of R: it is not intended to be saved and loaded into a different R session. This is safer for R >= 3.0.0.

Examples

```r
require(graphics)

x <- 1:10
y <- rnorm(10)
par(mfrow = c(2,1))
plot(x, y, main = "approx(.) and approxfun(.)")
points(approx(x, y), col = 2, pch = "*")
points(approx(x, y, method = "constant"), col = 4, pch = "*")

f <- approxfun(x, y)
curve(f(x), 0, 11, col = "green")
points(x, y)
if(is.function(fc <- approxfun(x, y, method = "const"))) # TRUE
curve(fc(x), 0, 10, col = "darkblue", add = TRUE)
## different extrapolation on left and right side:
plot(approxfun(x, y, rule = 2:1), 0, 11,
     col = "tomato", add = TRUE, lty = 3, lwd = 2)

## Show treatment of 'ties' :

x <- c(2,2,4,4,5,5,7,7)
y <- c(1:6, 5:4, 3:1)
approx(x, y, xout = x)# warning
(ay <- approx(x, y, xout = x, ties = "ordered")$y)
stopifnot(ay == c(2,2,3,6,6,6,4,4,1,1,1))
approx(x, y, xout = x, ties = min)$y
approx(x, y, xout = x, ties = max)$y
```

ar

Fit Autoregressive Models to Time Series

Description

Fit an autoregressive time series model to the data, by default selecting the complexity by AIC.
Usage

```r
ar(x, aic = TRUE, order.max = NULL,
    method = c("yule-walker", "burg", "ols", "mle", "yw"),
    na.action, series, ...)
```

```r
ar.burg(x, ...)
## Default S3 method:
ar.burg(x, aic = TRUE, order.max = NULL,
    na.action = na.fail, demean = TRUE, series,
    var.method = 1, ...)
## S3 method for class 'mts'
ar.burg(x, aic = TRUE, order.max = NULL,
    na.action = na.fail, demean = TRUE, series,
    var.method = 1, ...)
```

```r
ar.yw(x, ...)
## Default S3 method:
ar.yw(x, aic = TRUE, order.max = NULL,
    na.action = na.fail, demean = TRUE, series, ...)
## S3 method for class 'mts'
ar.yw(x, aic = TRUE, order.max = NULL,
    na.action = na.fail, demean = TRUE, series,
    var.method = 1, ...)
```

```r
ar.mle(x, aic = TRUE, order.max = NULL, na.action = na.fail,
    demean = TRUE, series, ...)
```

```r
## S3 method for class 'ar'
predict(object, newdata, n.ahead = 1, se.fit = TRUE, ...)
```

Arguments

- **x**: A univariate or multivariate time series.
- **aic**: Logical flag. If `TRUE` then the Akaike Information Criterion is used to choose the order of the autoregressive model. If `FALSE`, the model of order `order.max` is fitted.
- **order.max**: Maximum order (or order) of model to fit. Defaults to the smaller of $N - 1$ and $10 \log_{10}(N)$ where $N$ is the number of observations except for `method = "mle"` where it is the minimum of this quantity and 12.
- **method**: Character string giving the method used to fit the model. Must be one of the strings in the default argument (the first few characters are sufficient). Defaults to "yule-walker".
- **na.action**: function to be called to handle missing values.
- **demean**: should a mean be estimated during fitting?
- **series**: names for the series. Defaults to `deparse(substitute(x))`.
- **var.method**: the method to estimate the innovations variance (see 'Details').
- **...**: additional arguments for specific methods.
- **object**: a fit from `ar`.
- **newdata**: data to which to apply the prediction.
Details

For definiteness, note that the AR coefficients have the sign in

\[ x_t - \mu = a_1(x_{t-1} - \mu) + \cdots + a_p(x_{t-p} - \mu) + e_t \]

ar is just a wrapper for the functions ar.yw, ar.burg, ar.ols and ar.mle.

Order selection is done by AIC if aic is true. This is problematic, as of the methods here only ar.mle performs true maximum likelihood estimation. The AIC is computed as if the variance estimate were the MLE, omitting the determinant term from the likelihood. Note that this is not the same as the Gaussian likelihood evaluated at the estimated parameter values. In ar.yw the variance matrix of the innovations is computed from the fitted coefficients and the autocovariance of x.

ar.burg allows two methods to estimate the innovations variance and hence AIC. Method 1 is to use the update given by the Levinson-Durbin recursion (Brockwell and Davis, 1991, (8.2.6) on page 242), and follows S-PLUS. Method 2 is the mean of the sum of squares of the forward and backward prediction errors (as in Brockwell and Davis, 1996, page 145). Percival and Walden (1998) discuss both. In the multivariate case the estimated coefficients will depend (slightly) on the variance estimation method.

Remember that ar includes by default a constant in the model, by removing the overall mean of x before fitting the AR model, or (ar.mle) estimating a constant to subtract.

Value

For ar and its methods a list of class "ar" with the following elements:

- **order**: The order of the fitted model. This is chosen by minimizing the AIC if aic = TRUE, otherwise it is order.max.
- **ar**: Estimated autoregression coefficients for the fitted model.
- **var.pred**: The prediction variance: an estimate of the portion of the variance of the time series that is not explained by the autoregressive model.
- **x.mean**: The estimated mean of the series used in fitting and for use in prediction.
- **x.intercept**: (ar.ols only.) The intercept in the model for x - x.mean.
- **aic**: The differences in AIC between each model and the best-fitting model. Note that the latter can have an AIC of ~Inf.
- **n.used**: The number of observations in the time series.
- **order.max**: The value of the order.max argument.
- **partialacf**: The estimate of the partial autocorrelation function up to lag order.max.
- **resid**: residuals from the fitted model, conditioning on the first order observations. The first order residuals are set to NA. If x is a time series, so is resid.
- **method**: The value of the method argument.
- **series**: The name(s) of the time series.
- **frequency**: The frequency of the time series.
- **call**: The matched call.
- **asy.var.coef**: (univariate case, order > 0.) The asymptotic-theory variance matrix of the coefficient estimates.

For predict.ar, a time series of predictions, or if se.fit = TRUE, a list with components pred, the predictions, and se, the estimated standard errors. Both components are time series.
Note

Only the univariate case of \texttt{ar.mle} is implemented. Fitting by \texttt{method="mle"} to long series can be very slow.

Examples

```r
ar(lh)
ar(lh, method = "burg")
ar(lh, method = "ols")
ar(lh, FALSE, 4) # fit ar(4)
(sunspot.ar <- ar(sunspot.year))
predict(sunspot.ar, n.ahead = 25)
## try the other methods too
ar(ts.union(BISales, BJsales.lead))
## Burg is quite different here, as is OLS (see ar.ols)
ar(ts.union(BJsales, BJsales.lead), method = "burg")
```

\texttt{ar.ols} \hspace{1cm} Fit Autoregressive Models to Time Series by OLS

Description

Fit an autoregressive time series model to the data by ordinary least squares, by default selecting the complexity by AIC.
Usage

ar.ols(x, aic = TRUE, order.max = NULL, na.action = na.fail,
        demean = TRUE, intercept = demean, series, ...)

Arguments

x A univariate or multivariate time series.

aic Logical flag. If TRUE then the Akaike Information Criterion is used to choose
      the order of the autoregressive model. If FALSE, the model of order order.max
      is fitted.

order.max Maximum order (or order) of model to fit. Defaults to \(10 \log_{10}(N)\) where \(N\) is
      the number of observations.

na.action function to be called to handle missing values.

demean should the AR model be for \(x\) minus its mean?

intercept should a separate intercept term be fitted?

series names for the series. Defaults to deparse(substitute(x)).

... further arguments to be passed to or from methods.

Details

ar.ols fits the general AR model to a possibly non-stationary and/or multivariate system of series
\(x\). The resulting unconstrained least squares estimates are consistent, even if some of the series are
non-stationary and/or co-integrated. For definiteness, note that the AR coefficients have the sign in

\[ x_t - \mu = a_0 + a_1(x_{t-1} - \mu) + \cdots + a_p(x_{t-p} - \mu) + \epsilon_t \]

where \(a_0\) is zero unless intercept is true, and \(\mu\) is the sample mean if demean is true, zero other-
wise. Order selection is done by AIC if aic is true. This is problematic, as ar.ols does not perform
true maximum likelihood estimation. The AIC is computed as if the variance estimate (computed
from the variance matrix of the residuals) were the MLE, omitting the determinant term from the
likelihood. Note that this is not the same as the Gaussian likelihood evaluated at the estimated
parameter values.

Some care is needed if intercept is true and demean is false. Only use this if the series are roughly
centred on zero. Otherwise the computations may be inaccurate or fail entirely.

Value

A list of class "ar" with the following elements:

order The order of the fitted model. This is chosen by minimizing the AIC if
      aic = TRUE, otherwise it is order.max.

ar Estimated autoregression coefficients for the fitted model.

var.pred The prediction variance: an estimate of the portion of the variance of the time
      series that is not explained by the autoregressive model.

x.mean The estimated mean (or zero if demean is false) of the series used in fitting and
      for use in prediction.

x.intercept The intercept in the model for \(x - x.mean\), or zero if intercept is false.
arima

The differences in AIC between each model and the best-fitting model. Note that the latter can have an AIC of -Inf.

The number of observations in the time series.

The value of the order.max argument.

NULL. For compatibility with ar.

resid

residuals from the fitted model, conditioning on the first order observations. The first order residuals are set to NA. If x is a time series, so is resid.

The character string "Unconstrained LS".

The name(s) of the time series.

The frequency of the time series.

The matched call.

The asymptotic-theory standard errors of the coefficient estimates.

Author(s)

Adrian Trapletti, Brian Ripley.

ar

Examples

ar(1h, method = "burg")
ar.ols(1h)
ar.ols(1h, FALSE, 4) # fit ar(4)
ar.ols(ts.union(BJsales, BJsales.lead))
x <- diff(log(EuStockMarkets))
ar.ols(x, order.max = 6, demean = FALSE, intercept = TRUE)

Description

Fit an ARIMA model to a univariate time series.
Usage

arima(x, order = c(0, 0, 0),
seasonal = list(order = c(0, 0, 0), period = NA),
xreg = NULL, include.mean = TRUE,
transform.pars = TRUE,
fixed = NULL, init = NULL,
method = c("CSS-ML", "ML", "CSS"),
n.cond, optim.method = "BFGS",
optim.control = list(), kappa = 1e6)

Arguments

x a univariate time series

order A specification of the non-seasonal part of the ARIMA model: the three components \((p, d, q)\) are the AR order, the degree of differencing, and the MA order.

seasonal A specification of the seasonal part of the ARIMA model, plus the period (which defaults to `frequency(x)`). This should be a list with components `order` and `period`, but a specification of just a numeric vector of length 3 will be turned into a suitable list with the specification as the order.

xreg Optionally, a vector or matrix of external regressors, which must have the same number of rows as \(x\).

include.mean Should the ARMA model include a mean/intercept term? The default is `TRUE` for undifferenced series, and it is ignored for ARIMA models with differencing.

transform.pars Logical. If true, the AR parameters are transformed to ensure that they remain in the region of stationarity. Not used for `method = "CSS"`.

fixed optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in `fixed` will be varied. `transform.pars = TRUE` will be overridden (with a warning) if any AR parameters are fixed. It may be wise to set `transform.pars = FALSE` when fixing MA parameters, especially near non-invertibility.

init optional numeric vector of initial parameter values. Missing values will be filled in, by zeroes except for regression coefficients. Values already specified in `fixed` will be ignored.

method Fitting method: maximum likelihood or minimize conditional sum-of-squares. The default (unless there are missing values) is to use conditional-sum-of-squares to find starting values, then maximum likelihood.

n.cond Only used if fitting by conditional-sum-of-squares: the number of initial observations to ignore. It will be ignored if less than the maximum lag of an AR term.

optim.method The value passed as the `method` argument to `optim`.

optim.control List of control parameters for `optim`.

kappa the prior variance (as a multiple of the innovations variance) for the past observations in a differenced model. Do not reduce this.

Details

Different definitions of ARMA models have different signs for the AR and/or MA coefficients. The definition used here has
\[ X_t = a_1 X_{t-1} + \cdots + a_p X_{t-p} + \epsilon_t + b_1 \epsilon_{t-1} + \cdots + b_q \epsilon_{t-q} \]

and so the MA coefficients differ in sign from those of S-PLUS. Further, if `include.mean` is true (the default for an ARMA model), this formula applies to \( X - m \) rather than \( X \). For ARIMA models with differencing, the differenced series follows a zero-mean ARMA model. If an `xreg` term is included, a linear regression (with a constant term if `include.mean` is true and there is no differencing) is fitted with an ARMA model for the error term.

The variance matrix of the estimates is found from the Hessian of the log-likelihood, and so may only be a rough guide.

Optimization is done by `optim`. It will work best if the columns in `xreg` are roughly scaled to zero mean and unit variance, but does attempt to estimate suitable scalings.

**Value**

A list of class "Arima" with components:

- `coef` a vector of AR, MA and regression coefficients, which can be extracted by the `coef` method.
- `sigma2` the MLE of the innovations variance.
- `var.coef` the estimated variance matrix of the coefficients `coef`, which can be extracted by the `vcov` method.
- `loglik` the maximized log-likelihood (of the differenced data), or the approximation to it used.
- `arma` A compact form of the specification, as a vector giving the number of AR, MA, seasonal AR and seasonal MA coefficients, plus the period and the number of non-seasonal and seasonal differences.
- `aic` the AIC value corresponding to the log-likelihood. Only valid for `method = "ML"` fits.
- `residuals` the fitted innovations.
- `call` the matched call.
- `series` the name of the series `x`.
- `code` the convergence value returned by `optim`.
- `n.cond` the number of initial observations not used in the fitting.
- `model` A list representing the Kalman Filter used in the fitting. See `KalmanLike`.

**Fitting methods**

The exact likelihood is computed via a state-space representation of the ARIMA process, and the innovations and their variance found by a Kalman filter. The initialization of the differenced ARMA process uses stationarity and is based on Gardner *et al.* (1980). For a differenced process the non-stationary components are given a diffuse prior (controlled by `kappa`). Observations which are still controlled by the diffuse prior (determined by having a Kalman gain of at least 1e4) are excluded from the likelihood calculations. (This gives comparable results to `arima0` in the absence of missing values, when the observations excluded are precisely those dropped by the differencing.)

Missing values are allowed, and are handled exactly in method "ML".

If `transform.pars` is true, the optimization is done using an alternative parametrization which is a variation on that suggested by Jones (1980) and ensures that the model is stationary. For an AR(p)
model the parametrization is via the inverse tanh of the partial autocorrelations: the same procedure is applied (separately) to the AR and seasonal AR terms. The MA terms are not constrained to be invertible during optimization, but they will be converted to invertible form after optimization if transform.pars is true.

Conditional sum-of-squares is provided mainly for expositional purposes. This computes the sum of squares of the fitted innovations from observation n.cond on, (where n.cond is at least the maximum lag of an AR term), treating all earlier innovations to be zero. Argument n.cond can be used to allow comparability between different fits. The ‘part log-likelihood’ is the first term, half the log of the estimated mean square. Missing values are allowed, but will cause many of the innovations to be missing.

When regressors are specified, they are orthogonalized prior to fitting unless any of the coefficients is fixed. It can be helpful to roughly scale the regressors to zero mean and unit variance.

Note

The results are likely to be different from S-PLUS's arima.mle, which computes a conditional likelihood and does not include a mean in the model. Further, the convention used by arima.mle reverses the signs of the MA coefficients.

arima is very similar to arima0 for ARMA models or for differenced models without missing values, but handles differenced models with missing values exactly. It is somewhat slower than arima0, particularly for seasonally differenced models.

arima.sim

Simulate from an ARIMA Model

Description

Simulate from an ARIMA model.

Usage

arima.sim(model, n, rand.gen = rnorm, innov = rand.gen(n, ...),
    n.start = NA, start.innov = rand.gen(n.start, ...),
    ...)

Arguments

model A list with component ar and/or ma giving the AR and MA coefficients respectively. Optionally a component order can be used. An empty list gives an ARIMA(0, 0, 0) model, that is white noise.
n length of output series, before un-differencing. A strictly positive integer.
rand.gen optional: a function to generate the innovations.
innov an optional times series of innovations. If not provided, rand.gen is used.
n.start length of ‘burn-in’ period. If NA, the default, a reasonable value is computed.
start.innov an optional times series of innovations to be used for the burn-in period. If supplied there must be at least n.start values (and n.start is by default computed inside the function).
... additional arguments for rand.gen. Most usefully, the standard deviation of the innovations generated by rnorm can be specified by sd.

Details

See arima for the precise definition of an ARIMA model.
The ARMA model is checked for stationarity.
ARIMA models are specified via the order component of model, in the same way as for arima. Other aspects of the order component are ignored, but inconsistent specifications of the MA and AR orders are detected. The un-differencing assumes previous values of zero, and to remind the user of this, those values are returned.
Random inputs for the ‘burn-in’ period are generated by calling rand.gen.
arima

Value

A time-series object of class "ts".

See Also

arima

Examples

require(graphics)

arima.sim(n = 63, list(ar = c(0.8897, -0.4858), ma = c(-0.2279, 0.2488)),
        sd = sqrt(0.1796))
# mildly long-tailed
arima.sim(n = 63, list(ar = c(0.8897, -0.4858), ma = c(-0.2279, 0.2488)),
        rand.gen = function(n, ...) sqrt(0.1796) * rt(n, df = 5))
# An ARIMA simulation
ts.sim <- arima.sim(list(order = c(1,1,0), ar = 0.7), n = 200)
ts.plot(ts.sim)

Description

Fit an ARIMA model to a univariate time series, and forecast from the fitted model.

Usage

arima(x, order = c(0, 0, 0),
     seasonal = list(order = c(0, 0, 0), period = NA),
     xreg = NULL, include.mean = TRUE, delta = 0.01,
     transform.pars = TRUE, fixed = NULL, init = NULL,
     method = c("ML", "CSS"), n.cond, optim.control = list())

## S3 method for class 'arima0'
predict(object, n.ahead = 1, newxreg, se.fit = TRUE, ...)

Arguments

x

a univariate time series

order

A specification of the non-seasonal part of the ARIMA model: the three components (p, d, q) are the AR order, the degree of differencing, and the MA order.

seasonal

A specification of the seasonal part of the ARIMA model, plus the period (which defaults to frequency(x)). This should be a list with components order and period, but a specification of just a numeric vector of length 3 will be turned into a suitable list with the specification as the order.

xreg

Optionally, a vector or matrix of external regressors, which must have the same number of rows as x.
**include.mean**  
Should the ARIMA model include a mean term? The default is `TRUE` for undifferenced series, `FALSE` for differenced ones (where a mean would not affect the fit nor predictions).

**delta**  
A value to indicate at which point ‘fast recursions’ should be used. See the ‘Details’ section.

**transform.pars**  
Logical. If true, the AR parameters are transformed to ensure that they remain in the region of stationarity. Not used for `method = "CSS"`.

**fixed**  
optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in `fixed` will be varied. `transform.pars = TRUE` will be overridden (with a warning) if any ARMA parameters are fixed.

**init**  
optional numeric vector of initial parameter values. Missing values will be filled in, by zeroes except for regression coefficients. Values already specified in `fixed` will be ignored.

**method**  
Fitting method: maximum likelihood or minimize conditional sum-of-squares.

**n.cond**  
Only used if fitting by conditional-sum-of-squares: the number of initial observations to ignore. It will be ignored if less than the maximum lag of an AR term.

**optim.control**  
List of control parameters for `optim`.

**object**  
The result of an `arima0` fit.

**newxreg**  
New values of `xreg` to be used for prediction. Must have at least `n.ahead` rows.

**n.ahead**  
The number of steps ahead for which prediction is required.

**se.fit**  
Logical: should standard errors of prediction be returned?

**...**  
arguments passed to or from other methods.

**Details**

Different definitions of ARMA models have different signs for the AR and/or MA coefficients. The definition here has

\[ X_t = a_1 X_{t-1} + \cdots + a_p X_{t-p} + e_t + b_1 e_{t-1} + \cdots + b_q e_{t-q} \]

and so the MA coefficients differ in sign from those of S-PLUS. Further, if `include.mean` is true, this formula applies to \( X - m \) rather than \( X \). For ARIMA models with differencing, the differenced series follows a zero-mean ARMA model.

The variance matrix of the estimates is found from the Hessian of the log-likelihood, and so may only be a rough guide, especially for fits close to the boundary of invertibility.

Optimization is done by `optim`. It will work best if the columns in `xreg` are roughly scaled to zero mean and unit variance, but does attempt to estimate suitable scalings.

Finite-history prediction is used. This is only statistically efficient if the MA part of the fit is invertible, so `predict.arima0` will give a warning for non-invertible MA models.

**Value**

For `arima0`, a list of class "arima0" with components:

- **coef**  
a vector of AR, MA and regression coefficients,

- **sigma2**  
the MLE of the innovations variance.

- **var.coef**  
the estimated variance matrix of the coefficients `coef`. 

---

**arima0**

1181
loglik  the maximized log-likelihood (of the differenced data), or the approximation to it used.

arma  A compact form of the specification, as a vector giving the number of AR, MA, seasonal AR and seasonal MA coefficients, plus the period and the number of non-seasonal and seasonal differences.

aic  the AIC value corresponding to the log-likelihood. Only valid for method = "ML" fits.

residuals  the fitted innovations.

call  the matched call.

series  the name of the series x.

convergence  the value returned by optim.

n.cond  the number of initial observations not used in the fitting.

For predict.arima0, a time series of predictions, or if se.fit = TRUE, a list with components pred, the predictions, and se, the estimated standard errors. Both components are time series.

Fitting methods

The exact likelihood is computed via a state-space representation of the ARMA process, and the innovations and their variance found by a Kalman filter based on Gardner et al. (1980). This has the option to switch to ‘fast recursions’ (assume an effectively infinite past) if the innovations variance is close enough to its asymptotic bound. The argument delta sets the tolerance: at its default value the approximation is normally negligible and the speed-up considerable. Exact computations can be ensured by setting delta to a negative value.

If transform.pars is true, the optimization is done using an alternative parametrization which is a variation on that suggested by Jones (1980) and ensures that the model is stationary. For an AR(p) model the parametrization is via the inverse tanh of the partial autocorrelations: the same procedure is applied (separately) to the AR and seasonal AR terms. The MA terms are also constrained to be invertible during optimization by the same transformation if transform.pars is true. Note that the MLE for MA terms does sometimes occur for MA polynomials with unit roots: such models can be fitted by using transform.pars = FALSE and specifying a good set of initial values (often obtainable from a fit with transform.pars = TRUE).

Missing values are allowed, but any missing values will force delta to be ignored and full recursions used. Note that missing values will be propagated by differencing, so the procedure used in this function is not fully efficient in that case.

Conditional sum-of-squares is provided mainly for expositional purposes. This computes the sum of squares of the fitted innovations from observation n.cond on, (where n.cond is at least the maximum lag of an AR term), treating all earlier innovations to be zero. Argument n.cond can be used to allow comparability between different fits. The ‘part log-likelihood’ is the first term, half the log of the estimated mean square. Missing values are allowed, but will cause many of the innovations to be missing.

When regressors are specified, they are orthogonalized prior to fitting unless any of the coefficients is fixed. It can be helpful to roughly scale the regressors to zero mean and unit variance.

Note

This is a preliminary version, and will be replaced by arima.

The standard errors of prediction exclude the uncertainty in the estimation of the ARMA model and the regression coefficients.
The results are likely to be different from S-PLUS’s arima.mle, which computes a conditional likelihood and does not include a mean in the model. Further, the convention used by arima.mle reverses the signs of the MA coefficients.

ARMAacf

Compute Theoretical ACF for an ARMA Process

Description

Compute the theoretical autocorrelation function or partial autocorrelation function for an ARMA process.
Usage

ARMAacf(ar = numeric(), ma = numeric(), lag.max = r, pacf = FALSE)

Arguments

ar          numeric vector of AR coefficients
ma          numeric vector of MA coefficients
lag.max     integer. Maximum lag required. Defaults to max(p, q+1), where p, q are the numbers of AR and MA terms respectively.
pacf        logical. Should the partial autocorrelations be returned?

Details

The methods used follow Brockwell & Davis (1991, section 3.3). Their equations (3.3.8) are solved for the autocovariances at lags 0, ..., max(p, q+1), and the remaining autocorrelations are given by a recursive filter.

Value

A vector of (partial) autocorrelations, named by the lags.

ARMAtOma  

Convert ARMA Process to Infinite MA Process

Description

Convert ARMA process to infinite MA process.

Usage

ARMAtOma(ar = numeric(), ma = numeric(), lag.max)

Arguments

ar    numeric vector of AR coefficients
ma    numeric vector of MA coefficients
lag.max    Largest MA(Inf) coefficient required.

Value

A vector of coefficients.

References

## answer (1 + 3*n)*2^(-n)
n <- 1:10; (1 + 3*n)*2^(-n)

as.hclust  

Convert Objects to Class hclust

Description

Converts objects from other hierarchical clustering functions to class "hclust".

Usage

as.hclust(x, ...)
Arguments

\[ \begin{align*}
  x & \quad \text{Hierarchical clustering object} \\
  \ldots & \quad \text{further arguments passed to or from other methods.}
\end{align*} \]

Details

Currently there is only support for converting objects of class "twins" as produced by the functions diana and agnes from the package \texttt{cluster}. The default method throws an error unless passed an "hclust" object.

Value

An object of class "hclust".

See Also

\texttt{hclust}, and from package \texttt{cluster}, \texttt{diana} and \texttt{agnes}

Examples

\begin{verbatim}
x <- matrix(rnorm(30), ncol = 3)
hc <- hclust(dist(x), method = "complete")

if(require("cluster", quietly = TRUE)) {
  # is a recommended package
  ag <- agnes(x, method = "complete")
  hca <- as.hclust(ag)
  # The dendrograms order slightly differently:
  op <- par(mfrow = c(1,2))
  plot(hc); mtext("hclust", side = 1)
  plot(hca); mtext("agnes", side = 1)
  detach("package:cluster")
}
\end{verbatim}

\[
\text{asOneSidedFormula} \quad \text{Convert to One-Sided Formula}
\]

Description

Names, expressions, numeric values, and character strings are converted to one-sided formulae. If object is a formula, it must be one-sided, in which case it is returned unaltered.

Usage

\texttt{asOneSidedFormula(object)}

Arguments

\[ \begin{align*}
  \text{object} & \quad \text{a one-sided formula, an expression, a numeric value, or a character string.}
\end{align*} \]

Value

a one-sided formula representing object
Group Averages Over Level Combinations of Factors

Description
Subsets of \( x[] \) are averaged, where each subset consist of those observations with the same factor levels.

Usage
\[
\text{ave}(x, \ldots, \text{FUN} = \text{mean})
\]

Arguments
- \( x \): A numeric.
- \( \ldots \): Grouping variables, typically factors, all of the same length as \( x \).
- \( \text{FUN} \): Function to apply for each factor level combination.

Value
A numeric vector, say \( y \) of length \( \text{length}(x) \). If \( \ldots \) is \( g1, g2 \), e.g., \( y[i] \) is equal to \( \text{FUN}(x[j]) \), for all \( j \) with \( g1[j] == g1[i] \) and \( g2[j] == g2[i] \).

See Also
- \texttt{mean}, \texttt{median}.

Examples
\[
\text{require(graphics)}
\]
\[
\text{ave}(1:3) \quad \# \text{ no grouping -> grand mean}
\]
\[
\text{attach(warpbreaks)}
\]
\[
\text{ave(breaks, wool)}
\]
\[
\text{ave(breaks, tension)}
\]
\[
\text{ave(breaks, tension, FUN = function(x) mean(x, trim = 0.1))}
\]
\[
\text{plot(breaks, main =}
\]
\[
"\text{ave(Warpbreaks ) for wool x tension combinations")}
\]
\[
\text{lines(ave(breaks, wool, tension ), type = "s", col = "blue")}
\]
Bandwidth Selectors for Kernel Density Estimation

Description

Bandwidth selectors for Gaussian kernels in density.

Usage

bw.nrd0(x)

bw.nrd(x)

bw.ucv(x, nb = 1000, lower = 0.1 * hmax, upper = hmax,
       tol = 0.1 * lower)

bw.bcv(x, nb = 1000, lower = 0.1 * hmax, upper = hmax,
       tol = 0.1 * lower)

bw.SJ(x, nb = 1000, lower = 0.1 * hmax, upper = hmax,
       method = c("ste", "dpi"), tol = 0.1 * lower)

Arguments

x         numeric vector.
nb        number of bins to use.
lower, upper range over which to minimize. The default is almost always satisfactory. hmax
          is calculated internally from a normal reference bandwidth.
method    either "ste" ("solve-the-equation") or "dpi" ("direct plug-in").
tol       for method "ste", the convergence tolerance for unirroot. The default leads to
          bandwidth estimates with only slightly more than one digit accuracy, which is
          sufficient for practical density estimation, but possibly not for theoretical simu-
          lation studies.

Details

bw.nrd0 implements a rule-of-thumb for choosing the bandwidth of a Gaussian kernel density
estimator. It defaults to 0.9 times the minimum of the standard deviation and the interquartile range
divided by 1.34 times the sample size to the negative one-fifth power (= Silverman’s ‘rule of thumb’,
Silverman (1986, page 48, eqn (3.31)) unless the quartiles coincide when a positive result will be
guaranteed.

bw.nrd is the more common variation given by Scott (1992), using factor 1.06.

bw.ucv and bw.bcv implement unbiased and biased cross-validation respectively.

bw.SJ implements the methods of Sheather & Jones (1991) to select the bandwidth using pilot
estimation of derivatives.
The algorithm for method "ste" solves an equation (via \texttt{unir\texttt{root}}) and because of that, enlarges the interval \(c(\text{lower}, \text{upper})\) when the boundaries were not user-specified and do not bracket the root.

**Value**

A bandwidth on a scale suitable for the \texttt{bw} argument of \texttt{density}.

**References**

**See Also**

\texttt{density}.

\texttt{bandwidth.nrd}, \texttt{ucv}, \texttt{bcv} and \texttt{width.SJ} in package \texttt{MASS}, which are all scaled to the width argument of \texttt{density} and so give answers four times as large.

**Examples**

```r
require(graphics)
plot(density(precip, n = 1000))
rug(precip)
lines(density(precip, bw = "nrd"), col = 2)
lines(density(precip, bw = "ucv"), col = 3)
lines(density(precip, bw = "bcv"), col = 4)
lines(density(precip, bw = "SJ-ste"), col = 5)
lines(density(precip, bw = "SJ-dpi"), col = 6)
legend(55, 0.035,
legend = c("nrd","nrd","ucv","bcv","SJ-ste","SJ-dpi"),
col = 1:6, lty = 1)
```

**bartlett.test**

\textit{Bartlett Test of Homogeneity of Variances}

**Description**

Performs Bartlett’s test of the null that the variances in each of the groups (samples) are the same.

**Usage**

```r
bartlett.test(x, ...)
```

## Default S3 method:
bartlett.test(x, g, ...)

## S3 method for class 'formula'
bartlett.test(formula, data, subset, na.action, ...)
Arguments

- `x`: a numeric vector of data values, or a list of numeric data vectors representing the respective samples, or fitted linear model objects (inheriting from class "lm").
- `g`: a vector or factor object giving the group for the corresponding elements of `x`. Ignored if `x` is a list.
- `formula`: a formula of the form `lhs ~ rhs` where `lhs` gives the data values and `rhs` the corresponding groups.
- `data`: an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- `subset`: an optional vector specifying a subset of observations to be used.
- `na.action`: a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- `...`: further arguments to be passed to or from methods.

Details

If `x` is a list, its elements are taken as the samples or fitted linear models to be compared for homogeneity of variances. In this case, the elements must either all be numeric data vectors or fitted linear model objects, `g` is ignored, and one can simply use `bartlett.test(x)` to perform the test. If the samples are not yet contained in a list, use `bartlett.test(list(x, ...))`.

Otherwise, `x` must be a numeric data vector, and `g` must be a vector or factor object of the same length as `x` giving the group for the corresponding elements of `x`.

Value

A list of class "htest" containing the following components:

- `statistic`: Bartlett's K-squared test statistic.
- `parameter`: the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- `p.value`: the p-value of the test.
- `method`: the character string "Bartlett test of homogeneity of variances".
- `data.name`: a character string giving the names of the data.

References

See Also

`var.test` for the special case of comparing variances in two samples from normal distributions; `fligner.test` for a rank-based (nonparametric) k-sample test for homogeneity of variances; `ansari.test` and `mood.test` for two rank based two-sample tests for difference in scale.
Examples

require(graphics)

plot(count ~ spray, data = InsectSprays)
bartlett.test(InsectSprays$count, InsectSprays$spray)
bartlett.test(count ~ spray, data = InsectSprays)

Beta Distribution

Description

Density, distribution function, quantile function and random generation for the Beta distribution with parameters shape1 and shape2 (and optional non-centrality parameter ncp).

Usage

dbeta(x, shape1, shape2, ncp = 0, log = FALSE)
pbeta(q, shape1, shape2, ncp = 0, lower.tail = TRUE, log.p = FALSE)
qbeta(p, shape1, shape2, ncp = 0, lower.tail = TRUE, log.p = FALSE)
rbeta(n, shape1, shape2, ncp = 0)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
shape1, shape2 positive parameters of the Beta distribution.
cp non-centrality parameter.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are P[X ≤ x], otherwise, P[X > x].

Details

The Beta distribution with parameters shape1 = a and shape2 = b has density

\[ f(x) = \frac{\Gamma(a + b)}{\Gamma(a)\Gamma(b)} x^{a-1}(1-x)^{b-1} \]

for a > 0, b > 0 and 0 ≤ x ≤ 1 where the boundary values at x = 0 or x = 1 are defined as by continuity (as limits).

The mean is a/(a + b) and the variance is \(ab/((a+b)^2(a+b+1))\).

pbeta is closely related to the incomplete beta function. As defined by Abramowitz and Stegun 6.6.1

\[ B_x(a,b) = \int_0^x t^{a-1}(1-t)^{b-1} dt, \]

and 6.6.2 \( I_x(a,b) = B_x(a,b)/B(a,b) \) where \( B(a,b) = B_1(a,b) \) is the Beta function (beta).

\( I_x(a,b) \) is pbeta(x, a, b).

The noncentral Beta distribution (with ncp = λ) is defined (Johnson et al, 1995, pp. 502) as the distribution of \( X/(X+Y) \) where \( X \sim \chi^2_{2a}(\lambda) \) and \( Y \sim \chi^2_{2b} \).
Value

dbeta gives the density, pbeta the distribution function, qbeta the quantile function, and rbeta generates random deviates.
Invalid arguments will result in return value NaN, with a warning.
The length of the result is determined by n for rbeta, and is the maximum of the lengths of the numerical parameters for the other functions.
The numerical parameters other than n are recycled to the length of the result. Only the first elements of the logical parameters are used.

Note

Supplying ncp = 0 uses the algorithm for the non-central distribution, which is not the same algorithm used if ncp is omitted. This is to give consistent behaviour in extreme cases with values of ncp very near zero.

Source

The central dbeta is based on a binomial probability, using code contributed by Catherine Loader (see dbinom) if either shape parameter is larger than one, otherwise directly from the definition. The non-central case is based on the derivation as a Poisson mixture of betas (Johnson et al, 1995, pp. 502–3).
The central pbeta uses a C translation (and enhancement for log_p = TRUE) of
The non-central pbeta uses a C translation of
Frick, H. (1990)’s AS R84, Appl. Statist, 39, 311–2, and
This computes the lower tail only, so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant.
The central case of qbeta is based on a C translation of
The central case of rbeta is based on a C translation of

binom.test

Exact Binomial Test

Description

Performs an exact test of a simple null hypothesis about the probability of success in a Bernoulli experiment.

Usage

binom.test(x, n, p = 0.5,
        alternative = c("two.sided", "less", "greater"),
        conf.level = 0.95)

Arguments

x number of successes, or a vector of length 2 giving the numbers of successes and failures, respectively.
n number of trials; ignored if x has length 2.
p hypothesized probability of success.
alternative indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter.
conf.level confidence level for the returned confidence interval.

Details

Confidence intervals are obtained by a procedure first given in Clopper and Pearson (1934). This guarantees that the confidence level is at least conf.level, but in general does not give the shortest-length confidence intervals.

Value

A list with class "htest" containing the following components:

statistic the number of successes.
parameter the number of trials.
p.value the p-value of the test.
conf.int a confidence interval for the probability of success.
estimate the estimated probability of success.
null.value the probability of success under the null, p.
alternative a character string describing the alternative hypothesis.
method the character string "Exact binomial test".
data.name a character string giving the names of the data.

References

See Also
*prop.test* for a general (approximate) test for equal or given proportions.

Examples
```r
## Under (the assumption of) simple Mendelian inheritance, a cross
## between plants of two particular genotypes produces progeny 1/4 of
## which are "dwarf" and 3/4 of which are "giant", respectively.
## In an experiment to determine if this assumption is reasonable, a
## cross results in progeny having 243 dwarf and 682 giant plants.
## If "giant" is taken as success, the null hypothesis is that p =
binom.test(c(682, 243), p = 3/4)
binom.test(682, 682 + 243, p = 3/4)  # The same.
## => Data are in agreement with the null hypothesis.
```

The Binomial Distribution

**Description**

Density, distribution function, quantile function and random generation for the binomial distribution with parameters size and prob.

**Usage**

```r
dbinom(x, size, prob, log = FALSE)
pbinom(q, size, prob, lower.tail = TRUE, log.p = FALSE)
qbinom(p, size, prob, lower.tail = TRUE, log.p = FALSE)
rbinom(n, size, prob)
```
Binomial

Arguments

- x, q: vector of quantiles.
- p: vector of probabilities.
- n: number of observations. If length(n) > 1, the length is taken to be the number required.
- size: number of trials (zero or more).
- prob: probability of success on each trial.
- log, log.p: logical; if TRUE, probabilities p are given as log(p).
- lower.tail: logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The binomial distribution with size = n and prob = p has density

\[ p(x) = \binom{n}{x} p^x (1 - p)^{n-x} \]

for \( x = 0, \ldots, n \). Note that binomial coefficients can be computed by `choose` in R.

If an element of x is not integer, the result of `dbinom` is zero, with a warning. \( p(x) \) is computed using Loader’s algorithm, see the reference below.

The quantile is defined as the smallest value \( x \) such that \( F(x) \geq p \), where \( F \) is the distribution function.

Value

dbinom gives the density, pbinom gives the distribution function, qbinom gives the quantile function and rbinom generates random deviates.

If size is not an integer, NaN is returned.

The length of the result is determined by n for rbinom, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than n are recycled to the length of the result. Only the first elements of the logical parameters are used.

Source

For dbinom a saddle-point expansion is used: see

pbinom uses pbeta.

qbinom uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.

rbinom (for size < .Machine$integer.max) is based on

For larger values it uses inversion.

Distributions for other standard distributions, including dnbinom for the negative binomial, and dpois for the Poisson distribution.

Examples

```r
require(graphics)

# Compute P(45 < X < 55) for X Binomial(100, 0.5)
sum(dbinom(46:54, 100, 0.5))

## Using "log = TRUE" for an extended range :
set.seed(1)

r <- seq(0, n, by = 20)
plot(r, dbinom(k, n, pi/10, log = TRUE), type = "l", ylab = "log density",
     main = "dbinom(*, log=TRUE) is better than log(dbinom(*))")
lines(r, log(dbinom(k, n, pi/10)), col = "red", lwd = 2)
## extreme points are omitted since dbinom gives 0.

mtext("dbinom(k, log=TRUE)", adj = 0)

mtext("extended range", adj = 0, line = -1, font = 4)

mtext("log(dbinom(k))", col = "red", adj = 1)
```

---

### biplot

**Biplot of Multivariate Data**

**Description**

Plot a biplot on the current graphics device.

**Usage**

```r
biplot(x, ...)  
```

**Arguments**

- `x` The biplot, a fitted object. For `biplot.default`, the first set of points (a two-column matrix), usually associated with observations.
- `y` The second set of points (a two-column matrix), usually associated with variables.
- `var.axes` If `TRUE` the second set of points have arrows representing them as (unscaled) axes.
- `col` A vector of length 2 giving the colours for the first and second set of points respectively (and the corresponding axes). If a single colour is specified it will be used for both sets. If missing the default colour is looked for in the `palette`: if there it and the next colour as used, otherwise the first two colours of the palette are used.
The character expansion factor used for labelling the points. The labels can be of different sizes for the two sets by supplying a vector of length two.

A vector of character strings to label the first set of points: the default is to use the row dimname of x, or 1:n if the dimname is NULL.

A vector of character strings to label the second set of points: the default is to use the row dimname of y, or 1:n if the dimname is NULL.

An expansion factor to apply when plotting the second set of points relative to the first. This can be used to tweak the scaling of the two sets to a physically comparable scale.

The length of the arrow heads on the axes plotted in var.axes is true. The arrow head can be suppressed by arrow.len = 0.

Limits for the x and y axes in the units of the first set of variables.

Graphical parameters.

A biplot is plot which aims to represent both the observations and variables of a matrix of multivariate data on the same plot. There are many variations on biplots (see the references) and perhaps the most widely used one is implemented by `biplot.princomp`. The function `biplot.default` merely provides the underlying code to plot two sets of variables on the same figure.

Graphical parameters can also be given to `biplot`: the size of `x` and `y` is controlled by `cex`.

A plot is produced on the current graphics device.

See Also

`biplot.princomp`, also for examples.

**Description**

Produces a biplot (in the strict sense) from the output of `princomp` or `prcomp`
Usage

## S3 method for class 'prcomp'
biplot(x, choices = 1:2, scale = 1, pc.biplot = FALSE, ...)

## S3 method for class 'princomp'
biplot(x, choices = 1:2, scale = 1, pc.biplot = FALSE, ...)

Arguments

- **x**: an object of class "prcomp".
- **choices**: length 2 vector specifying the components to plot. Only the default is a biplot in the strict sense.
- **scale**: The variables are scaled by \( \lambda \) and the observations are scaled by \( \lambda \) \( (1 - \text{scale}) \) where \( \lambda \) are the singular values as computed by `princomp`. Normally \( 0 \leq \text{scale} \leq 1 \), and a warning will be issued if the specified scale is outside this range.
- **pc.biplot**: If true, use what Gabriel (1971) refers to as a "principal component biplot", with \( \lambda = 1 \) and observations scaled up by \( \sqrt{n} \) and variables scaled down by \( \sqrt{n} \). Then inner products between variables approximate covariances and distances between observations approximate Mahalanobis distance.
- **...**: optional arguments to be passed to `biplot.default`.

Details

This is a method for the generic function `biplot`. There is considerable confusion over the precise definitions: those of the original paper, Gabriel (1971), are followed here. Gabriel and Odoroff (1990) use the same definitions, but their plots actually correspond to `pc.biplot = TRUE`.

Side Effects

A plot is produced on the current graphics device.

References

See Also

- `biplot`, `princomp`.

Examples

```r
require(graphics)
biplot(princomp(USArrests))
```
Description

Computes answers to a generalised birthday paradox problem. `pbirthday` computes the probability of a coincidence and `qbirthday` computes the smallest number of observations needed to have at least a specified probability of coincidence.

Usage

```r
qbirthday(prob = 0.5, classes = 365, coincident = 2)
pbirthday(n, classes = 365, coincident = 2)
```

Arguments

- `classes` How many distinct categories the people could fall into
- `prob` The desired probability of coincidence
- `n` The number of people
- `coincident` The number of people to fall in the same category

Details

The birthday paradox is that a very small number of people, 23, suffices to have a 50–50 chance that two or more of them have the same birthday. This function generalises the calculation to probabilities other than 0.5, numbers of coincident events other than 2, and numbers of classes other than 365.

The formula used is approximate for `coincident > 2`. The approximation is very good for moderate values of `prob` but less good for very small probabilities.

Value

- `qbirthday` Minimum number of people needed for a probability of at least `prob` that `k` or more of them have the same one out of `classes` equiprobable labels.
- `pbirthday` Probability of the specified coincidence.

Note

Prior to R 2.14.0 the approximate formula was used even for `coincident = 2`.

References

Examples

```r
require(graphics)

## the standard version
qbirthday() # 23
## probability of > 2 people with the same birthday
qbirthday(23, coincident = 3)

## examples from Diaconis & Mosteller p. 858.
## 'coincidence' is that husband, wife, daughter all born on the 16th
qbirthday(classes = 30, coincident = 3) # approximately 18
qbirthday(coincident = 4) # exact value 187
qbirthday(coincident = 10) # exact value 1181

## same 4-digit PIN number
qbirthday(classes = 10^4)

## 0.9 probability of three or more coincident birthdays
qbirthday(coincident = 3, prob = 0.9)

## Chance of 4 or more coincident birthdays in 150 people
qbirthday(150, coincident = 4)

## 100 or more coincident birthdays in 1000 people: very rare
qbirthday(1000, coincident = 100)
```

---

**Box.test**

**Box-Pierce and Ljung-Box Tests**

Description

Compute the Box–Pierce or Ljung–Box test statistic for examining the null hypothesis of independence in a given time series. These are sometimes known as ‘portmanteau’ tests.

Usage

```r
Box.test(x, lag = 1, type = c("Box-Pierce", "Ljung-Box"), fitdf = 0)
```

Arguments

- **x**: a numeric vector or univariate time series.
- **lag**: the statistic will be based on lag autocorrelation coefficients.
- **type**: test to be performed: partial matching is used.
- **fitdf**: number of degrees of freedom to be subtracted if x is a series of residuals.

Details

These tests are sometimes applied to the residuals from an ARMA(p, q) fit, in which case the references suggest a better approximation to the null-hypothesis distribution is obtained by setting `fitdf = p+q`, provided of course that `lag > fitdf`. 
Value

A list with class "htest" containing the following components:

- **statistic**: the value of the test statistic.
- **parameter**: the degrees of freedom of the approximate chi-squared distribution of the test statistic (taking `fitdf` into account).
- **p.value**: the p-value of the test.
- **method**: a character string indicating which type of test was performed.
- **data.name**: a character string giving the name of the data.

Note

Missing values are not handled.

Author(s)

A. Trapletti

References

Examples

```r
x <- rnorm(100)
Box.test(x, lag = 1)
Box.test(x, lag = 1, type = "Ljung")
```

Description

Sets the "contrasts" attribute for the factor.

Usage

```r
C(object, contr, how.many, ...)
```

Arguments

- **object**: a factor or ordered factor
- **contr**: which contrasts to use. Can be a matrix with one row for each level of the factor or a suitable function like `contr.poly` or a character string giving the name of the function
- **how.many**: the number of contrasts to set, by default one less than `nlevels(object)`.
- **...**: additional arguments for the function `contr`.
Details
For compatibility with S, contr can be treatment, helmert, sum or poly (without quotes) as shorthand for contr.treatment and so on.

Value
The factor object with the "contrasts" attribute set.

References

See Also
contrasts, contr.sum, etc.

Examples
## reset contrasts to defaults
options(contrasts = c("contr.treatment", "contr.poly"))
tens <- with(warpbreaks, C(tension, poly, 1))
attributes(tens)
## tension SHOULD be an ordered factor, but as it is not we can use
aov(breaks ~ wool + tens + tension, data = warpbreaks)

## show the use of ... The default contrast is contr.treatment here
summary(lm(breaks ~ wool + C(tension, base = 2), data = warpbreaks))

# following on from help(esoph)
model3 <- glm(cbind(ncases, ncontrols) ~ agegp + C(tobgp, , 1) +
               C(alcgp, , 1), data = esoph, family = binomial())
summary(model3)

---

cancor  Canonical Correlations

Description
Compute the canonical correlations between two data matrices.

Usage
cancor(x, y, xcenter = TRUE, ycenter = TRUE)

Arguments
x numeric matrix \((n \times p_1)\), containing the x coordinates.
y numeric matrix \((n \times p_2)\), containing the y coordinates.
cancor

xcenter logical or numeric vector of length \( p_1 \), describing any centering to be done on the x values before the analysis. If \( \text{TRUE} \) (default), subtract the column means. If \( \text{FALSE} \), do not adjust the columns. Otherwise, a vector of values to be subtracted from the columns.

ycenter analogous to xcenter, but for the y values.

Details

The canonical correlation analysis seeks linear combinations of the y variables which are well explained by linear combinations of the x variables. The relationship is symmetric as ‘well explained’ is measured by correlations.

Value

A list containing the following components:

- cor correlations.
- xcoef estimated coefficients for the x variables.
- ycoef estimated coefficients for the y variables.
- xcenter the values used to adjust the x variables.
- ycenter the values used to adjust the x variables.

References

qr, svd.

Examples

```r
# signs of results are random
pop <- LifeCycleSavings[, 2:3]
oec <- LifeCycleSavings[, -(2:3)]
cancor(pop, oec)

x <- matrix(rnorm(150), 50, 3)
y <- matrix(rnorm(250), 50, 5)
cxy <- cancor(x, y)
all(abs(cor(x, y) - xcoef, y) < 1e-15)
all(abs(cor(x, y) - ycoef)[1:3 - diag(cxy cor) < 1e-15])
all(abs(cor(x, y) - diag(3)) < 1e-15)
all(abs(cor(y, x) - diag(5)) < 1e-15)
```
case+variable.names  

Case and Variable Names of Fitted Models

Description

Simple utilities returning (non-missing) case names, and (non-eliminated) variable names.

Usage

```r
case.names(object, ...)  
## S3 method for class 'lm'

variable.names(object, ...)  
## S3 method for class 'lm'
```

Arguments

- `object` : an R object, typically a fitted model.
- `full` : logical; if `TRUE`, all names (including zero weights, ...) are returned.
- `...` : further arguments passed to or from other methods.

Value

A character vector.

See Also

- `lm`; further, `all.names`, `all.vars` for functions with a similar name but only slightly related purpose.

Examples

```r
x <- 1:20
y <- setNames(x + (x/4 - 2)^3 + rnorm(20, sd = 3),
               paste("0", x, sep = "."))
ww <- rep(1, 20); ww[13] <- 0
summary(lmxy <- lm(y ~ x + I(x^2)+I(x^3) + I((x-10)^2), weights = ww),
         cor = TRUE)

variable.names(lmxy)
variable.names(lmxy, full = TRUE)  # includes the last

case.names(lmxy)

case.names(lmxy, full = TRUE)  # includes the 0-weight case
```
The Cauchy Distribution

Description
Density, distribution function, quantile function and random generation for the Cauchy distribution with location parameter location and scale parameter scale.

Usage
- `dcauchy(x, location = 0, scale = 1, log = FALSE)`
- ` pcauchy(q, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)`
- `qcauchy(p, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)`
- `rcauchy(n, location = 0, scale = 1)`

Arguments
- `x, q` vector of quantiles.
- `p` vector of probabilities.
- `n` number of observations. If `length(n) > 1`, the length is taken to be the number required.
- `location, scale` location and scale parameters.
- `log, log.p` logical; if TRUE, probabilities p are given as log(p).
- `lower.tail` logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details
If `location` or `scale` are not specified, they assume the default values of 0 and 1 respectively.

The Cauchy distribution with location $l$ and scale $s$ has density

$$f(x) = \frac{1}{\pi s} \left(1 + \left(\frac{x - l}{s}\right)^2\right)^{-1}$$

for all $x$.

Value
dcauchy, pcauchy, and qcauchy are respectively the density, distribution function and quantile function of the Cauchy distribution. rcauchy generates random deviates from the Cauchy.

The length of the result is determined by `n` for rcauchy, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than `n` are recycled to the length of the result. Only the first elements of the logical parameters are used.

Source
dcauchy, pcauchy and qcauchy are all calculated from numerically stable versions of the definitions.

rcauchy uses inversion.

---

**chisq.test**  
*Pearson’s Chi-squared Test for Count Data*

Description

chisq.test performs chi-squared contingency table tests and goodness-of-fit tests.

Usage

chisq.test(x, y = NULL, correct = TRUE,  
              p = rep(1/length(x), length(x)), rescale.p = FALSE,  
              simulate.p.value = FALSE, B = 2000)

Arguments

- **x**: a numeric vector or matrix. *x* and *y* can also both be factors.
- **y**: a numeric vector; ignored if *x* is a matrix. If *x* is a factor, *y* should be a factor of the same length.
- **correct**: a logical indicating whether to apply continuity correction when computing the test statistic for 2 by 2 tables: one half is subtracted from all \(|O - E|\) differences; however, the correction will not be bigger than the differences themselves. No correction is done if simulate.p.value = TRUE.
- **p**: a vector of probabilities of the same length of *x*. An error is given if any entry of *p* is negative.
- **rescale.p**: a logical scalar; if TRUE then *p* is rescaled (if necessary) to sum to 1. If rescale.p is FALSE, and *p* does not sum to 1, an error is given.
- **simulate.p.value**: a logical indicating whether to compute *p*-values by Monte Carlo simulation.
- **B**: an integer specifying the number of replicates used in the Monte Carlo test.
Details

If \( x \) is a matrix with one row or column, or if \( x \) is a vector and \( y \) is not given, then a **goodness-of-fit test** is performed (\( x \) is treated as a one-dimensional contingency table). The entries of \( x \) must be non-negative integers. In this case, the hypothesis tested is whether the population probabilities equal those in \( p \), or are all equal if \( p \) is not given.

If \( x \) is a matrix with at least two rows and columns, it is taken as a two-dimensional contingency table: the entries of \( x \) must be non-negative integers. Otherwise, \( x \) and \( y \) must be vectors or factors of the same length; cases with missing values are removed, the objects are coerced to factors, and the contingency table is computed from these. Then Pearson’s chi-squared test is performed of the null hypothesis that the joint distribution of the cell counts in a 2-dimensional contingency table is the product of the row and column marginals.

If `simulate.p.value` is `FALSE`, the p-value is computed from the asymptotic chi-squared distribution of the test statistic; continuity correction is only used in the 2-by-2 case (if `correct` is `TRUE`, the default). Otherwise the p-value is computed for a Monte Carlo test (Hope, 1968) with \( B \) replicates.

In the contingency table case simulation is done by random sampling from the set of all contingency tables with given marginals, and works only if the marginals are strictly positive. Continuity correction is never used, and the statistic is quoted without it. Note that this is not the usual sampling situation assumed for the chi-squared test but rather that for Fisher’s exact test.

In the goodness-of-fit case simulation is done by random sampling from the discrete distribution specified by \( p \), each sample being of size \( n = \text{sum}(x) \). This simulation is done in \( R \) and may be slow.

Value

A list with class "htest" containing the following components:

- `statistic` the value the chi-squared test statistic.
- `parameter` the degrees of freedom of the approximate chi-squared distribution of the test statistic, \( NA \) if the p-value is computed by Monte Carlo simulation.
- `p.value` the p-value for the test.
- `method` a character string indicating the type of test performed, and whether Monte Carlo simulation or continuity correction was used.
- `data.name` a character string giving the name(s) of the data.
- `observed` the observed counts.
- `expected` the expected counts under the null hypothesis.
- `residuals` the Pearson residuals, \((\text{observed} - \text{expected}) / \sqrt{\text{expected}}\).
- `stdres` standardized residuals, \((\text{observed} - \text{expected}) / \sqrt{V}\), where \( V \) is the residual cell variance (Agresti, 2007, section 2.4.5 for the case where \( x \) is a matrix, \( n \times p \times (1 - p) \) otherwise).

Source

The code for Monte Carlo simulation is a C translation of the Fortran algorithm of Patefield (1981).

References

**See Also**

For goodness-of-fit testing, notably of continuous distributions, *ks.test*.

**Examples**

```r
## From Agresti(2007) p.39
M <- as.table( rbind(c(762, 327, 468), c(484, 239, 477))
dimnames(M) <- list(gender=c("M","F"),
                    party=c("Democrat","Independent", "Republican"))
(Xsq <- chisq.test(M))  # Prints test summary
Xsq$observed  # observed counts (same as M)
Xsq$expected  # expected counts under the null
Xsq$residuals # Pearson residuals
Xsq$stdres   # standardized residuals

## Effect of simulating p-values
x <- matrix(c(12, 5, 7, 7), ncol = 2)
chisq.test(x)$p.value                # 0.4233
chisq.test(x, simulate.p.value = TRUE, B = 10000)$p.value
# around 0.29!

## Testing for population probabilities
## Case A. Tabulated data
x <- c(A = 20, B = 15, C = 25)
chisq.test(x)
chisq.test(as.table(x))              # the same
x <- c(89,37,30,28,2)
p <- c(40,20,20,15,5)
try{
  chisq.test(x, p = p)               # gives an error
}
chisq.test(x, p = p, rescale.p = TRUE)
# works
p <- c(0.40,0.20,0.20,0.19,0.01)
# Expected count in category 5
# is 1.86 < 5 ==> chi square approx.
# maybe doubtful, but is ok!
chisq.test(x, p = p)
chisq.test(x, p = p, simulate.p.value = TRUE)

## Case B. Raw data
x <- trunc(5 * runif(100))
chisq.test(table(x))          # NOT 'chisq.test(x)'!
```

**Chisquare**

*The (non-central) Chi-Squared Distribution*
**Description**

Density, distribution function, quantile function and random generation for the chi-squared (χ²) distribution with df degrees of freedom and optional non-centrality parameter ncp.

**Usage**

- `dchisq(x, df, ncp = 0, log = FALSE)`
- `pchisq(q, df, ncp = 0, lower.tail = TRUE, log.p = FALSE)`
- `qchisq(p, df, ncp = 0, lower.tail = TRUE, log.p = FALSE)`
- `rchisq(n, df, ncp = 0)`

**Arguments**

- `x, q` vector of quantiles.
- `p` vector of probabilities.
- `n` number of observations. If `length(n) > 1`, the length is taken to be the number required.
- `df` degrees of freedom (non-negative, but can be non-integer).
- `ncp` non-centrality parameter (non-negative).
- `log, log.p` logical; if TRUE, probabilities p are given as log(p).
- `lower.tail` logical; if TRUE (default), probabilities are `P[X ≤ x]`, otherwise, `P[X > x]`.

**Details**

The chi-squared distribution with df = n ≥ 0 degrees of freedom has density

\[ f_n(x) = \frac{1}{2^{n/2} \Gamma(n/2)} x^{n/2 - 1} e^{-x/2} \]

for x > 0. The mean and variance are n and 2n.

The non-central chi-squared distribution with df = n degrees of freedom and non-centrality parameter ncp = λ has density

\[ f(x) = e^{-\lambda/2} \sum_{r=0}^{\infty} \frac{(\lambda/2)^r}{r!} f_{n+2r}(x) \]

for x ≥ 0. For integer n, this is the distribution of the sum of squares of n normals each with variance one, λ being the sum of squares of the normal means; further, \( E(X) = n + \lambda \), \( Var(X) = 2(n + 2 \ast \lambda) \), and \( E((X - E(X))^3) = 8(n + 3 \ast \lambda) \).

Note that the degrees of freedom df = n, can be non-integer, and also n = 0 which is relevant for non-centrality λ > 0, see Johnson et al. (1995, chapter 29).

Note that ncp values larger than about 1e5 may give inaccurate results with many warnings for pchisq and qchisq.

**Value**

dchisq gives the density, pchisq gives the distribution function, qchisq gives the quantile function, and rchisq generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by n for rchisq, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than n are recycled to the length of the result. Only the first elements of the logical parameters are used.
Note

Supplying \(\text{ncp} = 0\) uses the algorithm for the non-central distribution, which is not the same algorithm used if \(\text{ncp}\) is omitted. This is to give consistent behaviour in extreme cases with values of \(\text{ncp}\) very near zero.

The code for non-zero \(\text{ncp}\) is principally intended to be used for moderate values of \(\text{ncp}\): it will not be highly accurate, especially in the tails, for large values.

Source

The central cases are computed via the gamma distribution. The non-central \(\text{dchisq}\) and \(\text{rchisq}\) are computed as a Poisson mixture central of chi-squares (Johnson et al, 1995, p.436).

which computes the lower tail only (so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant).

The non-central \(\text{qchisq}\) is based on inversion of \(\text{pchisq}\).

References

See Also

\texttt{Distributions} for other standard distributions.

A central chi-squared distribution with \(n\) degrees of freedom is the same as a Gamma distribution with shape \(\alpha = n/2\) and scale \(\sigma = 2\). Hence, see \texttt{dgamma} for the Gamma distribution.

Examples

```r
require(graphics)
dchisq(1, df = 1:3)
pchisq(1, df = 3)
pchisq(1, df = 3, ncp = 0:4) # includes the above

x <- 1:10
## Chi-squared(df = 2) is a special exponential distribution
all.equal(dchisq(x, df = 2), dexp(x, 1/2))
all.equal(pchisq(x, df = 2), pexp(x, 1/2))

## non-central RNG -- df = 0 with ncp > 0: Z0 has point mass at 0!
z0 <- rchisq(100, df = 0, ncp = 2.)
graphics::stem(z0)

## Not run: ## visual testing
## do P-P plots for 1000 points at various degrees of freedom
```
cmdsca

Classical (Metric) Multidimensional Scaling

Description

Classical multidimensional scaling of a data matrix. Also known as principal coordinates analysis (Gower, 1966).

Usage

```r
cmdsca(d, k = 2, eig = FALSE, add = FALSE, x.ret = FALSE)
```

Arguments

d a distance structure such as that returned by `dist` or a full symmetric matrix containing the dissimilarities.

k the maximum dimension of the space which the data are to be represented in; must be in \{1, 2, \ldots, n - 1\}.

eig indicates whether eigenvalues should be returned.

add logical indicating if an additive constant \(c_\star\) should be computed, and added to the non-diagonal dissimilarities such that the modified dissimilarities are Euclidean.

x.ret indicates whether the doubly centred symmetric distance matrix should be returned.
Details

Multidimensional scaling takes a set of dissimilarities and returns a set of points such that the distances between the points are approximately equal to the dissimilarities. (It is a major part of what ecologists call ‘ordination’.)

A set of Euclidean distances on \( n \) points can be represented exactly in at most \( n - 1 \) dimensions. \texttt{cmdscale} follows the analysis of Mardia (1978), and returns the best-fitting \( k \)-dimensional representation, where \( k \) may be less than the argument \( k \).

The representation is only determined up to location (\texttt{cmdscale} takes the column means of the configuration to be at the origin), rotations and reflections. The configuration returned is given in principal-component axes, so the reflection chosen may differ between \texttt{R} platforms (see \texttt{prcomp}).

When \texttt{add = TRUE}, a minimal additive constant \( c^* \) is computed such that the the dissimilarities \( d_{ij} + c^* \) are Euclidean and hence can be represented in \( n - 1 \) dimensions. Whereas \texttt{S} (Becker et al., 1988) computes this constant using an approximation suggested by Torgerson, \texttt{R} uses the analytical solution of Cailliez (1983), see also Cox and Cox (2001). Note that because of numerical errors the computed eigenvalues need not all be non-negative, and even theoretically the representation could be in fewer than \( n - 1 \) dimensions.

Value

If \texttt{eig = FALSE}, \texttt{add = FALSE} and \texttt{x.ret = FALSE} (default), a matrix with \( k \) columns whose rows give the coordinates of the points chosen to represent the dissimilarities.

Otherwise, a list containing the following components.

- **points**: a matrix with up to \( k \) columns whose rows give the coordinates of the points chosen to represent the dissimilarities.
- **eig**: the \( n \) eigenvalues computed during the scaling process if \texttt{eig} is true. **NB**: versions of \texttt{R} before 2.12.1 returned only \( k \) but were documented to return \( n - 1 \).
- **x**: the doubly centered distance matrix if \texttt{x.ret} is true.
- **ac**: the additive constant \( c^* \), 0 if \texttt{add} = \texttt{FALSE}.
- **GOF**: a numeric vector of length 2, equal to say \((g_1, g_2)\), where \( g_i = (\sum_{j=1}^k \lambda_j^i) / (\sum_{j=1}^n T_i(\lambda_j)) \), where \( \lambda_j \) are the eigenvalues (sorted in decreasing order), \( T_1(v) = |v| \), and \( T_2(v) = \max(v, 0) \).

isoMDS and sammon in package MASS provide alternative methods of multidimensional scaling.

Examples

require(graphics)

loc <- cmdscale(euclidist)
x <- loc[, 1]
y <- -loc[, 2] # reflect so North is at the top
## note asp = 1, to ensure Euclidean distances are represented correctly
plot(x, y, type = "n", xlab = "", ylab = "", asp = 1, axes = FALSE,
     main = "cmdscale(euclidist)"
     text(x, y, rownames(loc), cex = 0.6)

coef

Extract Model Coefficients

Description

coeff is a generic function which extracts model coefficients from objects returned by modeling functions. coefficients is an alias for it.

Usage

coeff(object, ...)
coefficients(object, ...)

Arguments

object an object for which the extraction of model coefficients is meaningful.
... other arguments.

Details

All object classes which are returned by model fitting functions should provide a coef method or use the default one. (Note that the method is for coef and not coefficients.) Class "aov" has a coef method that does not report aliased coefficients (see alias).

Value

Coefficients extracted from the model object object.
For standard model fitting classes this will be a named numeric vector.

References

See Also

fitted.values and residuals for related methods; glm, lm for model fitting.

Examples

```r
x <- 1:5; coef(lm(c(1:3, 7, 6) ~ x))
```

---

### complete.cases

**Find Complete Cases**

**Description**

Return a logical vector indicating which cases are complete, i.e., have no missing values.

**Usage**

```r
complete.cases(...)```

**Arguments**

... a sequence of vectors, matrices and data frames.

**Value**

A logical vector specifying which observations/rows have no missing values across the entire sequence.

**See Also**

is.na, na.omit, na.fail.

**Examples**

```r
x <- airquality[, -1] # x is a regression design matrix
y <- airquality[, 1] # y is the corresponding response
stopifnot(complete.cases(y) != is.na(y))
ok <- complete.cases(x, y)
sum(!ok) # how many are not "ok"?
x <- x[ok,]
y <- y[ok]
```
Description

Computes confidence intervals for one or more parameters in a fitted model. There is a default and a method for objects inheriting from class "lm".

Usage

confint(object, parm, level = 0.95, ...)

Arguments

object  a fitted model object.
parm    a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.
level   the confidence level required.
...     additional argument(s) for methods.

Details

confint is a generic function. The default method assumes asymptotic normality, and needs suitable coef and vcov methods to be available. The default method can be called directly for comparison with other methods.

For objects of class "lm" the direct formulae based on t values are used.

There are stub methods for classes "glm" and "nls" which invoke those in package MASS which are based on profile likelihoods.

Value

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1-level)/2 and 1 - (1-level)/2 in % (by default 2.5% and 97.5%).

See Also

confint.glm and confint.nls in package MASS.

Examples

fit <- lm(mpg ~ disp + hp + wt + am, data = mtcars)
confint(fit)
confint(fit, "wt")

## from example(glm)
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3, 1, 9); treatment <- gl(3, 3)
glm.093 <- glm(counts ~ outcome + treatment, family = poisson())
confint(glm.093) # needs MASS to be present on the system
confint.default(glm.093) # based on asymptotic normality
**Description**

Minimise a function subject to linear inequality constraints using an adaptive barrier algorithm.

**Usage**

```r
cstrOptim(theta, f, grad, ui, ci, mu = 1e-04, control = list(),
  method = if(is.null(grad)) "Nelder-Mead" else "BFGS",
  outer.iterations = 100, outer.eps = 1e-05, ..., 
  hessian = FALSE)
```

**Arguments**

- `theta`: numeric (vector) starting value (of length `p`): must be in the feasible region.
- `f`: function to minimise (see below).
- `grad`: gradient of `f` (a function as well), or NULL (see below).
- `ui`: constraint matrix (`k` × `p`), see below.
- `ci`: constraint vector of length `k` (see below).
- `mu`: (Small) tuning parameter.
- `control`, `method`, `hessian`: passed to `optim`.
- `outer.iterations`: iterations of the barrier algorithm.
- `outer.eps`: non-negative number; the relative convergence tolerance of the barrier algorithm.
- `...`: Other named arguments to be passed to `f` and `grad`: needs to be passed through `optim` so should not match its argument names.

**Details**

The feasible region is defined by `ui %*% theta - ci >= 0`. The starting value must be in the interior of the feasible region, but the minimum may be on the boundary.

A logarithmic barrier is added to enforce the constraints and then `optim` is called. The barrier function is chosen so that the objective function should decrease at each outer iteration. Minima in the interior of the feasible region are typically found quite quickly, but a substantial number of outer iterations may be needed for a minimum on the boundary.

The tuning parameter `mu` multiplies the barrier term. Its precise value is often relatively unimportant. As `mu` increases the augmented objective function becomes closer to the original objective function but also less smooth near the boundary of the feasible region.

Any `optim` method that permits infinite values for the objective function may be used (currently all but "L-BFGS-B").

The objective function `f` takes as first argument the vector of parameters over which minimisation is to take place. It should return a scalar result. Optional arguments `...` will be passed to `optim`
and then (if not used by `optim`) to \( f \). As with `optim`, the default is to minimise, but maximisation can be performed by setting `control$funscale` to a negative value.

The gradient function `grad` must be supplied except with `method = "Nelder-Mead"`. It should take arguments matching those of \( f \) and return a vector containing the gradient.

### Value

As for `optim`, but with two extra components: `barrier.value` giving the value of the barrier function at the optimum and `outer.iterations` gives the number of outer iterations (calls to `optim`). The `counts` component contains the `sum` of all `optim()`$counts.

`optim`, especially `method = "L-BFGS-B"` which does box-constrained optimisation.

### Examples

```r
## from optim
fr <- function(x) {  # Rosenbrock Banana function
  x1 <- x[1]
  x2 <- x[2]
  100 * (x2 - x1 * x1)^2 + (1 - x1)^2
}
grr <- function(x) {  # Gradient of 'fr'
  x1 <- x[1]
  x2 <- x[2]
  c(-400 * x1 * (x2 - x1 * x1) - 2 * (1 - x1),
    200 * (x2 - x1 * x1))
}
optim(c(-1.2, 1), fr, grr)
# Box-constraint, optimum on the boundary
constrOptim(c(-1.2, 0.9), fr, grr, ui = rbind(c(-1, 0), c(0, -1)), ci = c(-1, -1))
  # x <= 0.9, y - x > 0.1
constrOptim(c(0.5, 0), fr, grr, ui = rbind(c(-1, 0), c(1, -1)), ci = c(-0.9, 0.1))

## Solves linear and quadratic programming problems
## but needs a feasible starting value
# # from example(solve.QP) in 'quadprog'
# no derivative
fQP <- function(b) (-sum(c(0, 5, 0) * b) + 0.5 * sum(b * b))
Amat <- matrix(c(-4, -3, 0, 2, 1, 0, 0, -2, 1), 3, 3)
bvec <- c(-8, 2, 0)
constrOptim(c(2, -1, -1), fQP, NULL, ui = t(Amat), ci = bvec)
# derivative
gQP <- function(b) (-c(0, 5, 0) * b)
constrOptim(c(2, -1, -1), fQP, gQP, ui = t(Amat), ci = bvec)
# # Now with maximisation instead of minimisation
hQP <- function(b) (sum(c(0, 5, 0) * b) - 0.5 * sum(b * b))
```
contrOptim(c(2,-1,-1), hQP, NULL, ui = t(Amat), ci = bvec, 
control = list(fnscale = -1))

Contrast Matrices

Description

Return a matrix of contrasts.

Usage

contr.helmert(n, contrasts = TRUE, sparse = FALSE)
contr.poly(n, scores = 1:n, contrasts = TRUE, sparse = FALSE)
contr.sum(n, contrasts = TRUE, sparse = FALSE)
contr.treatment(n, base = 1, contrasts = TRUE, sparse = FALSE)
contr.SAS(n, contrasts = TRUE, sparse = FALSE)

Arguments

n a vector of levels for a factor, or the number of levels.
contrasts a logical indicating whether contrasts should be computed.
sparse logical indicating if the result should be sparse (of class
Matrix).
scores the set of values over which orthogonal polynomials are to be computed.
base an integer specifying which group is considered the baseline group. Ignored if
contrasts is FALSE.

details

These functions are used for creating contrast matrices for use in fitting analysis of variance and
regression models. The columns of the resulting matrices contain contrasts which can be used for
coding a factor with n levels. The returned value contains the computed contrasts. If the argument
contrasts is FALSE a square indicator matrix (the dummy coding) is returned except for
contr.poly (which includes the 0-degree, i.e. constant, polynomial when contrasts = FALSE).
contr.helmert returns Helmert contrasts, which contrast the second level with the first, the third
with the average of the first two, and so on. contr.poly returns contrasts based on orthogonal
polynomials. contr.sum uses ‘sum to zero contrasts’.
contr.treatment contrasts each level with the baseline level (specified by base): the baseline
level is omitted. Note that this does not produce ‘contrasts’ as defined in the standard theory for
linear models as they are not orthogonal to the intercept.
contr.SAS is a wrapper for contr.treatment that sets the base level to be the last level of the
factor. The coefficients produced when using these contrasts should be equivalent to those produced
by many (but not all) SAS procedures.

For consistency, sparse is an argument to all these contrast functions, however sparse = TRUE for
contr.poly is typically pointless and is rarely useful for contr.helmert.
contrasts

Value

A matrix with \( n \) rows and \( k \) columns, with \( k = n - 1 \) if contrasts is TRUE and \( k = n \) if contrasts is FALSE.

References

See Also

ccontrasts, C, and aov, glm, lm.

Examples

```r
(cH <- contr.helmert(4))
apply(cH, 2, sum) # column sums are 0
crossprod(cH) # diagonal -- columns are orthogonal
contr.helmert(4, contrasts = FALSE) # just the 4 x 4 identity matrix

(cT <- contr.treatment(5))
all(crossprod(cT) == diag(4)) # TRUE: orthonormal

(cT. <- contr.SAS(5))
all(crossprod(cT.) == diag(4)) # TRUE

zapsmall(cP <- contr.poly(3)) # Linear and Quadratic
zapsmall(crossprod(cP), digits = 15) # orthonormal up to fuzz
```

contrasts

Get and Set Contrast Matrices

Description

Set and view the contrasts associated with a factor.

Usage

```r
contrasts(x, contrasts = TRUE, sparse = FALSE)
contrasts(x, how.many) <- value
```

Arguments

- **x**: a factor or a logical variable.
- **contrasts**: logical. See ‘Details’.
- **sparse**: logical indicating if the result should be sparse (of class dgCMatrix), using package Matrix.
- **how.many**: How many contrasts should be made. Defaults to one less than the number of levels of \( x \). This need not be the same as the number of columns of \( value \).
- **value**: either a numeric matrix (or a sparse or dense matrix of a class extending dMatrix from package Matrix) whose columns give coefficients for contrasts in the levels of \( x \), or the (quoted) name of a function which computes such matrices.
Details

If contrasts are not set for a factor the default functions from `options("contrasts")` are used.
A logical vector `x` is converted into a two-level factor with levels c(FALSE, TRUE) (regardless of which levels occur in the variable).

The argument `contrasts` is ignored if `x` has a matrix `contrasts` attribute set. Otherwise if `contrasts = TRUE` it is passed to a contrasts function such as `contr.treatment` and if `contrasts = FALSE` an identity matrix is returned. Suitable functions have a first argument which is the character vector of levels, a named argument `contrasts` (always called with `contrasts = TRUE`) and optionally from R 2.10.0 a logical argument `sparse`.

If `value` supplies more than how many contrasts, the first how many are used. If too few are supplied, a suitable contrast matrix is created by extending `value` after ensuring its columns are contrasts (orthogonal to the constant term) and not collinear.

References

See Also

`C`, `contr.helmert`, `contr.poly`, `contr.sum`, `contr.treatment`: `glm`, `aov`, `lm`.

Examples

```r
utils::example(factor)
fff <- ff[, drop = TRUE] # reduce to 5 levels.
contrasts(fff) # treatment contrasts by default
contrasts(C(fff, sum))
contrasts(fff, contrasts = FALSE) # the 5x5 identity matrix

contrasts(fff) <- contr.sum(5); contrasts(fff) # set sum contrasts
contrasts(fff, 2) <- contr.sum(5); contrasts(fff) # set 2 contrasts
# supply 2 contrasts, compute 2 more to make full set of 4.
contrasts(fff) <- contr.sum(5)[, 1:2]; contrasts(fff)

## using sparse contrasts: % useful, once model.matrix() works with these:
ffs <- fff
contrasts(ffs) <- contr.sum(5, sparse = TRUE)[, 1:2]; contrasts(ffs)
ostifnot(all.equal(ffs, fff))
contrasts(ffs) <- contr.sum(5, sparse = TRUE); contrasts(ffs)
```

---

The `convolve` function is used for the Fast Fourier Transform to compute the several kinds of convolutions of two sequences.

### Usage

```r
convolve(x, y, conj = TRUE, type = c("circular", "open", "filter"))
```
**Arguments**

- `x, y` numeric sequences of the same length to be convolved.
- `conj` logical; if TRUE, take the complex conjugate before back-transforming (default, and used for usual convolution).
- `type` character; one of "circular", "open", "filter" (beginning of word is ok). For circular, the two sequences are treated as circular, i.e., periodic.
  For open and filter, the sequences are padded with 0s (from left and right) first; "filter" returns the middle sub-vector of "open", namely, the result of running a weighted mean of `x` with weights `y`.

**Details**

The Fast Fourier Transform, `fft`, is used for efficiency.

The input sequences `x` and `y` must have the same length if circular is true.

Note that the usual definition of convolution of two sequences `x` and `y` is given by `convolve(x, rev(y), type = "o")`.

**Value**

If `r <- convolve(x, y, type = "open")` and `n <- length(x), m <- length(y)`, then

\[
 r_k = \sum_i x_{k-m+i} y_i
\]

where the sum is over all valid indices `i`, for `k = 1, \ldots, n + m - 1`.

If `type == "circular", n = m` is required, and the above is true for `i, k = 1, \ldots, n` when `x_j := x_{n+j}` for `j < 1`.

**References**

**See Also**

`fft`, `nextn`, and particularly `filter` (from the `stats` package) which may be more appropriate.

**Examples**

```r
require(graphics)
x <- c(0,0,0,100,0,0,0)
y <- c(0,0,1,2,1,0,0)/4
zapsmall(convolve(x, y)) # *NOT* what you first thought.
zapsmall(convolve(x, y[3:5], type = "f")) # rather
x <- rnorm(50)
y <- rnorm(50)
# Circular convolution *has* this symmetry:
all.equal(convolve(x, y, conj = FALSE), rev(convolve(rev(y), x)))

n <- length(x <- -20:24)
y <- (x-10)^2/1000 + rnorm(x)/8
```
cophenetic

Cophenetic Distances for a Hierarchical Clustering

Description

Computes the cophenetic distances for a hierarchical clustering.

Usage

cophenetic(x)

## Default S3 method:
cophenetic(x)

## S3 method for class 'dendrogram'
cophenetic(x)

Arguments

x an R object representing a hierarchical clustering. For the default method, an object of class "hclust" or with a method for as.hclust() such as "agnes" in package cluster.

Details

The cophenetic distance between two observations that have been clustered is defined to be the intergroup dissimilarity at which the two observations are first combined into a single cluster. Note that this distance has many ties and restrictions.

It can be argued that a dendrogram is an appropriate summary of some data if the correlation between the original distances and the cophenetic distances is high. Otherwise, it should simply be viewed as the description of the output of the clustering algorithm.

cophenetic is a generic function. Support for classes which represent hierarchical clusterings (total indexed hierarchies) can be added by providing an as.hclust() or, more directly, a cophenetic() method for such a class.

The method for objects of class "dendrogram" requires that all leaves of the dendrogram object have non-null labels.

Value

An object of class "dist".

cor

Correlation, Variance and Covariance (Matrices)

Description

var, cov and cor compute the variance of x and the covariance or correlation of x and y if these are vectors. If x and y are matrices then the covariances (or correlations) between the columns of x and the columns of y are computed.

cov2cor scales a covariance matrix into the corresponding correlation matrix efficiently.

Usage

var(x, y = NULL, na.rm = FALSE, use)

cov(x, y = NULL, use = "everything",
    method = c("pearson", "kendall", "spearman"))

cor(x, y = NULL, use = "everything",
    method = c("pearson", "kendall", "spearman"))

cov2cor(V)
Arguments

- **x**: a numeric vector, matrix or data frame.
- **y**: NULL (default) or a vector, matrix or data frame with compatible dimensions to **x**. The default is equivalent to **y = x** (but more efficient).
- **na.rm**: logical. Should missing values be removed?
- **use**: an optional character string giving a method for computing covariances in the presence of missing values. This must be (an abbreviation of) one of the strings "everything", "all.obs", "complete.obs", "na.or.complete", or "pairwise.complete.obs".
- **method**: a character string indicating which correlation coefficient (or covariance) is to be computed. One of "pearson" (default), "kendall", or "spearman", can be abbreviated.
- **V**: symmetric numeric matrix, usually positive definite such as a covariance matrix.

Details

For **cov** and **cor** one must either give a matrix or data frame for **x** or give both **x** and **y**.

The inputs must be numeric (as determined by **is numeric**: logical values are also allowed for historical compatibility): the "kendall" and "spearman" methods make sense for ordered inputs but **xtfrm** can be used to find a suitable prior transformation to numbers.

**var** is just another interface to **cov**, where **na.rm** is used to determine the default for use when that is unspecified. If **na.rm** is TRUE then the complete observations (rows) are used (use = "na.or.complete") to compute the variance. Otherwise, by default use = "everything". If use is "everything", NAs will propagate conceptually, i.e., a resulting value will be NA whenever one of its contributing observations is NA.

If use is "all.obs", then the presence of missing observations will produce an error. If use is "complete.obs" then missing values are handled by casewise deletion (and if there are no complete cases, that gives an error).

"na.or.complete" is the same unless there are no complete cases, that gives NA. Finally, if use has the value "pairwise.complete.obs" then the correlation or covariance between each pair of variables is computed using all complete pairs of observations on those variables. This can result in covariance or correlation matrices which are not positive semi-definite, as well as NA entries if there are no complete pairs for that pair of variables. For **cov** and **var**, "pairwise.complete.obs" only works with the "pearson" method. Note that (the equivalent of) var(double(0), use = "r") gives NA for use = "everything" and "na.or.complete", and gives an error in the other cases.

The denominator **n** − 1 is used which gives an unbiased estimator of the (co)variance for i.i.d. observations. These functions return NA when there is only one observation (whereas S-PLUS has been returning NaN), and fail if x has length zero.

For **cor**(), if method is "kendall" or "spearman", Kendall’s τ or Spearman’s ρ statistic is used to estimate a rank-based measure of association. These are more robust and have been recommended if the data do not necessarily come from a bivariate normal distribution.

For **cov**(), a non-Pearson method is unusual but available for the sake of completeness. Note that "spearman" basically computes cor(R(x), R(y)) (or cov(., .)) where R(u) := rank(u, na.last = "keep"). In the case of missing values, the ranks are calculated depending on the value of use, either based on complete observations, or based on pairwise completeness with reranking for each pair.

Scaling a covariance matrix into a correlation one can be achieved in many ways, mathematically most appealing by multiplication with a diagonal matrix from left and right, or more efficiently by using sweep(., FUN = "/") twice. The cov2cor function is even a bit more efficient, and provided mostly for didactical reasons.
Value

For r <- cor(*, use = "all.obs"), it is now guaranteed that all(r <= 1).

Note

Some people have noted that the code for Kendall’s tau is slow for very large datasets (many more than 1000 cases). It rarely makes sense to do such a computation, but see function cor.fk in package pcaPP.

References

cor.test

Test for Association/Correlation Between Paired Samples

description

Test for association between paired samples, using one of Pearson’s product moment correlation coefficient, Kendall’s \( \tau \) or Spearman’s \( \rho \).

usage

cor.test(x, 

# Default S3 method:
cor.test(x, y, 
   alternative = c("two.sided", "less", "greater"),
   method = c("pearson", "kendall", "spearman"),
   exact = NULL, conf.level = 0.95, continuity = FALSE, 

# S3 method for class 'formula'
cor.test(formula, data, subset, na.action, 

arguments

x, y numeric vectors of data values. \( x \) and \( y \) must have the same length.

alternative indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. "greater" corresponds to positive association, "less" to negative association.
cor.test

method a character string indicating which correlation coefficient is to be used for the test. One of "pearson", "kendall", or "spearman", can be abbreviated.

exact a logical indicating whether an exact p-value should be computed. Used for Kendall’s τ and Spearman’s ρ. See ‘Details’ for the meaning of NULL (the default).

conf.level confidence level for the returned confidence interval. Currently only used for the Pearson product moment correlation coefficient if there are at least 4 complete pairs of observations.

continuity logical: if true, a continuity correction is used for Kendall’s τ and Spearman’s ρ when not computed exactly.

formula a formula of the form ~ u + v, where each of u and v are numeric variables giving the data values for one sample. The samples must be of the same length.

data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").

... further arguments to be passed to or from methods.

Details

The three methods each estimate the association between paired samples and compute a test of the value being zero. They use different measures of association, all in the range \([-1, 1]\) with 0 indicating no association. These are sometimes referred to as tests of no correlation, but that term is often confined to the default method.

If method is "pearson", the test statistic is based on Pearson’s product moment correlation coefficient \(r\) and follows a t distribution with \(n-2\) degrees of freedom if the samples follow independent normal distributions. If there are at least 4 complete pairs of observation, an asymptotic confidence interval is given based on Fisher’s Z transform.

If method is "kendall" or "spearman", Kendall’s τ or Spearman’s ρ statistic is used to estimate a rank-based measure of association. These tests may be used if the data do not necessarily come from a bivariate normal distribution.

For Kendall’s test, by default (if exact is NULL), an exact p-value is computed if there are less than 50 paired samples containing finite values and there are no ties. Otherwise, the test statistic is the estimate scaled to zero mean and unit variance, and is approximately normally distributed.

For Spearman’s test, p-values are computed using algorithm AS 89 for \(n < 1290\) and exact = TRUE, otherwise via the asymptotic t approximation. Note that these are ‘exact’ for \(n < 10\), and use an Edgeworth series approximation for larger sample sizes (the cutoff has been changed from the original paper).

Value

A list with class "htest" containing the following components:

statistic the value of the test statistic.

parameter the degrees of freedom of the test statistic in the case that it follows a t distribution.

p.value the p-value of the test.
estimate  the estimated measure of association, with name "cor", "tau", or "rho" corresponding to the method employed.
null.value the value of the association measure under the null hypothesis, always 0.
alternative a character string describing the alternative hypothesis.
method a character string indicating how the association was measured.
data.name a character string giving the names of the data.
conf.int a confidence interval for the measure of association. Currently only given for Pearson's product moment correlation coefficient in case of at least 4 complete pairs of observations.

## Assessment of tuna quality. We compare the Hunter L measure of
## lightness to the averages of consumer panel scores (recoded as
## integer values from 1 to 6 and averaged over 80 such values) in
## 9 lots of canned tuna.
x <- c(44.4, 45.9, 41.9, 53.3, 44.7, 44.1, 50.7, 45.2, 60.1)
y <- c(2.6, 3.1, 2.5, 5.0, 3.6, 4.0, 5.2, 2.8, 3.8)

## The alternative hypothesis of interest is that the
## Hunter L value is positively associated with the panel score.
cor.test(x, y, method = "kendall", alternative = "greater")
## => p=0.05972

cor.test(x, y, method = "kendall", alternative = "greater",
          exact = FALSE) # using large sample approximation
## => p=0.04765

## Compare this to
cor.test(x, y, method = "spearm", alternative = "g")
cor.test(x, y, alternative = "g")

## Formula interface.
require(graphics)
pairs(USJudgeRatings)
cor.test(~ CONT + INTG, data = USJudgeRatings)
```
Description

Returns a list containing estimates of the weighted covariance matrix and the mean of the data, and optionally of the (weighted) correlation matrix.

Usage

cov.wt(x, wt = rep(1/nrow(x), nrow(x)), cor = FALSE, center = TRUE,
method = c("unbiased", "ML"))

Arguments

x  a matrix or data frame. As usual, rows are observations and columns are variables.
wt  a non-negative and non-zero vector of weights for each observation. Its length must equal the number of rows of x.
cor  a logical indicating whether the estimated correlation weighted matrix will be returned as well.
center  either a logical or a numeric vector specifying the centers to be used when computing covariances. If TRUE, the (weighted) mean of each variable is used, if FALSE, zero is used. If center is numeric, its length must equal the number of columns of x.
method  string specifying how the result is scaled, see 'Details' below.

Details

By default, method = "unbiased". The covariance matrix is divided by one minus the sum of squares of the weights, so if the weights are the default (1/n) the conventional unbiased estimate of the covariance matrix with divisor (n − 1) is obtained. This differs from the behaviour in S-PLUS which corresponds to method = "ML" and does not divide.

Value

A list containing the following named components:

cov  the estimated (weighted) covariance matrix
center  an estimate for the center (mean) of the data.
n.obs  the number of observations (rows) in x.
wt  the weights used in the estimation. Only returned if given as an argument.
cor  the estimated correlation matrix. Only returned if cor is TRUE.

See Also

cov and var.
Examples

```r
(xy <- cbind(x = 1:10, y = c(1:3, 8:5, 8:10)))
w1 <- c(0, 0, 0, 1, 1, 1, 1, 1, 0, 0)
cov.wt(xy, wt = w1) # i.e. method = "unbiased"
cov.wt(xy, wt = w1, method = "ML", cor = TRUE)
```

Description

Plots a cumulative periodogram.

Usage

```r
cpgram(ts, taper = 0.1,
       main = paste("Series: ", deparse(substitute(ts))),
       ci.col = "blue")
```

Arguments

- `ts`: a univariate time series
- `taper`: proportion tapered in forming the periodogram
- `main`: main title
- `ci.col`: colour for confidence band.

Value

None.

Side Effects

Plots the cumulative periodogram in a square plot.

Note

From package MASS.

cpgram(lh.ar$resid, main = "AR(3) fit to lh")
cpgram(ldeaths)
```
**cutree**  
*Cut a Tree into Groups of Data*

**Description**
Cuts a tree, e.g., as resulting from `hclust`, into several groups either by specifying the desired number(s) of groups or the cut height(s).

**Usage**
```r
cutree(tree, k = NULL, h = NULL)
```

**Arguments**
- `tree` a tree as produced by `hclust`. `cutree()` only expects a list with components `merge`, `height`, and `labels`, of appropriate content each.
- `k` an integer scalar or vector with the desired number of groups
- `h` numeric scalar or vector with heights where the tree should be cut. At least one of `k` or `h` must be specified, `k` overrides `h` if both are given.

**Details**
Cutting trees at a given height is only possible for ultrametric trees (with monotone clustering heights).

**Value**
cutree returns a vector with group memberships if `k` or `h` are scalar, otherwise a matrix with group memberships is returned where each column corresponds to the elements of `k` or `h`, respectively (which are also used as column names).

**References**

**See Also**
- `hclust`, `dendrogram` for cutting trees themselves.

**Examples**
```r
hc <- hclust(dist(USArrests))
cutree(hc, k = 1:5) # k = 1 is trivial  
cutree(hc, h = 250)
```

```r
# Compare the 2 and 4 grouping:
g24 <- cutree(hc, k = c(2,4))
table(grp2 = g24[,"2"], grp4 = g24[,"4"])
```
decompose

Classical Seasonal Decomposition by Moving Averages

Description

Decompose a time series into seasonal, trend and irregular components using moving averages. Deals with additive or multiplicative seasonal component.

Usage

decompose(x, type = c("additive", "multiplicative"), filter = NULL)

Arguments

x A time series.
type The type of seasonal component. Can be abbreviated.
filter A vector of filter coefficients in reverse time order (as for AR or MA coefficients), used for filtering out the seasonal component. If NULL, a moving average with symmetric window is performed.

Details

The additive model used is:

\[ Y_t = T_t + S_t + e_t \]

The multiplicative model used is:

\[ Y_t = T_t S_t e_t \]

The function first determines the trend component using a moving average (if filter is NULL, a symmetric window with equal weights is used), and removes it from the time series. Then, the seasonal figure is computed by averaging, for each time unit, over all periods. The seasonal figure is then centered. Finally, the error component is determined by removing trend and seasonal figure (recycled as needed) from the original time series.

This only works well if x covers an integer number of complete periods.

Value

An object of class "decomposed.ts" with following components:

- x The original series. (Only since R 2.14.0.)
- seasonal The seasonal component (i.e., the repeated seasonal figure).
- figure The estimated seasonal figure only.
- trend The trend component.
- random The remainder part.
- type The value of type.

Note

The function stl provides a much more sophisticated decomposition.
**delete.response**

**Description**

`delete.response` returns a `terms` object for the same model but with no response variable.

`drop.terms` removes variables from the right-hand side of the model. There is also a `"[.terms"` method to perform the same function (with `keep.response = TRUE`).

`reformulate` creates a formula from a character vector.

**Usage**

```r
delete.response(termobj)

reformulate(termlabels, response = NULL, intercept = TRUE)

drop.terms(termobj, dropx = NULL, keep.response = FALSE)
```

**Author(s)**

David Meyer <David.Meyer@wu.ac.at>

**References**

**See Also**

`stl`

**Examples**

```r
require(graphics)

m <- decompose(co2)
m$figure
plot(m)

## example taken from Kendall/Stuart
x <- c(-50, 175, 149, 214, 247, 237, 225, 329, 729, 809,
      530, 489, 540, 457, 195, 176, 337, 239, 128, 102, 232, 429, 3,
      98, 43, -141, -77, -13, 125, 361, -45, 184)
x <- ts(x, start = c(1951, 1), end = c(1958, 4), frequency = 4)
m <- decompose(x)
## seasonal figure: 6.25, 8.62, -8.84, -6.03
round(decompose(x)$figure / 10, 2)
```

---

**delete.response**

*Modify Terms Objects*

---

**Description**

`delete.response` returns a `terms` object for the same model but with no response variable.

`drop.terms` removes variables from the right-hand side of the model. There is also a `"[.terms"` method to perform the same function (with `keep.response = TRUE`).

`reformulate` creates a formula from a character vector.

**Usage**

```r
delete.response(termobj)

reformulate(termlabels, response = NULL, intercept = TRUE)

drop.terms(termobj, dropx = NULL, keep.response = FALSE)
```
Arguments

- **termobj**: A terms object.
- **termlabels**: Character vector giving the right-hand side of a model formula. Cannot be zero-length.
- **response**: Character string, symbol or call giving the left-hand side of a model formula, or NULL.
- **intercept**: Logical: should the formula have an intercept? New in R 2.13.0.
- **dropx**: Vector of positions of variables to drop from the right-hand side of the model.
- **keep.response**: Keep the response in the resulting object?

Value

- `delete.response` and `drop.terms` return a terms object.
- `reformulate` returns a formula.

See Also

- terms

Examples

```r
ff <- y ~ z + x + w
tt <- terms(ff)

# delete.response
delete.response(tt)

# keep variables 2:3
drop.terms(tt, 2:3, keep.response = TRUE)

# return a formula
reformulate(attr(tt, "term.labels"))
```

```r
## keep LHS:
reformulate("x*w", ff[2])

fs <- surv(ft, case) ~ a + b
reformulate(c("a", "b+f"), fs[[2]])
```

## using non-syntactic names:
```r
reformulate(c("%P/E", "% Growth"), response = as.name("+-"))
```

```r
stopifnot(identical(~ var, reformulate("var")),
identical(~ a + b + c, reformulate(letters[1:3])),
identical(~ y ~ a + b, reformulate(letters[1:2], "y"))
)
```

dendrapply  
Apply a Function to All Nodes of a Dendrogram

Description

Apply function FUN to each node of a dendrogram recursively. When y <- dendrapply(x, fn), then y is a dendrogram of the same graph structure as x and for each node, y.node[j] <- FUN(x.node[j], ...) (where y.node[j] is an (invalid!) notation for the j-th node of y.)
dendrapply

Usage

dendrapply(X, FUN, ...)

Arguments

X               an object of class "dendrogram".
FUN             an R function to be applied to each dendrogram node, typically working on its
                attributes alone, returning an altered version of the same node.
...             potential further arguments passed to FUN.

Value

Usually a dendrogram of the same (graph) structure as X. For that, the function must be conceptually
of the form FUN <- function(X) { attributes(X) <- ......; X }, i.e. returning the node
with some attributes added or changed.

Note

this is still somewhat experimental, and suggestions for enhancements (or nice examples of usage)
are very welcome.

## a smallish simple dendrogram
dhc <- as.dendrogram(hc <- hclust(dist(USArrests), "ave"))
(dhc21 <- dhc[[2]][[1]])

## too simple:
dendrapply(dhc21, function(n) utils::str(attributes(n)))

## toy example to set colored leaf labels:
local({
  colLab <- function(n) {
    if(is.leaf(n)) {
      a <- attributes(n)
      i <- i+1
      attr(n, "nodePar") <-
        c(a$nodePar, list(lab.col = mycols[i], lab.font = i%%3))
    }

  }
}
mycols <- grDevices::rainbow(attr(dhc21,"members"))
i <- 0
})
dendrogram

General Tree Structures

Description

Class "dendrogram" provides general functions for handling tree-like structures. It is intended as a replacement for similar functions in hierarchical clustering and classification/regression trees, such that all of these can use the same engine for plotting or cutting trees.

Usage

as.dendrogram(object, ...)
## S3 method for class 'hclust'

as.dendrogram(object, hang = -1, ...)

## S3 method for class 'dendrogram'
as.hclust(x, ...)

## S3 method for class 'dendrogram'
plot(x, type = c("rectangle", "triangle"),
    center = FALSE,
    edge.root = is.leaf(x) || !is.null(attr(x,"edgetext")),
    nodePar = NULL, edgePar = list(),
    leaflab = c("perpendicular", "textlike", "none"),
    dLeaf = NULL, xlab = "", ylab = "", xaxt = "n", yaxt = "s",
    horiz = FALSE, frame.plot = FALSE, xlim, ylim, ...)

## S3 method for class 'dendrogram'
cut(x, h, ...)

## S3 method for class 'dendrogram'
merge(x, y, ..., height)

## S3 method for class 'dendrogram'
print(x, digits, ...)

## S3 method for class 'dendrogram'
rev(x)

## S3 method for class 'dendrogram'
str(object, max.level = NA, digits.d = 3,
    give.attr = FALSE, wid =getOption("width"),
    nest.lev = 0, indent.str = " ",
    last.str = getOption("str.dendrogram.last"), stem = "--",
    ...)

dl <- dendrapply(dhc21, colLabel)
op <- par(mfrow = 2:1)
plot(dhc21)
plot(dl) ## --> colored labels!
par(op)
is.leaf(object)

Arguments

object any R object that can be made into one of class "dendrogram".
x, y object(s) of class "dendrogram".
hang numeric scalar indicating how the height of leaves should be computed from the heights of their parents; see plot.hclust.
type type of plot.
center logical; if TRUE, nodes are plotted centered with respect to the leaves in the branch. Otherwise (default), plot them in the middle of all direct child nodes.
edge.root logical; if true, draw an edge to the root node.
nodePar a list of plotting parameters to use for the nodes (see points) or NULL by default which does not draw symbols at the nodes. The list may contain components named pch, cex, col, xpd, and/or bg each of which can have length two for specifying separate attributes for inner nodes and leaves. Note that the default of pch is 1:2, so you may want to use pch = NA if you specify nodePar.
edgePar a list of plotting parameters to use for the edge segments and labels (if there's an edgetext). The list may contain components named col, lty and lwd (for the segments), p.col, p.lwd, and p.lty (for the polygon around the text) and t.col for the text color. As with nodePar, each can have length two for differentiating leaves and inner nodes.
leaflab a string specifying how leaves are labeled. The default "perpendicular" write text vertically (by default). "textlike" writes text horizontally (in a rectangle), and "none" suppresses leaf labels.
dLeaf a number specifying the distance in user coordinates between the tip of a leaf and its label. If NULL as per default, 3/4 of a letter width or height is used.
horiz logical indicating if the dendrogram should be drawn horizontally or not.
frame.plot logical indicating if a box around the plot should be drawn, see plot.default.
h height at which the tree is cut.
height height at which the two dendrogram should be merged. If not specified (or NULL), the default is ten percent larger than the (larger of the) two component heights.
xlim, ylim optional x- and y-limits of the plot, passed to plot.default. The defaults for these show the full dendrogram.
..., xlab, ylab, xaxt, yaxt graphical parameters, or arguments for other methods.
digits integer specifying the precision for printing, see print.default.
max.level, digits.d, give.attr, wid, nest.lev, indent.str arguments to str, see str.default(). Note that give.attr = FALSE still shows height and members attributes for each node.
last.str, stem strings used for str() specifying how the last branch (at each level) should start and the stem to use for each dendrogram branch. In some environments, using last.str = "" will provide much nicer looking output, than the historical default last.str = "\"."
The dendrogram is directly represented as a nested list where each component corresponds to a branch of the tree. Hence, the first branch of tree $z$ is $z[[1]]$, the second branch of the corresponding subtree is $z[[1]][[2]]$, or shorter $z[1:2]$, etc. Each node of the tree carries some information needed for efficient plotting or cutting as attributes, of which only members, height and leaf for leaves are compulsory:

- **members** total number of leaves in the branch
- **height** numeric non-negative height at which the node is plotted.
- **midpoint** numeric horizontal distance of the node from the left border (the leftmost leaf) of the branch (unit 1 between all leaves). This is used for plot(*, center = FALSE).
- **label** character; the label of the node
- **x.member** for cut(), the number of *former* members; more generally a substitute for the members component used for ‘horizontal’ (when horiz = FALSE, else ‘vertical’) alignment.
- **edgetext** character; the label for the edge leading to the node
- **nodePar** a named list (of length-1 components) specifying node-specific attributes for points plotting, see the nodePar argument above.
- **edgePar** a named list (of length-1 components) specifying attributes for segments plotting of the edge leading to the node, and drawing of the edgetext if available, see the edgePar argument above.
- **leaf** logical, if TRUE, the node is a leaf of the tree.

`cut.dendrogram()` returns a list with components `$upper` and `$lower`, the first is a truncated version of the original tree, also of class dendrogram, the latter a list with the branches obtained from cutting the tree, each a dendrogram.

There are [[, print, and str methods for "dendrogram" objects where the first one (extraction) ensures that selecting sub-branches keeps the class.

Objects of class "hclust" can be converted to class "dendrogram" using method as.dendrogram(), and since R 2.13.0, there is also a as.hclust() method as an inverse.

`rev.dendrogram` simply returns the dendrogram $x$ with reversed nodes, see also reorder.dendrogram.

The `merge(x, y, ...)` method which merges two or more dendrograms into a new one which has $x$ and $y$ (and optional further arguments) as branches.

`is.leaf(object)` returns logical indicating if object is a leaf (the most simple dendrogram).

`plotNode()` and `plotNodeLimit()` are helper functions.

**Warning**

Some operations on dendrograms (including plotting) make use of recursion. For very deep trees it may be necessary to increase options("expressions"): if you do you are likely to need to set the C stack size larger than the default where possible.

**Note**

- **plot():** When using type = "triangle", center = TRUE often looks better.
- **str(d):** If you really want to see the *internal* structure, use str(unch class(d)) instead.
See Also

dendrapply for applying a function to each node. order.dendrogram and reorder.dendrogram; further, the labels method.

Examples

require(graphics); require(utils)

hc <- hclust(dist(USArrests), "ave")
(dend1 <- as.dendrogram(hc)) # "print()" method
str(dend1)                  # "str()" method
str(dend1, max = 2, last.str = "") # only the first two sub-levels
oo <- options(str.dendrogram.last = "\"") # yet another possibility
str(dend1, max = 2) # only the first two sub-levels
options(oo)  # .. resetting them

op <- par(mfrow = c(2,2), mar = c(5,2,1,4))
plot(dend1)
## "triangle" type and show inner nodes:
plot(dend1, nodePar = list(pch = c(1,NA), cex = 0.8, lab.cex = 0.8,
                          type = "t", center = TRUE))
plot(dend1, edgePar = list(col = 1:2, lty = 2:3),
dLeaf = 1, edge.root = TRUE)
plot(dend1, nodePar = list(pch = 2:1, cex = .4*2:1, col = 2:3),
     horiz = TRUE)

## simple test for as.hclust() as the inverse of as.dendrogram():
stopifnot(identical(as.hclust(as.dendrogram(dend1)[1:4], hc[1:4])))

dend2 <- cut(dend1, h = 70)
plot(dend2$upper)
## leaves are wrong horizontally:
plot(dend2$upper, nodePar = list(pch = c(1,7), col = 2:1))
## dend2$lower is NOT a dendrogram, but a list of ..:
plot(dend2$lower[3], nodePar = list(col = 4), horiz = TRUE, type = "tr")
## "inner" and "leaf" edges in different type & color:
plot(dend2$lower[2], nodePar = list(col = 1),  # non empty list
     edgePar = list(lty = 1:2, col = 2:1), edge.root = TRUE)
par(op)
d3 <- dend2$lower[[2]][[2]][[1]]
stopifnot(identical(d3, dend2$lower[[2]][[c(2,1)]]))
str(d3, last.str = "")

## merge() to join dendrograms:
(d3 <- merge(dend2$lower[[1]], dend2$lower[[3]]))
## merge() all parts back (using default 'height' instead of original one):
den.1 <- Reduce(merge, dend2$lower)
## or merge() all four parts at same height --> 4 branches (!)
d. <- merge(dend2$lower[[1]], dend2$lower[[2]], dend2$lower[[3]],
dend2$lower[[4]]))
## (with a warning) or the same using do.call :
stopifnot(identical(d., do.call(merge, dend2$lower)))
plot(d., main = "merge(d1, d2, d3, d4) |-> dendrogram with a 4-split")

## "Zoom" in to the first dendrogram :
plot(dend1, xlim = c(1,20), ylim = c(1,50))
density

Kernel Density Estimation

Description

The (S3) generic function **density** computes kernel density estimates. Its default method does so with the given kernel and bandwidth for univariate observations.

Usage

```r
density(x, ...) 
## Default S3 method:
density(x, bw = "nrd0", adjust = 1,
  kernel = c("gaussian", "epanechnikov", "rectangular",
  "triangular", "biweight", 
  "cosine", "optcosine"),
  weights = NULL, window = kernel, width,
  give.Rkern = FALSE,
  n = 512, from, to, cut = 3, na.rm = FALSE, ...)
```

Arguments

- **x**
  the data from which the estimate is to be computed.
- **bw**
  the smoothing bandwidth to be used. The kernels are scaled such that this is the standard deviation of the smoothing kernel. (Note this differs from the reference books cited below, and from S-PLUS.)
  bw can also be a character string giving a rule to choose the bandwidth. See `bw.nrd`.
  The default, "nrd0", has remained the default for historical and compatibility reasons, rather than as a general recommendation, where e.g., "SJ" would rather fit, see also V&R (2002).
  The specified (or computed) value of bw is multiplied by adjust.
density

The algorithm used in `density.default` disperses the mass of the empirical distribution function over a regular grid of at least 512 points and then uses the fast Fourier transform to convolve this approximation with a discretized version of the kernel and then uses linear approximation to evaluate the density at the specified points.

The statistical properties of a kernel are determined by $\sigma^2_K = \int t^2 K(t) \, dt$ which is always 1 for our kernels (and hence the bandwidth $bw$ is the standard deviation of the kernel) and $R(K) = \int K^2(t) \, dt$. MSE-equivalent bandwidths (for different kernels) are proportional to $\sigma_K R(K)$ which is scale invariant and for our kernels equal to $R(K)$. This value is returned when `give.Rkern = TRUE`. See the examples for using exact equivalent bandwidths.

Infinite values in `x` are assumed to correspond to a point mass at +/-Inf and the density estimate is of the sub-density on (-Inf, +Inf).

Value

If `give.Rkern` is true, the number $R(K)$, otherwise an object with class "density" whose underlying structure is a list containing the following components.
density

x  the n coordinates of the points where the density is estimated.
y  the estimated density values. These will be non-negative, but can be zero.
bw  the bandwidth used.
  n  the sample size after elimination of missing values.
call  the call which produced the result.
data.name  the deparsed name of the x argument.
  has.na  logical, for compatibility (always FALSE).

The print method reports summary values on the x and y components.

## Simulation from a density() fit

A kernel density fit is an equally-weighted mixture.

```r
fit <- density(xx)
N <- 1e6
x.new <- rnorm(N, sample(xx, size = N, replace = TRUE), fit$bw)
plot(fit)
lines(density(x.new), col = "blue")
```

(kernel <- eval(formals(density.default)$kernel))

### Show the kernels in the R parametrization

```r
plot(density(0, bw = 1), xlab = "", main = "R's density() kernels with bw = 1")
for(i in 2:length(kernel))
  lines(density(0, bw = 1, kernel = kernel[i]), col = i)
legend(1.5,.4, legend = kernel, col = seq(kernel), lty = 1, cex = .8, y.intersp = 1)
```

### Show the kernels in the S parametrization

```r
density(0, from = -1.2, to = 1.2, width = 2, kernel = "gaussian"),
  type = "l", ylim = c(0, 1), xlab = ""
for(i in 2:length(kernel))
  lines(density(0, width = 2, kernel = kernel[i]), col = i)
legend(0.6, 1.0, legend = kernel, col = seq(kernel), lty = 1)
```

## Semi-advanced theoretic from here on

```r
(RKs <- cbind(sapply(kernel, function(k) density(kernel = k, give.Rkern = TRUE))))
100*round(RKs["epanechnikov",] / RKs, 4)  ## Efficiencies
```

bw <- bw.SJ(precip)  ## Sensible automatic choice

```r
plot(density(precip, bw = bw),
  main = "same sd bandwidths, 7 different kernels")
for(i in 2:length(kernel))
  lines(density(precip, bw = bw, kernel = kernel[i]), col = i)
```

### Bandwidth Adjustment for "Exactly Equivalent Kernels"

```r
h.f <- sapply(kernel, function(k) density(kernel = k, give.Rkern = TRUE))
(h.f <- (h.f["gaussian"] / h.f)^.2)
## -> 1, 1.01, .995, 1.007,... close to 1 => adjustment barely visible..
```

```r
plot(density(precip, bw = bw),
  main = "equivalent bandwidths, 7 different kernels")
for(i in 2:length(kernel))
  lines(density(precip, bw = bw, adjust = h.f[i], kernel = kernel[i]),
    col = i)
legend(55, 0.035, legend = kernel, col = seq(kernel), lty = 1)
```
Description

Compute derivatives of simple expressions, symbolically.

Usage

D (expr, name)
derv(expr, ...)
derv3(expr, ...)

## Default S3 method:
deriv(expr, namevec, function.arg = NULL, tag = ".expr",
hessian = FALSE, ...)

## S3 method for class 'formula'
deriv(expr, namevec, function.arg = NULL, tag = ".expr",
hessian = FALSE, ...)

## Default S3 method:
deriv3(expr, namevec, function.arg = NULL, tag = ".expr",
hessian = TRUE, ...)

## S3 method for class 'formula'
deriv3(expr, namevec, function.arg = NULL, tag = ".expr",
hessian = TRUE, ...)

Arguments

expr A expression or call or (except D) a formula with no lhs.
name, namevec character vector, giving the variable names (only one for D()) with respect to
which derivatives will be computed.
function.arg If specified and non-NULL, a character vector of arguments for a function return,
or a function (with empty body) or TRUE, the latter indicating that a function
with argument names namevec should be used.
tag character; the prefix to be used for the locally created variables in result.
hessian a logical value indicating whether the second derivatives should be calculated
and incorporated in the return value.
... arguments to be passed to or from methods.

Details

D is modelled after its S namesake for taking simple symbolic derivatives.
deriv is a generic function with a default and a formula method. It returns a call for computing
the expr and its (partial) derivatives, simultaneously. It uses so-called algorithmic derivatives. If
function.arg is a function, its arguments can have default values, see the fx example below.
Currently, deriv.formula just calls deriv.default after extracting the expression to the right of
~.
deriv3 and its methods are equivalent to deriv and its methods except that hessian defaults to
TRUE for deriv3.
The internal code knows about the arithmetic operators +, -, *, / and ^, and the single-variable
functions exp, log, sin, cos, tan, sinh, cosh, sqrt, pnorm, dnorm,asin, acos, atan, gamma,
lgamma, digamma and trigamma, as well as psigamma for one or two arguments (but derivative only
with respect to the first). (Note that only the standard normal distribution is considered.)
Value

\(D\) returns a call and therefore can easily be iterated for higher derivatives.

`deriv` and `deriv3` normally return an `expression` object whose evaluation returns the function values with a "gradient" attribute containing the gradient matrix. If `hessian` is TRUE the evaluation also returns a "hessian" attribute containing the Hessian array.

If `function.arg` is not NULL, `deriv` and `deriv3` return a function with those arguments rather than an expression.

References

See Also

`nlm` and `optim` for numeric minimization which could make use of derivatives,

Examples

```r
## formula argument :
dx2x <- deriv(~ x^2, "x") ; dx2x
## Not run: expression(
  .value <- x^2
  .grad <- array(0, c(length(.value), 1), list(NULL, c("x"))
  .grad[,"x"] <- 2 * x
  attr(.value, "gradient") <- .grad
  .value
)
## End(Not run)
mode(dx2x)
x <- -1:2
eval(dx2x)

## Something 'tougher':
trig.exp <- expression(sin(cos(x + y^2)))
(D.sc <- D(trig.exp, "x") )
all.equal(D(D(trig.exp[[1]], "x"), D.sc)

  ( dxy <- deriv(trig.exp, c("x", "y")) )
y <- 1
eval(dxy)
eval(D.sc)

## function returned:
deriv((y = sin(cos(x) * y)), c("x","y"), func = TRUE)

## function with defaulted arguments:
(fx <- deriv(y ~ b0 + b1 * x^2, c("b0", "b1", "th"),
         function(b0, b1, th, x = 1:7){}) )
fx(2, 3, 4)
## Higher derivatives
```
deviance

## Description

Returns the deviance of a fitted model object.

## Usage

```r
deviance(object, ...)
```

## Arguments

- `object`: an object for which the deviance is desired.
- `...`: additional optional argument.

## Details

This is a generic function which can be used to extract deviances for fitted models. Consult the individual modeling functions for details on how to use this function.

## Value

The value of the deviance extracted from the object object.

## References

## See Also

- `df.residual`, `extractAIC`, `glm`, `lm`
**df.residual**

*Residual Degrees-of-Freedom*

**Description**

Returns the residual degrees-of-freedom extracted from a fitted model object.

**Usage**

```r
df.residual(object, ...)
```

**Arguments**

- `object`: an object for which the degrees-of-freedom are desired.
- `...`: additional optional arguments.

**Details**

This is a generic function which can be used to extract residual degrees-of-freedom for fitted models. Consult the individual modeling functions for details on how to use this function.

The default method just extracts the `df.residual` component.

**Value**

The value of the residual degrees-of-freedom extracted from the object `x`.

**See Also**

`deviance.glm`, `lm`.

---

**diffinv**

*Discrete Integration: Inverse of Differencing*

**Description**

Computes the inverse function of the lagged differences function `diff`.

**Usage**

```r
diffinv(x, ...)
```

## Default S3 method:
`diffinv(x, lag = 1, differences = 1, xi, ...)`

## S3 method for class 'ts'
`diffinv(x, lag = 1, differences = 1, xi, ...)`
Arguments

- `x`: a numeric vector, matrix, or time series.
- `lag`: a scalar lag parameter.
- `differences`: an integer representing the order of the difference.
- `xi`: a numeric vector, matrix, or time series containing the initial values for the integrals. If missing, zeros are used.
- `...`: arguments passed to or from other methods.

Details

diffinv is a generic function with methods for class "ts" and default for vectors and matrices. Missing values are not handled.

Value

A numeric vector, matrix, or time series (the latter for the "ts" method) representing the discrete integral of `x`.

diff

Examples

```r
s <- 1:10
d <- diff(s)
diffinv(d, xi = 1)
```

---

dist

Distance Matrix Computation

Description

This function computes and returns the distance matrix computed by using the specified distance measure to compute the distances between the rows of a data matrix.

Usage

```r
dist(x, method = "euclidean", diag = FALSE, upper = FALSE, p = 2)

as.dist(m, diag = FALSE, upper = FALSE)

## Default S3 method:
as.dist(m, diag = FALSE, upper = FALSE)

## S3 method for class 'dist'
print(x, diag = NULL, upper = NULL,
```
digits = getOption("digits"), justify = "none",
right = TRUE, ...)

## S3 method for class 'dist'
as.matrix(x, ...)

### Arguments

- **x**: a numeric matrix, data frame or "dist" object.
- **method**: the distance measure to be used. This must be one of "euclidean", "maximum", "manhattan", "canberra", "binary" or "minkowski". Any unambiguous substring can be given.
- **diag**: logical value indicating whether the diagonal of the distance matrix should be printed by print.dist.
- **upper**: logical value indicating whether the upper triangle of the distance matrix should be printed by print.dist.
- **p**: The power of the Minkowski distance.
- **m**: An object with distance information to be converted to a "dist" object. For the default method, a "dist" object, or a matrix (of distances) or an object which can be coerced to such a matrix using as.matrix(). (Only the lower triangle of the matrix is used, the rest is ignored).
- **digits, justify**: passed to format inside of print().
- **right, ...**: further arguments, passed to other methods.

### Details

Available distance measures are (written for two vectors $x$ and $y$):

- **euclidean**: Usual square distance between the two vectors (2 norm).
- **maximum**: Maximum distance between two components of $x$ and $y$ (supremum norm)
- **manhattan**: Absolute distance between the two vectors (1 norm).
- **canberra**: $\sum_i |x_i - y_i|/|x_i + y_i|$. Terms with zero numerator and denominator are omitted from the sum and treated as if the values were missing.
  
  This is intended for non-negative values (e.g. counts): taking the absolute value of the denominator is a 1998 R modification to avoid negative distances.
- **binary**: (aka asymmetric binary): The vectors are regarded as binary bits, so non-zero elements are ‘on’ and zero elements are ‘off’. The distance is the proportion of bits in which only one is on amongst those in which at least one is on.
- **minkowski**: The $p$ norm, the $p$th root of the sum of the $p$th powers of the differences of the components.

Missing values are allowed, and are excluded from all computations involving the rows within which they occur. Further, when Inf values are involved, all pairs of values are excluded when their contribution to the distance gave NaN or NA. If some columns are excluded in calculating a Euclidean, Manhattan, Canberra or Minkowski distance, the sum is scaled up proportionally to the number of columns used. If all pairs are excluded when calculating a particular distance, the value is NA.

The "dist" method of as.matrix() and as.dist() can be used for conversion between objects of class "dist" and conventional distance matrices.
as.dist() is a generic function. Its default method handles objects inheriting from class "dist", or coercible to matrices using as.matrix(). Support for classes representing distances (also known as dissimilarities) can be added by providing an as.matrix() or, more directly, an as.dist method for such a class.

Value
dist returns an object of class "dist".
The lower triangle of the distance matrix stored by columns in a vector, say do. If \( n \) is the number of observations, i.e., \( n \leftarrow attr(do, \text{"Size"}) \), then for \( i < j \leq n \), the dissimilarity between (row) \( i \) and \( j \) is \( [n \times (i - 1) - i \times (i - 1)/2 + j - 1] \). The length of the vector is \( n \times (n - 1)/2 \), i.e., of order \( n^2 \).
The object has the following attributes (besides \text{"class"} equal to \text{"dist"}):

- \text{Size} integer, the number of observations in the dataset.
- \text{Labels} optionally, contains the labels, if any, of the observations of the dataset.
- \text{Diag, Upper} logicals corresponding to the arguments \text{diag} and \text{upper} above, specifying how the object should be printed.
- \text{call} optionally, the call used to create the object.
- \text{method} optionally, the distance method used; resulting from dist(), the (match.arg()ed) method argument.

daisy in the cluster package with more possibilities in the case of mixed (continuous / categorical) variables. hclust.

Examples

require(graphics)
x <- matrix(rnorm(100), nrow = 5)
dist(x)
dist(x, diag = TRUE)
dist(x, upper = TRUE)
m <- as.matrix(dist(x))
d <- as.dist(m)
stopifnot(d == dist(x))

## Use correlations between variables "as distance"
dd <- as.dist((1 - cor(USJudgeRatings))/2)
round(1000 * dd) # (prints more nicely)
plot(hclust(dd)) # to see a dendrogram of clustered variables
Distributions

## Example of binary and canberra distances.
```
x <- c(0, 0, 1, 1, 1)
y <- c(1, 0, 1, 1, 0, 1)
dist(rbind(x, y), method = "binary")
```
## answer 0.4 = 2/5
```
dist(rbind(x, y), method = "canberra")
```
## answer 2 * (6/5)

## To find the names
```
labels(eurodist)
```

## Examples involving "Inf"
```
## 1)
x[6] <- Inf
(m2 <- rbind(x, y))
dist(m2, method = "binary")  # warning, answer 0.5 = 2/4
## These all give "Inf":
stopifnot(Inf == dist(m2, method = "euclidean"),
          Inf == dist(m2, method = "maximum"),
          Inf == dist(m2, method = "manhattan"))
## "Inf" is the same as very large number:
x1 <- x; x[6] <- 1e100
stopifnot(dist(cbind(x, y), method = "canberra") ==
          print(dist(cbind(x1, y), method = "canberra")))
## 2)
y[6] <- Inf #-> 6-th pair is excluded
dist(rbind(x, y), method = "binary")  # warning; 0.5
dist(rbind(x, y), method = "canberra")  # 3
dist(rbind(x, y), method = "maximum")  # 1
dist(rbind(x, y), method = "manhattan")  # 2.4
```

## Distributions in the stats package

### Description
Density, cumulative distribution function, quantile function and random variate generation for many standard probability distributions are available in the `stats` package.

### Details
The functions for the density/mass function, cumulative distribution function, quantile function and random variate generation are named in the form `dxxx`, `pxxx`, `qxxx` and `rxxx` respectively.

- For the beta distribution see `dbeta`.
- For the binomial (including Bernoulli) distribution see `dbinom`.
- For the Cauchy distribution see `dcauchy`.
- For the chi-squared distribution see `dchisq`.
- For the exponential distribution see `dexp`.
- For the F distribution see `df`.
- For the gamma distribution see `dgamma`. 

For the geometric distribution see `dgeom`. (This is also a special case of the negative binomial.)
For the hypergeometric distribution see `dhyper`.
For the log-normal distribution see `dnorm`.
For the multinomial distribution see `dmultinom`.
For the negative binomial distribution see `dnbinom`.
For the normal distribution see `dnorm`.
For the Poisson distribution see `dpois`.
For the Student’s t distribution see `dt`.
For the uniform distribution see `dunif`.
For the Weibull distribution see `dweibull`.
For less common distributions of test statistics see `pbirthday`, `dsignrank`, `ptukey` and `d wilco x` (and see the ‘See Also’ section of `cor.test`).

See Also

` RNG ` about random number generation in R.
The CRAN task view on distributions, `http://cran.r-project.org/web/views/Distributions.html`, mentioning several CRAN packages for additional distributions.

dummy.coef

Extract Coefficients in Original Coding

Description

This extracts coefficients in terms of the original levels of the coefficients rather than the coded variables.

Usage

dummy.coef(object, ...)

# S3 method for class 'lm'
dummy.coef(object, use.na = FALSE, ...)

# S3 method for class 'aovlist'
dummy.coef(object, use.na = FALSE, ...)

Arguments

object a linear model fit.
use.na logical flag for coefficients in a singular model. If use.na is true, undetermined coefficients will be missing; if false they will get one possible value.
... arguments passed to or from other methods.
Details
A fitted linear model has coefficients for the contrasts of the factor terms, usually one less in number than the number of levels. This function re-expresses the coefficients in the original coding; as the coefficients will have been fitted in the reduced basis, any implied constraints (e.g., zero sum for contr.helmert or contr.sum) will be respected. There will be little point in using dummy.coef for contr.treatment contrasts, as the missing coefficients are by definition zero.

The method used has some limitations, and will give incomplete results for terms such as poly(x, 2). However, it is adequate for its main purpose, aov models.

Value
A list giving for each term the values of the coefficients. For a multistratum aov model, such a list for each stratum.

Warning
This function is intended for human inspection of the output: it should not be used for calculations. Use coded variables for all calculations.

The results differ from S for singular values, where S can be incorrect.

See Also
aov, model.tables

Examples
options(contrasts = c("contr.helmert", "contr.poly"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
dummy.coef(npk.aov)
npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
dummy.coef(npk.aovE)

ecdf

Empirical Cumulative Distribution Function

Description
Compute an empirical cumulative distribution function, with several methods for plotting, printing and computing with such an "ecdf" object.

Usage
ecdf(x)

## S3 method for class 'ecdf'
plot(x, ..., ylab="Fn(x)", verticals = FALSE,
     col.01line = "gray70", pch = 19)

## S3 method for class 'ecdf'
print(x, digits = getOption("digits") - 2, ...)

## S3 method for class 'ecdf'
summary(object, ...)
## S3 method for class 'ecdf'
quantile(x, ...)

Arguments

x, object numeric vector of the observations for ecdf; for the methods, an object inheriting from class "ecdf".

... arguments to be passed to subsequent methods, e.g., plot.stepfun for the plot method.

ylab label for the y-axis.

verticals see plot.stepfun.

col01line numeric or character specifying the color of the horizontal lines at y = 0 and 1, see colors.

pch plotting character.

digits number of significant digits to use, see print.

Details

The e.c.d.f. (empirical cumulative distribution function) $F_n$ is a step function with jumps $i/n$ at observation values, where $i$ is the number of tied observations at that value. Missing values are ignored.

For observations $x = (x_1, x_2, \ldots, x_n)$, $F_n$ is the fraction of observations less or equal to $t$, i.e.,

$$F_n(t) = \frac{\# \{ x_i \leq t \}}{n} = \frac{1}{n} \sum_{i=1}^{n} 1[x_i \leq t].$$

The function plot.ecdf which implements the plot method for ecdf objects, is implemented via a call to plot.stepfun; see its documentation.

Value

For ecdf, a function of class "ecdf", inheriting from the "stepfun" class, and hence inheriting a knots() method.

For the summary method, a summary of the knots of object with a "header" attribute.

The quantile(obj, ...) method computes the same quantiles as quantile(x, ...) would where x is the original sample.

abline(v = knots(Fn12), lty = 2, col = "gray70")

plot(xx, F12(xx), type = "o", cex = .1)  #-- plot.default (ugly)
plot(Fn12, col.hor = "red", add = TRUE)  #-- plot method
abline(v = knots(Fn12), lty = 2, col = "gray70")

### luxury plot
plot(Fn12, verticals = TRUE, col.points = "blue",
     col.hor = "red", col.vert = "bisque")

###-- this works too (automatic call to ecdf(.)):
plot.ecdf(rnorm(24))
title("via simple plot.ecdf(x)", adj = 1)

par(op)
```
Description

Computes the efficiencies of fixed-effect terms in an analysis of variance model with multiple strata.

Usage

eff.aovlist(aovlist)

Arguments

- **aovlist**: The result of a call to `aov` with an `Error` term.

Details

Fixed-effect terms in an analysis of variance model with multiple strata may be estimable in more than one stratum, in which case there is less than complete information in each. The efficiency for a term is the fraction of the maximum possible precision (inverse variance) obtainable by estimating in just that stratum. Under the assumption of balance, this is the same for all contrasts involving that term.

This function is used to pick strata in which to estimate terms in `model.tables.aovlist` and `se.contrast.aovlist`.

In many cases terms will only occur in one stratum, when all the efficiencies will be one: this is detected and no further calculations are done.

The calculation used requires orthogonal contrasts for each term, and will throw an error if non-orthogonal contrasts (e.g. treatment contrasts or an unbalanced design) are detected.

Value

A matrix giving for each non-pure-error stratum (row) the efficiencies for each fixed-effect term in the model.

options(contrasts = c("contr.helmert", "contr.poly"))
(fit <- aov(Yield ~ A*B*C + Error(Block), data = aovdat))

options(contrasts = old)

effects  Effects from Fitted Model

Description

Returns (orthogonal) effects from a fitted model, usually a linear model. This is a generic function, but currently only has a methods for objects inheriting from classes "lm" and "glm".

Usage

effects(object, ...)

## S3 method for class 'lm'
effects(object, set.sign = FALSE, ...)

Arguments

object an R object; typically, the result of a model fitting function such as lm.
set.sign logical. If TRUE, the sign of the effects corresponding to coefficients in the model will be set to agree with the signs of the corresponding coefficients, otherwise the sign is arbitrary.
... arguments passed to or from other methods.

Details

For a linear model fitted by lm or aov, the effects are the uncorrelated single-degree-of-freedom values obtained by projecting the data onto the successive orthogonal subspaces generated by the QR decomposition during the fitting process. The first r (the rank of the model) are associated with coefficients and the remainder span the space of residuals (but are not associated with particular residuals).

Empty models do not have effects.

Value

A (named) numeric vector of the same length as residuals, or a matrix if there were multiple responses in the fitted model, in either case of class "coef".

The first r rows are labelled by the corresponding coefficients, and the remaining rows are unlabelled. Note that in rank-deficient models the corresponding coefficients will be in a different order if pivoting occurred.
References

c$\text{coef}$

Examples

```r
y <- c(1:3, 7, 5)
x <- c(1:3, 6:7)
  ( ee <- effects(lm(y ~ x)) )
c( round(ee - effects(lm(y+10 ~ I(x-3.8))), 3) )
# just the first is different
```

### embed

**Embedding a Time Series**

**Description**

Embeds the time series $x$ into a low-dimensional Euclidean space.

**Usage**

```r
embed (x, dimension = 1)
```

**Arguments**

- **x**
  - a numeric vector, matrix, or time series.
- **dimension**
  - a scalar representing the embedding dimension.

**Details**

Each row of the resulting matrix consists of sequences $x[t], x[t-1], \ldots, x[t\text{-dimension}+1]$, where $t$ is the original index of $x$. If $x$ is a matrix, i.e., $x$ contains more than one variable, then $x[t]$ consists of the $t$th observation on each variable.

**Value**

A matrix containing the embedded time series $x$.

**Author(s)**

A. Trapletti, B.D. Ripley

**Examples**

```r
x <- 1:10
embed (x, 3)
```
Description

Evaluates new variables as if they had been part of the formula of the specified model. This ensures that the same na.action and subset arguments are applied and allows, for example, x to be recovered for a model using sin(x) as a predictor.

Usage

```r
expand.model.frame(model, extras,
    envir = environment(formula(model)),
    na.expand = FALSE)
```

Arguments

- `model`: a fitted model
- `extras`: one-sided formula or vector of character strings describing new variables to be added
- `envir`: an environment to evaluate things in
- `na.expand`: logical; see below

Details

If `na.expand = FALSE` then NA values in the extra variables will be passed to the `na.action` function used in `model`. This may result in a shorter data frame (with `na.omit`) or an error (with `na.fail`). If `na.expand = TRUE` the returned data frame will have precisely the same rows as `model.frame(model)`, but the columns corresponding to the extra variables may contain NA.

Value

A data frame.

See Also

`model.frame`, `predict`

Examples

```r
model <- lm(log(Volume) ~ log(Girth) + log(Height), data = trees)
expand.model.frame(model, ~ Girth) # prints data.frame like

dd <- data.frame(x = 1:5, y = rnorm(5), z = c(1,2,NA,4,5))
model <- glm(y ~ x, data = dd, subset = 1:4, na.action = na.omit)
expand.model.frame(model, "z", na.expand = FALSE) # = default
expand.model.frame(model, "z", na.expand = TRUE)
```
Description
Density, distribution function, quantile function and random generation for the exponential distribution with rate rate (i.e., mean 1/rate).

Usage

dexp(x, rate = 1, log = FALSE)
pexp(q, rate = 1, lower.tail = TRUE, log.p = FALSE)
qexp(p, rate = 1, lower.tail = TRUE, log.p = FALSE)
rexp(n, rate = 1)

Arguments
x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
rate vector of rates.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are P[X ≤ x], otherwise, P[X > x].

Details
If rate is not specified, it assumes the default value of 1.
The exponential distribution with rate λ has density
\[ f(x) = \lambda e^{-\lambda x} \]
for \( x \geq 0 \).

Value
dexp gives the density, pexp gives the distribution function, qexp gives the quantile function, and rexp generates random deviates.
The length of the result is determined by n for rexp, and is the maximum of the lengths of the numerical parameters for the other functions.
The numerical parameters other than n are recycled to the length of the result. Only the first elements of the logical parameters are used.

Note
The cumulative hazard \( H(t) = -\log(1 - F(t)) \) is -pexp(t, r, lower = FALSE, log = TRUE).
Source
dexp, pexp and qexp are all calculated from numerically stable versions of the definitions.
rexp uses

extractAIC

*Extract AIC from a Fitted Model*

Description
Computes the (generalized) Akaike An Information Criterion for a fitted parametric model.

Usage
extractAIC(fit, scale, k = 2, ...)

Arguments

| fit  | fitted model, usually the result of a fitter like *lm*. |
| scale | optional numeric specifying the scale parameter of the model, see scale in *step*. Currently only used in the "*lm*" method, where scale specifies the estimate of the error variance, and scale = 0 indicates that it is to be estimated by maximum likelihood. |
| k    | numeric specifying the ‘weight’ of the equivalent degrees of freedom (≡ edf) part in the AIC formula. |
| ...  | further arguments (currently unused in base *R*). |
Details

This is a generic function, with methods in base \( R \) for classes "aov", "glm" and "lm" as well as for "negbin" (package \texttt{MASS}) and "coxph" and "survreg" (package \texttt{survival}).

The criterion used is

\[
AIC = -2 \log L + k \times \text{edf},
\]

where \( L \) is the likelihood and \( \text{edf} \) the equivalent degrees of freedom (i.e., the number of free parameters for usual parametric models) of \( \text{fit} \).

For linear models with unknown scale (i.e., for \texttt{lm} and \texttt{aov}), \(-2 \log L\) is computed from the deviance and uses a different additive constant to \texttt{logLik} and hence \texttt{AIC}. If \( \text{RSS} \) denotes the (weighted) residual sum of squares then \texttt{extractAIC} uses for \(-2 \log L\) the formulae \( \text{RSS}/s - n \) (corresponding to Mallows' \( C_p \)) in the case of known scale \( s \) and \( n \log(\text{RSS}/n) \) for unknown scale. \texttt{AIC} only handles unknown scale and uses the formula \( n \log(\text{RSS}/n) + n + n \log 2\pi - \sum \log w \) where \( w \) are the weights. Further \texttt{AIC} counts the scale estimation as a parameter in the \text{edf} and \texttt{extractAIC} does not.

For \texttt{glm} fits the family's \texttt{aic()} function is used to compute the AIC: see the note under \texttt{logLik} about the assumptions this makes.

\[ k = 2 \] corresponds to the traditional AIC, using \( k = \log(n) \) provides the BIC (Bayesian IC) instead.

Note that the methods for this function may differ in their assumptions from those of methods for \texttt{AIC} (usually via a method for \texttt{logLik}). We have already mentioned the case of "lm" models with estimated scale, and there are similar issues in the "glm" and "negbin" methods where the dispersion parameter may or may not be taken as ‘free’. This is immaterial as \texttt{extractAIC} is only used to compare models of the same class (where only differences in AIC values are considered).

Value

A numeric vector of length 2, with first and second elements giving

\begin{itemize}
  \item \texttt{edf} \hspace{1cm} the ‘equivalent degrees of freedom’ for the fitted model \texttt{fit}.
  \item \texttt{AIC} \hspace{1cm} the (generalized) Akaike Information Criterion for \texttt{fit}.
\end{itemize}

Note

This function is used in \texttt{add1}, \texttt{drop1} and \texttt{step} and the similar functions in package \texttt{MASS} from which it was adopted.

**factanal**

**Examples**

```r
utils::example(glm)
extractAIC(glm.D93) #>> 5 15.129
```

---

**Description**

Perform maximum-likelihood factor analysis on a covariance matrix or data matrix.

**Usage**

```r
factanal(x, factors, data = NULL, covmat = NULL, n.obs = NA,
  subset, na.action, start = NULL,
  scores = c("none", "regression", "Bartlett"),
  rotation = "varimax", control = NULL, ...)
```

**Arguments**

- **x**: A formula or a numeric matrix or an object that can be coerced to a numeric matrix.
- **factors**: The number of factors to be fitted.
- **data**: An optional data frame (or similar: see `model.frame`), used only if `x` is a formula. By default the variables are taken from `environment(formula)`.
- **covmat**: A covariance matrix, or a covariance list as returned by `cov.wt`. Of course, correlation matrices are covariance matrices.
- **n.obs**: The number of observations, used if `covmat` is a covariance matrix.
- **subset**: A specification of the cases to be used, if `x` is used as a matrix or formula.
- **na.action**: The `na.action` to be used if `x` is used as a formula.
- **start**: NULL or a matrix of starting values, each column giving an initial set of unique-nesses.
- **scores**: Type of scores to produce, if any. The default is `none`, "regression" gives Thompson’s scores, "Bartlett" given Bartlett’s weighted least-squares scores. Partial matching allows these names to be abbreviated.
- **rotation**: character. "none" or the name of a function to be used to rotate the factors: it will be called with first argument the loadings matrix, and should return a list with component loadings giving the rotated loadings, or just the rotated loadings.
- **control**: A list of control values,
  - `nstart`: The number of starting values to be tried if `start = NULL`. Default 1.
  - `trace`: logical. Output tracing information? Default FALSE.
  - `lower`: The lower bound for uniquenesses during optimization. Should be > 0. Default 0.005.
  - `opt`: A list of control values to be passed to `optim`'s control argument.
  - `rotate`: a list of additional arguments for the rotation function.
  - `...`: Components of `control` can also be supplied as named arguments to `factanal`.

---

Factor Analysis

---

**Description**

Perform maximum-likelihood factor analysis on a covariance matrix or data matrix.

**Usage**

```r
factanal(x, factors, data = NULL, covmat = NULL, n.obs = NA,
  subset, na.action, start = NULL,
  scores = c("none", "regression", "Bartlett"),
  rotation = "varimax", control = NULL, ...)
```

**Arguments**

- **x**: A formula or a numeric matrix or an object that can be coerced to a numeric matrix.
- **factors**: The number of factors to be fitted.
- **data**: An optional data frame (or similar: see `model.frame`), used only if `x` is a formula. By default the variables are taken from `environment(formula)`.
- **covmat**: A covariance matrix, or a covariance list as returned by `cov.wt`. Of course, correlation matrices are covariance matrices.
- **n.obs**: The number of observations, used if `covmat` is a covariance matrix.
- **subset**: A specification of the cases to be used, if `x` is used as a matrix or formula.
- **na.action**: The `na.action` to be used if `x` is used as a formula.
- **start**: NULL or a matrix of starting values, each column giving an initial set of unique-nesses.
- **scores**: Type of scores to produce, if any. The default is `none`, "regression" gives Thompson’s scores, "Bartlett" given Bartlett’s weighted least-squares scores. Partial matching allows these names to be abbreviated.
- **rotation**: character. "none" or the name of a function to be used to rotate the factors: it will be called with first argument the loadings matrix, and should return a list with component loadings giving the rotated loadings, or just the rotated loadings.
- **control**: A list of control values,
  - `nstart`: The number of starting values to be tried if `start = NULL`. Default 1.
  - `trace`: logical. Output tracing information? Default FALSE.
  - `lower`: The lower bound for uniquenesses during optimization. Should be > 0. Default 0.005.
  - `opt`: A list of control values to be passed to `optim`'s control argument.
  - `rotate`: a list of additional arguments for the rotation function.
  - `...`: Components of `control` can also be supplied as named arguments to `factanal`.

Details

The factor analysis model is

\[ x = \Lambda f + e \]

for a \( p \)-element row-vector \( x \), a \( p \times k \) matrix \( \Lambda \) of loadings, a \( k \)-element vector \( f \) of scores and a \( p \)-element vector \( e \) of errors. None of the components other than \( x \) is observed, but the major restriction is that the scores be uncorrelated and of unit variance, and that the errors be independent with variances \( \Psi \), the uniquenesses. It is also common to scale the observed variables to unit variance, and done in this function.

Thus factor analysis is in essence a model for the correlation matrix of \( x \),

\[ \Sigma = \Lambda'^t \Lambda + \Psi \]

There is still some indeterminacy in the model for it is unchanged if \( \Lambda \) is replaced by \( G\Lambda \) for any orthogonal matrix \( G \). Such matrices \( G \) are known as rotations (although the term is applied also to non-orthogonal invertible matrices).

If \( \text{covmat} \) is supplied it is used. Otherwise \( x \) is used if it is a matrix, or a formula \( x \) is used with data to construct a model matrix, and that is used to construct a covariance matrix. (It makes no sense for the formula to have a response, and all the variables must be numeric.) Once a covariance matrix is found or calculated from \( x \), it is converted to a correlation matrix for analysis. The correlation matrix is returned as component correlation of the result.

The fit is done by optimizing the log likelihood assuming multivariate normality over the uniquenesses. (The maximizing loadings for given uniquenesses can be found analytically: Lawley & Maxwell (1971, p. 27).) All the starting values supplied in \( \text{start} \) are tried in turn and the best fit obtained is used. If \( \text{start} = {\text{NULL}} \) then the first fit is started at the value suggested by Jöreskog (1963) and given by Lawley & Maxwell (1971, p. 31), and then \( \text{control}\$\text{start} = 1 \) other values are tried, randomly selected as equal values of the uniquenesses.

The uniquenesses are technically constrained to lie in \([0, 1]\), but near-zero values are problematical, and the optimization is done with a lower bound of \( \text{control}\$\text{lower} \), default 0.005 (Lawley & Maxwell, 1971, p. 32).

Scores can only be produced if a data matrix is supplied and used. The first method is the regression method of Thomson (1951), the second the weighted least squares method of Bartlett (1937, 8). Both are estimates of the unobserved scores \( f \). Thomson’s method regresses (in the population) the unknown \( f \) on \( x \) to yield

\[ \hat{f} = \Lambda'\Sigma^{-1}x \]

and then substitutes the sample estimates of the quantities on the right-hand side. Bartlett’s method minimizes the sum of squares of standardized errors over the choice of \( f \), given (the fitted) \( \Lambda \).

If \( x \) is a formula then the standard NA-handling is applied to the scores (if requested): see \text{napredict}.

The print method (documented under \text{loadings}) follows the factor analysis convention of drawing attention to the patterns of the results, so the default precision is three decimal places, and small loadings are suppressed.

Value

An object of class \"factanal\" with components

\text{loadings} \quad A \text{ matrix of loadings, one column for each factor. The factors are ordered in decreasing order of sums of squares of loadings, and given the sign that will make the sum of the loadings positive. This is of class \"loadings\": see \text{loadings} for its print method.}

\text{uniquenesses} \quad The uniquenesses computed.
correlation  The correlation matrix used.
criteria The results of the optimization: the value of the negative log-likelihood and
information on the iterations used.
factors The argument factors.
dof The number of degrees of freedom of the factor analysis model.
method The method: always "mle".
rotmat The rotation matrix if relevant.
scores If requested, a matrix of scores. napredict is applied to handle the treatment
of values omitted by the na.action.
n.obs The number of observations if available, or NA.
call The matched call.

Note
There are so many variations on factor analysis that it is hard to compare output from different
programs. Further, the optimization in maximum likelihood factor analysis is hard, and many other
examples we compared had less good fits than produced by this function. In particular, solutions
which are 'Heywood cases' (with one or more uniquenesses essentially zero) are much more com-
mon than most texts and some other programs would lead one to believe.

v4 <- c(3,3,4,3,3,1,2,1,1,1,2,1,1,5,6,4)
factor.scope

Compute Allowed Changes in Adding to or Dropping from a Formula

Description

add.scope and drop.scope compute those terms that can be individually added to or dropped from a model while respecting the hierarchy of terms.

Usage

add.scope(terms1, terms2)

drop.scope(terms1, terms2)

factor.scope(factor, scope)

Arguments

terms1

the terms or formula for the base model.

terms2

the terms or formula for the upper (add.scope) or lower (drop.scope) scope. If missing for drop.scope it is taken to be the null formula, so all terms (except any intercept) are candidates to be dropped.

factor

the "factor" attribute of the terms of the base object.

scope

a list with one or both components drop and add giving the "factor" attribute of the lower and upper scopes respectively.

Details

factor.scope is not intended to be called directly by users.

Value

For add.scope and drop.scope a character vector of terms labels. For factor.scope, a list with components drop and add, character vectors of terms labels.
family

See Also

add1, drop1, aov, lm

Examples

add.scope(~ a + b + c + a:b, ~ (a + b + c)^3)
# [1] "a:c" "b:c"
drop.scope(~ a + b + c + a:b)
# [1] "c" "a:b"

Description

Family objects provide a convenient way to specify the details of the models used by functions such as \texttt{glm}. See the documentation for \texttt{glm} for the details on how such model fitting takes place.

Usage

\texttt{family(object, \ldots)}

\texttt{binomial(link = "logit")}
\texttt{gaussian(link = "identity")}
\texttt{Gamma(link = "inverse")}
\texttt{inverse.gaussian(link = "1/mu^2")}
\texttt{poisson(link = "log")}
\texttt{quasi(link = "identity", variance = "constant")}
\texttt{quasibinomial(link = "logit")}
\texttt{quasipoisson(link = "log")}

Arguments

\texttt{link}

a specification for the model link function. This can be a name/expression, a literal character string, a length-one character vector or an object of class \texttt{"link-glm"} (such as generated by \texttt{make.link}) provided it is not specified via one of the standard names given next.

The \texttt{gaussian} family accepts the links \texttt{(as names)} \texttt{identity}, \texttt{log} and \texttt{inverse}; the \texttt{binomial} family the links \texttt{logit}, \texttt{probit}, \texttt{cauchit}, (corresponding to logistic, normal and Cauchy CDFs respectively) \texttt{log} and \texttt{cloglog} (complementary log-log); the \texttt{Gamma} family the links \texttt{inverse}, \texttt{identity} and \texttt{log}; the \texttt{poisson} family the links \texttt{log}, \texttt{identity}, and \texttt{sqrt} and the inverse. \texttt{gaussian} family the links \texttt{1/mu^2}, \texttt{inverse}, \texttt{identity} and \texttt{log}.

The \texttt{quasi} family accepts the links \texttt{logit}, \texttt{probit}, \texttt{cloglog}, \texttt{identity}, \texttt{inverse}, \texttt{log}, \texttt{1/mu^2} and \texttt{sqrt}, and the function \texttt{power} can be used to create a power link function.

\texttt{variance}

for all families other than \texttt{quasi}. The variance function is determined by the family. The \texttt{quasi} family will accept the literal character string (or unquoted as a name/expression) specifications \texttt{"constant"}, \texttt{"mu(1-mu)"}, \texttt{"mu"}, \texttt{"mu^2"} and \texttt{"mu^3"}, a length-one character vector taking one of those values, or a list containing components \texttt{varfun}, \texttt{validmu}, \texttt{dev.resids}, \texttt{initialize} and \texttt{name}.
family accesses the family objects which are stored within objects created by modelling functions (e.g., glm).

... further arguments passed to methods.

Details

family is a generic function with methods for classes "glm" and "lm" (the latter returning gaussian()).

The quasibinomial and quasipoisson families differ from the binomial and poisson families only in that the dispersion parameter is not fixed at one, so they can model over-dispersion. For the binomial case see McCullagh and Nelder (1989, pp. 124–8). Although they show that there is (under some restrictions) a model with variance proportional to mean as in the quasi-binomial model, note that glm does not compute maximum-likelihood estimates in that model. The behaviour of S is closer to the quasi- variants.

Value

An object of class "family" (which has a concise print method). This is a list with elements

family character: the family name.
link character: the link name.
linkfun function: the link.
linkinv function: the inverse of the link function.
variance function: the variance as a function of the mean.
dev.resids function giving the deviance residuals as a function of (y, mu, wt).
aic function giving the AIC value if appropriate (but NA for the quasi- families). See logLik for the assumptions made about the dispersion parameter.
mu.eta function: derivative function(eta) dµ/dη.
initialize expression. This needs to set up whatever data objects are needed for the family as well as n (needed for AIC in the binomial family) and nstart (see glm).
valid.mu logical function. Returns TRUE if a mean vector mu is within the domain of variance.
valid.eta logical function. Returns TRUE if a linear predictor eta is within the domain of linkinv.
simulate (optional) function simulate(object, nsim) to be called by the "lm" method of simulate. It will normally return a matrix with nsim columns and one row for each fitted value, but it can also return a list of length nsim. Clearly this will be missing for 'quasi-' families.

Note

The link and variance arguments have rather awkward semantics for back-compatibility. The recommended way is to supply them is as quoted character strings, but they can also be supplied unquoted (as names or expressions). In addition, they can also be supplied as a length-one character vector giving the name of one of the options, or as a list (for link, of class "link-glm"). The restrictions apply only to links given as names: when given as a character string all the links known to make.link are accepted.

This is potentially ambiguous: supplying link = logit could mean the unquoted name of a link or the value of object logit. It is interpreted if possible as the name of an allowed link, then as an object. (You can force the interpretation to always be the value of an object via logit[1].)
Author(s)

The design was inspired by S functions of the same names described in Hastie & Pregibon (1992) (except quasibinomial and quasipoisson).

## in practice this would be used with a vector of 'days', in
## which case use an offset of 0 in the corresponding formula
## to get the null deviance right.

## Binomial with identity link: often not a good idea.
## Not run: binomial(link = make.link("identity"))

## tests of quasi
x <- rnorm(100)
y <- rpois(100, exp(1+x))
glm(y ~ x, family = quasi(variance = "mu", link = "log"))
# which is the same as
glm(y ~ x, family = poisson)
glm(y ~ x, family = quasi(variance = "mu+2", link = "log"))
## Not run: glm(y ~ x, family = quasi(variance = "mu+3", link = "log")) # fails
y <- rbinom(100, 1, plogis(x))
# needs to set a starting value for the next fit
glm(y ~ x, family = quasi(variance = "mu(1-mu)", link = "logit"), start = c(0,1))

FDist

The F Distribution

Description
Density, distribution function, quantile function and random generation for the F distribution with
df1 and df2 degrees of freedom (and optional non-centrality parameter ncp).

Usage
df(x, df1, df2, ncp, log = FALSE)
pf(q, df1, df2, ncp, lower.tail = TRUE, log.p = FALSE)
qf(p, df1, df2, ncp, lower.tail = TRUE, log.p = FALSE)
rf(n, df1, df2, ncp)

Arguments
x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number
required.
df1, df2 degrees of freedom. Inf is allowed.
ncp non-centrality parameter. If omitted the central F is assumed.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are P[X ≤ x], otherwise, P[X > x].
Details

The F distribution with $df_1 = n_1$ and $df_2 = n_2$ degrees of freedom has density

$$f(x) = \frac{\Gamma\left(\frac{n_1}{2} + \frac{n_2}{2}\right)}{\Gamma\left(\frac{n_1}{2}\right)\Gamma\left(\frac{n_2}{2}\right)} \left(\frac{n_1}{n_2}\right)^{n_1/2} x^{n_1/2-1} \left(1 + \frac{n_1x}{n_2}\right)^{-\left(\frac{n_1+n_2}{2}\right)}$$

for $x > 0$.

It is the distribution of the ratio of the mean squares of $n_1$ and $n_2$ independent standard normals, and hence of the ratio of two independent chi-squared variates each divided by its degrees of freedom. Since the ratio of a normal and the root mean-square of $m$ independent normals has a Student’s $t_m$ distribution, the square of a $t_m$ variate has a F distribution on 1 and $m$ degrees of freedom.

The non-central F distribution is again the ratio of mean squares of independent normals of unit variance, but those in the numerator are allowed to have non-zero means and $ncp$ is the sum of squares of the means. See Chisquare for further details on non-central distributions.

Value

df gives the density, pf gives the distribution function qf gives the quantile function, and rf generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by $n$ for rf, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than $n$ are recycled to the length of the result. Only the first elements of the logical parameters are used.

Note

Supplying $ncp = 0$ uses the algorithm for the non-central distribution, which is not the same algorithm used if $ncp$ is omitted. This is to give consistent behaviour in extreme cases with values of $ncp$ very near zero.

The code for non-zero $ncp$ is principally intended to be used for moderate values of $ncp$: it will not be highly accurate, especially in the tails, for large values.

Source

For the central case of df, computed via a binomial probability, code contributed by Catherine Loader (see dbinom); for the non-central case computed via dbeta, code contributed by Peter Ruckdeschel.

For pf, via pbeta (or for large df2, via pchisq).
For qf, via qchisq for large df2, else via qbeta.

Examples

```r
### Equivalence of pt(.,nu) with pf(.,2, 1,nu):
x <- seq(0.001, 5, len = 100)
nu <- 4
stopifnot(all.equal(2*pt(x,nu) - 1, pf(x^2, 1,nu)),
  ## upper tails:
  all.equal(2*pt(x, nu, lower=FALSE),
            pf(x^2, 1,nu, lower=FALSE)))

### the density of the square of a t_m is 2*dt(x, m)/(2*x)
# check this is the same as the density of F_[1,m]
all.equal(df(x^2, 1, 5), dt(x, 5)/x)

### Identity: qf(2*p - 1, 1, df) == qt(p, df)^2) for p >= 1/2
p <- seq(1/2, .99, length = 50); df <- 10
rel.err <- function(x, y) ifelse(x == y, 0, abs(x-y)/mean(abs(c(x,y))))
quantile(rel.err(qf(2*p - 1, df1 = 1, df2 = df), qt(p, df)^2), .90) # ~= 7e-9
```

fft

Fast Discrete Fourier Transform

Description

Performs the Fast Fourier Transform of an array.

Usage

```r
fft(z, inverse = FALSE)
mvfft(z, inverse = FALSE)
```

Arguments

- `z` a real or complex array containing the values to be transformed.
- `inverse` if TRUE, the unnormalized inverse transform is computed (the inverse has a + in the exponent of e, but here, we do not divide by 1/\text{length}(x)).

Value

When `z` is a vector, the value computed and returned by `fft` is the unnormalized univariate Fourier transform of the sequence of values in `z`.

When `z` contains an array, `fft` computes and returns the multivariate (spatial) transform. If `inverse` is TRUE, the (unnormalized) inverse Fourier transform is returned, i.e., if `y <- fft(z)`, then `z` is `fft(y, inverse = TRUE) / \text{length}(y)`.

By contrast, `mvfft` takes a real or complex matrix as argument, and returns a similar shaped matrix, but with each column replaced by its discrete Fourier transform. This is useful for analyzing vector-valued series.
The FFT is fastest when the length of the series being transformed is highly composite (i.e., has many factors). If this is not the case, the transform may take a long time to compute and will use a large amount of memory.

Source

References

See Also

`convolve`, `nextn`.

Examples

```r
x <- 1:4
fft(x)
fft(fft(x), inverse = TRUE)/length(x)
```

Description

Applies linear filtering to a univariate time series or to each series separately of a multivariate time series.

Usage

```r
filter(x, filter, method = c("convolution", "recursive"),
       sides = 2, circular = FALSE, init)
```

Arguments

- **x**: a univariate or multivariate time series.
- **filter**: a vector of filter coefficients in reverse time order (as for AR or MA coefficients).
- **method**: Either "convolution" or "recursive" (and can be abbreviated). If "convolution" a moving average is used; if "recursive" an autoregression is used.
- **sides**: for convolution filters only. If sides = 1 the filter coefficients are for past values only; if sides = 2 they are centred around lag 0. In this case the length of the filter should be odd, but if it is even, more of the filter is forward in time than backward.
- **circular**: for convolution filters only. If TRUE, wrap the filter around the ends of the series, otherwise assume external values are missing (NA).
- **init**: for recursive filters only. Specifies the initial values of the time series just prior to the start value, in reverse time order. The default is a set of zeros.
Details

Missing values are allowed in \( x \) but not in \( \text{filter} \) (where they would lead to missing values everywhere in the output).

Note that there is an implied coefficient 1 at lag 0 in the recursive filter, which gives

\[
y_t = x_t + \sum_{i=1}^{p} f_i y_{t-i} + \cdots + f_p y_{t-p}
\]

No check is made to see if recursive filter is invertible: the output may diverge if it is not.

The convolution filter is

\[
y_t = f_1 x_{t+o} + \cdots + f_p x_{t+o-(p-1)}
\]

where \( o \) is the offset; see \texttt{sides} for how it is determined.

Value

A time series object.

Note

\texttt{convolve(, type = "filter")} uses the FFT for computations and so \textit{may} be faster for long filters on univariate series, but it does not return a time series (and so the time alignment is unclear), nor does it handle missing values. \texttt{filter} is faster for a filter of length 100 on a series of length 1000, for example.

See Also

\texttt{convolve, arima.sim}

Examples

\begin{verbatim}
x <- 1:100
filter(x, rep(1, 3))
filter(x, rep(1, 3), sides = 1)
filter(x, rep(1, 3), sides = 1, circular = TRUE)
filter(presidents, rep(1, 3))
\end{verbatim}

---

\textit{fisher.test}  \quad \textit{Fisher’s Exact Test for Count Data}

Description

Performs Fisher’s exact test for testing the null of independence of rows and columns in a contingency table with fixed marginals.

Usage

\begin{verbatim}
fisher.test(x, y = NULL, workspace = 200000, hybrid = FALSE,
control = list(), or = 1, alternative = "two.sided",
conf.int = TRUE, conf.level = 0.95,
simulate.p.value = FALSE, B = 2000)
\end{verbatim}
Arguments

- **x**: either a two-dimensional contingency table in matrix form, or a factor object.
- **y**: a factor object; ignored if x is a matrix.
- **workspace**: an integer specifying the size of the workspace used in the network algorithm. In units of 4 bytes. Only used for non-simulated p-values larger than $2 \times 2$ tables.
- **hybrid**: a logical. Only used for larger than $2 \times 2$ tables, in which cases it indicates whether the exact probabilities (default) or a hybrid approximation thereof should be computed. See ‘Details’.
- **control**: a list with named components for low level algorithm control. At present the only one used is "mult", a positive integer $\geq 2$ with default 30 used only for larger than $2 \times 2$ tables. This says how many times as much space should be allocated to paths as to keys: see file 'fexact.c' in the sources of this package.
- **or**: the hypothesized odds ratio. Only used in the $2 \times 2$ case.
- **alternative**: indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. Only used in the $2 \times 2$ case.
- **conf.int**: logical indicating if a confidence interval for the odds ratio in a $2 \times 2$ table should be computed (and returned).
- **conf.level**: confidence level for the returned confidence interval. Only used in the $2 \times 2$ case and if conf.int = TRUE.
- **simulate.p.value**: a logical indicating whether to compute p-values by Monte Carlo simulation, in larger than $2 \times 2$ tables.
- **B**: an integer specifying the number of replicates used in the Monte Carlo test.

Details

If x is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both x and y must be vectors of the same length. Incomplete cases are removed, the vectors are coerced into factor objects, and the contingency table is computed from these.

For $2 \times 2$ cases, p-values are obtained directly using the (central or non-central) hypergeometric distribution. Otherwise, computations are based on a C version of the FORTRAN subroutine FEXACT which implements the network developed by Mehta and Patel (1986) and improved by Clarkson, Fan and Joe (1993). The FORTRAN code can be obtained from [http://www.netlib.org/toms/643](http://www.netlib.org/toms/643). Note this fails (with an error message) when the entries of the table are too large. (It transposes the table if necessary so it has no more rows than columns. One constraint is that the product of the row marginals be less than $2^{31} - 1$.)

For $2 \times 2$ tables, the null of conditional independence is equivalent to the hypothesis that the odds ratio equals one. ‘Exact’ inference can be based on observing that in general, given all marginal totals fixed, the first element of the contingency table has a non-central hypergeometric distribution with non-centrality parameter given by the odds ratio (Fisher, 1935). The alternative for a one-sided test is based on the odds ratio, so alternative = “greater” is a test of the odds ratio being bigger than or.

Two-sided tests are based on the probabilities of the tables, and take as ‘more extreme’ all tables with probabilities less than or equal to that of the observed table, the p-value being the sum of such probabilities.
For larger than $2 \times 2$ tables and $\text{hybrid} = \text{TRUE}$, asymptotic chi-squared probabilities are only used if the ‘Cochran conditions’ are satisfied, that is if no cell has count zero, and more than 80% of the cells have counts at least 5: otherwise the exact calculation is used.

Simulation is done conditional on the row and column marginals, and works only if the marginals are strictly positive. (A C translation of the algorithm of Patefield (1981) is used.)

**Value**

A list with class "htest" containing the following components:

- `p.value` the p-value of the test.
- `conf.int` a confidence interval for the odds ratio. Only present in the $2 \times 2$ case and if argument `conf.int = TRUE`.
- `estimate` an estimate of the odds ratio. Note that the *conditional* Maximum Likelihood Estimate (MLE) rather than the unconditional MLE (the sample odds ratio) is used. Only present in the $2 \times 2$ case.
- `null.value` the odds ratio under the null, or. Only present in the $2 \times 2$ case.
- `alternative` a character string describing the alternative hypothesis.
- `method` the character string "Fisher's Exact Test for Count Data".
- `data.name` a character string giving the names of the data.

dimnames = list(income = c("< 15k", "15-25k", "25-40k", "> 40k"),
               satisfaction = c("VeryD", "LittleD", "ModerateS", "VeryS")))

fisher.test(Job)

fisher.test(Job, simulate.p.value = TRUE, B = 1e5)

fitted

Extract Model Fitted Values

Description

fitted is a generic function which extracts fitted values from objects returned by modeling functions. fitted.values is an alias for it.

All object classes which are returned by model fitting functions should provide a fitted method. (Note that the generic is fitted and not fitted.values.)

Methods can make use of napredict methods to compensate for the omission of missing values. The default and nls methods do.

Usage

fitted(object, ...)

fitted.values(object, ...)
Arguments

- **object**: an object for which the extraction of model fitted values is meaningful.
- **...**: other arguments.

Value

Fitted values extracted from the object `object`.

References

See Also

- `coefficients`, `glm`, `lm`, `residuals`.

---

### fivenum

Tukey Five-Number Summaries

**Description**

Returns Tukey’s five number summary (minimum, lower-hinge, median, upper-hinge, maximum) for the input data.

**Usage**

```r
fivenum(x, na.rm = TRUE)
```

**Arguments**

- **x**: numeric, maybe including `NA`s and `Inf`s.
- **na.rm**: logical; if TRUE, all `NA` and `NaN`s are dropped, before the statistics are computed.

**Value**

A numeric vector of length 5 containing the summary information. See `boxplot.stats` for more details.

**See Also**

- `IQR`, `boxplot.stats`, `median`, `quantile`, `range`.

**Examples**

```r
fivenum(c(rnorm(100), -1:1/0))
```
Fligner-Killeen Test of Homogeneity of Variances

Description
Performs a Fligner-Killeen (median) test of the null that the variances in each of the groups (samples) are the same.

Usage

fligner.test(x, ...)

## Default S3 method:
fligner.test(x, g, ...)

## S3 method for class 'formula'
fligner.test(formula, data, subset, na.action, ...)

Arguments

x
  a numeric vector of data values, or a list of numeric data vectors.

g
  a vector or factor object giving the group for the corresponding elements of x. Ignored if x is a list.

formula
  a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.

data
  an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset
  an optional vector specifying a subset of observations to be used.

na.action
  a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").

...
  further arguments to be passed to or from methods.

Details

If x is a list, its elements are taken as the samples to be compared for homogeneity of variances, and hence have to be numeric data vectors. In this case, g is ignored, and one can simply use fligner.test(x) to perform the test. If the samples are not yet contained in a list, use fligner.test(list(x, ...)).

Otherwise, x must be a numeric data vector, and g must be a vector or factor object of the same length as x giving the group for the corresponding elements of x.

The Fligner-Killeen (median) test has been determined in a simulation study as one of the many tests for homogeneity of variances which is most robust against departures from normality, see Conover, Johnson & Johnson (1981). It is a k-sample simple linear rank which uses the ranks of the absolute values of the centered samples and weights \( a(i) = \text{qnorm}((1+i/(n+1))/2) \). The version implemented here uses median centering in each of the samples (F-K:med \( X^2 \) in the reference).
Value
A list of class "htest" containing the following components:

statistic the Fligner-Killeen:med $X^2$ test statistic.

parameter the degrees of freedom of the approximate chi-squared distribution of the test statistic.

p.value the p-value of the test.

method the character string "Fligner-Killeen test of homogeneity of variances".

data.name a character string giving the names of the data.

References

plot(count ~ spray, data = InsectSprays)
fligner.test(InsectSprays$count, InsectSprays$spray)
fligner.test(count ~ spray, data = InsectSprays)
## Compare this to bartlett.test()

---

Description
The generic function formula and its specific methods provide a way of extracting formulae which have been included in other objects.

as.formula is almost identical, additionally preserving attributes when object already inherits from "formula".

Usage

formula(x, ...)

as.formula(object, env = parent.frame())

## S3 method for class 'formula'
print(x, showEnv = !identical(e, .GlobalEnv), ...)
Arguments

- **x**, **object** \( R \) object.
- ... further arguments passed to or from other methods.
- **env** the environment to associate with the result, if not already a formula.
- **showEnv** logical indicating if the environment should be printed as well.

Details

The models fit by, e.g., the `lm` and `glm` functions are specified in a compact symbolic form. The ~ operator is basic in the formation of such models. An expression of the form \( y \sim \text{model} \) is interpreted as a specification that the response \( y \) is modelled by a linear predictor specified symbolically by `model`. Such a model consists of a series of terms separated by + operators. The terms themselves consist of variable and factor names separated by : operators. Such a term is interpreted as the interaction of all the variables and factors appearing in the term.

In addition to + and :, a number of other operators are useful in model formulae. The * operator denotes factor crossing: \( a:b \) interpreted as \( a + b + a:b \). The ^ operator indicates crossing to the specified degree. For example \( (a+b+c)^2 \) is identical to \( (a+b+c)*(a+b+c) \) which in turn expands to a formula containing the main effects for \( a, b \) and \( c \) together with their second-order interactions. The %in% operator indicates that the terms on its left are nested within those on the right. For example \( a+b \%in\% a \) expands to the formula \( a + a:b \). The ~ operator removes the specified terms, so that \( (a+b+c)^2 - a:b \) is identical to \( a + b + c + b:c + a:c \). It can also be used to remove the intercept term: when fitting a linear model \( y \sim x - 1 \) specifies a line through the origin. A model with no intercept can be also specified as \( y \sim x \) or \( y \sim P \).

While formulae usually involve just variable and factor names, they can also involve arithmetic expressions. The formula \( \log(y) \sim a + \log(x) \) is quite legal. When such arithmetic expressions involve operators which are also used symbolically in model formulae, there can be confusion between arithmetic and symbolic operator use.

To avoid this confusion, the function `I()` can be used to bracket those portions of a model formula where the operators are used in their arithmetic sense. For example, in the formula \( y \sim a + I(b+c) \), the term \( b+c \) is to be interpreted as the sum of \( b \) and \( c \).

Variable names can be quoted by backticks `like this` in formulae, although there is no guarantee that all code using formulae will accept such non-syntactic names.

Most model-fitting functions accept formulae with right-hand-side including the function `offset` to indicate terms with a fixed coefficient of one. Some functions accept other `specials` such as `strata` or `cluster` (see the `specials` argument of `terms.formula`).

There are two special interpretations of . in a formula. The usual one is in the context of a data argument of model fitting functions and means 'all columns not otherwise in the formula': see `terms.formula`. In the context of `update.formula`, only, it means 'what was previously in this part of the formula'.

When `formula` is called on a fitted model object, either a specific method is used (such as that for class "nls") or the default method. The default first looks for a "formula" component of the object (and evaluates it), then a "terms" component, then a `formula` parameter of the call (and evaluates its value) and finally a "formula" attribute.

There is a `formula` method for data frames. If there is only one column this forms the RHS with an empty LHS. For more columns, the first column is the LHS of the formula and the remaining columns separated by + form the RHS.
Value

All the functions above produce an object of class "formula" which contains a symbolic model formula.

Environments

A formula object has an associated environment, and this environment (rather than the parent environment) is used by model.frame to evaluate variables that are not found in the supplied data argument.

Formulas created with the ~ operator use the environment in which they were created. Formulas created with as.formula will use the env argument for their environment.

Examples

```r
class(fo <- y ~ x1*x2) # "formula"
fo
typeof(fo) # R internal : "language"
terms(fo)

environment(fo)
environment(as.formula("y ~ x"))
environment(as.formula("y ~ x", env = new.env()))

## Create a formula for a model with a large number of variables:
xnam <- paste0("x", 1:25)
(fmla <- as.formula(paste("y ~ ", paste(xnam, collapse = "+")))))
```

---

**formula.nls**

*Extract Model Formula from nls Object*

**Description**

Returns the model used to fit object.

**Usage**

```r
## S3 method for class 'nls'
formula(x, ...)
```
friedman.test

Arguments

x an object inheriting from class "nls", representing a nonlinear least squares fit.
... further arguments passed to or from other methods.

Value

a formula representing the model used to obtain object.

Author(s)

José Pinheiro and Douglas Bates

See Also

nls, formula

Examples

fm1 <- nls(circumference ~ A/(1+exp((B-age)/C)), Orange,
start = list(A = 160, B = 700, C = 350))
formula(fm1)

Description

Performs a Friedman rank sum test with unreplicated blocked data.

Usage

friedman.test(y, ...)

## Default S3 method:
friedman.test(y, groups, blocks, ...)

## S3 method for class 'formula'
friedman.test(formula, data, subset, na.action, ...)

Arguments

y either a numeric vector of data values, or a data matrix.
groups a vector giving the group for the corresponding elements of y if this is a vector;
ignored if y is a matrix. If not a factor object, it is coerced to one.
blocks a vector giving the block for the corresponding elements of y if this is a vector;
ignored if y is a matrix. If not a factor object, it is coerced to one.
formula a formula of the form a ~ b | c, where a, b and c give the data values and
corresponding groups and blocks, respectively.
data an optional matrix or data frame (or similar: see model.frame) containing
the variables in the formula formula. By default the variables are taken from
environment(formula).
friedman.test

subset an optional vector specifying a subset of observations to be used.
na.action a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").
... further arguments to be passed to or from methods.

Details

friedman.test can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in y for each combination of levels of groups and blocks) where the normality assumption may be violated.
The null hypothesis is that apart from an effect of blocks, the location parameter of y is the same in each of the groups.
If y is a matrix, groups and blocks are obtained from the column and row indices, respectively. NA's are not allowed in groups or blocks; if y contains NA's, corresponding blocks are removed.

Value

A list with class "htest" containing the following components:
statistic the value of Friedman's chi-squared statistic.
parameter the degrees of freedom of the approximate chi-squared distribution of the test statistic.
p.value the p-value of the test.
method the character string "Friedman rank sum test".
data.name a character string giving the names of the data.

RoundingTimes <- matrix(c(5.40, 5.50, 5.55, 5.85, 5.70, 5.75, 5.20, 5.60, 5.90, 5.55, 5.50, 5.40, 5.90, 5.85, 5.70, 5.45, 5.55, 5.60, 5.40, 5.40, 5.35, 5.45, 5.50, 5.35, 5.25, 5.15, 5.00), nrow=3)
Description

Create ‘flat’ contingency tables.

Usage

ftable(x, ...)

## Default S3 method:
ftable(..., exclude = c(NA, NaN), row.vars = NULL, col.vars = NULL)

Arguments

x, ... R objects which can be interpreted as factors (including character strings), or a
list (or data frame) whose components can be so interpreted, or a contingency
table object of class "table" or "ftable".

exclude values to use in the exclude argument of factor when interpreting non-factor
objects.

row.vars a vector of integers giving the numbers of the variables, or a character vector
giving the names of the variables to be used for the rows of the flat contingency
table.
col vars a vector of integers giving the numbers of the variables, or a character vector giving the names of the variables to be used for the columns of the flat contingency table.

Details

ftable creates ‘flat’ contingency tables. Similar to the usual contingency tables, these contain the counts of each combination of the levels of the variables (factors) involved. This information is then re-arranged as a matrix whose rows and columns correspond to unique combinations of the levels of the row and column variables (as specified by row.vars and col.vars, respectively). The combinations are created by looping over the variables in reverse order (so that the levels of the left-most variable vary the slowest). Displaying a contingency table in this flat matrix form (via print.ftable, the print method for objects of class “ftable”) is often preferable to showing it as a higher-dimensional array.

ftable is a generic function. Its default method, ftable.default, first creates a contingency table in array form from all arguments except row.vars and col.vars. If the first argument is of class "table", it represents a contingency table and is used as is; if it is a flat table of class "ftable", the information it contains is converted to the usual array representation using as.ftable. Otherwise, the arguments should be R objects which can be interpreted as factors (including character strings), or a list (or data frame) whose components can be so interpreted, which are cross-tabulated using table. Then, the arguments row.vars and col.vars are used to collapse the contingency table into flat form. If neither of these two is given, the last variable is used for the columns. If both are given and their union is a proper subset of all variables involved, the other variables are summed out.

When the arguments are R expressions interpreted as factors, additional arguments will be passed to table to control how the variable names are displayed; see the last example below.

Function ftable.formula provides a formula method for creating flat contingency tables.

There are methods for as.table and as.data.frame.

Value

ftable returns an object of class “ftable”, which is a matrix with counts of each combination of the levels of variables with information on the names and levels of the (row and columns) variables stored as attributes "row.vars" and "col.vars".

See Also

ftable.formula for the formula interface (which allows a data = . argument); read.ftable for information on reading, writing and coercing flat contingency tables; table for ordinary cross-tabulation; xtabs for formula-based cross-tabulation.

Examples

## Start with a contingency table.
ftable(Titanic, row.vars = 1:3)
ftable(Titanic, row.vars = 1:2, col.vars = "Survived")
ftable(Titanic, row.vars = 2:1, col.vars = "Survived")

## Start with a data frame.
x <- ftable(mtcars[c("cyl", "vs", "am", "gear")])
x
ftable(x, row.vars = c(2, 4))
### ftable.formula

```
## Start with expressions, use table()'s "dnn" to change labels
ftable(mtcars$cyl, mtcars$vs, mtcars$am, mtcars$gear, row.vars = c(2, 4),
       dnn = c("Cylinders", "V/S", "Transmission", "Gears"))
```

---

**Description**

Produce or manipulate a flat contingency table using formula notation.

**Usage**

```r
## S3 method for class 'formula'
ftable(formula, data = NULL, subset, na.action, ...)  
```

**Arguments**

- `formula` a formula object with both left and right hand sides specifying the column and row variables of the flat table.
- `data` a data frame, list or environment (or similar: see `model.frame`) containing the variables to be cross-tabulated, or a contingency table (see below).
- `subset` an optional vector specifying a subset of observations to be used. Ignored if `data` is a contingency table.
- `na.action` a function which indicates what should happen when the data contain NAs. Ignored if `data` is a contingency table.
- `...` further arguments to the default ftable method may also be passed as arguments, see `ftable.default`.

**Details**

This is a method of the generic function `ftable`.

The left and right hand side of `formula` specify the column and row variables, respectively, of the flat contingency table to be created. Only the `+` operator is allowed for combining the variables. A `.` may be used once in the formula to indicate inclusion of all the remaining variables.

If `data` is an object of class "table" or an array with more than 2 dimensions, it is taken as a contingency table, and hence all entries should be nonnegative. Otherwise, if it is not a flat contingency table (i.e., an object of class "ftable"), it should be a data frame or matrix, list or environment containing the variables to be cross-tabulated. In this case, `na.action` is applied to the data to handle missing values, and, after possibly selecting a subset of the data as specified by the `subset` argument, a contingency table is computed from the variables.

The contingency table is then collapsed to a flat table, according to the row and column variables specified by `formula`.

**Value**

A flat contingency table which contains the counts of each combination of the levels of the variables, collapsed into a matrix for suitably displaying the counts.

Examples

Titanic
  x <- ftable(Survived ~ ., data = Titanic)
  x
  ftable(Sex ~ Class + Age, data = x)

The Gamma Distribution

Density, distribution function, quantile function and random generation for the Gamma distribution with parameters shape and scale.

Usage

dgamma(x, shape, rate = 1, scale = 1/rate, log = FALSE)
pgamma(q, shape, rate = 1, scale = 1/rate, lower.tail = TRUE, log.p = FALSE)
qgamma(p, shape, rate = 1, scale = 1/rate, lower.tail = TRUE, log.p = FALSE)
rgamma(n, shape, rate = 1, scale = 1/rate)

Arguments

  x, q  vector of quantiles.
  p    vector of probabilities.
  n    number of observations. If length(n) > 1, the length is taken to be the number required.
  rate  an alternative way to specify the scale.
  shape, scale shape and scale parameters. Must be positive, scale strictly.
  log, log.p  logical; if TRUE, probabilities/densities p are returned as log(p).
  lower.tail  logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

If scale is omitted, it assumes the default value of 1.

The Gamma distribution with parameters shape = \( \alpha \) and scale = \( \sigma \) has density

\[
f(x) = \frac{1}{\sigma^\alpha \Gamma(\alpha)} x^{\alpha-1} e^{-x/\sigma}
\]

for \( x \geq 0, \alpha > 0 \) and \( \sigma > 0 \). (Here \( \Gamma(\alpha) \) is the function implemented by R’s \texttt{gamma()} and defined in its help. Note that \( \alpha = 0 \) corresponds to the trivial distribution with all mass at point 0.)

The mean and variance are \( E(X) = \alpha \sigma \) and \( Var(X) = \alpha \sigma^2 \).

The cumulative hazard \( H(t) = -\log(1 - F(t)) \) is
Note that for smallish values of shape (and moderate scale) a large parts of the mass of the Gamma distribution is on values of \( x \) so near zero that they will be represented as zero in computer arithmetic. So rgamma may well return values which will be represented as zero. (This will also happen for very large values of scale since the actual generation is done for scale = 1.)

Value

dgamma gives the density, pgamma gives the distribution function, qgamma gives the quantile function, and rgamma generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by \( n \) for rgamma, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than \( n \) are recycled to the length of the result. Only the first elements of the logical parameters are used.

Note

The S (Becker et al. 1988) parametrization was via shape and rate: S had no scale parameter. In R 2.x.y scale took precedence over rate, but now it is an error to supply both.

gamma is closely related to the incomplete gamma function. As defined by Abramowitz and Stegun 6.5.1 (and by ‘Numerical Recipes’) this is

\[
P(a, x) = \frac{1}{\Gamma(a)} \int_0^x t^{a-1} e^{-t} dt
\]

\( P(a, x) \) is pgamma(x, a). Other authors (for example Karl Pearson in his 1922 tables) omit the normalizing factor, defining the incomplete gamma function \( \gamma(a, x) \) as \( \gamma(a, x) = \int_0^x t^{a-1} e^{-t} dt \), i.e., pgamma(x, a) * gamma(a). Yet other use the ‘upper’ incomplete gamma function,

\[
\Gamma(a, x) = \int_x^\infty t^{a-1} e^{-t} dt,
\]

which can be computed by pgamma(x, a, lower = FALSE) * gamma(a).

Note however that pgamma(x, a, ...) currently requires \( a > 0 \), whereas the incomplete gamma function is also defined for negative \( a \). In that case, you can use gamma_inc(a,x) (for \( \Gamma(a, x) \)) from package gsl.

Source

dgamma is computed via the Poisson density, using code contributed by Catherine Loader (see dbinom).

pgamma uses an unpublished (and not otherwise documented) algorithm ‘mainly by Morten Welinder’.

qgamma is based on a C translation of

plus a final Newton step to improve the approximation.
rgamma for shape \( \geq 1 \) uses

and for \( 0 < \text{shape} < 1 \) uses

References

gamma for the gamma function.

Distributions for other standard distributions, including `dbeta` for the Beta distribution and `dchisq` for the chi-squared distribution which is a special case of the Gamma distribution.

Examples

```r
-log(dgamma(1:4, shape = 1))
p <- (1:9)/10
pgamma(qgamma(p, shape = 2), shape = 2)
1 - 1/exp(qgamma(p, shape = 1))

# even for shape = 0.001 about half the mass is on numbers
# that cannot be represented accurately (and most of those as zero)
pgamma(.Machine$double.xmin, 0.001)
pgamma(5e-324, 0.001)  # on most machines 5e-324 is the smallest
# representable non-zero number

table(rgamma(1e4, 0.001) == 0)/1e4
```

---

**Geometric**

*The Geometric Distribution*

Description

Density, distribution function, quantile function and random generation for the geometric distribution with parameter `prob`.

Usage

```r
dgeom(x, prob, log = FALSE)
pgeom(q, prob, lower.tail = TRUE, log.p = FALSE)
qgeom(p, prob, lower.tail = TRUE, log.p = FALSE)
```

---

**Geometric**
Arguments

- \(x\), \(q\) vector of quantiles representing the number of failures in a sequence of Bernoulli trials before success occurs.
- \(p\) vector of probabilities.
- \(n\) number of observations. If \(\text{length}(n) > 1\), the length is taken to be the number required.
- \(\text{prob}\) probability of success in each trial. \(0 < \text{prob} <= 1\).
- \(\text{log}, \text{log.p}\) logical; if TRUE, probabilities \(p\) are given as \(\log(p)\).
- \(\text{lower.tail}\) logical; if TRUE (default), probabilities are \(P[X \leq x]\), otherwise, \(P[X > x]\).

Details

The geometric distribution with \(\text{prob} = p\) has density

\[ p(x) = p(1 - p)^x \]

for \(x = 0, 1, 2, \ldots, 0 < p \leq 1\).

If an element of \(x\) is not integer, the result of \(\text{dgeom}\) is zero, with a warning.

The quantile is defined as the smallest value \(x\) such that \(F(x) \geq p\), where \(F\) is the distribution function.

Value

dgeom gives the density, pgeom gives the distribution function, qgeom gives the quantile function, and rgeom generates random deviates.

Invalid prob will result in return value NaN, with a warning.

The length of the result is determined by \(n\) for rgeom, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than \(n\) are recycled to the length of the result. Only the first elements of the logical parameters are used.

Source

dgeom computes via dbinom, using code contributed by Catherine Loader (see dbinom).
pgeom and qgeom are based on the closed-form formulae.
rgeom uses the derivation as an exponential mixture of Poissons, see

See Also

Distributions for other standard distributions, including dnbinom for the negative binomial which generalizes the geometric distribution.

Examples

Ni <- rgeom(20, prob = 1/4); table(factor(Ni, 0:max(Ni)))
getInitial  

Get Initial Parameter Estimates

Description
This function evaluates initial parameter estimates for a nonlinear regression model. If data is a parameterized data frame or pframe object, its parameters attribute is returned. Otherwise the object is examined to see if it contains a call to a selfStart object whose initial attribute can be evaluated.

Usage
getInitial(object, data, ...)

Arguments

- object: a formula or a selfStart model that defines a nonlinear regression model
- data: a data frame in which the expressions in the formula or arguments to the selfStart model can be evaluated
- ...: optional additional arguments

Value
A named numeric vector or list of starting estimates for the parameters. The construction of many selfStart models is such that these “starting” estimates are, in fact, the converged parameter estimates.

Author(s)
José Pinheiro and Douglas Bates

glm

Fitting Generalized Linear Models

Description

glm is used to fit generalized linear models, specified by giving a symbolic description of the linear predictor and a description of the error distribution.

Usage

glm(formula, family = gaussian, data, weights, subset, 
na.action, start = NULL, etastart, mustart, offset, 
control = list(...), model = TRUE, method = "glm.fit", 
x = FALSE, y = TRUE, contrasts = NULL, ...)

glm.fit(x, y, weights = rep(1, nobs), 
start = NULL, etastart = NULL, mustart = NULL, 
offset = rep(0, nobs), family = gaussian(), 
control = list(), intercept = TRUE)

## S3 method for class 'glm'
weights(object, type = c("prior", "working"), ...)

Arguments

formula an object of class "formula" (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under 'Details'.

family a description of the error distribution and link function to be used in the model. This can be a character string naming a family function, a family function or the result of a call to a family function. (See family for details of family functions.)

data an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment(formula), typically the environment from which glm is called.

weights an optional vector of ‘prior weights’ to be used in the fitting process. Should be NULL or a numeric vector.

subset an optional vector specifying a subset of observations to be used in the fitting process.

na.action a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The ‘factory-fresh’ default is na.omit. Another possible value is NULL, no action. Value na.exclude can be useful.

start starting values for the parameters in the linear predictor.

etastart starting values for the linear predictor.

mustart starting values for the vector of means.
this can be used to specify an a priori known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length equal to the number of cases. One or more offset terms can be included in the formula instead or as well, and if more than one is specified their sum is used. See `model.offset`.

A list of parameters for controlling the fitting process. For `glm.fit` this is passed to `glm.control`.

A logical value indicating whether model frame should be included as a component of the returned value.

The method to be used in fitting the model. The default method "glm.fit" uses iteratively reweighted least squares (IWLS): the alternative "model.frame" returns the model frame and does no fitting.

User-supplied fitting functions can be supplied either as a function or a character string naming a function, with a function which takes the same arguments as `glm.fit`. If specified as a character string it is looked up from within the `stats` namespace.

For `glm`: logical values indicating whether the response vector and model matrix used in the fitting process should be returned as components of the returned value.

For `glm.fit`: `x` is a design matrix of dimension $n \times p$, and `y` is a vector of observations of length $n$.

An optional list. See the `contrasts.arg` of `model.matrix.default`.

logical. Should an intercept be included in the null model?

An object inheriting from class "glm".

character, partial matching allowed. Type of weights to extract from the fitted model object.

For `glm`: arguments to be used to form the default `control` argument if it is not supplied directly.

For `weights`: further arguments passed to or from other methods.

Details

A typical predictor has the form `response ~ terms` where `response` is the (numeric) response vector and `terms` is a series of terms which specifies a linear predictor for `response`. For binomial and quasibinomial families the response can also be specified as a `factor` (when the first level denotes failure and all others success) or as a two-column matrix with the columns giving the numbers of successes and failures. A terms specification of the form `first + second` indicates all the terms in `first` together with all the terms in `second` with any duplicates removed.

A specification of the form `first:second` indicates the the set of terms obtained by taking the interactions of all terms in `first` with all terms in `second`. The specification `first*second` indicates the cross of `first` and `second`. This is the same as `first + second + first:second`.

The terms in the formula will be re-ordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on: to avoid this pass a `terms` object as the formula.

Non-NULL weights can be used to indicate that different observations have different dispersions (with the values in `weights` being inversely proportional to the dispersions); or equivalently, when the elements of `weights` are positive integers $w_i$, that each response $y_i$ is the mean of $w_i$ unit-weight observations. For a binomial GLM prior weights are used to give the number of trials when the response is the proportion of successes: they would rarely be used for a Poisson GLM.
glm is the workhorse function: it is not normally called directly but can be more efficient where the response vector and design matrix have already been calculated.

If more than one of etastart, start and mustart is specified, the first in the list will be used. It is often advisable to supply starting values for a quasi family, and also for families with unusual links such as gaussian("log").

All of weights, subset, offset, etastart and mustart are evaluated in the same way as variables in formula, that is first in data and then in the environment of formula.

For the background to warning messages about ‘fitted probabilities numerically 0 or 1 occurred’ for binomial GLMs, see Venables & Ripley (2002, pp. 197–8).

Value

glm returns an object of class inheriting from "glm" which inherits from the class "lm". See later in this section. If a non-standard method is used, the object will also inherit from the class (if any) returned by that function.

The function summary (i.e., summary.glm) can be used to obtain or print a summary of the results and the function anova (i.e., anova.glm) to produce an analysis of variance table.

The generic accessor functions coefficients, effects, fitted.values and residuals can be used to extract various useful features of the value returned by glm.

weights extracts a vector of weights, one for each case in the fit (after subsetting and na.action). An object of class "lm" is a list containing at least the following components:

- coefficients: a named vector of coefficients
- residuals: the working residuals, that is the residuals in the final iteration of the IWLS fit. Since cases with zero weights are omitted, their working residuals are NA.
- fitted.values: the fitted mean values, obtained by transforming the linear predictors by the inverse of the link function.
- rank: the numeric rank of the fitted linear model.
- family: the family object used.
- linear.predictors: the linear fit on link scale.
- deviance: up to a constant, minus twice the maximized log-likelihood. Where sensible, the constant is chosen so that a saturated model has deviance zero.
- aic: A version of Akaike’s An Information Criterion, minus twice the maximized log-likelihood plus twice the number of parameters, computed by the aic component of the family. For binomial and Poison families the dispersion is fixed at one and the number of parameters is the number of coefficients. For gaussian, Gamma and inverse gaussian families the dispersion is estimated from the residual deviance, and the number of parameters is the number of coefficients plus one. For a gaussian family the MLE of the dispersion is used so this is a valid value of AIC, but for Gamma and inverse gaussian families it is not. For families fitted by quasi-likelihood the value is NA.
- null.deviance: the deviance for the null model, comparable with deviance. The null model will include the offset, and an intercept if there is one in the model. Note that this will be incorrect if the link function depends on the data other than through the fitted mean: specify a zero offset to force a correct calculation.
- iter: the number of iterations of IWLS used.
- weights: the working weights, that is the weights in the final iteration of the IWLS fit.
prior.weights  the weights initially supplied, a vector of 1s if none were.
df.residual   the residual degrees of freedom.
df.null      the residual degrees of freedom for the null model.
y           if requested (the default) the y vector used. (It is a vector even for a binomial model.)
x           if requested, the model matrix.
model        if requested (the default), the model frame.
converged    logical. Was the IWLS algorithm judged to have converged?
boundary     logical. Is the fitted value on the boundary of the attainable values?
call          the matched call.
formula      the formula supplied.
terms        the terms object used.
data         the data argument.
offset       the offset vector used.
control      the value of the control argument used.
method       the name of the fitter function used, currently always "glm.fit".
contrasts    (where relevant) the contrasts used.
xlevels     (where relevant) a record of the levels of the factors used in fitting.
na.action   (where relevant) information returned by model.frame on the special handling of NAs.

In addition, non-empty fits will have components qr, R and effects relating to the final weighted linear fit.

Objects of class "glm" are normally of class c("glm", "lm"), that is inherit from class "lm", and well-designed methods for class "lm" will be applied to the weighted linear model at the final iteration of IWLS. However, care is needed, as extractor functions for class "glm" such as residuals and weights do not just pick out the component of the fit with the same name.

If a binomial glm model was specified by giving a two-column response, the weights returned by prior.weights are the total numbers of cases (factored by the supplied case weights) and the component y of the result is the proportion of successes.

Fitting functions

The argument method serves two purposes. One is to allow the model frame to be recreated with no fitting. The other is to allow the default fitting function glm.fit to be replaced by a function which takes the same arguments and uses a different fitting algorithm. If glm.fit is supplied as a character string it is used to search for a function of that name, starting in the stats namespace.

The class of the object return by the fitter (if any) will be prepended to the class returned by glm.

Author(s)

The original R implementation of glm was written by Simon Davies working for Ross Ihaka at the University of Auckland, but has since been extensively re-written by members of the R Core team.

The design was inspired by the S function of the same name described in Hastie & Pregibon (1992).

glm.control
Auxiliary for Controlling GLM Fitting

Description

Auxiliary function for glm fitting. Typically only used internally by glm.fit, but may be used to construct a control argument to either function.

Usage

glm.control(epsilon = 1e-8, maxit = 25, trace = FALSE)

Arguments

epsilon positive convergence tolerance \( \epsilon \); the iterations converge when \[ \frac{|\text{dev} - \text{dev}_{\text{old}}|}{|\text{dev}| + 0.1} < \epsilon. \]

maxit integer giving the maximal number of IWLS iterations.

trace logical indicating if output should be produced for each iteration.

Details

The control argument of glm is by default passed to the control argument of glm.fit, which uses its elements as arguments to glm.control: the latter provides defaults and sanity checking.

If epsilon is small (less than \(10^{-10}\)) it is also used as the tolerance for the detection of collinearity in the least squares solution.

When trace is true, calls to cat produce the output for each IWLS iteration. Hence, options(digits = *) can be used to increase the precision, see the example.

Value

A list with components named as the arguments.

References

See Also

glm.fit, the fitting procedure used by glm.

Examples

### A variation on example(glm):

## Annette Dobson's example ...
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3,1,9)
treatment <- gl(3,3)
co <- options(digits = 12) # to see more when tracing:
glm.D93X <- glm(counts ~ outcome + treatment, family = poisson()),
glm.summaries

Description

These functions are all methods for class glm or summary.glm objects.

Usage

### S3 method for class 'glm'

family(object, ...)

### S3 method for class 'glm'

residuals(object, type = c("deviance", "pearson", "working", "response", "partial"), ...)

Arguments

- **object**: an object of class glm, typically the result of a call to glm.
- **type**: the type of residuals which should be returned. The alternatives are: "deviance" (default), "pearson", "working", "response", and "partial".
- **...**: further arguments passed to or from other methods.

Details

The references define the types of residuals: Davison & Snell is a good reference for the usages of each.

The partial residuals are a matrix of working residuals, with each column formed by omitting a term from the model.

How residuals treats cases with missing values in the original fit is determined by the na.action argument of that fit. If na.action = na.omit omitted cases will not appear in the residuals, whereas if na.action = na.exclude they will appear, with residual value NA. See also naresid.

For fits done with y = FALSE the response values are computed from other components.

References

See Also

`glm` for computing `glm.obj`, `anova.glm`; the corresponding `generic` functions, `summary.glm`, `coef`, `deviance`, `df.residual`, `effects`, `fitted`, `residuals`.

`influence.measures` for deletion diagnostics, including standardized (`rstandard`) and studentized (`rstudent`) residuals.

---

**hclust**

*Hierarchical Clustering*

**Description**

Hierarchical cluster analysis on a set of dissimilarities and methods for analyzing it.

**Usage**

```r
hclust(d, method = "complete", members = NULL)
```

```r
# S3 method for class 'hclust'
plot(x, labels = NULL, hang = 0.1,
     axes = TRUE, frame.plot = FALSE, ann = TRUE,
     main = "Cluster Dendrogram",
     sub = NULL, xlab = NULL, ylab = "Height", ...)
```

**Arguments**

- `d` a dissimilarity structure as produced by `dist`.
- `method` the agglomeration method to be used. This should be (an unambiguous abbreviation of) one of "ward", "single", "complete", "average", "mcquitty", "median" or "centroid".
- `members` NULL or a vector with length size of `d`. See the ‘Details’ section.
- `x` an object of the type produced by `hclust`.
- `hang` The fraction of the plot height by which labels should hang below the rest of the plot. A negative value will cause the labels to hang down from 0.
- `labels` A character vector of labels for the leaves of the tree. By default the row names or row numbers of the original data are used. If `labels = FALSE` no labels at all are plotted.
- `axes`, `frame.plot`, `ann` logical flags as in `plot.default`.
- `main`, `sub`, `xlab`, `ylab` character strings for `title`. `sub` and `xlab` have a non-NULL default when there’s a `tree$call`.
- `...` Further graphical arguments. E.g. `cex` controls the size of the labels (if plotted) in the same way as `text`. 
Details

This function performs a hierarchical cluster analysis using a set of dissimilarities for the \( n \) objects being clustered. Initially, each object is assigned to its own cluster and then the algorithm proceeds iteratively, at each stage joining the two most similar clusters, continuing until there is just a single cluster. At each stage distances between clusters are recomputed by the Lance–Williams dissimilarity update formula according to the particular clustering method being used.

A number of different clustering methods are provided. Ward’s minimum variance method aims at finding compact, spherical clusters. The complete linkage method finds similar clusters. The single linkage method (which is closely related to the minimal spanning tree) adopts a ‘friends of friends’ clustering strategy. The other methods can be regarded as aiming for clusters with characteristics somewhere between the single and complete link methods. Note however, that methods "median" and "centroid" are not leading to a monotone distance measure, or equivalently the resulting dendrograms can have so called inversions (which are hard to interpret).

If \texttt{members} ! = \texttt{NULL}, then \texttt{d} is taken to be a dissimilarity matrix between clusters instead of dissimilarities between singletons and \texttt{members} gives the number of observations per cluster. This way the hierarchical cluster algorithm can be ‘started in the middle of the dendrogram’, e.g., in order to reconstruct the part of the tree above a cut (see examples). Dissimilarities between clusters can be efficiently computed (i.e., without \texttt{hclust} itself) only for a limited number of distance/linkage combinations, the simplest one being squared Euclidean distance and centroid linkage. In this case the dissimilarities between the clusters are the squared Euclidean distances between cluster means.

In hierarchical cluster displays, a decision is needed at each merge to specify which subtree should go on the left and which on the right. Since, for \( n \) observations there are \( n - 1 \) merges, there are \( 2^{(n-1)} \) possible orderings for the leaves in a cluster tree, or dendrogram. The algorithm used in \texttt{hclust} is to order the subtree so that the tighter cluster is on the left (the last, i.e., most recent, merge of the left subtree is at a lower value than the last merge of the right subtree). Single observations are the tightest clusters possible, and merges involving two observations place them in order by their observation sequence number.

Value

An object of class \texttt{hclust} which describes the tree produced by the clustering process. The object is a list with components:

- \texttt{merge} an \( n - 1 \) by 2 matrix. Row \( i \) of \texttt{merge} describes the merging of clusters at step \( i \) of the clustering. If an element \( j \) in the row is negative, then observation \( -j \) was merged at this stage. If \( j \) is positive then the merge was with the cluster formed at the (earlier) stage \( j \) of the algorithm. Thus negative entries in \texttt{merge} indicate agglomerations of singletons, and positive entries indicate agglomerations of non-singletons.

- \texttt{height} a set of \( n - 1 \) real values (non-decreasing for ultrametric trees). The clustering \texttt{height}: that is, the value of the criterion associated with the clustering method for the particular agglomeration.

- \texttt{order} a vector giving the permutation of the original observations suitable for plotting, in the sense that a cluster plot using this ordering and matrix \texttt{merge} will not have crossings of the branches.

- \texttt{labels} labels for each of the objects being clustered.

- \texttt{call} the call which produced the result.

- \texttt{method} the cluster method that has been used.

- \texttt{dist.method} the distance that has been used to create \texttt{d} (only returned if the distance object has a "method" attribute).
There are `print`, `plot` and `identify` (see `identify.hclust`) methods and the `rect.hclust()` function for `hclust` objects.

**Author(s)**

The `hclust` function is based on Fortran code contributed to STATLIB by F. Murtagh.

**References**

**See Also**

`identify.hclust`, `rect.hclust`, `cutree`, `dendrogram`, `kmeans`.

For the Lance–Williams formula and methods that apply it generally, see `agnes` from package `cluster`.

**Examples**

```r
require(graphics)

hc <- hclust(dist(USArrests), "ave")
plot(hc)
plot(hc, hang = -1)

## Do the same with centroid clustering and squared Euclidean distance,
## cut the tree into ten clusters and reconstruct the upper part of the
## tree from the cluster centers.
hc <- hclust(dist(USArrests)^2, "cen")
memb <- cutree(hc, k = 10)
cent <- NULL
for(k in 1:10){
  cent <- rbind(cent, colMeans(USArrests[memb == k, ]))
}
hc1 <- hclust(dist(cent)^2, method = "cen", members = table(memb))
opar <- par(mfrow = c(1, 2))
plot(hc, labels = FALSE, hang = -1, main = "Original Tree")
plot(hc1, labels = FALSE, hang = -1, main = "Re-start from 10 clusters")
par(opar)
```
heatmap

**Description**

A heat map is a false color image (basically \( \text{image}(t(x)) \)) with a dendrogram added to the left side and to the top. Typically, reordering of the rows and columns according to some set of values (row or column means) within the restrictions imposed by the dendrogram is carried out.

**Usage**

```r
heatmap(x, Rowv = NULL, Colv = if(symm)"Rowv" else NULL, 
distfun = dist, hclustfun = hclust, 
reorderfun = function(d, w) reorder(d, w), 
add.expr, symm = FALSE, revC = identical(Colv, "Rowv"), 
scale = c("row", "column", "none"), na.rm = TRUE, 
margins = c(5, 5), ColSideColors, RowSideColors, 
cexRow = 0.2 + 1/log10(nr), cexCol = 0.2 + 1/log10(nc), 
labRow = NULL, labCol = NULL, main = NULL, 
xlab = NULL, ylab = NULL, 
keep.dendro = FALSE, verbose =getOption("verbose"), ...)
```

**Arguments**

- **x**
  - numeric matrix of the values to be plotted.
- **Rowv**
  - determines if and how the row dendrogram should be computed and reordered. Either a `dendrogram` or a vector of values used to reorder the row dendrogram or `NA` to suppress any row dendrogram (and reordering) or by default, `NULL`, see ‘Details’ below.
- **Colv**
  - determines if and how the column dendrogram should be reordered. Has the same options as the `Rowv` argument above and additionally when \( x \) is a square matrix, `Colv = Rowv` means that columns should be treated identically to the rows (and so if there is to be no row dendrogram there will not be a column one either).
- **distfun**
  - function used to compute the distance (dissimilarity) between both rows and columns. Defaults to `dist`.
- **hclustfun**
  - function used to compute the hierarchical clustering when `Rowv` or `Colv` are not dendrograms. Defaults to `hclust`. Should take as argument a result of `distfun` and return an object to which `as.dendrogram` can be applied.
- **reorderfun**
  - function of dendrogram and weights for reordering the row and column dendrograms. The default uses `reorder.dendrogram`.
- **add.expr**
  - expression that will be evaluated after the call to `image`. Can be used to add components to the plot.
- **symm**
  - logical indicating if \( x \) should be treated symmetrically; can only be true when \( x \) is a square matrix.
- **revC**
  - logical indicating if the column order should be reversed for plotting, such that e.g., for the symmetric case, the symmetry axis is as usual.
scale character indicating if the values should be centered and scaled in either the row direction or the column direction, or none. The default is "row" if symm false, and "none" otherwise.

na.rm logical indicating whether NA's should be removed.

margins numeric vector of length 2 containing the margins (see `par`(`mar` = *)) for column and row names, respectively.

ColSideColors (optional) character vector of length ncol(x) containing the color names for a horizontal side bar that may be used to annotate the columns of x.

RowSideColors (optional) character vector of length nrow(x) containing the color names for a vertical side bar that may be used to annotate the rows of x.

cexRow, cexCol positive numbers, used as cex.axis in for the row or column axis labeling. The defaults currently only use number of rows or columns, respectively.

labRow, labCol character vectors with row and column labels to use; these default to rownames(x) or colnames(x), respectively.

main, xlab, ylab main, x- and y-axis titles; defaults to none.

keep.dendro logical indicating if the dendrogram(s) should be kept as part of the result (when Rowv and/or Colv are not NA).

verbose logical indicating if information should be printed.

... additional arguments passed on to `image`, e.g., col specifying the colors.

details

If either Rowv or Colv are dendrograms they are honored (and not reordered). Otherwise, dendrograms are computed as `dd <- as.dendrogram(hclustfun(distfun(x)))` where X is either x or t(x).

If either is a vector (of 'weights') then the appropriate dendrogram is reordered according to the supplied values subject to the constraints imposed by the dendrogram, by `reorder(dd, Rowv)`, in the row case. If either is missing, as by default, then the ordering of the corresponding dendrogram is by the mean value of the rows/columns, i.e., in the case of rows, Rowv <- rowMeans(x, na.rm = na.rm). If either is NA, no reordering will be done for the corresponding side.

By default (scale = "row") the rows are scaled to have mean zero and standard deviation one. There is some empirical evidence from genomic plotting that this is useful.

The default colors are not pretty. Consider using enhancements such as the RColorBrewer package.

value

Invisibly, a list with components

rowInd row index permutation vector as returned by `order.dendrogram`.

colInd column index permutation vector.

Rowv the row dendrogram; only if input Rowv was not NA and keep.dendro is true.

Colv the column dendrogram; only if input Colv was not NA and keep.dendro is true.
Note

Unless \texttt{Rowv = NA} (or \texttt{Colw = NA}), the original rows and columns are reordered \textit{in any case} to match the dendrogram, e.g., the rows by \texttt{order.dendrogram(Rowv)} where \texttt{Rowv} is the (possibly \texttt{reorder}()ed) row dendrogram.

\texttt{heatmap()} uses \texttt{layout} and draws the \texttt{image} in the lower right corner of a 2x2 layout. Consequentially, it can \textbf{not} be used in a multi column/row layout, i.e., when \texttt{par(mfrow = *)} or \texttt{(mfcol = *)} has been called.

```

HoltWinters

Holt-Winters Filtering

Description
Computes Holt-Winters Filtering of a given time series. Unknown parameters are determined by minimizing the squared prediction error.

Usage
HoltWinters(x, alpha = NULL, beta = NULL, gamma = NULL,
seasonal = c("additive", "multiplicative"),
start.periods = 2, l.start = NULL, b.start = NULL,
s.start = NULL,
optim.start = c(alpha = 0.3, beta = 0.1, gamma = 0.1),
optim.control = list())

Arguments
x An object of class ts
alpha alpha parameter of Holt-Winters Filter.
beta beta parameter of Holt-Winters Filter. If set to FALSE, the function will do exponential smoothing.
gamma gamma parameter used for the seasonal component. If set to FALSE, an non-seasonal model is fitted.
seasonal Character string to select an "additive" (the default) or "multiplicative" seasonal model. The first few characters are sufficient. (Only takes effect if gamma is non-zero).
start.periods Start periods used in the autodetection of start values. Must be at least 2.
l.start Start value for level (a[0]).
b.start Start value for trend (b[0]).
s.start Vector of start values for the seasonal component (s1[0]...sp[0])
optim.start Vector with named components alpha, beta, and gamma containing the starting values for the optimizer. Only the values needed must be specified. Ignored in the one-parameter case.
optim.control Optional list with additional control parameters passed to optim if this is used. Ignored in the one-parameter case.
Details

The additive Holt-Winters prediction function (for time series with period length p) is

$$\hat{Y}[t+h] = a[t] + hb[t] + s[t-p+1 + (h-1) \mod p],$$

where $a[t]$, $b[t]$ and $s[t]$ are given by

- $a[t] = \alpha(Y[t] - s[t-p]) + (1 - \alpha)(a[t-1] + b[t-1])$
- $b[t] = \beta(a[t] - a[t-1]) + (1 - \beta)b[t-1]$
- $s[t] = \gamma(Y[t] - a[t]) + (1 - \gamma)s[t-p]$

The multiplicative Holt-Winters prediction function (for time series with period length p) is

$$\hat{Y}[t+h] = (a[t] + hb[t]) \times s[t-p+1 + (h-1) \mod p].$$

where $a[t]$, $b[t]$ and $s[t]$ are given by

- $a[t] = \alpha(Y[t]/s[t-p]) + (1 - \alpha)(a[t-1] + b[t-1])$
- $b[t] = \beta(a[t] - a[t-1]) + (1 - \beta)b[t-1]$
- $s[t] = \gamma(Y[t]/a[t]) + (1 - \gamma)s[t-p]$

The data in $x$ are required to be non-zero for a multiplicative model, but it makes most sense if they are all positive.

The function tries to find the optimal values of $\alpha$ and/or $\beta$ and/or $\gamma$ by minimizing the squared one-step prediction error if they are NULL (the default). optimize will be used for the single-parameter case, and optim otherwise.

For seasonal models, start values for $a$, $b$ and $s$ are inferred by performing a simple decomposition in trend and seasonal component using moving averages (see function decompose) on the $\text{startNperiods}$ first periods (a simple linear regression on the trend component is used for starting level and trend). For level/trend-models (no seasonal component), start values for $a$ and $b$ are $x[2]$ and $x[1]$, respectively. For level-only models (ordinary exponential smoothing), the start value for $a$ is $x[1]$.

Value

An object of class "HoltWinters", a list with components:

- **fitted**: A multiple time series with one column for the filtered series as well as for the level, trend and seasonal components, estimated contemporaneously (that is at time $t$ and not at the end of the series).
- **x**: The original series
- **alpha**: alpha used for filtering
- **beta**: beta used for filtering
- **gamma**: gamma used for filtering
- **coefficients**: A vector with named components $a$, $b$, $s1$, $s2$, ..., $sp$ containing the estimated values for the level, trend and seasonal components
- **seasonal**: The specified seasonal parameter
- **SSE**: The final sum of squared errors achieved in optimizing
- **call**: The call used

---

**Hypergeometric**

**The Hypergeometric Distribution**

**Description**

Density, distribution function, quantile function and random generation for the hypergeometric distribution.

**Usage**

```r
dhyper(x, m, n, k, log = FALSE)
phyper(q, m, n, k, lower.tail = TRUE, log.p = FALSE)
qhyper(p, m, n, k, lower.tail = TRUE, log.p = FALSE)
rhyper(nn, m, n, k)
```
Hypergeometric

Arguments

- **x, q**: vector of quantiles representing the number of white balls drawn without replacement from an urn which contains both black and white balls.
- **m**: the number of white balls in the urn.
- **n**: the number of black balls in the urn.
- **k**: the number of balls drawn from the urn.
- **p**: probability, it must be between 0 and 1.
- **nn**: number of observations. If `length(nn) > 1`, the length is taken to be the number required.
- **log, log.p**: logical; if TRUE, probabilities p are given as log(p).
- **lower.tail**: logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

The hypergeometric distribution is used for sampling without replacement. The density of this distribution with parameters $m$, $n$ and $k$ (named $Np$, $N - Np$, and $n$, respectively in the reference below) is given by

$$p(x) = \binom{m}{x} \binom{n}{k - x} / \binom{m + n}{k}$$

for $x = 0, \ldots, k$.

The quantile is defined as the smallest value $x$ such that $F(x) \geq p$, where $F$ is the distribution function.

Value

dhyper gives the density, phyper gives the distribution function, qhyper gives the quantile function, and rhyper generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by $n$ for rhyper, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than $n$ are recycled to the length of the result. Only the first elements of the logical parameters are used.

Source

dhyper computes via binomial probabilities, using code contributed by Catherine Loader (see `dbinom`).

phyper is based on calculating dhyper and phyper(...)/dhyper(...) (as a summation), based on ideas of Ian Smith and Morten Welinder.

qhyper is based on inversion.

rhyper is based on a corrected version of

References

identify.hclust

Identify Clusters in a Dendrogram

Description

identify.hclust reads the position of the graphics pointer when the (first) mouse button is pressed. It then cuts the tree at the vertical position of the pointer and highlights the cluster containing the horizontal position of the pointer. Optionally a function is applied to the index of data points contained in the cluster.

Usage

```r
## S3 method for class 'hclust'
identify(x, FUN = NULL, N = 20, MAXCLUSTER = 20, DEV.FUN = NULL, 
         ...)
```

Arguments

- `x` an object of the type produced by `hclust`.
- `FUN` (optional) function to be applied to the index numbers of the data points in a cluster (see ‘Details’ below).
- `N` the maximum number of clusters to be identified.
- `MAXCLUSTER` the maximum number of clusters that can be produced by a cut (limits the effective vertical range of the pointer).
- `DEV.FUN` (optional) integer scalar. If specified, the corresponding graphics device is made active before `FUN` is applied.
- `...` further arguments to `FUN`.

Details

By default clusters can be identified using the mouse and an `invisible` list of indices of the respective data points is returned.

If `FUN` is not `NULL`, then the index vector of data points is passed to this function as first argument, see the examples below. The active graphics device for `FUN` can be specified using `DEV.FUN`.

The identification process is terminated by pressing any mouse button other than the first, see also `identify`.

See Also

- `Distributions` for other standard distributions.

Examples

```r
m <- 10; n <- 7; k <- 8
x <- 0:(k+1)
rbind(phyper(x, m, n, k), dhyper(x, m, n, k))
all(phyper(x, m, n, k) == cumsum(dhyper(x, m, n, k))) # FALSE
## but error is very small:
signif(phyper(x, m, n, k) - cumsum(dhyper(x, m, n, k)), digits = 3)
```
Value

Either a list of data point index vectors or a list of return values of FUN.

See Also

hclust, rect.hclust

Examples

```r
## Not run:
require(graphics)

hca <- hclust(dist(USArrests))
plot(hca)
(x <- identify(hca)) ## Terminate with 2nd mouse button !!

hci <- hclust(dist(iris[,1:4]))
plot(hci)
identify(hci, function(k) print(table(iris[k,5])))

# open a new device (one for dendrogram, one for bars):
dev.new() # << make that narrow (& small)
# and *beside* 1st one
nD <- dev.cur()   # to be for the barplot
dev.set(dev.prev()) # old one for dendrogram
plot(hci)
## select subtrees in dendrogram and "see" the species distribution:
identify(hci, function(k) barplot(table(iris[k,5]), col = 2:4), DEV.FUN = nD)

## End(Not run)
```

influence.measures  Regression Deletion Diagnostics

Description

This suite of functions can be used to compute some of the regression (leave-one-out deletion) diagnostics for linear and generalized linear models discussed in Belsley, Kuh and Welsch (1980), Cook and Weisberg (1982), etc.

Usage

```r
influence.measures(model)

rstandard(model, ...)
## S3 method for class 'lm'

rstandard(model, infl = lm.influence(model, do.coef = FALSE),
   sd = sqrt(deviance(model)/df.residual(model)), ...)
## S3 method for class 'glm'

rstandard(model, infl = influence(model, do.coef = FALSE),
   type = c("deviance", "pearson"), ...)
```
influence.measures

```r
rstudent(model, ...) # S3 method for class 'lm'
  rstudent(model, infl = lm.influence(model, do.coef = FALSE),
           res = infl$wt.res, ...)
  rstudent(model, infl = glm)
  rstudent(model, infl = influence(model, do.coef = FALSE), ...)

dffits(model, infl = , res = )

dfbeta(model, ...)
  dfbeta(model, infl = lm.influence(model, do.coef = TRUE), ...)

dfbetas(model, ...)
  dfbetas(model, infl = lm.influence(model, do.coef = TRUE), ...)

covratio(model, infl = lm.influence(model, do.coef = FALSE),
          res = weighted.residuals(model))

cooks.distance(model, ...)
  cooks.distance(model, infl = lm.influence(model, do.coef = FALSE),
                 res = weighted.residuals(model),
                 sd = sqrt(deviance(model)/df.residual(model)),
                 hat = infl$hat, ...)
  cooks.distance(model, infl = influence(model, do.coef = FALSE),
                 res = infl$pear.res,
                 dispersion = summary(model)$dispersion,
                 hat = infl$hat, ...)

hatvalues(model, ...)
  hatvalues(model, infl = lm.influence(model, do.coef = FALSE), ...)
  hat(x, intercept = TRUE)
```

**Arguments**

- `model`: an R object, typically returned by `lm` or `glm`.
- `infl`: influence structure as returned by `lm.influence` or `influence` (the latter only for the glm method of `rstudent` and `cooks.distance`).
- `res`: (possibly weighted) residuals, with proper default.
- `sd`: standard deviation to use, see default.
- `dispersion`: dispersion (for `glm` objects) to use, see default.
- `hat`: hat values $H_{ii}$, see default.
- `type`: type of residuals for `glm` method for `rstandard`.
- `x`: the $X$ or design matrix.
- `intercept`: should an intercept column be prepended to x?
- `...`: further arguments passed to or from other methods.
The primary high-level function is `influence.measures` which produces a class "infl" object tabular display showing the DFBETAS for each model variable, DFFITS, covariance ratios, Cook’s distances and the diagonal elements of the hat matrix. Cases which are influential with respect to any of these measures are marked with an asterisk.

The functions `dfbetas`, `dffits`, `covratio` and `cooks.distance` provide direct access to the corresponding diagnostic quantities. Functions `rstandard` and `rstudent` give the standardized and Studentized residuals respectively. (These re-normalize the residuals to have unit variance, using an overall and leave-one-out measure of the error variance respectively.)

Values for generalized linear models are approximations, as described in Williams (1987) (except that Cook’s distances are scaled as $F$ rather than as chi-square values). The approximations can be poor when some cases have large influence.

The optional `inf` and `res` arguments are there to encourage the use of these direct access functions, in situations where, e.g., the underlying basic influence measures (from `lm.influence` or the generic `influence`) are already available.

Note that cases with weights == 0 are dropped from all these functions, but that if a linear model has been fitted with `na.action = na.exclude`, suitable values are filled in for the cases excluded during fitting.

The function `hatvalues()` exists mainly for S (version 2) compatibility; we recommend using `hatvalues()` instead.

For `hatvalues`, `dfbeta`, and `dfbetas`, the method for linear models also works for generalized linear models.

Several R core team members and John Fox, originally in his ‘car’ package.

See Also

`influence` (containing `lm.influence`).

`'plotmath'` for the use of `hat` in plot annotation.
Examples

```r
require(graphics)

## Analysis of the life-cycle savings data
## given in Belsley, Kuh and Welsch.
lm.SR <- lm(sr ~ pop75 + pop75 + dpi + ddpi, data = LifeCycleSavings)

inflm.SR <- influence.measures(lm.SR)
which(apply(inflm.SR$is.inf, 1, any))
# which observations 'are' influential
summary(inflm.SR) # only these
inflm.SR
# all
plot(rstudent(lm.SR) ~ hatvalues(lm.SR)) # recommended by some

## The 'infl' argument is not needed, but avoids recomputation:
rs <- rstandard(lm.SR)
inflSR <- influence(lm.SR)
identical(rs, rstandard(lm.SR, infl = inflSR))
# to "see" the larger values:
1000 * round(dfbetas(lm.SR, infl = inflSR), 3)

## Huber's data [Atkinson 1985]
xh <- c(-4:0, 10)
yh <- c(2.48, .73, -.04, -1.44, -1.32, 0)
summary(lmH <- lm(yh ~ xh))
{im <- influence.measures(lmH)}
plot(xh,yh, main = "Huber's data: L.S. line and influential obs.")
abline(lmH); points(xh[im$infl], yh[im$infl], pch = 20, col = 2)

## Irwin's data [Williams 1987]
xi <- 1:5
yi <- c(0,2,14,19,30)  # number of mice responding to dose xi
mi <- rep(40, 5)  # number of mice exposed
summary(lmI <- glm(cbind(yi, mi - yi) ~ xi, family = binomial))
signif(cooks.distance(lmI), 3)  # *= Ci in Table 3, p.184
{imI <- influence.measures(lmI)}
stopifnot(all.equal(imI$inflmat[,"cook.d"],
                   cooks.distance(lmI)))
```

**integrate**

*Integration of One-Dimensional Functions*

**Description**

Adaptive quadrature of functions of one variable over a finite or infinite interval.

**Usage**

```r
integrate(f, lower, upper, ..., subdivisions = 100L,
         rel.tol = .Machine$double.eps^0.25, abs.tol = rel.tol,
         stop.on.error = TRUE, keep.xy = FALSE, aux = NULL)
```
Arguments

- **f**: an R function taking a numeric first argument and returning a numeric vector of the same length. Returning a non-finite element will generate an error.
- **lower, upper**: the limits of integration. Can be infinite.
- **subdivisions**: the maximum number of subintervals.
- **rel.tol**: relative accuracy requested.
- **abs.tol**: absolute accuracy requested.
- **stop.on.error**: logical. If true (the default) an error stops the function. If false some errors will give a result with a warning in the message component.
- **keep.xy**: unused. For compatibility with S.
- **aux**: unused. For compatibility with S.

Details

Note that arguments after ... must be matched exactly.

If one or both limits are infinite, the infinite range is mapped onto a finite interval.

For a finite interval, globally adaptive interval subdivision is used in connection with extrapolation by Wynn’s Epsilon algorithm, with the basic step being Gauss–Kronrod quadrature.

**rel.tol** cannot be less than \( \text{max}(50 \times \text{double} \cdot \text{eps}, 0.5 \times 2^{-28}) \) if **abs.tol** <= 0.

Value

A list of class "integrate" with components

- **value**: the final estimate of the integral.
- **abs.error**: estimate of the modulus of the absolute error.
- **subdivisions**: the number of subintervals produced in the subdivision process.
- **message**: "OK" or a character string giving the error message.
- **call**: the matched call.

Note

Like all numerical integration routines, these evaluate the function on a finite set of points. If the function is approximately constant (in particular, zero) over nearly all its range it is possible that the result and error estimate may be seriously wrong.

When integrating over infinite intervals do so explicitly, rather than just using a large number as the endpoint. This increases the chance of a correct answer – any function whose integral over an infinite interval is finite must be near zero for most of that interval.

For values at a finite set of points to be a fair reflection of the behaviour of the function elsewhere, the function needs to be well-behaved, for example differentiable except perhaps for a small number of jumps or integrable singularities.

**f** must accept a vector of inputs and produce a vector of function evaluations at those points. The **Vectorize** function may be helpful to convert **f** to this form.

Examples

```r
integrate(dnorm, -1.96, 1.96)
integrate(dnorm, -Inf, Inf)

## a slowly-convergent integral
integrand <- function(x) {1/((x+1)*sqrt(x))}
integrate(integrand, lower = 0, upper = Inf)

## don't do this if you really want the integral from 0 to Inf
integrate(integrand, lower = 0, upper = 10)
integrate(integrand, lower = 0, upper = 100000)
integrate(integrand, lower = 0, upper = 1000000, stop.on.error = FALSE)

## some functions do not handle vector input properly
f <- function(x) 2.0
try(integrate(f, 0, 1))
integrate(Vectorize(f), 0, 1) ## correct
integrate(function(x) rep(2.0, length(x)), 0, 1) ## correct

## integrate can fail if misused
integrate(dnorm, 0, 2)
integrate(dnorm, 0, 20)
integrate(dnorm, 0, 200)
integrate(dnorm, 0, 2000)
integrate(dnorm, 0, 20000) ## fails on many systems
integrate(dnorm, 0, Inf) ## works
```

interaction.plot

Two-way Interaction Plot

Description

Plots the mean (or other summary) of the response for two-way combinations of factors, thereby illustrating possible interactions.

Usage

```r
interaction.plot(x.factor, trace.factor, response, fun = mean,
    type = c("l", "p", "b", "o", "c"), legend = TRUE,
    trace.label = deparse(substitute(trace.factor)),
    fixed = FALSE,
    xlab = deparse(substitute(x.factor)),
    ylab = ylabel,
    ylim = range(cells, na.rm = TRUE),
    lty = nc:1, col = 1, pch = c(1:9, 0, letters),
    xpd = NULL, leg.bg = par("bg"), leg.bty = "n",
    xtick = FALSE, xaxt = par("xaxt"), axes = TRUE,
    ...)```
**Arguments**

- `x.factor`: A factor whose levels will form the x axis.
- `trace.factor`: Another factor whose levels will form the traces.
- `response`: A numeric variable giving the response.
- `fun`: The function to compute the summary. Should return a single real value.
- `type`: The type of plot (see `plot.default`): lines or points or both.
- `legend`: Logical. Should a legend be included?
- `trace.label`: Overall label for the legend.
- `fixed`: Logical. Should the legend be in the order of the levels of `trace.factor` or in the order of the traces at their right-hand ends?
- `xlab,ylab`: The x and y label of the plot each with a sensible default.
- `ylim`: Numeric of length 2 giving the y limits for the plot.
- `lty`: Line type for the lines drawn, with sensible default.
- `col`: The color to be used for plotting.
- `pch`: A vector of plotting symbols or characters, with sensible default.
- `xpd`: Determines clipping behaviour for the `legend` used, see `par(xpd)`. Per default, the legend is not clipped at the figure border.
- `leg.bg, leg.bty`: Arguments passed to `legend()`.
- `xtick`: Logical. Should tick marks be used on the x axis?
- `xaxt, axes, ...`: Graphics parameters to be passed to the plotting routines.

**Details**

By default the levels of `x.factor` are plotted on the x axis in their given order, with extra space left at the right for the legend (if specified). If `x.factor` is an ordered factor and the levels are numeric, these numeric values are used for the x axis.

The response and hence its summary can contain missing values. If so, the missing values and the line segments joining them are omitted from the plot (and this can be somewhat disconcerting). The graphics parameters `xlab, ylab, ylim, lty, col` and `pch` are given suitable defaults (and `xlim` and `xaxs` are set and cannot be overridden). The defaults are to cycle through the line types, use the foreground colour, and to use the symbols 1:9, 0, and the capital letters to plot the traces.

**Note**

Some of the argument names and the precise behaviour are chosen for S-compatibility.

**References**

Examples

```r
require(graphics)

with(ToothGrowth, {
  interaction.plot(dose, supp, len, fixed = TRUE)
  dose <- ordered(dose)
  interaction.plot(dose, supp, len, fixed = TRUE, col = 2:3, leg.bty = "o")
  interaction.plot(dose, supp, len, fixed = TRUE, col = 2:3, type = "p")
})

with(OrchardSprays, {
  interaction.plot(treatment, rowpos, decrease)
  interaction.plot(rowpos, treatment, decrease, cex.axis = 0.8)
  ## order the rows by their mean effect
  rowpos <- factor(rowpos, levels = sort.list(tapply(decrease, rowpos, mean)))
  interaction.plot(rowpos, treatment, decrease, col = 2:9, lty = 1)
})

with(esoph, {
  interaction.plot(agegp, alcgp, ncases/ncontrols, main = "esoph Data")
  interaction.plot(agegp, tobgp, ncases/ncontrols, trace.label = "tobacco",
                  fixed = TRUE, xaxt = "n")
})
## deal with NAs:
esoph[66,] # second to last age group: 65-74
esophNA <- esoph; esophNA$ncases[66] <- NA
with(esophNA, {
  interaction.plot(agegp, alcgp, ncases/ncontrols, col = 2:5)
  # doesn't show *last* group either
  interaction.plot(agegp, alcgp, ncases/ncontrols, col = 2:5, type = "b")
  ## alternative take non-NA's ("cheating")
  interaction.plot(agegp, alcgp, ncases/ncontrols, col = 2:5,
                  fun = function(x) mean(x, na.rm = TRUE),
                  sub = "function(x) mean(x, na.rm=TRUE)")
})
rm(esophNA) # to clear up
```

---

**IQR**

**The Interquartile Range**

Description

computes interquartile range of the x values.

Usage

```r
IQR(x, na.rm = FALSE, type = 7)
```

Arguments

- **x**: a numeric vector.
- **na.rm**: logical. Should missing values be removed?
- **type**: an integer selecting one of the many quantile algorithms, see `quantile`.
is.empty.model

Details

Note that this function computes the quartiles using the `quantile` function rather than following Tukey's recommendations, i.e., \( \text{IQR}(x) = \text{quantile}(x, 3/4) - \text{quantile}(x, 1/4) \).

For normally \( N(m,1) \) distributed \( X \), the expected value of \( \text{IQR}(X) \) is \( 2 \times \text{qnorm}(3/4) = 1.349 \), i.e., for a normal-consistent estimate of the standard deviation, use \( \text{IQR}(x) / 1.349 \).

IQR(rivers)
```

---

is.empty.model Test if a Model's Formula is Empty

Description

R's formula notation allows models with no intercept and no predictors. These require special handling internally. `is.empty.model()` checks whether an object describes an empty model.

Usage

```r
is.empty.model(x)
```

Arguments

- `x` A `terms` object or an object with a `terms` method.

Value

TRUE if the model is empty

See Also

`lm`, `glm`

Examples

```r
y <- rnorm(20)
is.empty.model(y ~ 0)
is.empty.model(y ~ -1)
is.empty.model(lm(y ~ 0))
```
**isoreg**

*Isotonic / Monotone Regression*

**Description**

Compute the isotonic (monotonely increasing nonparametric) least squares regression which is piecewise constant.

**Usage**

```r
isoreg(x, y = NULL)
```

**Arguments**

- `x, y` coordinate vectors of the regression points. Alternatively a single plotting structure can be specified: see `xy.coords`.

**Details**

The algorithm determines the convex minorant $m(x)$ of the cumulative data (i.e., `cumsum(y)`) which is piecewise linear and the result is $m'(x)$, a step function with level changes at locations where the convex $m(x)$ touches the cumulative data polygon and changes slope.

`as.stepfun()` returns a `stepfun` object which can be more parsimonious.

**Value**

`isoreg()` returns an object of class `isoreg` which is basically a list with components:

- `x` original (constructed) abscissa values.
- `y` corresponding y values.
- `yf` fitted values corresponding to `ordered` x values.
- `yc` cumulative y values corresponding to `ordered` x values.
- `iKnots` integer vector giving indices where the fitted curve jumps, i.e., where the convex minorant has kinks.
- `isOrd` logical indicating if original x values were ordered increasingly already.
- `ord` if(!isOrd): integer permutation `order(x)` of original x.
- `call` the `call` to `isoreg()` used.

**Note**

The code should be improved to accept `weights` additionally and solve the corresponding weighted least squares problem.

‘Patches are welcome!’

**References**

KalmanLike

See Also

the plotting method plot.isoreg with more examples; isoMDS() from the MASS package internally uses isotonic regression.

Examples

require(graphics)

(ir <- isoreg(c(1,0,4,3,3,5,4,2,0)))
plot(ir, plot.type = "row")

(ir3 <- isoreg(y3 <- c(1,0,4,3,3,5,4,2, 3))) # last "3", not "0"
(f3 <- as.stepfun(ir3))
(ir4 <- isoreg(1:10, y4 <- c(5, 9, 1:2, 5:8, 3, 8)))
cat(sprintf("R^2 = %5.2f\n", 1 - sum(residuals(ir4)^2) / ((10-1)*var(y4))))

## If you are interested in the knots alone:
with(ir4, cbind(iKnots, yf[iKnots]))

## Example of unordered x[] with ties:
x <- sample(c(0:30)/8)
y <- exp(x)
x. <- round(x) # ties!
plot(m <- isoreg(x, y))
stopifnot(all.equal(with(m, yf[iKnots]),
as.vector(tapply(y, x, mean))))

KalmanLike  Kalman Filtering

Description

Use Kalman Filtering to find the (Gaussian) log-likelihood, or for forecasting or smoothing.

Usage

KalmanLike(y, mod, nit = 0, fast = TRUE)
KalmanRun(y, mod, nit = 0, fast = TRUE)
KalmanSmooth(y, mod, nit = 0)
KalmanForecast(n.ahead = 10, mod, fast = TRUE)
makeARIMA(phi, theta, Delta, kappa = 1e6)

Arguments

y a univariate time series.

mod A list describing the state-space model: see ‘Details’.

nit The time at which the initialization is computed. nit = 0 implies that the initialization is for a one-step prediction, so Pn should not be computed at the first step.

n.ahead The number of steps ahead for which prediction is required.
phi, theta numeric vectors of length ≥ 0 giving AR and MA parameters.
Delta vector of differencing coefficients, so an ARMA model is fitted to y[t] = Delta[1]*y[t-1] - ....
kappa the prior variance (as a multiple of the innovations variance) for the past observations in a differenced model.
fast If TRUE the mod object may be modified.

Details

These functions work with a general univariate state-space model with state vector ‘a’, transitions ‘a <- T a + R e', e ~ \mathcal{N}(0, \kappa Q) and observation equation ‘y = Z' a + eta', (eta \equiv \eta), \eta ~ \mathcal{N}(0, \kappa h). The likelihood is a profile likelihood after estimation of \kappa.

The model is specified as a list with at least components
T the transition matrix
Z the observation coefficients
h the observation variance
V ‘RQR’
a the current state estimate
P the current estimate of the state uncertainty matrix
Pn the estimate at time t - 1 of the state uncertainty matrix
KalmanSmooth is the workhorse function for tsSmooth.
makeARIMA constructs the state-space model for an ARIMA model.

Value

For KalmanLike, a list with components Lik (the log-likelihood less some constants) and s2, the estimate of \kappa.

For KalmanRun, a list with components values, a vector of length 2 giving the output of KalmanLike, resid (the residuals) and states, the contemporaneous state estimates, a matrix with one row for each time.

For KalmanSmooth, a list with two components. Component smooth is a n by p matrix of state estimates based on all the observations, with one row for each time. Component var is a n by p by p array of variance matrices.

For KalmanForecast, a list with components pred, the predictions, and var, the unscaled variances of the prediction errors (to be multiplied by s2).

For makeARIMA, a model list including components for its arguments.

Warning

These functions are designed to be called from other functions which check the validity of the arguments passed, so very little checking is done.

In particular, KalmanLike alters the objects passed as the elements a, P and Pn of mod, so these should not be shared. Use fast=FALSE to prevent this.

**kernapply**

**See Also**

arima, StructTS::tsSmooth.

---

### kernapply: Apply Smoothing Kernel

**Description**

kernapply computes the convolution between an input sequence and a specific kernel.

**Usage**

```r
kernapply(x, ...)  
```

- **kernapply(x, k, circular = FALSE, ...)**
- **kernapply(x, k, circular = FALSE, ...) for class 'ts'**
- **kernapply(x, k, circular = FALSE, ...) for class 'vector'**
- **kernapply(x, k, circular = FALSE, ...) for class 'tskernel'**

**Arguments**

- `x`: an input vector, matrix, time series or kernel to be smoothed.
- `k`: smoothing "tskernel" object.
- `circular`: a logical indicating whether the input sequence to be smoothed is treated as circular, i.e., periodic.
- `...`: arguments passed to or from other methods.

**Value**

A smoothed version of the input sequence.

**Note**

This uses `fft` to perform the convolution, so is fastest when `NROW(x)` is a power of 2 or some other highly composite integer.

**Author(s)**

A. Trapletti

**See Also**

kernel, convolve, filter, spectrum

**Examples**

- ## see 'kernel' for examples
Smoothing Kernel Objects

Description

The "tskernel" class is designed to represent discrete symmetric normalized smoothing kernels. These kernels can be used to smooth vectors, matrices, or time series objects.

There are print.plot and [] methods for these kernel objects.

Usage

kernel(coef, m = 2, r, name)

df.kernel(k)
bandwidth.kernel(k)
is.tskernel(k)

## S3 method for class 'tskernel'
plot(x, type = "h", xlab = "k", ylab = "W[k]",
main = attr(x,"name"), ...)

Arguments

- **coef**
  - the upper half of the smoothing kernel coefficients (including coefficient zero)
  - or the name of a kernel (currently "daniell", "dirichlet", "fejer" or
  - "modified.daniell".

- **m**
  - the kernel dimension(s) if coef is a name. When m has length larger than one,
  - it means the convolution of kernels of dimension m[j], for j in 1:length(m).
  - Currently this is supported only for the named "^daniell" kernels.

- **name**
  - the name the kernel will be called.

- **r**
  - the kernel order for a Fejer kernel.

- **k, x**
  - a "tskernel" object.

- **type, xlab, ylab, main, ...**
  - arguments passed to plot.default.

Details

kernel is used to construct a general kernel or named specific kernels. The modified Daniell kernel
halves the end coefficients (as used by S-PLUS).

The [] method allows natural indexing of kernel objects with indices in (-m) : m. The normalization
is such that for k <- kernel(*). sum(k[ -k^m : k^m ]) is one.

df.kernel returns the ‘equivalent degrees of freedom’ of a smoothing kernel as defined in Brockwell
and Davis (1991), page 362, and bandwidth.kernel returns the equivalent bandwidth as de-
defined in Bloomfield (1976), p. 201, with a continuity correction.

Value

kernel() returns an object of class "tskernel" which is basically a list with the two components
coe and the kernel dimension m. An additional attribute is "name".
kmeans

K-Means Clustering

Description

Perform k-means clustering on a data matrix.

Usage

kmeans(x, centers, iter.max = 10, nstart = 1, algorithm = c("Hartigan-Wong", "Lloyd", "Forgy", "MacQueen"), trace=FALSE)

# S3 method for class 'kmeans'
fitted(object, method = c("centers", "classes"), ...)
Arguments

- **x**: numeric matrix of data, or an object that can be coerced to such a matrix (such as a numeric vector or a data frame with all numeric columns).

- **centers**: either the number of clusters, say \(k\), or a set of initial (distinct) cluster centres. If a number, a random set of (distinct) rows in \(x\) is chosen as the initial centres.

- **iter.max**: the maximum number of iterations allowed.

- **nstart**: if centers is a number, how many random sets should be chosen?

- **algorithm**: character: may be abbreviated. Note that "lloyd" and "Forgy" and alternative names for one algorithm.

- **object**: an R object of class "kmeans", typically the result of `ob <- kmeans(.)`.

- **method**: character: may be abbreviated. "centers" causes fitted to return cluster centres (one for each input point) and "classes" causes fitted to return a vector of class assignments.

- **trace**: logical or integer number, currently only used in the default method ("Hartigan-Wong"): if positive (or true), tracing information on the progress of the algorithm is produced. Higher values may produce more tracing information.

- **...**: not used.

Details

The data given by \(x\) are clustered by the \(k\)-means method, which aims to partition the points into \(k\) groups such that the sum of squares from points to the assigned cluster centres is minimized. At the minimum, all cluster centres are at the mean of their Voronoi sets (the set of data points which are nearest to the cluster centre).

The algorithm of Hartigan and Wong (1979) is used by default. Note that some authors use \(k\)-means to refer to a specific algorithm rather than the general method: most commonly the algorithm given by MacQueen (1967) but sometimes that given by Lloyd (1957) and Forgy (1965). The Hartigan–Wong algorithm generally does a better job than either of those, but trying several random starts (nstart > 1) is often recommended. In rare cases, when some of the points (rows of \(x\)) are extremely close, the algorithm may not converge in the "Quick-Transfer" stage, signalling a warning (and returning `ifault = 4`). Slight rounding of the data may be advisable in that case.

For ease of programmatic exploration, \(k = 1\) is allowed, notably returning the center and `withinss`. Except for the Lloyd–Forgy method, \(k\) clusters will always be returned if a number is specified. If an initial matrix of centres is supplied, it is possible that no point will be closest to one or more centres, which is currently an error for the Hartigan–Wong method.

Value

`kmeans` returns an object of class "kmeans" which has a `print` and a `fitted` method. It is a list with at least the following components:

- **cluster**: A vector of integers (from 1:k) indicating the cluster to which each point is allocated.

- **centers**: A matrix of cluster centres.

- **totss**: The total sum of squares.

- **withinss**: Vector of within-cluster sum of squares, one component per cluster.

- **tot.withinss**: Total within-cluster sum of squares, i.e., `sum(withinss)`.
betweenss The between-cluster sum of squares, i.e. \( \text{totss} - \text{tot.withinss} \).

size The number of points in each cluster.

iter The number of (outer) iterations.

ifault integer: indicator of a possible algorithm problem – for experts.

References

Examples

```r
require(graphics)

# a 2-dimensional example
x <- rbind(matrix(rnorm(100, sd = 0.3), ncol = 2),
           matrix(rnorm(100, mean = 1, sd = 0.3), ncol = 2))
colnames(x) <- c("x", "y")
(cl <- kmeans(x, 2))
plot(x, col = cl$cluster)
points(cl$centers, col = 1:2, pch = 8, cex = 2)

# sum of squares
ss <- function(x) sum(scale(x, scale = FALSE)^2)

## cluster centers "fitted" to each obs.:
fitted.x <- fitted(cl); head(fitted.x)
resid.x <- x - fitted(cl)

## Equalities: ------------------------------------------
cbind(cl[1,"betweenss", "tot.withinss", "totss"],
     # the same two columns
c(ss(fitted.x), ss(resid.x), ss(x)))
stopifnot(all.equal(cl$totss, ss(x)));
all.equal(cl$tot.withinss, ss(resid.x)),
## these three are the same:
all.equal(cl$betweenss, ss(fitted.x)),
all.equal(cl$betweenss, cl$totss - cl$tot.withinss),
## and hence also
all.equal(ss(x), ss(fitted.x) + ss(resid.x))
)

kmeans(x, 1)$withinss # trivial one-cluster, (its W.SS == ss(x))

## random starts do help here with too many clusters
## (and are often recommended anyway!):
(cl <- kmeans(x, 5, nstart = 25))
plot(x, col = cl$cluster)
points(cl$centers, col = 1:5, pch = 8)
```
kruskal.test  Kruskal-Wallis Rank Sum Test

Description

Performs a Kruskal-Wallis rank sum test.

Usage

kruskal.test(x, ...)

### Default S3 method:
kruskal.test(x, g, ...)

### S3 method for class 'formula'
kruskal.test(formula, data, subset, na.action, ...)

Arguments

x  a numeric vector of data values, or a list of numeric data vectors.

x  a vector or factor object giving the group for the corresponding elements of x. Ignored if x is a list.

formula  a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.

data  an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset  an optional vector specifying a subset of observations to be used.

na.action  a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").

...  further arguments to be passed to or from methods.

Details

kruskal.test performs a Kruskal-Wallis rank sum test of the null that the location parameters of the distribution of x are the same in each group (sample). The alternative is that they differ in at least one.

If x is a list, its elements are taken as the samples to be compared, and hence have to be numeric data vectors. In this case, g is ignored, and one can simply use kruskal.test(x) to perform the test. If the samples are not yet contained in a list, use kruskal.test(list(x, ...)).

Otherwise, x must be a numeric data vector, and g must be a vector or factor object of the same length as x giving the group for the corresponding elements of x.

Value

A list with class "htest" containing the following components:

statistic  the Kruskal-Wallis rank sum statistic.
ks.test

Perform a one- or two-sample Kolmogorov-Smirnov test.

References

See Also

The Wilcoxon rank sum test (*wilcox.test*) as the special case for two samples; `lm` together with `anova` for performing one-way location analysis under normality assumptions; with Student’s t test (`t.test`) as the special case for two samples.

`wilcox.test` in package `coin` for exact, asymptotic and Monte Carlo conditional p-values, including in the presence of ties.

Examples

```r
## Hollander & Wolfe (1973), 116.
## Mucociliary efficiency from the rate of removal of dust in normal
## subjects, subjects with obstructive airway disease, and subjects
## with asbestosis.
x <- c(2.9, 3.0, 2.5, 2.6, 3.2) # normal subjects
y <- c(3.8, 2.7, 4.0, 2.4)     # with obstructive airway disease
z <- c(2.8, 3.4, 3.7, 2.2, 2.0) # with asbestosis
kruskal.test(list(x, y, z))

## Equivalently,
x <- c(x, y, z)
g <- factor(rep(1:3, c(5, 4, 5)),
    labels = c("Normal subjects",
        "Subjects with obstructive airway disease",
        "Subjects with asbestosis"))
kruskal.test(x, g)

## Formula interface.
require(graphics)
boxplot(Ozone ~ Month, data = airquality)
kruskal.test(Ozone ~ Month, data = airquality)
```
Usage

ks.test(x, y, ..., alternative = c("two.sided", "less", "greater"),
        exact = NULL)

Arguments

x  a numeric vector of data values.
y  either a numeric vector of data values, or a character string naming a cumulative
distribution function or an actual cumulative distribution function such as pnorm.
Only continuous CDFs are valid.
...
parameters of the distribution specified (as a character string) by y.
alternative  indicates the alternative hypothesis and must be one of "two.sided" (default),
"less", or "greater". You can specify just the initial letter of the value, but
the argument name must be give in full. See 'Details' for the meanings of the
possible values.
exact    NULL or a logical indicating whether an exact p-value should be computed. See
'Details' for the meaning of NULL. Not available in the two-sample case for a
one-sided test or if ties are present.

Details

If y is numeric, a two-sample test of the null hypothesis that x and y were drawn from the same
continuous distribution is performed.

Alternatively, y can be a character string naming a continuous (cumulative) distribution function, or
such a function. In this case, a one-sample test is carried out of the null that the distribution function
which generated x is distribution y with parameters specified by ... .

The presence of ties always generates a warning, since continuous distributions do not generate
them. If the ties arose from rounding the tests may be approximately valid, but even modest amounts
of rounding can have a significant effect on the calculated statistic.

Missing values are silently omitted from x and (in the two-sample case) y.

The possible values "two.sided", "less" and "greater" of alternative specify the null hy-
pothesis that the true distribution function of x is equal to, not less than or not greater than
the hypothesized distribution function (one-sample case) or the distribution function of y (two-
sample case), respectively. This is a comparison of cumulative distribution functions, and the test
statistic is the maximum difference in value, with the statistic in the "greater" alternative being
\[ D^+ = \max_u [F_x(u) - F_y(u)] \]. Thus in the two-sample case alternative = "greater" includes
distributions for which x is stochastically smaller than y (the CDF of x lies above and hence to the
left of that for y), in contrast to t.test or wilcox.test.

Exact p-values are not available for the two-sample case if one-sided or in the presence of ties. If
exact = NULL (the default), an exact p-value is computed if the sample size is less than 100 in
the one-sample case and there are no ties, and if the product of the sample sizes is less than 10000
in the two-sample case. Otherwise, asymptotic distributions are used whose approximations may
be inaccurate in small samples. In the one-sample two-sided case, exact p-values are obtained as
described in Marsaglia, Tsang & Wang (2003) (but not using the optional approximation in the right
tail, so this can be slow for small p-values). The formula of Birnbaum & Tingey (1951) is used for
the one-sample one-sided case.

If a single-sample test is used, the parameters specified in ... must be pre-specified and not esti-
mated from the data. There is some more refined distribution theory for the KS test with estimated
parameters (see Durbin, 1973), but that is not implemented in ks.test.
ks.test

Value

A list with class "htest" containing the following components:

- **statistic**: the value of the test statistic.
- **p.value**: the p-value of the test.
- **alternative**: a character string describing the alternative hypothesis.
- **method**: a character string indicating what type of test was performed.
- **data.name**: a character string giving the name(s) of the data.

Examples

```r
require(graphics)

x <- rnorm(50)
y <- runif(30)
# Do x and y come from the same distribution?
ks.test(x, y)
# Does x come from a shifted gamma distribution with shape 3 and rate 2?
ks.test(x+2, "pgamma", 3, 2) # two-sided, exact
ks.test(x+2, "pgamma", 3, 2, exact = FALSE)
ks.test(x+2, "pgamma", 3, 2, alternative = "gr")

# test if x is stochastically larger than x2
x2 <- rnorm(50, -1)
plot(ecdf(x), xlim = range(c(x, x2)))
plot(ecdf(x2), add = TRUE, lty = "dashed")
t.test(x, x2, alternative = "g")
wilcox.test(x, x2, alternative = "g")
ks.test(x, x2, alternative = "l")
```
description
The Nadaraya–Watson kernel regression estimate.

Usage
ksmooth(x, y, kernel = c("box", "normal"), bandwidth = 0.5,
range.x = range(x),
n.points = max(100L, length(x)), x.points)

Arguments
x input x values. Long vectors are supported.
y input y values. Long vectors are supported.
kernel the kernel to be used.
bandwidth the bandwidth. The kernels are scaled so that their quartiles (viewed as probability densities) are at ± 0.25*bandwidth.
range.x the range of points to be covered in the output.
n.points the number of points at which to evaluate the fit.
x.points points at which to evaluate the smoothed fit. If missing, n.points are chosen uniformly to cover range.x. Long vectors are supported.

Value
A list with components
x values at which the smoothed fit is evaluated. Guaranteed to be in increasing order.
y fitted values corresponding to x.

Note
This function was implemented for compatibility with S, although it is nowhere near as slow as the S function. Better kernel smoothers are available in other packages such as KernSmooth.

Examples
require(graphics)
with(cars, {
  plot(speed, dist)
  lines(ksmooth(speed, dist, "normal", bandwidth = 2), col = 2)
  lines(ksmooth(speed, dist, "normal", bandwidth = 5), col = 3)
})
Description

Compute a lagged version of a time series, shifting the time base back by a given number of observations.

Usage

```r
lag(x, ...)  
```

### Default S3 method:

```r
lag(x, k = 1, ...)  
```

Arguments

- **x**: A vector or matrix or univariate or multivariate time series
- **k**: The number of lags (in units of observations).
- **...**: further arguments to be passed to or from methods.

Details

Vector or matrix arguments `x` are coerced to time series.

`lag` is a generic function; this page documents its default method.

Value

A time series object.

Note

Note the sign of `k`: a series lagged by a positive `k` starts earlier.

References

See Also

`diff`, `deltat`

Examples

```r
lag(Ideaths, 12)  # starts one year earlier  
```
lag.plot

Time Series Lag Plots

Description

Plot time series against lagged versions of themselves. Helps visualizing ‘auto-dependence’ even when auto-correlations vanish.

Usage

```r
lag.plot(x, lags = 1, layout = NULL, set.lags = 1:lags,
        main = NULL, asp = 1,
        diag = TRUE, diag.col = "gray", type = "p", oma = NULL,
        ask = NULL, do.lines = (n <= 150), labels = do.lines,
        ...)```

Arguments

- `x` time-series (univariate or multivariate)
- `lags` number of lag plots desired, see arg `set.lags`.
- `layout` the layout of multiple plots, basically the `mrow` `par()` argument. The default uses about a square layout (see `n2mfrow` such that all plots are on one page.
- `set.lags` vector of positive integers allowing specification of the set of lags used; defaults to `1:lags`.
- `main` character with a main header title to be done on the top of each page.
- `asp` Aspect ratio to be fixed, see `plot.default`.
- `diag` logical indicating if the x=y diagonal should be drawn.
- `diag.col` color to be used for the diagonal if(diag).
- `type` plot type to be used, but see `plot.ts` about its restricted meaning.
- `oma` outer margins, see `par`.
- `ask` logical or NULL; if true, the user is asked to confirm before a new page is started.
- `do.lines` logical indicating if lines should be drawn.
- `labels` logical indicating if labels should be used.
- `...` Further arguments to `plot.ts`. Several graphical parameters are set in this function and so cannot be changed: these include `xlab`, `ylab`, `mgp`, `col.lab` and `font.lab`: this also applies to the arguments `xy.labels` and `xy.lines`.

Details

If just one plot is produced, this is a conventional plot. If more than one plot is to be produced, `par(mfrow)` and several other graphics parameters will be set, so it is not (easily) possible to mix such lag plots with other plots on the same page.

If `ask = NULL, par(ask = TRUE)` will be called if more than one page of plots is to be produced and the device is interactive.
Note

It is more flexible and has different default behaviour than the S version. We use `main` instead of `head` for internal consistency.

`plot.ts` which is the basic work horse.

Examples

```r
require(graphics)

lag.plot(nhtemp, 8, diag.col = "forest green")
lag.plot(nhtemp, 5, main = "Average Temperatures in New Haven")
# ask defaults to TRUE when we have more than one page:
lag.plot(nhtemp, 6, layout = c(2,1), asp = NA,
        main = "New Haven Temperatures", col.main = "blue")

# Multivariate (but non-stationary! ...)
lag.plot(frency.x, lags = 3)
# Not run:
no lines for long series :
lag.plot(sqrt(sunspots), set = c(1:4, 9:12), pch = ".", col = "gold")

# End(Not run)
```

Description

Fit a line robustly as recommended in *Exploratory Data Analysis*.

Usage

```r
line(x, y)
```

Arguments

- `x, y`
  
  the arguments can be any way of specifying x-y pairs. See `xy.coords`.

Details

Cases with missing values are omitted.

Long vectors are not supported.
Value
An object of class "tukeyline". Methods are available for the generic functions coef, residuals, fitted, and print.

References

See Also
lm.

Examples
```r
require(graphics)
plot(cars)
(z <- line(cars))
abline(coef(z))
## Tukey-Anscombe Plot:
plot(residuals(z) ~ fitted(z), main = deparse(z$call))
```

Description
`lm` is used to fit linear models. It can be used to carry out regression, single stratum analysis of variance and analysis of covariance (although `aoe` may provide a more convenient interface for these).

Usage
```r
lm(formula, data, subset, weights, na.action, 
   method = "qr", model = TRUE, x = FALSE, y = FALSE, qr = TRUE, 
   singular.ok = TRUE, contrasts = NULL, offset, ...)
```

Arguments
- `formula` an object of class "formula" (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under 'Details'.
- `data` an optional data frame, list or environment (or object coercible by `as.data.frame` to a data frame) containing the variables in the model. If not found in `data`, the variables are taken from `environment(formula)`, typically the environment from which `lm` is called.
- `subset` an optional vector specifying a subset of observations to be used in the fitting process.
weights: an optional vector of weights to be used in the fitting process. Should be NULL or a numeric vector. If non-NULL, weighted least squares is used with weights weights (that is, minimizing sum(w*e^2)); otherwise ordinary least squares is used. See also 'Details'.

na.action: a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The 'factory-fresh' default is na.omit. Another possible value is NULL, no action. Value na.exclude can be useful.

method: the method to be used; for fitting, currently only method = "qr" is supported; method = "model.frame" returns the model frame (the same as with model = TRUE, see below).

model, x, y, qr: logicals. If TRUE the corresponding components of the fit (the model frame, the model matrix, the response, the QR decomposition) are returned.

singular.ok: logical. If FALSE (the default in S but not in R) a singular fit is an error.

contrasts: an optional list. See the contrasts.arg of model.matrix.default.

offset: this can be used to specify an a priori known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length equal to the number of cases. One or more offset terms can be included in the formula instead or as well, and if more than one are specified their sum is used. See model.offset.

...: additional arguments to be passed to the low level regression fitting functions (see below).

Details

Models for lm are specified symbolically. A typical model has the form response ~ terms where response is the (numeric) response vector and terms is a series of terms which specifies a linear predictor for response. A terms specification of the form first + second indicates all the terms in first together with all the terms in second with duplicates removed. A specification of the form first:second indicates the set of terms obtained by taking the interactions of all terms in first with all terms in second. The specification first*second indicates the cross of first and second. This is the same as first + second + first:second.

If the formula includes an offset, this is evaluated and subtracted from the response.

If response is a matrix a linear model is fitted separately by least-squares to each column of the matrix.

See model.matrix for some further details. The terms in the formula will be re-ordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on: to avoid this pass a terms object as the formula (see aov and demo(glm.vr) for an example).

A formula has an implied intercept term. To remove this use either y ~ x - 1 or y ~ 0 + x. See formula for more details of allowed formulae.

Non-NULL weights can be used to indicate that different observations have different variances (with the values in weights being inversely proportional to the variances); or equivalently, when the elements of weights are positive integers w_i, that each response y_i is the mean of w_i unit-weight observations (including the case that there are w_i observations equal to y_i and the data have been summarized).

lm calls the lower level functions lm.fit, etc, see below, for the actual numerical computations. For programming only, you may consider doing likewise.

All of weights, subset and offset are evaluated in the same way as variables in formula, that is first in data and then in the environment of formula.
Value

lm returns an object of class "lm" or for multiple responses of class c("mlm", "lm").

The functions summary and anova are used to obtain and print a summary and analysis of variance table of the results. The generic accessor functions coefficients, effects, fitted.values and residuals extract various useful features of the value returned by lm.

An object of class "lm" is a list containing at least the following components:

- coefficients a named vector of coefficients
- residuals the residuals, that is response minus fitted values.
- fitted.values the fitted mean values.
- rank the numeric rank of the fitted linear model.
- weights (only for weighted fits) the specified weights.
- df.residual the residual degrees of freedom.
- call the matched call.
- terms the terms object used.
- contrasts (only where relevant) the contrasts used.
- xlevels (only where relevant) a record of the levels of the factors used in fitting.
- offset the offset used (missing if none were used).
- y if requested, the response used.
- x if requested, the model matrix used.
- model if requested (the default), the model frame used.
- na.action (where relevant) information returned by model.frame on the special handling of NAs.

In addition, non-null fits will have components assign, effects and (unless not requested) qr relating to the linear fit, for use by extractor functions such as summary and effects.

Using time series

Considerable care is needed when using lm with time series.

Unless na.action = NULL, the time series attributes are stripped from the variables before the regression is done. (This is necessary as omitting NAs would invalidate the time series attributes, and if NAs are omitted in the middle of the series the result would no longer be a regular time series.)

Even if the time series attributes are retained, they are not used to line up series, so that the time shift of a lagged or differenced regressor would be ignored. It is good practice to prepare a data argument by ts.intersect(..., dframe = TRUE), then apply a suitable na.action to that data frame and call lm with na.action = NULL so that residuals and fitted values are time series.

Note

Offsets specified by offset will not be included in predictions by predict.lm, whereas those specified by an offset term in the formula will be.

Author(s)

The design was inspired by the S function of the same name described in Chambers (1992). The implementation of model formula by Ross Ihaka was based on Wilkinson & Rogers (1973).

plot(lm.D9, las = 1) # Residuals, Fitted, ...
par(opar)

### less simple examples in "See Also" above
```

Description

These are the basic computing engines called by `lm` used to fit linear models. These should usually *not* be used directly unless by experienced users.
Usage

lm.fit (x, y, offset = NULL, method = "qr", tol = 1e-7,
         singular.ok = TRUE, ...)

lm.wfit(x, y, w, offset = NULL, method = "qr", tol = 1e-7,
         singular.ok = TRUE, ...)

Arguments

x design matrix of dimension \( n \times p \).
y vector of observations of length \( n \), or a matrix with \( n \) rows.
w vector of weights (length \( n \)) to be used in the fitting process for the \( w \)fit functions. Weighted least squares is used with weights \( w \), i.e., \( \sum(w \times e^2) \) is minimized.
offset numeric of length \( n \). This can be used to specify an \textit{a priori} known component to be included in the linear predictor during fitting.
method currently, only \textit{method = "qr"} is supported.
tol tolerance for the \textit{qr} decomposition. Default is \( 1e-7 \).
singular.ok logical. If \textit{false}, a singular model is an error.
... currently disregarded.

Value

a list with components

coefficients \( p \) vector
residuals \( n \) vector or matrix
fitted.values \( n \) vector or matrix
effects (not null fits) vector of orthogonal single-df effects. The first rank of them correspond to non-aliased coefficients, and are named accordingly.
weights \( n \) vector — \textit{only} for the \( \ast \)fit functions.
rank integer, giving the rank
df.residual degrees of freedom of residuals
qr (not null fits) the QR decomposition, see \textit{qr}.

See Also

\textit{lm} which you should use for linear least squares regression, unless you know better.

Examples

require(utils)
set.seed(129)
n <- 7; p <- 2
X <- matrix(rnorm(n * p), n, p) # no intercept!
y <- rnorm(n)
w <- rnorm(n)^2
str(lm.w <- lm.wfit(x = X, y = y, w = w))
str(lm. <- lm.fit (x = X, y = y))

---

### lm.influence

#### Regression Diagnostics

**Description**

This function provides the basic quantities which are used in forming a wide variety of diagnostics for checking the quality of regression fits.

**Usage**

```r
influence(model, ...)
# S3 method for class 'lm'
influence(model, do.coef = TRUE, ...)
# S3 method for class 'glm'
influence(model, do.coef = TRUE, ...)

lm.influence(model, do.coef = TRUE)
```

**Arguments**

- `model` an object as returned by `lm` or `glm`.
- `do.coef` logical indicating if the changed coefficients (see below) are desired. These need \(O(n^2 p)\) computing time.
- `...` further arguments passed to or from other methods.

**Details**

The `influence.measures()` and other functions listed in **See Also** provide a more user oriented way of computing a variety of regression diagnostics. These all build on `lm.influence`. Note that for GLMs (other than the Gaussian family with identity link) these are based on one-step approximations which may be inadequate if a case has high influence.

An attempt is made to ensure that computed hat values that are probably one are treated as one, and the corresponding rows in `sigma` and `coefficients` are NaN. (Dropping such a case would normally result in a variable being dropped, so it is not possible to give simple drop-one diagnostics.)

`naresid` is applied to the results and so will fill in with NAs if the fit had `na.action = na.exclude`.

**Value**

A list containing the following components of the same length or number of rows \(n\), which is the number of non-zero weights. Cases omitted in the fit are omitted unless a `na.action` method was used (such as `na.exclude`) which restores them.

- `hat` a vector containing the diagonal of the ‘hat’ matrix.
- `coefficients` (unless `do.coef` is false) a matrix whose \(i\)-th row contains the change in the estimated coefficients which results when the \(i\)-th case is dropped from the regression. Note that aliased coefficients are not included in the matrix.
sigma  a vector whose i-th element contains the estimate of the residual standard devi-
ation obtained when the i-th case is dropped from the regression. (The approxi-
mations needed for GLMs can result in this being NaN.)

wt.res a vector of weighted (or for class glm rather deviance) residuals.

Note

The coefficients returned by the \texttt{R} version of \texttt{lm.influence} differ from those computed by S. Rather than returning the coefficients which result from dropping each case, we return the changes in the coefficients. This is more directly useful in many diagnostic measures. Since these need $O(n^2 p)$ computing time, they can be omitted by \texttt{do.coef = FALSE}.

Note that cases with weights $= 0$ are dropped (contrary to the situation in S).

If a model has been fitted with \texttt{na.action = na.exclude} (see \texttt{na.exclude}), cases excluded in the fit are considered here.

References

See the list in the documentation for \texttt{influence.measures}.

\texttt{influence.measures},
\texttt{hat} for the hat matrix diagonals,
\texttt{dfbetas, dffits, covratio, cooks.distance.lm}.

Examples

```r
## Analysis of the life-cycle savings data
## given in Belsley, Kuh and Welsch.
summary(lm.SR <- lm(sr ~ pop15 + pop75 + dpi + ddpi,
                  data = LifeCycleSavings),
       corr = TRUE)
utils::str(lmI <- lm.influence(lm.SR))

## For more "user level" examples, use example(influence.measures)
```

### lm.summaries

\textit{Accessing Linear Model Fits}

\textbf{Description}

All these functions are \texttt{methods} for class "lm" objects.
Usage

```r
## S3 method for class 'lm'
family(object, ...)

## S3 method for class 'lm'
formula(x, ...)

## S3 method for class 'lm'
residuals(object,
    type = c("working", "response", "deviance", "pearson",
            "partial"),
    ...)

## S3 method for class 'lm'
labels(object, ...)
```

Arguments

- `object, x` an object inheriting from class `lm`, usually the result of a call to `lm` or `aov`.
- `...` further arguments passed to or from other methods.
- `type` the type of residuals which should be returned.

Details

The generic accessor functions `coef`, `effects`, `fitted` and `residuals` can be used to extract various useful features of the value returned by `lm`.

The working and response residuals are 'observed - fitted'. The deviance and pearson residuals are weighted residuals, scaled by the square root of the weights used in fitting. The partial residuals are a matrix with each column formed by omitting a term from the model. In all these, zero weight cases are never omitted (as opposed to the standardized `rstudent` residuals, and the `weighted.residuals`).

How `residuals` treats cases with missing values in the original fit is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the residuals, whereas if `na.action = na.exclude` they will appear, with residual value `NA`. See also `naresid`.

The "lm" method for generic `labels` returns the term labels for estimable terms, that is the names of the terms with an at least one estimable coefficient.

References

See Also

The model fitting function `lm`, `anova.lm`. `coef`, `deviance`, `df.residual`, `effects`, `fitted`, `glm` for generalized linear models, `influence` (etc on that page) for regression diagnostics, `weighted.residuals`, `residuals`, `residuals.glm`, `summary.lm`, `weights`.

`influence.measures` for deletion diagnostics, including standardized (`rstandard`) and studentized (`rstudent`) residuals.
Examples

```r
##-- Continuing the lm(.) example:
coef(lm.D90) # the bare coefficients

## The 2 basic regression diagnostic plots [plot.lm(.) is preferred]
plot(resid(lm.D90), fitted(lm.D90)) # Tukey-Anscombe's
abline(h = 0, lty = 2, col = "gray")
qqnorm(residuals(lm.D90))
```

Description

Extract or print loadings in factor analysis (or principal components analysis).

Usage

```r
loadings(x)
```

## S3 method for class 'loadings'
```r
print(x, digits = 3, cutoff = 0.1, sort = FALSE, ...)
```

## S3 method for class 'factanal'
```r
print(x, digits = 3, ...)
```

Arguments

- `x` an object of class "factanal" or "princomp" or the loadings component of such an object.
- `digits` number of decimal places to use in printing uniquenesses and loadings.
- `cutoff` loadings smaller than this (in absolute value) are suppressed.
- `sort` logical. If true, the variables are sorted by their importance on each factor. Each variable with any loading larger than 0.5 (in modulus) is assigned to the factor with the largest loading, and the variables are printed in the order of the factor they are assigned to, then those unassigned.
- `...` further arguments for other methods.

Details

‘Loadings’ is a term from factor analysis, but because factor analysis and principal component analysis (PCA) are often conflated in the social science literature, it was used for PCA by SPSS and hence by princomp in S-PLUS to help SPSS users.

Small loadings are conventionally not printed (replaced by spaces), to draw the eye to the pattern of the larger loadings.

The print method for class "factanal" calls the "loadings" method to print the loadings, and so passes down arguments such as cutoff and sort.
**loess**

*Local Polynomial Regression Fitting*

**Description**

Fit a polynomial surface determined by one or more numerical predictors, using local fitting.

**Usage**

```r
loess(formula, data, weights, subset, na.action, model = FALSE, 
span = 0.75, enp.target, degree = 2, 
parametric = FALSE, drop.square = FALSE, normalize = TRUE, 
family = c("gaussian", "symmetric"), 
method = c("loess", "model.frame"), 
control = loess.control(...), ...)
```

**Arguments**

- `formula`: a formula specifying the numeric response and one to four numeric predictors (best specified via an interaction, but can also be specified additively). Will be coerced to a formula if necessary.
- `data`: an optional data frame, list or environment (or object coercible by `as.data.frame` to a data frame) containing the variables in the model. If not found in data, the variables are taken from `environment(formula)`, typically the environment from which `loess` is called.
- `weights`: optional weights for each case.
- `subset`: an optional specification of a subset of the data to be used.
- `na.action`: the action to be taken with missing values in the response or predictors. The default is given by `getOption("na.action")`.
- `model`: should the model frame be returned?
- `span`: the parameter $\alpha$ which controls the degree of smoothing.
- `enp.target`: an alternative way to specify `span`, as the approximate equivalent number of parameters to be used.
- `degree`: the degree of the polynomials to be used, normally 1 or 2. (Degree 0 is also allowed, but see the ‘Note’.)
- `parametric`: should any terms be fitted globally rather than locally? Terms can be specified by name, number or as a logical vector of the same length as the number of predictors.
- `drop.square`: for fits with more than one predictor and `degree = 2`, should the quadratic term be dropped for particular predictors? Terms are specified in the same way as for `parametric`.
- `normalize`: should the predictors be normalized to a common scale if there is more than one? The normalization used is to set the 10% trimmed standard deviation to one. Set to false for spatial coordinate predictors and others know to be a common scale.
family if "gaussian" fitting is by least-squares, and if "symmetric" a re-descending M estimator is used with Tukey’s biweight function.
method fit the model or just extract the model frame.
control control parameters: see loess.control.
... control parameters can also be supplied directly.

Details
Fitting is done locally. That is, for the fit at point \( x \), the fit is made using points in a neighbourhood of \( x \), weighted by their distance from \( x \) (with differences in ‘parametric’ variables being ignored when computing the distance). The size of the neighbourhood is controlled by \( \alpha \) (set by span or enp.target). For \( \alpha < 1 \), the neighbourhood includes proportion \( \alpha \) of the points, and these have tricubic weighting (proportional to \( (1 - (dist/maxdist)^3)^3 \)). For \( \alpha > 1 \), all points are used, with the ‘maximum distance’ assumed to be \( \alpha^{1/p} \) times the actual maximum distance for \( p \) explanatory variables.

For the default family, fitting is by (weighted) least squares. For family="symmetric" a few iterations of an M-estimation procedure with Tukey’s biweight are used. Be aware that as the initial value is the least-squares fit, this need not be a very resistant fit.

It can be important to tune the control list to achieve acceptable speed. See loess.control for details.

Value
An object of class "loess".

Note
As this is based on c1oess, it is similar to but not identical to the loess function of S. In particular, conditioning is not implemented.

The memory usage of this implementation of loess is roughly quadratic in the number of points, with 1000 points taking about 10Mb.

degree = 0, local constant fitting, is allowed in this implementation but not documented in the reference. It seems very little tested, so use with caution.

Author(s)
B. D. Ripley, based on the c1oess package of Cleveland, Grosse and Shyu.

Source
The 1998 version of c1oess package of Cleveland, Grosse and Shyu. A later version is available as d1oess at http://www.netlib.org/a.

loess.control, predict.loess.
lowess, the ancestor of loess (with different defaults!).
Examples

```r
cars.lo <- loess(dist ~ speed, cars)
predict(cars.lo, data.frame(speed = seq(5, 30, 1)), se = TRUE)
# to allow extrapolation
cars.lo2 <- loess(dist ~ speed, cars,
control = loess.control(surface = "direct"))
predict(cars.lo2, data.frame(speed = seq(5, 30, 1)), se = TRUE)
```

loess.control

Set Parameters for Loess

Description
Set control parameters for `loess` fits.

Usage

```r
loess.control(surface = c("interpolate", "direct"),
statistics = c("approximate", "exact"),
trace.hat = c("exact", "approximate"),
cell = 0.2, iterations = 4, ...)
```

Arguments

- `surface`: should the fitted surface be computed exactly or via interpolation from a kd tree?
- `statistics`: should the statistics be computed exactly or approximately? Exact computation can be very slow.
- `trace.hat`: should the trace of the smoother matrix be computed exactly or approximately? It is recommended to use the approximation for more than about 1000 data points.
- `cell`: if interpolation is used this controls the accuracy of the approximation via the maximum number of points in a cell in the kd tree. Cells with more than `floor(n*span*cell)` points are subdivided.
- `iterations`: the number of iterations used in robust fitting.
- `...`: further arguments which are ignored.

Value
A list with components
- `surface`
- `statistics`
- `trace.hat`
- `cell`
- `iterations`
with meanings as explained under ‘Arguments’.

See Also

- `loess`
The Logistic Distribution

Description

Density, distribution function, quantile function and random generation for the logistic distribution with parameters location and scale.

Usage

dlogis(x, location = 0, scale = 1, log = FALSE)
plogis(q, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
qlogis(p, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
rllogis(n, location = 0, scale = 1)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
location, scale location and scale parameters.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

If location or scale are omitted, they assume the default values of 0 and 1 respectively.

The Logistic distribution with \( \text{location} = \mu \) and \( \text{scale} = \sigma \) has distribution function

\[
F(x) = \frac{1}{1 + e^{-(x-\mu)/\sigma}}
\]

and density

\[
f(x) = \frac{1}{\sigma} \frac{e^{(x-\mu)/\sigma}}{1 + e^{(x-\mu)/\sigma}}^2
\]

It is a long-tailed distribution with mean \( \mu \) and variance \( \pi^2/3\sigma^2 \).

Value

dlogis gives the density, plogis gives the distribution function, qlogis gives the quantile function, and rlogis generates random deviates.

The length of the result is determined by n for rlogis, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than n are recycled to the length of the result. Only the first elements of the logical parameters are used.
Note

qlogis(p) is the same as the well known ‘logit’ function, logit(p) = \log p/(1 – p), and plogis(x) has consequently been called the ‘inverse logit’.

The distribution function is a rescaled hyperbolic tangent, plogis(x) = (1 + \tanh(x/2))/2, and it is called a sigmoid function in contexts such as neural networks.

Source

[dpq]logis are calculated directly from the definitions.

rlogis uses inversion.

References

See Also

Distributions for other standard distributions.

Examples

var(rlogis(4000, 0, scale = 5)) # approximately (+/- 3)
pi^2/3 * 5^2

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which have methods for this function include: "glm", "lm", "nls" and "Arima". Packages contain methods for other classes, such as "fitdistr", "negbin" and "polr" in package MASS, "multinom" in package nnet and "gls", "gnls" "lme" and others in package nlme.

Usage

logLik(object, ...)

## S3 method for class 'lm'
logLik(object, REML = FALSE, ...)

Arguments

object any object from which a log-likelihood value, or a contribution to a log-likelihood value, can be extracted.

... some methods for this generic function require additional arguments.

REML an optional logical value. If TRUE the restricted log-likelihood is returned, else, if FALSE, the log-likelihood is returned. Defaults to FALSE.
Details

logLik is most commonly used for a model fitted by maximum likelihood, and some uses, e.g. by AIC, assume this. So care is needed where other fit criteria have been used, for example REML (the default for "lme").

For a "glm" fit the family does not have to specify how to calculate the log-likelihood, so this is based on using the family’s aic() function to compute the AIC. For the gaussian, Gamma and inverse.gaussian families it assumed that the dispersion of the GLM is estimated and has been counted as a parameter in the AIC value, and for all other families it is assumed that the dispersion is known. Note that this procedure does not give the maximized likelihood for "glm" fits from the Gamma and inverse gaussian families, as the estimate of dispersion used is not the MLE.

For "lm" fits it is assumed that the scale has been estimated (by maximum likelihood or REML), and all the constants in the log-likelihood are included. That method is only applicable to single-response fits.

Value

Returns an object of class logLik. This is a number with at least one attribute, "df" (degrees of freedom), giving the number of (estimated) parameters in the model.

There is a simple print method for "logLik" objects.

There may be other attributes depending on the method used: see the appropriate documentation. One that is used by several methods is "nobs", the number of observations used in estimation (after the restrictions if REML = TRUE).

Author(s)

José Pinheiro and Douglas Bates

logLik.gls, logLik.lme, in package nlme, etc.

AIC

Examples

x <- 1:5
lmx <- lm(x ~ 1)
logLik(lmx) # using print.logLik() method
utils::str(logLik(lmx))

## lm method
(fml <- lm(rating ~ ., data = attitude))
logLik(fml)
logLik(fml, REML = TRUE)

utils::data(Orthodont, package = "nlme")
fml <- lm(distance ~ Sex * age, Orthodont)
loglin

Description

loglin is used to fit log-linear models to multidimensional contingency tables by Iterative Proportional Fitting.

Usage

loglin(table, margin, start = rep(1, length(table)), fit = FALSE, eps = 0.1, iter = 20, param = FALSE, print = TRUE)

Arguments

table: a contingency table to be fit, typically the output from `table`.

margin: a list of vectors with the marginal totals to be fit. (Hierarchical) log-linear models can be specified in terms of these marginal totals which give the ‘maximal’ factor subsets contained in the model. For example, in a three-factor model, `list(c(1, 2), c(1, 3))` specifies a model which contains parameters for the grand mean, each factor, and the 1-2 and 1-3 interactions, respectively (but no 2-3 or 1-2-3 interaction), i.e., a model where factors 2 and 3 are independent conditional on factor 1 (sometimes represented as ‘[1][2][3]’). The names of factors (i.e., `names(dimnames(table))`) may be used rather than numeric indices.

start: a starting estimate for the fitted table. This optional argument is important for incomplete tables with structural zeros in `table` which should be preserved in the fit. In this case, the corresponding entries in `start` should be zero and the others can be taken as one.

fit: a logical indicating whether the fitted values should be returned.

eseps: maximum deviation allowed between observed and fitted margins.

iter: maximum number of iterations.

param: a logical indicating whether the parameter values should be returned.

print: a logical. If TRUE, the number of iterations and the final deviation are printed.

Details

The Iterative Proportional Fitting algorithm as presented in Haberman (1972) is used for fitting the model. At most `iter` iterations are performed, convergence is taken to occur when the maximum deviation between observed and fitted margins is less than `eps`. All internal computations are done in double precision; there is no limit on the number of factors (the dimension of the table) in the model.

Assuming that there are no structural zeros, both the Likelihood Ratio Test and Pearson test statistics have an asymptotic chi-squared distribution with `df` degrees of freedom.
Note that the IPF steps are applied to the factors in the order given in margin. Hence if the model is decomposable and the order given in margin is a running intersection property ordering then IPF will converge in one iteration.

Package MASS contains loglm, a front-end to loglin which allows the log-linear model to be specified and fitted in a formula-based manner similar to that of other fitting functions such as lm or glm.

Value

A list with the following components.

- `lrt` the Likelihood Ratio Test statistic.
- `pearson` the Pearson test statistic (X-squared).
- `df` the degrees of freedom for the fitted model. There is no adjustment for structural zeros.
- `margin` list of the margins that were fit. Basically the same as the input margin, but with numbers replaced by names where possible.
- `fit` An array like `table` containing the fitted values. Only returned if `fit` is TRUE.
- `param` A list containing the estimated parameters of the model. The ‘standard’ constraints of zero marginal sums (e.g., zero row and column sums for a two factor parameter) are employed. Only returned if `param` is TRUE.

table.

loglm in package MASS for a user-friendly wrapper.

glm for another way to fit log-linear models.

Examples

```r
## Model of joint independence of sex from hair and eye color.
fm <- loglm(HairEyeColor, list(c(1, 2), c(1, 3), c(2, 3)))
fm
1 - pchisq(fm$lrt, fm$df)
## Model with no three-factor interactions fits well.
```
The Log Normal Distribution

Description
Density, distribution function, quantile function and random generation for the log normal distribution whose logarithm has mean equal to \( \text{meanlog} \) and standard deviation equal to \( \text{sdlog} \).

Usage
- `dlnorm(x, meanlog = 0, sdlog = 1, log = FALSE)`
- `plnorm(q, meanlog = 0, sdlog = 1, lower.tail = TRUE, log.p = FALSE)`
- `qlnorm(p, meanlog = 0, sdlog = 1, lower.tail = TRUE, log.p = FALSE)`
- `rlnorm(n, meanlog = 0, sdlog = 1)`

Arguments
- \( x, q \) vector of quantiles.
- \( p \) vector of probabilities.
- \( n \) number of observations. If \( \text{length}(n) > 1 \), the length is taken to be the number required.
- \( \text{meanlog}, \text{sdlog} \) mean and standard deviation of the distribution on the log scale with default values of 0 and 1 respectively.
- \( \text{log}, \text{log.p} \) logical; if \( \text{TRUE} \), probabilities \( p \) are given as \( \log(\text{p}) \).
- \( \text{lower.tail} \) logical; if \( \text{TRUE} \) (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details
The log normal distribution has density

\[
    f(x) = \frac{1}{\sqrt{2\pi}\sigma x} e^{-\frac{(\log(x) - \mu)^2}{2\sigma^2}}
\]

where \( \mu \) and \( \sigma \) are the mean and standard deviation of the logarithm. The mean is \( E(X) = \exp(\mu + 1/2\sigma^2) \), the median is \( \text{med}(X) = \exp(\mu) \), and the variance \( \text{Var}(X) = \exp(2\mu + \sigma^2)(\exp(\sigma^2) - 1) \) and hence the coefficient of variation is \( \sqrt{\exp(\sigma^2) - 1} \) which is approximately \( \sigma \) when that is small (e.g., \( \sigma < 1/2 \)).

Value
`dlnorm` gives the density, `plnorm` gives the distribution function, `qlnorm` gives the quantile function, and `rlnorm` generates random deviates.

The length of the result is determined by \( n \) for `rlnorm`, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than \( n \) are recycled to the length of the result. Only the first elements of the logical parameters are used.

Note
The cumulative hazard \( H(t) = -\log(1 - F(t)) \) is \(-\text{plnorm}(t, r, \text{lower} = \text{FALSE}, \text{log} = \text{TRUE})\).
lowess

Source
dnorm is calculated from the definition (in ‘Details’). [pqr]norm are based on the relationship to the normal.

References

See Also
Distributions for other standard distributions, including dnorm for the normal distribution.

Examples
dnorm(1) == dnorm(0)

Description
This function performs the computations for the LOWESS smoother which uses locally-weighted polynomial regression (see the references).

Usage
lowess(x, y = NULL, f = 2/3, iter = 3, delta = 0.01 * diff(range(x)))

Arguments
x, y vectors giving the coordinates of the points in the scatter plot. Alternatively a single plotting structure can be specified – see xy.coords.
f the smoother span. This gives the proportion of points in the plot which influence the smooth at each value. Larger values give more smoothness.
iter the number of ‘robustifying’ iterations which should be performed. Using smaller values of iter will make lowess run faster.
delta See ‘Details’. Defaults to 1/100th of the range of x.

Details
lowess is defined by a complex algorithm, the Ratfor original of which (by W. S. Cleveland) can be found in the R sources as file ‘src/app1/lowess.doc’. Normally a local linear polynomial fit is used, but under some circumstances (see the file) a local constant fit can be used. ‘Local’ is defined by the distance to the floor(f*n)th nearest neighbour, and tricubic weighting is used for x which fall within the neighbourhood.

The initial fit is done using weighted least squares. If iter > 0, further weighted fits are done using the product of the weights from the proximity of the x values and case weights derived from the
residuals at the previous iteration. Specifically, the case weight is Tukey’s biweight, with cutoff 6
times the MAD of the residuals. (The current R implementation differs from the original in stopping
iteration if the MAD is effectively zero since the algorithm is highly unstable in that case.)

delta is used to speed up computation: instead of computing the local polynomial fit at each data
point it is not computed for points within delta of the last computed point, and linear interpolation
is used to fill in the fitted values for the skipped points.

Value

lowess returns a list containing components x and y which give the coordinates of the smooth. The
smooth can be added to a plot of the original points with the function lines: see the examples.

ls.diag

Compute Diagnostics for lsfit Regression Results

Description

Computes basic statistics, including standard errors, t- and p-values for the regression coefficients.

Usage

ls.diag(ls.out)

Arguments

ls.out Typically the result of lsfit()
Value

A list with the following numeric components.

- `std.dev`: The standard deviation of the errors, an estimate of \( \sigma \).
- `hat`: diagonal entries \( h_{ii} \) of the hat matrix \( H \).
- `std.res`: standardized residuals.
- `stud.res`: studentized residuals.
- `cooks`: Cook’s residuals.
- `dfits`: DFITS statistics.
- `correlation`: correlation matrix.
- `std.err`: standard errors of the regression coefficients.
- `cov.scaled`: Scaled covariance matrix of the coefficients.
- `cov.unscaled`: Unscaled covariance matrix of the coefficients.

References

See Also

- `hat` for the hat matrix diagonals, `ls.print`, `lm.influence`, `summary.lm`, `anova`.

Examples

```r
###-- Using the same data as the lm(.) example:
lsD9 <- lsfit(x = as.numeric(gl(2, 10, 20)), y = weight)
lsD9 <- ls.diag(lsD9)
utils::str(lsD9, give.attr = FALSE)
abs(1 - sum(lsD9$hat) / 2) < 10*.Machine$double.eps # sum(h.ii) = p
plot(lsD9$hat, lsD9$stud.res, xlim = c(0, 0.1))
abline(h = 0, lty = 2, col = "lightgray")
```

---

**ls.print**

**Print lsfit Regression Results**

Description

Computes basic statistics, including standard errors, t- and p-values for the regression coefficients and prints them if `print.it` is TRUE.

Usage

```r
ls.print(ls.out, digits = 4, print.it = TRUE)
```

Arguments

- `ls.out`: Typically the result of `lsfit()`.
- `digits`: The number of significant digits used for printing.
- `print.it`: A logical indicating whether the result should also be printed.
Value

A list with the components

summary The ANOVA table of the regression
coeff.table matrix with regression coefficients, standard errors, t- and p-values

Note

Usually you would use summary(lm(...)) and anova(lm(...)) to obtain similar output.

See Also

ls.diag, lsfit, also for examples; lm, lm.influence which usually are preferable.

Description

The least squares estimate of $\beta$ in the model

$$Y = X\beta + \epsilon$$

is found.

Usage

lsfit(x, y, wt = NULL, intercept = TRUE, tolerance = 1e-07, yname = NULL)

Arguments

x a matrix whose rows correspond to cases and whose columns correspond to variables.
y the responses, possibly a matrix if you want to fit multiple left hand sides.
wt an optional vector of weights for performing weighted least squares.
intercept whether or not an intercept term should be used.
tolerance the tolerance to be used in the matrix decomposition.
yname names to be used for the response variables.

Details

If weights are specified then a weighted least squares is performed with the weight given to the $j$th case specified by the $j$th entry in wt.

If any observation has a missing value in any field, that observation is removed before the analysis is carried out. This can be quite inefficient if there is a lot of missing data.

The implementation is via a modification of the LINPACK subroutines which allow for multiple left-hand sides.
Value

A list with the following named components:

- **coef**
  - the least squares estimates of the coefficients in the model ($\beta$ as stated above).
- **residuals**
  - residuals from the fit.
- **intercept**
  - indicates whether an intercept was fitted.
- **qr**
  - the QR decomposition of the design matrix.

References

See Also

- `lm` which usually is preferable; `ls.print`, `ls.diag`.

Examples

```r
## Using the same data as the `lm(.)` example:
lsD9 <- lsfit(x = unclass(gl(2, 10)), y = weight)
ls.print(lsD9)
```

### mad

Median Absolute Deviation

Description

Compute the median absolute deviation, i.e., the (lo-/hi-) median of the absolute deviations from the median, and (by default) adjust by a factor for asymptotically normal consistency.

Usage

```r
mad(x, center = median(x), constant = 1.4826, na.rm = FALSE,
   low = FALSE, high = FALSE)
```

Arguments

- **x**
  - a numeric vector.
- **center**
  - Optionally, the centre: defaults to the median.
- **constant**
  - scale factor.
- **na.rm**
  - if TRUE then NA values are stripped from x before computation takes place.
- **low**
  - if TRUE, compute the ‘lo-median’, i.e., for even sample size, do not average the two middle values, but take the smaller one.
- **high**
  - if TRUE, compute the ‘hi-median’, i.e., take the larger of the two middle values for even sample size.
Details

The actual value calculated is $c \times cMedian(abs(x - center))$ with the default value of center being $median(x)$, and $cMedian$ being the usual, the 'low' or 'high' median, see the arguments description for low and high above.

The default constant $= 1.4826$ (approximately $1/\Phi^{-1}(3/4) = 1/qnorm(3/4)$) ensures consistency, i.e.,

$$E[mad(X_1, \ldots, X_n)] = \sigma$$

for $X_i$ distributed as $N(\mu, \sigma^2)$ and large $n$.

If na.rm is TRUE then NA values are stripped from $x$ before computation takes place. If this is not done then an NA value in $x$ will cause mad to return NA.

See Also

IQR which is simpler but less robust, median, var.

Examples

```r
mad(c(1:9))
print(mad(c(1:9), constant = 1)) ==
mad(c(1:8, 100), constant = 1) # = 2 ; TRUE
x <- c(1,2,3,5,7,8)
sort(abs(x - median(x)))
c(mad(x, constant = 1),
  mad(x, constant = 1, low = TRUE),
  mad(x, constant = 1, high = TRUE))
```

mahalanobis

**Mahalanobis Distance**

Description

Returns the squared Mahalanobis distance of all rows in $x$ and the vector $\mu = center$ with respect to $\Sigma = cov$. This is (for vector $x$) defined as

$$D^2 = (x - \mu)' \Sigma^{-1} (x - \mu)$$

Usage

mahalanobis(x, center, cov, inverted = FALSE, ...)

Arguments

- **x**: vector or matrix of data with, say, $p$ columns.
- **center**: mean vector of the distribution or second data vector of length $p$.
- **cov**: covariance matrix ($p \times p$) of the distribution.
- **inverted**: logical. If TRUE, cov is supposed to contain the inverse of the covariance matrix.
- ...: passed to solve for computing the inverse of the covariance matrix (if inverted is false).
See Also

cov, var

Examples

```r
require(graphics)

ma <- cbind(1:6, 1:3)
(S <- var(ma))
mahalanobis(c(0, 0), 1:2, S)

x <- matrix(rnorm(100*3), ncol = 3)
stopifnot(mahalanobis(x, 0, diag(ncol(x))) == rowSums(x*x))

## Here, D^2 = usual squared Euclidean distances
Sx <- cov(x)
D2 <- mahalanobis(x, colMeans(x), Sx)
plot(density(D2, bw = 0.5),
     main="Squared Mahalanobis distances, n=100, p=3")

qqplot(qchisq(ppoints(100), df = 3), D2,
       main = expression("Q-Q plot of Mahalanobis" * ~D^2 * 
                       " vs. quantiles of" * ~ chi[3]^2))

abline(0, 1, col = 'gray')
```

Description

This function is used with the `family` functions in `glm()`. Given the name of a link, it returns a link function, an inverse link function, the derivative \(d\mu/d\eta\) and a function for domain checking.

Usage

```r
make.link(link)
```

Arguments

- `link` character: one of "logit", "probit", "cauchit", "cloglog", "identity", "log", "sqrt", "1/mu^2", "inverse".

Value

A object of class "link-glm", a list with components

- `linkfun` Link function function of \(\mu\)
- `linkinv` Inverse link function function of \(\eta\)
- `mu.eta` Derivative function of \(\eta\) \(d\mu/d\eta\)
- `valideta` function of \(\eta\) [ TRUE if \(\eta\) is in the domain of `linkinv`]
- `name` a name to be used for the link
**makepredictcall**

**Utility Function for Safe Prediction**

**Description**

A utility to help `model.frame.default` create the right matrices when predicting from models with terms like `poly` or `ns`.

**Usage**

```
makepredictcall(var, call)
```

**Arguments**

- `var` A variable.
- `call` The term in the formula, as a call.

**Details**

This is a generic function with methods for `poly`, `bs` and `ns`: the default method handles `scale`. If `model.frame.default` encounters such a term when creating a model frame, it modifies the `predvars` attribute of the terms supplied by replacing the term with one which will work for predicting new data. For example `makepredictcall.ns` adds arguments for the knots and intercept.

To make use of this, have your model-fitting function return the `terms` attribute of the model frame, or copy the `predvars` attribute of the `terms` attribute of the model frame to your `terms` object.

To extend this, make sure the term creates variables with a class, and write a suitable method for that class.

**Value**

A replacement for `call` for the `predvars` attribute of the terms.

**See Also**

- `model.frame`, `poly`, `scale`; `bs` and `ns` in package `splines`.
- `cars` for an example of prediction from a polynomial fit.

**Examples**

```
utils::str(make.link("logit"))
```
Examples

```r
require(graphics)

## using poly: this did not work in R < 1.5.0
fm <- lm(weight ~ poly(height, 2), data = women)
plot(women, xlab = "Height (in)", ylab = "Weight (lb)"
ht <- seq(57, 73, len = 200)
lines(ht, predict(fm, data.frame(height = ht)))

## see also example(cars)

## see bs and ns for spline examples.
```

---

**manova**  
*Multivariate Analysis of Variance*

**Description**

A class for the multivariate analysis of variance.

**Usage**

```r
manova(...)```

**Arguments**

```r
... Arguments to be passed to aov.
```

**Details**

Class "manova" differs from class "aov" in selecting a different summary method. Function manova calls `aov` and then add class "manova" to the result object for each stratum.

**Value**

See `aov` and the comments in ‘Details’ here.

**References**

**See Also**

`aov`, `summary.manova`, the latter containing examples.
mantelhaen.test

Examples

```r
## Set orthogonal contrasts.
op <- options(contrasts = c("contr.helmert", "contr.poly"))

## Fake a 2nd response variable
npk2 <- within(npk, foo <- rnorm(24))
( npk2.aov <- manova(cbind(yield, foo) ~ block + N*P*K, npk2) )
summary(npk2.aov)

( npk2.aovE <- manova(cbind(yield, foo) ~ N*P*K + Error(block), npk2) )
summary(npk2.aovE)
```

Description

Performs a Cochran-Mantel-Haenszel chi-squared test of the null that two nominal variables are conditionally independent in each stratum, assuming that there is no three-way interaction.

Usage

```r
mantelhaen.test(x, y = NULL, z = NULL,
    alternative = c("two.sided", "less", "greater"),
    correct = TRUE, exact = FALSE, conf.level = 0.95)
```

Arguments

- `x`: either a 3-dimensional contingency table in array form where each dimension is at least 2 and the last dimension corresponds to the strata, or a factor object with at least 2 levels.
- `y`: a factor object with at least 2 levels; ignored if `x` is an array.
- `z`: a factor object with at least 2 levels identifying to which stratum the corresponding elements in `x` and `y` belong; ignored if `x` is an array.
- `alternative`: indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. Only used in the 2 by 2 by `K` case.
- `correct`: a logical indicating whether to apply continuity correction when computing the test statistic. Only used in the 2 by 2 by `K` case.
- `exact`: a logical indicating whether the Mantel-Haenszel test or the exact conditional test (given the strata margins) should be computed. Only used in the 2 by 2 by `K` case.
- `conf.level`: confidence level for the returned confidence interval. Only used in the 2 by 2 by `K` case.

Details

If `x` is an array, each dimension must be at least 2, and the entries should be nonnegative integers. NA’s are not allowed. Otherwise, `x`, `y` and `z` must have the same length. Triples containing NA’s are removed. All variables must take at least two different values.
Value

A list with class "htest" containing the following components:

- **statistic**: Only present if no exact test is performed. In the classical case of a $2 \times 2$ by $K$ table (i.e., of dichotomous underlying variables), the Mantel-Haenszel chi-squared statistic; otherwise, the generalized Cochran-Mantel-Haenszel statistic.

- **parameter**: the degrees of freedom of the approximate chi-squared distribution of the test statistic (1 in the classical case). Only present if no exact test is performed.

- **p.value**: the p-value of the test.

- **conf.int**: a confidence interval for the common odds ratio. Only present in the $2 \times 2$ by $K$ case.

- **estimate**: an estimate of the common odds ratio. If an exact test is performed, the conditional Maximum Likelihood Estimate is given; otherwise, the Mantel-Haenszel estimate. Only present in the $2 \times 2$ by $K$ case.

- **null.value**: the common odds ratio under the null of independence, 1. Only present in the $2 \times 2$ by $K$ case.

- **alternative**: a character string describing the alternative hypothesis. Only present in the $2 \times 2$ by $K$ case.

- **method**: a character string indicating the method employed, and whether or not continuity correction was used.

- **data.name**: a character string giving the names of the data.

Note

The asymptotic distribution is only valid if there is no three-way interaction. In the classical $2 \times 2$ by $K$ case, this is equivalent to the conditional odds ratios in each stratum being identical. Currently, no inference on homogeneity of the odds ratios is performed.

See also the example below.

mauchly.test

Description

Tests whether a Wishart-distributed covariance matrix (or transformation thereof) is proportional to a given matrix.

Usage

mauchly.test(object, ...)  
## S3 method for class 'm1m'
mauchly.test(object, ...)  
## S3 method for class 'SSD'
mauchly.test(object, Sigma = diag(nrow = p),  
T = Thin.row(proj(M) - proj(X)), M = diag(nrow = p), X = ~0,  
idata = data.frame(index = seq_len(p)), ...)

Arguments

object          object of class SSD or m1m.
Sigma           matrix to be proportional to.
T               transformation matrix. By default computed from M and X.
M               formula or matrix describing the outer projection (see below).
X               formula or matrix describing the inner projection (see below).
idata           data frame describing intra-block design.
...             arguments to be passed to or from other methods.

Details

Mauchly’s test test for whether a covariance matrix can be assumed to be proportional to a given matrix.

This is a generic function with methods for classes "m1m" and "SSD".

The basic method is for objects of class SSD the method for m1m objects just extracts the SSD matrix and invokes the corresponding method with the same options and arguments.

The T argument is used to transform the observations prior to testing. This typically involves transformation to intra-block differences, but more complicated within-block designs can be encountered, making more elaborate transformations necessary. A matrix T can be given directly or specified as the difference between two projections onto the spaces spanned by M and X, which in turn can be given as matrices or as model formulas with respect to idata (the tests will be invariant to parametrization of the quotient space M/X).

The common use of this test is in repeated measurements designs, with X = ~1. This is almost, but not quite the same as testing for compound symmetry in the untransformed covariance matrix.

Notice that the defaults involve p, which is calculated internally as the dimension of the SSD matrix, and a couple of hidden functions in the stats namespace, namely proj which calculates projection matrices from design matrices or model formulas and Thin.row which removes linearly dependent rows from a matrix until it has full row rank.

Value

An object of class "htest"
Note
The p-value differs slightly from that of SAS because a second order term is included in the asymptotic approximation in R.

mauchly.test(mlmfit, M = ~ deg + noise, X = ~ noise, idata = idata)

mcnemar.test
McNemar’s Chi-squared Test for Count Data

Description
Performs McNemar’s chi-squared test for symmetry of rows and columns in a two-dimensional contingency table.

Usage
mcnemar.test(x, y = NULL, correct = TRUE)

Arguments
x
either a two-dimensional contingency table in matrix form, or a factor object.
y
a factor object; ignored if x is a matrix.
correct
a logical indicating whether to apply continuity correction when computing the test statistic.

Details
The null is that the probabilities of being classified into cells [i, j] and [j, i] are the same.
If x is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both x and y must be vectors or factors of the same length. Incomplete cases are removed, vectors are coerced into factors, and the contingency table is computed from these.
Continuity correction is only used in the 2-by-2 case if correct is TRUE.
median

Value

A list with class "htest" containing the following components:

- **statistic**: the value of McNemar's statistic.
- **parameter**: the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- **p.value**: the p-value of the test.
- **method**: a character string indicating the type of test performed, and whether continuity correction was used.
- **data.name**: a character string giving the name(s) of the data.

Performance
mcnemar.test(Performance)
## => significant change (in fact, drop) in approval ratings
```

---

**median**

**Median Value**

Description

Compute the sample median.

Usage

```r
median(x, na.rm = FALSE)
```

Arguments

- **x**: an object for which a method has been defined, or a numeric vector containing the values whose median is to be computed.
- **na.rm**: a logical value indicating whether NA values should be stripped before the computation proceeds.
Details

This is a generic function for which methods can be written. However, the default method makes use of is.na, sort and mean from package base all of which are generic, and so the default method will work for most classes (e.g. "Date") for which a median is a reasonable concept.

Value

The default method returns a length-one object of the same type as x, except when x is integer of even length, when the result will be double.

If there are no values or if na.rm = FALSE and there are NA values the result is NA of the same type as x (or more generally the result of x[!is.na(x)]).

References

quantile for general quantiles.

Examples

median(1:4)  # = 2.5 [even number]
median(c(1:3, 100, 1000))  # = 3 [odd, robust]

medpolish(x, eps = 0.01, maxiter = 10, trace.iter = TRUE, na.rm = FALSE)

Arguments

x  a numeric matrix.
eps  real number greater than 0. A tolerance for convergence: see ‘Details’.
maxiter  the maximum number of iterations
trace.iter  logical. Should progress in convergence be reported?
na.rm  logical. Should missing values be removed?

medpolish  Median Polish of a Matrix

Description

Fits an additive model using Tukey’s median polish procedure.

Usage

medpolish(x, eps = 0.01, maxiter = 10, trace.iter = TRUE, na.rm = FALSE)
Details

The model fitted is additive (constant + rows + columns). The algorithm works by alternately removing the row and column medians, and continues until the proportional reduction in the sum of absolute residuals is less than \( \epsilon \) or until there have been \( \text{maxiter} \) iterations. The sum of absolute residuals is printed at each iteration of the fitting process, if \( \text{trace.iter} \) is \( \text{TRUE} \). If \( \text{na.rm} \) is \( \text{FALSE} \) the presence of any \( \text{NA} \) value in \( x \) will cause an error, otherwise \( \text{NA} \) values are ignored.

\text{medpolish} \text{ } \text{return} \text{ } \text{an } \text{object of class } \text{medpolish} \text{ (see below). There are printing and plotting methods for this class, which are invoked via the generics } \text{print} \text{ and } \text{plot}.

Value

An object of class \text{medpolish} with the following named components:

- \text{overall} the fitted constant term.
- \text{row} the fitted row effects.
- \text{col} the fitted column effects.
- \text{residuals} the residuals.
- \text{name} the name of the dataset.

model.extract

Extract Components from a Model Frame

Description

Returns the response, offset, subset, weights or other special components of a model frame passed as optional arguments to `model.frame`.

Usage

```r
model.extract(frame, component)
model.offset(x)
model.response(data, type = "any")
model.weights(x)
```

Arguments

- `frame`, `x`, `data` A model frame.
- `component` literal character string or name. The name of a component to extract, such as "weights", "subset".
- `type` One of "any", "numeric", "double". Using either of latter two coerces the result to have storage mode "double".

Details

`model.extract` is provided for compatibility with S, which does not have the more specific functions. It is also useful to extract e.g. the etastart and mustart components of a `glm` fit.

`model.offset` and `model.response` are equivalent to `model.extract(, "offset")` and `model.extract(, "response")` respectively. `model.offset` sums any terms specified by `offset` terms in the formula or by `offset` arguments in the call producing the model frame: it does check that the offset is numeric.

`model.weights` is slightly different from `model.frame(, "weights")` in not naming the vector it returns.

Value

The specified component of the model frame, usually a vector.

See Also

`model.frame`, `offset`

Examples

```r
a <- model.frame(cbind(ncases, ncontrols) ~ agegp + tobgp + alcp, data = esoph)
model.extract(a, "response")
stopifnot(model.extract(a, "response") == model.response(a))

a <- model.frame(ncases/(ncases+ncontrols) ~ agegp + tobgp + alcp,
data = esoph, weights = ncases+ncontrols)
model.response(a)
```
model.frame

Extracting the Model Frame from a Formula or Fit

Description

model.frame (a generic function) and its methods return a data.frame with the variables needed to use formula and any ... arguments.

Usage

model.frame(formula, ...)

## Default S3 method:
model.frame(formula, data = NULL,
    subset = NULL, na.action = na.fail,
    drop.unused.levels = FALSE, xlev = NULL, ...)

## S3 method for class 'aovlist'
model.frame(formula, data = NULL, ...)

## S3 method for class 'glm'
model.frame(formula, ...)

## S3 method for class 'lm'
model.frame(formula, ...)

get_all_vars(formula, data, ...)

Arguments

formula  a model formula or terms object or an R object.
data a data.frame, list or environment (or object coercible by as.data.frame to a data.frame), containing the variables in formula. Neither a matrix nor an array will be accepted.
subset a specification of the rows to be used: defaults to all rows. This can be any valid indexing vector (see [.data.frame) for the rows of data or if that is not supplied, a data frame made up of the variables used in formula.
na.action how NAs are treated. The default is first, any na.action attribute of data, second a na.action setting of options, and third na.fail if that is unset. The 'factory-fresh' default is na.omit. Another possible value is NULL.
drop.unused.levels should factors have unused levels dropped? Defaults to FALSE.
xlev a named list of character vectors giving the full set of levels to be assumed for each factor.
further arguments such as data, na.action, subset. Any additional arguments such as offset and weights which reach the default method are used to create further columns in the model frame, with parenthesised names such as "(offset)".

Details

Exactly what happens depends on the class and attributes of the object formula. If this is an object of fitted-model class such as "lm", the method will either return the saved model frame used when fitting the model (if any, often selected by argument model = TRUE) or pass the call used when fitting on to the default method. The default method itself can cope with rather standard model objects such as those of class "lqs" from package MASS if no other arguments are supplied.

The rest of this section applies only to the default method.

If either formula or data is already a model frame (a data frame with a "terms" attribute) and the other is missing, the model frame is returned. Unless formula is a terms object, as.formula and then terms is called on it. (If you wish to use the keep.order argument of terms.formula, pass a terms object rather than a formula.)

Row names for the model frame are taken from the data argument if present, then from the names of the response in the formula (or rownames if it is a matrix), if there is one.

All the variables in formula, subset and in ... are looked for first in data and then in the environment of formula (see the help for formula() for further details) and collected into a data frame. Then the subset expression is evaluated, and it is used as a row index to the data frame. Then the na.action function is applied to the data frame (and may well add attributes). The levels of any factors in the data frame are adjusted according to the drop.unused.levels and xlev arguments: if xlev specifies a factor and a character variable is found, it is converted to a factor (as from R 2.10.0).

Unless na.action = NULL, time-series attributes will be removed from the variables found (since they will be wrong if NAs are removed).

Note that all the variables in the formula are included in the data frame, even those preceded by `-`

Only variables whose type is raw, logical, integer, real, complex or character can be included in a model frame: this includes classed variables such as factors (whose underlying type is integer), but excludes lists.

get_all_vars returns a data.frame containing the variables used in formula plus those specified .... Unlike model.frame.default, it returns the input variables and not those resulting from function calls in formula.

Value

A data.frame containing the variables used in formula plus those specified in .... It will have additional attributes, including "terms" for an object of class "terms" derived from formula, and possibly "na.action" giving information on the handling of NAs (which will not be present if no special handling was done, e.g. by na.pass).

model.frame manipulation.

Examples

data.class(model.frame(dist ~ speed, data = cars))

model.matrix

Construct Design Matrices

Description

model.matrix creates a design (or model) matrix.

Usage

model.matrix(object, ...)

## Default S3 method:
model.matrix(object, data = environment(object),
contrasts.arg = NULL, xlev = NULL, ...)

Arguments

object an object of an appropriate class. For the default method, a model formula or a
terms object.
data a data frame created with model.frame. If another sort of object, model.frame
is called first.
contrasts.arg A list, whose entries are values (numeric matrices or character strings nam-
ing functions) to be used as replacement values for the contrasts replacement
function and whose names are the names of columns of data containing
factors.
xlev to be used as argument of model.frame if data is such that model.frame is
called.
... further arguments passed to or from other methods.

details

model.matrix creates a design matrix from the description given in terms(object), using the
data in data which must supply variables with the same names as would be created by a call to
model.frame(object) or, more precisely, by evaluating attr(terms(object), "variables").
If data is a data frame, there may be other columns and the order of columns is not important. Any
character variables are coerced to factors. After coercion, all the variables used on the right-hand
side of the formula must be logical, integer, numeric or factor.
If contrasts.arg is specified for a factor it overrides the default factor coding for that variable and
any "contrasts" attribute set by C or contrasts.
In an interaction term, the variable whose levels vary fastest is the first one to appear in the formula
(and not in the term), so in ~ a + b + b:a the interaction will have a varying fastest.
By convention, if the response variable also appears on the right-hand side of the formula it is
dropped (with a warning), although interactions involving the term are retained.
Value

The design matrix for a regression-like model with the specified formula and data.

There is an attribute "assign", an integer vector with an entry for each column in the matrix giving the term in the formula which gave rise to the column. Value 0 corresponds to the intercept (if any), and positive values to terms in the order given by the term.labels attribute of the terms structure corresponding to object.

If there are any factors in terms in the model, there is an attribute "contrasts", a named list with an entry for each factor. This specifies the contrasts that would be used in terms in which the factor is coded by contrasts (in some terms dummy coding may be used), either as a character vector naming a function or as a numeric matrix.

dd <- data.frame(a = gl(3,4), b = gl(4,1,12)) # balanced 2-way
options("contrasts")
model.matrix(~ a + b, dd)
model.matrix(~ a + b, dd, contrasts = list(a = "contr.sum"))
model.matrix(~ a + b, dd, contrasts = list(a = "contr.sum", b = "contr.poly"))
m.orth <- model.matrix(~a+b, dd, contrasts = list(a = "contr.helmert"))
crossprod(m.orth) # m.orth is ALMOST orthogonal

model.tables

Compute Tables of Results from an Aov Model Fit

Description

Computes summary tables for model fits, especially complex aov fits.

Usage

model.tables(x, ...)

## S3 method for class 'aov'
model.tables(x, type = "effects", se = FALSE, cterms, ...)

## S3 method for class 'aovlist'
model.tables(x, type = "effects", se = FALSE, ...)
Arguments

- **x**: A model object, usually produced by `aov`.
- **type**: The type of table: currently only "effects" and "means" are implemented.
- **se**: Should standard errors be computed?
- **cterms**: A character vector giving the names of the terms for which tables should be computed. The default is all tables.
- **...**: Further arguments passed to or from other methods.

Details

For **type = "effects"**, give tables of the coefficients for each term, optionally with standard errors. For **type = "means"**, give tables of the mean response for each combination of levels of the factors in a term.

The "aov" method cannot be applied to components of a "aovlist" fit.

Value

An object of class "tables.aov", as list which may contain components

- **tables**: A list of tables for each requested term.
- **n**: The replication information for each term.
- **se**: Standard error information.

Warning

The implementation is incomplete, and only the simpler cases have been tested thoroughly.

Weighted `aov` fits are not supported.

See Also

- `aov`, `proj`, `replications`, `TukeyHSD`, `se.contrast`

Examples

```r
options(contrasts = c("contr.helmert", "contr.treatment"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
model.tables(npk.aov, "means", se = TRUE)

## as a test, not particularly sensible statistically
npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
model.tables(npk.aovE, se = TRUE)
model.tables(npk.aovE, "means")
```
monthplot  

**Plot a Seasonal or other Subseries from a Time Series**

**Description**

These functions plot seasonal (or other) subseries of a time series. For each season (or other category), a time series is plotted.

**Usage**

```r
monthplot(x, ...)  

## S3 method for class 'stl'
monthplot(x, labels = NULL, ylab = choice, choice = "seasonal", ...)

## S3 method for class 'StructTS'
monthplot(x, labels = NULL, ylab = choice, choice = "sea", ...)

## S3 method for class 'ts'
monthplot(x, labels = NULL, times = time(x), phase = cycle(x),  
ylab = deparse(substitute(x)), ...)

## Default S3 method:
monthplot(x, labels = 1L:12L,  
ylab = deparse(substitute(x)),  
times = seq_along(x),  
phase = (times - 1L)*%length(labels) + 1L, base = mean,  
axes = TRUE, type = c("l", "h"), box = TRUE,  
add = FALSE,  
col = par("col"), lty = par("lty") , lwd = par("lwd"),  
col.base = col, lty.base = lty, lwd.base = lwd, ...)
```

**Arguments**

- **x**  
  Time series or related object.

- **labels**  
  Labels to use for each 'season'.

- **ylab**  
  y label.

- **times**  
  Time of each observation.

- **phase**  
  Indicator for each 'season'.

- **base**  
  Function to use for reference line for subseries.

- **choice**  
  Which series of an stl or StructTS object?

- **...**  
  Arguments to be passed to the default method or graphical parameters.

- **axes**  
  Should axes be drawn (ignored if add = TRUE)?

- **type**  
  Type of plot. The default is to join the points with lines, and "h" is for histogram-like vertical lines.

- **box**  
  Should a box be drawn (ignored if add = TRUE)?

- **add**  
  Should thus just add on an existing plot.
col, lty, lwd  Graphics parameters for the series.
col.base, lty.base, lwd.base
    Graphics parameters for the segments used for the reference lines.

Details

These functions extract subseries from a time series and plot them all in one frame. The \texttt{ts}, \texttt{stl}, and \texttt{StructTS} methods use the internally recorded frequency and start and finish times to set the scale and the seasons. The default method assumes observations come in groups of 12 (though this can be changed).

If the labels are not given but the phase is given, then the labels default to the unique values of the phase. If both are given, then the phase values are assumed to be indices into the labels array, i.e., they should be in the range from 1 to \texttt{length(labels)}.

Value

These functions are executed for their side effect of drawing a seasonal subseries plot on the current graphical window.

mood.test

Mood Two-Sample Test of Scale

Description

Performs Mood's two-sample test for a difference in scale parameters.

Usage

mood.test(x, y, alternative = c("two.sided", "less", "greater"), ...
## Default S3 method:
mood.test(x, y,
    alternative = c("two.sided", "less", "greater"), ...)

## S3 method for class 'formula'
mood.test(formula, data, subset, na.action, ...)

Arguments

x, y numeric vectors of data values.
alternative indicates the alternative hypothesis and must be one of "two.sided" (default), "greater" or "less" all of which can be abbreviated.
formula a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.
data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset an optional vector specifying a subset of observations to be used.
na.action a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").
... further arguments to be passed to or from methods.

Details

The underlying model is that the two samples are drawn from \( f(x - l) \) and \( f((x - l)/s)/s \), respectively, where \( l \) is a common location parameter and \( s \) is a scale parameter.

The null hypothesis is \( s = 1 \).

There are more useful tests for this problem.

In the case of ties, the formulation of Mielke (1967) is employed.

Value

A list with class "htest" containing the following components:

statistic the value of the test statistic.
p.value the p-value of the test.
alternative a character string describing the alternative hypothesis.
method the character string "Mood two-sample test of scale".
data.name a character string giving the names of the data.
Multinom

`fligner.test` for a rank-based (nonparametric) k-sample test for homogeneity of variances; `ansari.test` for another rank-based two-sample test for a difference in scale parameters; `var.test` and `bartlett.test` for parametric tests for the homogeneity in variance.

Examples

```r
## Same data as for the Ansari-Bradley test:
## Serum iron determination using Hyland control sera
ramsay <- c(111, 107, 100, 99, 102, 106, 109, 108, 104, 99,
           101, 96, 97, 102, 107, 113, 116, 113, 110, 98)
jung.parekh <- c(107, 108, 106, 98, 105, 103, 110, 105, 104,
mood.test(ramsay, jung.parekh)
## Compare this to ansari.test(ramsay, jung.parekh)
```

The Multinomial Distribution

Description

Generate multinomially distributed random number vectors and compute multinomial probabilities.

Usage

```r
rmultinom(n, size, prob)
dmultinom(x, size = NULL, prob, log = FALSE)
```

Arguments

- `x` vector of length \( K \) of integers in \( \theta : \text{size} \).
- `n` number of random vectors to draw.
- `size` integer, say \( N \), specifying the total number of objects that are put into \( K \) boxes in the typical multinomial experiment. For `dmultinom`, it defaults to \( \text{sum}(x) \).
- `prob` numeric non-negative vector of length \( K \), specifying the probability for the \( K \) classes; is internally normalized to sum 1.
- `log` logical; if `TRUE`, log probabilities are computed.
Details

If \( x \) is a \( K \)-component vector, \( \text{dmultinom}(x, \text{prob}) \) is the probability

\[
P(X_1 = x_1, \ldots, X_K = x_k) = C \times \prod_{j=1}^{K} \pi_{x_j}^j
\]

where \( C \) is the ‘multinomial coefficient’ \( C = N!/(x_1! \cdots x_K!) \) and \( N = \sum_{j=1}^{K} x_j \).

By definition, each component \( X_j \) is binomially distributed as \( \text{Bin}(n_j, \pi_j) \) for \( j = 1, \ldots, K \).

The \( \text{rmultinom}\) algorithm draws binomials \( X_j \) from \( \text{Bin}(n_j, P_j) \) sequentially, where \( n_1 = N \) (\( N := \text{size} \)), \( P_1 = \pi_1 \) (\( \pi \) is prob scaled to sum 1), and for \( j \geq 2 \), recursively, \( n_j = N - \sum_{k=1}^{j-1} X_k \) and \( P_j = \pi_j/(1 - \sum_{k=1}^{j-1} \pi_k) \).

Value

For \( \text{rmultinom}\), an integer \( K \times n \) matrix where each column is a random vector generated according to the desired multinomial law, and hence summing to \( \text{size} \). Whereas the transposed result would seem more natural at first, the returned matrix is more efficient because of columnwise storage.

Note

dmultinom is currently not vectorized at all and has no C interface (API); this may be amended in the future.

See Also

\( \text{Distributions} \) for standard distributions, including \( \text{dbinom} \) which is a special case conceptually.

Examples

\[
\text{rmultinom}(10, \text{size} = 12, \text{prob} = c(0.1, 0.2, 0.8))
\]

\[
\text{pr} <- c(1, 3, 6, 10) \# \text{normalization not necessary for generation}
\]

\[
\text{rmultinom}(10, 20, \text{prob} = \text{pr})
\]

### all possible outcomes of \( \text{Multinom}(N = 3, K = 3) \)

\[
X <- \text{as.matrix(expand.grid(0:3, 0:3))}; X <- X[, \text{colSums}(X) <= 3]
\]

\[
X <- \text{rbind}(X, 3:3 - \text{colSums}(X)); \text{dimnames}(X) <- \text{list(letters[1:3], \text{NULL})}
\]

\[
\text{X}
\]

\[
\text{round(apply(X, 2, function(x) dmultinom(x, \text{prob} = c(1,2,5)), 3))}
\]

na.action

\( NA \) Action

Description

Extract information on the NA action used to create an object.

Usage

\[
\text{na.action(object, ...)}
\]
Arguments

object any object whose NA action is given.
... further arguments special methods could require.

Details

na.action is a generic function, and na.action.default its default method. The latter extracts the "na.action" component of a list if present, otherwise the "na.action" attribute.

When model.frame is called, it records any information on NA handling in a "na.action" attribute. Most model-fitting functions return this as a component of their result.

Value

Information from the action which was applied to object if NAs were handled specially, or NULL.

References

See Also

options("na.action"), na.omit, na.fail, also for na.exclude, na.pass.

Examples

na.action(na.omit(c(1, NA)))
**Examples**

```r
na.contiguous(presidents)
```

---

**Description**

These generic functions are useful for dealing with NAs in e.g., data frames. `na.fail` returns the object if it does not contain any missing values, and signals an error otherwise. `na.omit` returns the object with incomplete cases removed. `na.pass` returns the object unchanged.

**Usage**

```r
na.fail(object, ...)
na.omit(object, ...)
na.exclude(object, ...)
na.pass(object, ...)
```

**Arguments**

- `object` an R object, typically a data frame
- `...` further arguments special methods could require.

**Details**

At present these will handle vectors, matrices and data frames comprising vectors and matrices (only).

If `na.omit` removes cases, the row numbers of the cases form the "na.action" attribute of the result, of class "omit".

`na.exclude` differs from `na.omit` only in the class of the "na.action" attribute of the result, which is "exclude". This gives different behaviour in functions making use of `naresid` and `napredict`: when `na.exclude` is used the residuals and predictions are padded to the correct length by inserting NAs for cases omitted by `na.exclude`.

**References**

**See Also**

`na.action`; `options` with argument `na.action` for setting NA actions; and `lm` and `glm` for functions using these. `na.contiguous` as alternative for time series.
Examples

```r
DF <- data.frame(x = c(1, 2, 3), y = c(0, 10, NA))
n.a.omit(DF)
m <- as.matrix(DF)
n.a.omit(m)
stopifnot(all(na.omit(1:3) == 1:3))  # does not affect objects with no NA's
try(na.fail(DF))  # Error: missing values in ...  
options("na.action")
```

---

```r
naprint
```

**Adjust for Missing Values**

Description

Use missing value information to report the effects of an `na.action`.

Usage

```r
naprint(x, ...)
```

Arguments

- `x` An object produced by an `na.action` function.
- `...` further arguments passed to or from other methods.

Details

This is a generic function, and the exact information differs by method. `naprint.omit` reports the number of rows omitted: `naprint.default` reports an empty string.

Value

A character string providing information on missing values, for example the number.

---

```r
naresid
```

**Adjust for Missing Values**

Description

Use missing value information to adjust residuals and predictions.

Usage

```r
naresid(omit, x, ...)
napredict(omit, x, ...)
```
Arguments

omit an object produced by an `na.action` function, typically the “na.action” attribute of the result of `na.omit` or `na.exclude`.

x a vector, data frame, or matrix to be adjusted based upon the missing value information.

... further arguments passed to or from other methods.

Details

These are utility functions used to allow `predict`, `fitted` and `residuals` methods for modelling functions to compensate for the removal of NAs in the fitting process. They are used by the default, "lm", "glm" and "nls" methods, and by further methods in packages `MASS`, `rpart` and `survival`. Also used for the scores returned by `factanal`, `prcomp` and `princomp`.

The default methods do nothing. The default method for the `na.exclude` action is to pad the object with NAs in the correct positions to have the same number of rows as the original data frame.

Currently `naresid` and `napredict` are identical, but future methods need not be. `naresid` is used for residuals, and `napredict` for fitted values, predictions and `weights`.

Value

These return a similar object to `x`.

Note

In the early 2000s, packages `rpart` and `survival` contained versions of these functions that had an `na.omit` action equivalent to that now used for `na.exclude`.

---

The Negative Binomial Distribution

Description

Density, distribution function, quantile function and random generation for the negative binomial distribution with parameters `size` and `prob`.

Usage

```r
dnbinom(x, size, prob, mu, log = FALSE)
pnbinom(q, size, prob, mu, lower.tail = TRUE, log.p = FALSE)
qnbinom(p, size, prob, mu, lower.tail = TRUE, log.p = FALSE)
rnbinom(n, size, prob, mu)
```

Arguments

- `x` vector of (non-negative integer) quantiles.
- `q` vector of quantiles.
- `p` vector of probabilities.
- `n` number of observations. If `length(n) > 1`, the length is taken to be the number required.
size

target for number of successful trials, or dispersion parameter (the shape parameter of the gamma mixing distribution). Must be strictly positive, need not be integer.

prob

probability of success in each trial. 0 < prob <= 1.

mu

alternative parametrization via mean: see ‘Details’.

log, log.p

logical; if TRUE, probabilities p are given as log(p).

lower.tail

logical; if TRUE (default), probabilities are P[X ≤ x], otherwise, P[X > x].

Details

The negative binomial distribution with size = n and prob = p has density

\[ p(x) = \frac{\Gamma(x + n)}{\Gamma(n)x!} p^n (1 - p)^x \]

for x = 0, 1, 2, ..., n > 0 and 0 < p ≤ 1.

This represents the number of failures which occur in a sequence of Bernoulli trials before a target number of successes is reached. The mean is \( n(1 - p)/p \) and variance \( n(1 - p)/p^2 \).

A negative binomial distribution can also arise as a mixture of Poisson distributions with mean distributed as a gamma distribution (see pgamma) with scale parameter \( HQ_M pr®bIOpr®bI \) and shape parameter size. (This definition allows non-integer values of size.)

An alternative parametrization (often used in ecology) is by the mean mu, and size, the dispersion parameter, where prob = size/(size+mu). The variance is mu + mu^2/size in this parametrization.

If an element of x is not integer, the result of dnbinom is zero, with a warning.

The case size == 0 is the distribution concentrated at zero. This is the limiting distribution for size approaching zero, even if mu rather than prob is held constant. Notice though, that the mean of the limit distribution is 0, whatever the value of mu.

The quantile is defined as the smallest value x such that \( F(x) ≥ p \), where F is the distribution function.

Value

dnbinom gives the density, pbinom gives the distribution function, qbinom gives the quantile function, and rbinom generates random deviates.

Invalid size or prob will result in return value NaN, with a warning.

The length of the result is determined by n for rbinom, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than n are recycled to the length of the result. Only the first elements of the logical parameters are used.

Source

dnbinom computes via binomial probabilities, using code contributed by Catherine Loader (see dbinom).
pbinom uses pbeta.
qbinom uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.
See Also

Distributions for standard distributions, including `dbinom` for the binomial, `dpois` for the Poisson and `dgeom` for the geometric distribution, which is a special case of the negative binomial.

Examples

```r
require(graphics)
x <- 0:11
dnbinom(x, size = 1, prob = 1/2) * 2^((1 + x) == 1)
126 / dnbinom(0:8, size = 2, prob = 1/2) #-- theoretically integer

## Cumulative ('p') = Sum of discrete prob.s ('d'); Relative error:
summary(1 - cumsum(dnbinom(x, size = 2, prob = 1/2)) / pnbinom(x, size = 2, prob = 1/2))

x <- 0:15
size <- (1:20)/4
persp(x, size, dnb <- outer(x, size, function(x,s) dnbinom(x, s, prob = 0.4)),
      xlab = "x", ylab = "s", zlab = "density", theta = 150)
title(tit <- "negative binomial density(x,s, pr = 0.4) vs. x & s")

image (x, size, log10(dnb), main = paste("log [", tit, "]")
 contour(x, size, log10(dnb), add = TRUE)

## Alternative parametrization
x1 <- rbinom(500, mu = 4, size = 1)
x2 <- rbinom(500, mu = 4, size = 10)
x3 <- rbinom(500, mu = 4, size = 100)
h1 <- hist(x1, breaks = 20, plot = FALSE)
h2 <- hist(x2, breaks = h1$breaks, plot = FALSE)
h3 <- hist(x3, breaks = h1$breaks, plot = FALSE)
barplot(rbind(h1$counts, h2$counts, h3$counts),
       beside = TRUE, col = c("red","blue","cyan"),
       names.arg = round(h1$breaks[-length(h1$breaks)]))
```

**nextn**

*Highly Composite Numbers*

**Description**

`nextn` returns the smallest integer, greater than or equal to `n`, which can be obtained as a product of powers of the values contained in `factors`. `nextn` is intended to be used to find a suitable length to zero-pad the argument of `fft` to so that the transform is computed quickly. The default value for `factors` ensures this.

**Usage**

```r
nextn(n, factors = c(2,3,5))
```

**Arguments**

- `n` an integer.
- `factors` a vector of positive integer factors.
See Also
convolve, fft.

Examples

nextn(1001) # 1024
table(sapply(599:630, nextn))

Description

This function carries out a minimization of the function \( f \) using a Newton-type algorithm. See the references for details.

Usage

\[
\text{nlm}(f, p, ..., \text{hessian} = \text{FALSE}, \text{typsize} = \text{rep}(1, \text{length}(p)), \\
\text{fscale} = 1, \text{print.level} = 0, \text{ndigit} = 12, \text{gradtol} = 1e-6, \\
\text{stepmax} = \max(1000 \times \text{sqrt(sum((p/typsize)^2))), 1000), \\
\text{steptol} = 1e-6, \text{iterlim} = 100, \text{check.analyicals} = \text{TRUE})
\]

Arguments

- **f**: the function to be minimized, returning a single numeric value. This should be a function with first argument a vector of the length of \( p \) followed by any other arguments specified by the ... argument.
  
  If the function value has an attribute called gradient or both gradient and hessian attributes, these will be used in the calculation of updated parameter values. Otherwise, numerical derivatives are used. \text{deriv} returns a function with suitable gradient attribute and optionally a hessian attribute.

- **p**: starting parameter values for the minimization.

- **...**: additional arguments to be passed to \( f \).

- **hessian**: if TRUE, the hessian of \( f \) at the minimum is returned.

- **typsize**: an estimate of the size of each parameter at the minimum.

- **fscale**: an estimate of the size of \( f \) at the minimum.

- **print.level**: this argument determines the level of printing which is done during the minimization process. The default value of 0 means that no printing occurs, a value of 1 means that initial and final details are printed and a value of 2 means that full tracing information is printed.

- **ndigit**: the number of significant digits in the function \( f \).

- **gradtol**: a positive scalar giving the tolerance at which the scaled gradient is considered close enough to zero to terminate the algorithm. The scaled gradient is a measure of the relative change in \( f \) in each direction \( p[i] \) divided by the relative change in \( p[i] \).
**stepmax**
a positive scalar which gives the maximum allowable scaled step length. stepmax is used to prevent steps which would cause the optimization function to overflow, to prevent the algorithm from leaving the area of interest in parameter space, or to detect divergence in the algorithm. stepmax would be chosen small enough to prevent the first two of these occurrences, but should be larger than any anticipated reasonable step.

**steptol**
A positive scalar providing the minimum allowable relative step length.

**iterlim**
a positive integer specifying the maximum number of iterations to be performed before the program is terminated.

**check.analyticals**
a logical scalar specifying whether the analytic gradients and Hessians, if they are supplied, should be checked against numerical derivatives at the initial parameter values. This can help detect incorrectly formulated gradients or Hessians.

**Details**

Note that arguments after ... must be matched exactly.

If a gradient or hessian is supplied but evaluates to the wrong mode or length, it will be ignored if check.analyticals = TRUE (the default) with a warning. The hessian is not even checked unless the gradient is present and passes the sanity checks.

From the three methods available in the original source, we always use method “1” which is line search.

The functions supplied should always return finite (including not NA and not NaN) values: for the function value itself non-finite values are replaced by the maximum positive value with a warning.

The parameter vector passed to f and hessian has special semantics and is shared between calls. The functions should not copy it.

**Value**

A list containing the following components:

**minimum**
the value of the estimated minimum of f.

**estimate**
the point at which the minimum value of f is obtained.

**gradient**
the gradient at the estimated minimum of f.

**hessian**
the hessian at the estimated minimum of f (if requested).

**code**
an integer indicating why the optimization process terminated.

1: relative gradient is close to zero, current iterate is probably solution.

2: successive iterates within tolerance, current iterate is probably solution.

3: last global step failed to locate a point lower than estimate. Either estimate is an approximate local minimum of the function or steptol is too small.

4: iteration limit exceeded.

5: maximum step size stepmax exceeded five consecutive times. Either the function is unbounded below, becomes asymptotic to a finite value from above in some direction or stepmax is too small.

**iterations**
the number of iterations performed.
Source

The current code is by Saikat DebRoy and the R Core team, using a C translation of Fortran code by Richard H. Jones.

nlminb

Optimization using PORT routines

Description

Unconstrained and box-constrained optimization using PORT routines.

For historical compatibility.

Usage

nlminb(start, objective, gradient = NULL, hessian = NULL, ..., 
  scale = 1, control = list(), lower = -Inf, upper = Inf)
nlminb

Arguments

- **start**: numeric vector, initial values for the parameters to be optimized.
- **objective**: Function to be minimized. Must return a scalar value. The first argument to objective is the vector of parameters to be optimized, whose initial values are supplied through start. Further arguments (fixed during the course of the optimization) to objective may be specified as well (see ...).
- **gradient**: Optional function that takes the same arguments as objective and evaluates the gradient of objective at its first argument. Must return a vector as long as start.
- **hessian**: Optional function that takes the same arguments as objective and evaluates the hessian of objective at its first argument. Must return a square matrix of order length(start). Only the lower triangle is used.
- **...**: Further arguments to be supplied to objective.
- **scale**: See PORT documentation (or leave alone).
- **control**: A list of control parameters. See below for details.
- **lower, upper**: vectors of lower and upper bounds, replicated to be as long as start. If unspecified, all parameters are assumed to be unconstrained.

Details

Any names of start are passed on to objective and where applicable, gradient and hessian. The parameter vector will be coerced to double.

The parameter vector passed to objective, gradient and hessian has special semantics and is shared between calls. The functions should not copy it.

If any of the functions returns NA or NaN the internal code could infinite-loop in R prior to 2.15.2: this is now an error for the gradient and Hessian, and such values for function evaluation are replaced by +Inf with a warning.

Value

A list with components:

- **par**: The best set of parameters found.
- **objective**: The value of objective corresponding to par.
- **convergence**: An integer code. 0 indicates successful convergence.
- **message**: A character string giving any additional information returned by the optimizer, or NULL. For details, see PORT documentation.
- **iterations**: Number of iterations performed.
- **evaluations**: Number of objective function and gradient function evaluations

Control parameters

Possible names in the control list and their default values are:

- **eval.max**: Maximum number of evaluations of the objective function allowed. Defaults to 200.
- **iter.max**: Maximum number of iterations allowed. Defaults to 150.
trace  The value of the objective function and the parameters is printed every trace’th iteration.
     Defaults to 0 which indicates no trace information is to be printed.

abs.tol  Absolute tolerance. Defaults to 0 so the absolute convergence test is not used. If the
          objective function is known to be non-negative, the previous default of 1e-20 would be more
          appropriate.

rel.tol  Relative tolerance. Defaults to 1e-10.

x.tol   X tolerance. Defaults to 1.5e-8.

xf.tol  False convergence tolerance. Defaults to 2.2e-14.

step.min, step.max   Minimum and maximum step size. Both default to 1..

sing.tol  Singular convergence tolerance; defaults to rel.tol.

scale.init ...

  diff.g an estimated bound on the relative error in the objective function value.

# now use the hessian, too
sumsq.h <- function(x, y) diag(2, nrow = length(x))
nlminb(start = x0, sumsq, sumsq.g, sumsq.h)
nls

Description

Determine the nonlinear (weighted) least-squares estimates of the parameters of a nonlinear model.

Usage

nls(formula, data, start, control, algorithm, 
trace, subset, weights, na.action, model, 
lower, upper, ...) 

Arguments

formula a nonlinear model formula including variables and parameters. Will be coerced to a formula if necessary.
data an optional data frame in which to evaluate the variables in formula and weights. Can also be a list or an environment, but not a matrix.
start a named list or named numeric vector of starting estimates. When start is missing, a very cheap guess for start is tried (if algorithm != "plinear").
control an optional list of control settings. See nls.control for the names of the settable control values and their effect.
algorithm character string specifying the algorithm to use. The default algorithm is a Gauss-Newton algorithm. Other possible values are "plinear" for the Golub-Pereyra algorithm for partially linear least-squares models and "port" for the 'nl2sol' algorithm from the Port library – see the references.

trace logical value indicating if a trace of the iteration progress should be printed. Default is FALSE. If TRUE the residual (weighted) sum-of-squares and the parameter values are printed at the conclusion of each iteration. When the "plinear" algorithm is used, the conditional estimates of the linear parameters are printed after the nonlinear parameters. When the "port" algorithm is used the objective function value printed is half the residual (weighted) sum-of-squares.

subset an optional vector specifying a subset of observations to be used in the fitting process.

weights an optional numeric vector of (fixed) weights. When present, the objective function is weighted least squares.

na.action a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The ‘factory-fresh’ default is na.omit. Value na.exclude can be useful.

model logical. If true, the model frame is returned as part of the object. Default is FALSE.

lower, upper vectors of lower and upper bounds, replicated to be as long as start. If unspecified, all parameters are assumed to be unconstrained. Bounds can only be used with the "port" algorithm. They are ignored, with a warning, if given for other algorithms.

Additional optional arguments. None are used at present.

Details

An nls object is a type of fitted model object. It has methods for the generic functions anova, coef, confint, deviance, df.residual, fitted, formula, logLik, predict, print, profile, summary, residuals, vcov and weights.

Variables in formula (and weights if not missing) are looked for first in data, then the environment of formula and finally along the search path. Functions in formula are searched for first in the environment of formula and then along the search path.

Arguments subset and na.action are supported only when all the variables in the formula taken from data are of the same length: other cases give a warning.

Note that the anova method does not check that the models are nested: this cannot easily be done automatically, so use with care.

Value

A list of

- m an nlsModel object incorporating the model.
- data the expression that was passed to nls as the data argument. The actual data values are present in the environment of the m component.
- call the matched call with several components, notably algorithm.
- na.action the "na.action" attribute (if any) of the model frame.
- dataClasses the "dataClasses" attribute (if any) of the "terms" attribute of the model frame.
model if model = TRUE, the model frame.
weights if weights is supplied, the weights.
convInfo a list with convergence information.
control the control list used, see the control argument.
convergence, message for an algorithm = "port" fit only, a convergence code (0 for convergence) and message.

To use these is deprecated, as they are available from convInfo now.

Warning

**Do not use nls on artificial "zero-residual" data.**

The nls function uses a relative-offset convergence criterion that compares the numerical imprecision at the current parameter estimates to the residual sum-of-squares. This performs well on data of the form

\[ y = f(x, \theta) + \epsilon \]

(with var(\epsilon) > 0). It fails to indicate convergence on data of the form

\[ y = f(x, \theta) \]

because the criterion amounts to comparing two components of the round-off error. If you wish to test nls on artificial data please add a noise component, as shown in the example below.

The algorithm = "port" code appears unfinished, and does not even check that the starting value is within the bounds. Use with caution, especially where bounds are supplied.

Note

Setting warnOnly = TRUE in the control argument (see nls.control) returns a non-converged object (since R version 2.5.0) which might be useful for further convergence analysis, *but not for inference*.

### nls.control

**Control the Iterations in nls**

#### Description

Allow the user to set some characteristics of the nls nonlinear least squares algorithm.

#### Usage

```
nls.control(maxiter = 50, tol = 1e-05, minFactor = 1/1024,
             printEval = FALSE, warnOnly = FALSE)
```

#### Arguments

- `maxiter` A positive integer specifying the maximum number of iterations allowed.
tol A positive numeric value specifying the tolerance level for the relative offset convergence criterion.

minFactor A positive numeric value specifying the minimum step-size factor allowed on any step in the iteration. The increment is calculated with a Gauss-Newton algorithm and successively halved until the residual sum of squares has been decreased or until the step-size factor has been reduced below this limit.

printEval a logical specifying whether the number of evaluations (steps in the gradient direction taken each iteration) is printed.

warnOnly a logical specifying whether nls() should return instead of signalling an error in the case of termination before convergence. Termination before convergence happens upon completion of maxiter iterations, in the case of a singular gradient, and in the case that the step-size factor is reduced below minFactor.

Value

A list with exactly five components:

maxiter
tol
minFactor
printEval
warnOnly

with meanings as explained under ‘Arguments’.

**NLSstAsymptotic**  
*Fit the Asymptotic Regression Model*

**Description**

Fits the asymptotic regression model, in the form \( b_0 + b_1 \times (1 - \exp(-\exp(lrc) \times x)) \) to the \( xy \) data. This can be used as a building block in determining starting estimates for more complicated models.

**Usage**

\[ \text{NLSstAsymptotic}(xy) \]

**Arguments**

- **xy**: a sortedXyData object

**Value**

A numeric value of length 3 with components labelled \( b_0 \), \( b_1 \), and \( lrc \). \( b_0 \) is the estimated intercept on the \( y \)-axis, \( b_1 \) is the estimated difference between the asymptote and the \( y \)-intercept, and \( lrc \) is the estimated logarithm of the rate constant.

**Author(s)**

José Pinheiro and Douglas Bates

**Examples**

```r
Lob.329 <- Loblolly[ Loblolly$Seed == "329", ]
print(NLSstAsymptotic(sortedXyData(expression(age),
                     expression(height),
                     Lob.329)), digits = 3)
```

---

**NLSstClosestX**  
*Inverse Interpolation*

**Description**

Use inverse linear interpolation to approximate the \( x \) value at which the function represented by \( xy \) is equal to \( yval \).

**Usage**

\[ \text{NLSstClosestX}(xy, yval) \]
**NLSstLfAsymptote**

**Description**

Provide an initial guess at the horizontal asymptote on the left side (i.e., small values of \( x \)) of the graph of \( y \) versus \( x \) from the \( xy \) object. Primarily used within initial functions for self-starting nonlinear regression models.

**Usage**

\[
\text{NLSstLfAsymptote}(xy)
\]

**Arguments**

- \( xy \): a \text{sortedXyData} object

**Value**

A single numeric value estimating the horizontal asymptote for small \( x \).

**Author(s)**

José Pinheiro and Douglas Bates

**See Also**

\text{sortedXyData, NLSstClosestX, NLSstRtAsymptote, selfStart}
**Examples**

```
DNase.2 <- DNase[ DNase$Run == "2", ]
DN.srt <- sortedXYData( expression(log(conc)), expression(density), DNase.2 )
NLSstLfAsymptote( DN.srt )
```

---

**NLSstRtAsymptote**  
*Horizontal Asymptote on the Right Side*

**Description**

Provide an initial guess at the horizontal asymptote on the right side (i.e., large values of $x$) of the graph of $y$ versus $x$ from the `xy` object. Primarily used within initial functions for self-starting nonlinear regression models.

**Usage**

```
NLSstRtAsymptote(xy)
```

**Arguments**

- `xy`  
a `sortedXYData` object

**Value**

A single numeric value estimating the horizontal asymptote for large $x$.

**Author(s)**

José Pinheiro and Douglas Bates

**See Also**

`sortedXYData, NLSstClosestX, NLSstRtAsymptote, selfStart`

**Examples**

```
DNase.2 <- DNase[ DNase$Run == "2", ]
DN.srt <- sortedXYData( expression(log(conc)), expression(density), DNase.2 )
NLSstRtAsymptote( DN.srt )
```
Description

Extract the number of ‘observations’ from a model fit. This is principally intended to be used in computing BIC (see AIC).

Usage

nobs(object, ...)

## Default S3 method:
nobs(object, use.fallback = FALSE, ...)

Arguments

  object      A fitted model object.
  use.fallback logical: should fallback methods be used to try to guess the value?
  ...         Further arguments to be passed to methods.

Details

This is a generic function, with an S4 generic in package stats4. There are methods in this package for objects of classes "lm", "glm", "nls" and "logLik", as well as a default method (which throws an error, unless use.fallback = TRUE when it looks for weights and residuals components – use with care!).

The main usage is in determining the appropriate penalty for BIC, but nobs is also used by the stepwise fitting methods step, add1 and drop1 as a quick check that different fits have been fitted to the same set of data (and not, say, that further rows have been dropped because of NAs in the new predictors).

For lm, glm and nls fits, observations with zero weight are not included.

Value

A single number, normally an integer. Could be NA.

See Also

AIC.
The Normal Distribution

Description

Density, distribution function, quantile function and random generation for the normal distribution with mean equal to mean and standard deviation equal to sd.

Usage

dnorm(x, mean = 0, sd = 1, log = FALSE)
pnorm(q, mean = 0, sd = 1, lower.tail = TRUE, log.p = FALSE)
qnorm(p, mean = 0, sd = 1, lower.tail = TRUE, log.p = FALSE)
rnorm(n, mean = 0, sd = 1)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
mean vector of means.
sd vector of standard deviations.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \) otherwise, \( P[X > x] \).

Details

If mean or sd are not specified they assume the default values of 0 and 1, respectively.

The normal distribution has density

\[
f(x) = \frac{1}{\sqrt{2\pi}\sigma} e^{- (x-\mu)^2 / 2\sigma^2}
\]

where \( \mu \) is the mean of the distribution and \( \sigma \) the standard deviation.

qnorm is based on Wichura’s algorithm AS 241 which provides precise results up to about 16 digits.

Value

dnorm gives the density, pnorm gives the distribution function, qnorm gives the quantile function, and rnorm generates random deviates.

The length of the result is determined by n for rnorm, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than n are recycled to the length of the result. Only the first elements of the logical parameters are used.
Normal

Source

For pnorm, based on

For qnorm, the code is a C translation of

For rnorm, see RNG for how to select the algorithm and for references to the supplied methods.

References

Examples

require(graphics)

dnorm(0) == 1/sqrt(2*pi)
dnorm(1) == exp(-1/2)/sqrt(2*pi)
dnorm(1) == 1/sqrt(2*pi*exp(1))

## Using "log = TRUE" for an extended range :
par(mfrow = c(2,1))
plot(function(x) dnorm(x, log = TRUE), -50, 50,
main = "log ( Normal density )")
curve(log(dnorm(x))), add = TRUE, col = "red", lwd = 2)

mtext("dnorm(x, log=TRUE)", adj = 0)

mtext("log(dnorm(x))", col = "red", adj = 1)

plot(function(x) pnorm(x, log.p = TRUE), -50, 10,
main = "log ( Normal Cumulative )")
curve(log(pnorm(x))), add = TRUE, col = "red", lwd = 2)

mtext("pnorm(x, log=TRUE)", adj = 0)

mtext("log(pnorm(x))", col = "red", adj = 1)

## if you want the so-called 'error function'
erf <- function(x) 2 * pnorm(x * sqrt(2)) - 1

## (see Abramowitz and Stegun 29.2.29)

## and the so-called 'complementary error function'
erfc <- function(x) 2 * pnorm(x * sqrt(2), lower = FALSE)

## and the inverses
erfinv <- function (x) qnorm((1 + x)/2)/sqrt(2)
erfcinv <- function (x) qnorm(x/2, lower = FALSE)/sqrt(2)
numericDeriv  Evaluate Derivatives Numerically

Description

numericDeriv numerically evaluates the gradient of an expression.

Usage

numericDeriv(expr, theta, rho = parent.frame(), dir = 1:0)

Arguments

expr The expression to be differentiated. The value of this expression should be a numeric vector.
theta A character vector of names of numeric variables used in expr.
rho An environment containing all the variables needed to evaluate expr.
dir A numeric vector of directions to use for the finite differences.

Details

This is a front end to the C function numeric_deriv, which is described in Writing R Extensions. The numeric variables must be of type real and not integer.

Value

The value of eval(expr, envir = rho) plus a matrix attribute called gradient. The columns of this matrix are the derivatives of the value with respect to the variables listed in theta.

Author(s)

Saikat DebRoy <saikat@stat.wisc.edu>

Examples

myenv <- new.env()
assign("mean", 0, envir = myenv)
assign("sd", 1, envir = myenv)
assign("x", seq(-3, 3, len = 3), envir = myenv)
numericDeriv(quote(pnorm(x, mean, sd)), c("mean", "sd"), myenv)
offset

Include an Offset in a Model Formula

Description

An offset is a term to be added to a linear predictor, such as in a generalised linear model, with known coefficient 1 rather than an estimated coefficient.

Usage

offset(object)

Arguments

object An offset to be included in a model frame

Details

There can be more than one offset in a model formula, but - is not supported for offset terms (and is equivalent to +).

Value

The input value.

See Also

model.offset, model.frame.

For examples see glm and Insurance in package MASS.

oneway.test

Test for Equal Means in a One-Way Layout

Description

Test whether two or more samples from normal distributions have the same means. The variances are not necessarily assumed to be equal.

Usage

oneway.test(formula, data, subset, na.action, var.equal = FALSE)
Arguments

formula a formula of the form lhs ~ rhs where lhs gives the sample values and rhs
the corresponding groups.
data an optional matrix or data frame (or similar: see model.frame) containing
the variables in the formula formula. By default the variables are taken from
environment(formula).
subset an optional vector specifying a subset of observations to be used.
na.action a function which indicates what should happen when the data contain NAs. De-
defaults togetOption("na.action").
var.equal a logical variable indicating whether to treat the variances in the samples as
equal. If TRUE, then a simple F test for the equality of means in a one-way
analysis of variance is performed. If FALSE, an approximate method of Welch
(1951) is used, which generalizes the commonly known 2-sample Welch test to
the case of arbitrarily many samples.

Value

A list with class "htest" containing the following components:

statistic the value of the test statistic.
parameter the degrees of freedom of the exact or approximate F distribution of the test
statistic.
p.value the p-value of the test.
method a character string indicating the test performed.
data.name a character string giving the names of the data.

References

B. L. Welch (1951), On the comparison of several mean values: an alternative approach.

See Also

The standard t test (t.test) as the special case for two samples; the Kruskal-Wallis test
kruskal.test for a nonparametric test for equal location parameters in a one-way layout.

Examples

## Not assuming equal variances
oneway.test(extra ~ group, data = sleep)
## Assuming equal variances
oneway.test(extra ~ group, data = sleep, var.equal = TRUE)
## which gives the same result as
anova(lm(extra ~ group, data = sleep))
General-purpose Optimization

**Description**

General-purpose optimization based on Nelder–Mead, quasi-Newton and conjugate-gradient algorithms. It includes an option for box-constrained optimization and simulated annealing.

**Usage**

```r
optim(par, fn, gr = NULL, ..., 
method = c("Nelder-Mead", "BFGS", "CG", "L-BFGS-B", "SANN", 
"Brent"), 
lower = -Inf, upper = Inf, 
control = list(), hessian = FALSE)

optimHess(par, fn, gr = NULL, ..., control = list())
```

**Arguments**

- `par` Initial values for the parameters to be optimized over.
- `fn` A function to be minimized (or maximized), with first argument the vector of parameters over which minimization is to take place. It should return a scalar result.
- `gr` A function to return the gradient for the “BFGS”, “CG” and “L-BFGS-B” methods. If it is `null`, a finite-difference approximation will be used. For the “SANN” method it specifies a function to generate a new candidate point. If it is `null` a default Gaussian Markov kernel is used.
- `...` Further arguments to be passed to `fn` and `gr`.
- `method` The method to be used. See ‘Details’.
- `lower, upper` Bounds on the variables for the “L-BFGS-B” method, or bounds in which to search for method “Brent”.
- `control` A list of control parameters. See ‘Details’.
- `hessian` Logical. Should a numerically differentiated Hessian matrix be returned?

**Details**

- Note that arguments after `...` must be matched exactly.
- By default `optim` performs minimization, but it will maximize if `control$fn.scale` is negative. `optimHess` is an auxiliary function to compute the Hessian at a later stage if `hessian = TRUE` was forgotten.
- The default method is an implementation of that of Nelder and Mead (1965), that uses only function values and is robust but relatively slow. It will work reasonably well for non-differentiable functions.
- Method “BFGS” is a quasi-Newton method (also known as a variable metric algorithm), specifically that published simultaneously in 1970 by Broyden, Fletcher, Goldfarb and Shanno. This uses function values and gradients to build up a picture of the surface to be optimized.
Method "CG" is a conjugate gradients method based on that by Fletcher and Reeves (1964) (but with the option of Polak–Ribiere or Beale–Sorenson updates). Conjugate gradient methods will generally be more fragile than the BFGS method, but as they do not store a matrix they may be successful in much larger optimization problems.

Method "L-BFGS-B" is that of Byrd et. al. (1995) which allows box constraints, that is each variable can be given a lower and/or upper bound. The initial value must satisfy the constraints. This uses a limited-memory modification of the BFGS quasi-Newton method. If non-trivial bounds are supplied, this method will be selected, with a warning.

Nocedal and Wright (1999) is a comprehensive reference for the previous three methods.

Method "SANN" is by default a variant of simulated annealing given in Belisle (1992). Simulated annealing belongs to the class of stochastic global optimization methods. It uses only function values but is relatively slow. It will also work for non-differentiable functions. This implementation uses the Metropolis function for the acceptance probability. By default the next candidate point is generated from a Gaussian Markov kernel with scale proportional to the actual temperature. If a function to generate a new candidate point is given, method "SANN" can also be used to solve combinatorial optimization problems. Temperatures are decreased according to the logarithmic cooling schedule as given in Belisle (1992, p. 890); specifically, the temperature is set to \( \text{temp} = \text{temp}_0 \times \exp(-t/t_{\text{max}}) \), where \( t \) is the current iteration step and \( \text{temp}_0 \) and \( t_{\text{max}} \) are specifiable via control, see below. Note that the "SANN" method depends critically on the settings of the control parameters. It is not a general-purpose method but can be very useful in getting to a good value on a very rough surface.

Method "Brent" is for one-dimensional problems only, using optimize(). It can be useful in cases where optim() is used inside other functions where only method can be specified, such as in mle from package stats4.

Function fn can return NA or Inf if the function cannot be evaluated at the supplied value, but the initial value must have a computable finite value of fn. (Except for method "L-BFGS-B" where the values should always be finite.)

optim can be used recursively, and for a single parameter as well as many. It also accepts a zero-length par, and just evaluates the function with that argument.

The control argument is a list that can supply any of the following components:

- trace Non-negative integer. If positive, tracing information on the progress of the optimization is produced. Higher values may produce more tracing information: for method "L-BFGS-B" there are six levels of tracing. (To understand exactly what these do see the source code: higher levels give more detail.)

- fnscale An overall scaling to be applied to the value of fn and gr during optimization. If negative, turns the problem into a maximization problem. Optimization is performed on fn(par)/fnscale.

- parscale A vector of scaling values for the parameters. Optimization is performed on par/parscale and these should be comparable in the sense that a unit change in any element produces about a unit change in the scaled value. Not used (nor needed) for method = "Brent".

- ndeps A vector of step sizes for the finite-difference approximation to the gradient, on par/parscale scale. Defaults to 1e-3.

- maxit The maximum number of iterations. Defaults to 100 for the derivative-based methods, and 500 for "Nelder–Mead". For "SANN" maxit gives the total number of function evaluations: there is no other stopping criterion. Defaults to 10000.

- abstol The absolute convergence tolerance. Only useful for non-negative functions, as a tolerance for reaching zero.
reltol Relative convergence tolerance. The algorithm stops if it is unable to reduce the value by a factor of reltol * (abs(val) + reltol) at a step. Defaults to \( \text{sqrt(Machine\$double\_eps)} \), typically about \( 1e-8 \).

alpha, beta, gamma Scaling parameters for the "Nelder–Mead" method. alpha is the reflection factor (default 1.0), beta the contraction factor (0.5) and gamma the expansion factor (2.0).

REPORT The frequency of reports for the "BFGS", "L-BFGS-B" and "SANN" methods if control$trace is positive. Defaults to every 10 iterations for "BFGS" and "L-BFGS-B", or every 100 temperatures for "SANN".

lmm is an integer giving the number of BFGS updates retained in the "L-BFGS-B" method. It defaults to 5.

factr controls the convergence of the "L-BFGS-B" method. Convergence occurs when the reduction in the objective is within this factor of the machine tolerance. Default is \( 1e7 \), that is a tolerance of about \( 1e-8 \).

pgtol helps control the convergence of the "L-BFGS-B" method. It is a tolerance on the projected gradient in the current search direction. This defaults to zero, when the check is suppressed.

temp controls the "SANN" method. It is the starting temperature for the cooling schedule. Defaults to 10.

tmax is the number of function evaluations at each temperature for the "SANN" method. Defaults to 10.

Any names given to par will be copied to the vectors passed to fn and gr. Note that no other attributes of par are copied over.

The parameter vector passed to fn has special semantics and may be shared between calls: the function should not change or copy it.

**Value**

For optim, a list with components:

- **par** The best set of parameters found.
- **value** The value of fn corresponding to par.
- **counts** A two-element integer vector giving the number of calls to fn and gr respectively. This excludes those calls needed to compute the Hessian, if requested, and any calls to fn to compute a finite-difference approximation to the gradient.
- **convergence** An integer code. 0 indicates successful completion (which is always the case for "SANN" and "Brent"). Possible error codes are:
  - 1 indicates that the iteration limit maxit had been reached.
  - 10 indicates degeneracy of the Nelder–Mead simplex.
  - 51 indicates a warning from the "L-BFGS-B" method; see component message for further details.
  - 52 indicates an error from the "L-BFGS-B" method; see component message for further details.
- **message** A character string giving any additional information returned by the optimizer, or NULL.
- **hessian** Only if argument hessian is true. A symmetric matrix giving an estimate of the Hessian at the solution found. Note that this is the Hessian of the unconstrained problem even if the box constraints are active.

For optimHess, the description of the hessian component applies.
Note

optim will work with one-dimensional pars, but the default method does not work well (and will warn). Method "Brent" uses optimize and needs bounds to be available; "BFGS" often works well enough if not.

Source

The code for methods "Nelder-Mead", "BFGS" and "CG" was based originally on Pascal code in Nash (1990) that was translated by p2c and then hand-optimized. Dr Nash has agreed that the code can be made freely available.

The code for method "L-BFGS-B" is based on Fortran code by Zhu, Byrd, Lu-Chen and Nocedal obtained from Nettib (file ‘opt/1bfgs_bcm.shar’: another version is in ‘toms/778’).

The code for method "SANN" was contributed by A. Trapletti.

optimize for one-dimensional minimization and constrOptim for constrained optimization.

Examples

```r
require(graphics)

fr <- function(x) {  # Rosenbrock Banana function
  x1 <- x[1]
  x2 <- x[2]
  100 * (x2 - x1 * x1)^2 + (1 - x1)^2
}

grr <- function(x) {  # Gradient of 'fr'
  x1 <- x[1]
  x2 <- x[2]
  c(-400 * x1 * (x2 - x1 * x1) - 2 * (1 - x1),
     200 * (x2 - x1 * x1))
}

optim(c(-1.2,1), fr)
(res <- optim(c(-1.2,1), fr, grr, method = "BFGS"))
optimHess(res$par, fr, grr)
optim(c(-1.2,1), fr, NULL, method = "BFGS", hessian = TRUE)
```
## These do not converge in the default number of steps

```r
optim(c(-1.2,1), fr, grr, method = "CG")
optim(c(-1.2,1), fr, grr, method = "CG", control = list(type = 2))
optim(c(-1.2,1), fr, grr, method = "L-BFGS-B")
```

## 25-dimensional box constrained

```r
optim(rep(3, 25), flb, NULL, method = "L-BFGS-B",
      lower = rep(2, 25), upper = rep(4, 25)) # par[24] is not at boundary
```

### "Wild" function, global minimum at about -15.81515

```r
fw <- function(x)
  10*sin(0.3*x)*sin(1.3*x*2) + 0.00001*x^4 + 0.2*x+80
plot(fw, -50, 50, n = 1000, main = "optim() minimising 'wild function'")
```

### Now improve locally (typically only by a small bit):

```r
(r2 <- optim(res$par, fw, method = "BFGS"))
points(r2$par, r2$value, pch = 8, col = "red", cex = 2)
```

### Combinatorial optimization: Traveling salesman problem

```r
eurodistmat <- as.matrix(euordist)
distance <- function(sq) {
  # Target function
  sq2 <- embed(sq, 2)
  sum(eurodistmat[cbind(sq2[,2], sq2[,1]))
}

genseq <- function(sq) {
  # Generate new candidate sequence
  idx <- seq(2, NROW(eurodistmat)-1)
  changepoints <- sample(idx, size = 2, replace = FALSE)
  tmp <- sq[changepoints[1]]
  sq[changepoints[1]] <- sq[changepoints[2]]
  sq[changepoints[2]] <- tmp
  sq
}

sq <- c(1:nrow(eurodistmat), 1)  # Initial sequence: alphabetic
distance(sq)
# rotate for conventional orientation
loc <- -cmdscale(eurodist, add = TRUE)$points
x <- loc[,1]; y <- loc[,2]
s <- seq_len(nrow(eurodistmat))
tspinit <- loc[sq,]
plot(x, y, type = "n", xlab = "", ylab = "",
     main = "initial solution of traveling salesman problem", axes = FALSE)
arrows(tspinit[s[1], tspinit[s[2], tspinit[s+1,1], tspinit[s+1,2],
     angle = 10, col = "green"]
text(x, y, labels(euordist), cex = 0.8)
set.seed(123) # chosen to get a good soln relatively quickly
```
The function `optimize` searches the interval from `lower` to `upper` for a minimum or maximum of the function `f` with respect to its first argument. `optimise` is an alias for `optimize`.

**Usage**

```r
optimize(f = , interval = , ..., lower = min(interval),
          upper = max(interval), maximum = FALSE,
          tol = .Machine$double.eps^0.25)
optimise(f = , interval = , ..., lower = min(interval),
          upper = max(interval), maximum = FALSE,
          tol = .Machine$double.eps^0.25)
```

**Arguments**

- **f** the function to be optimized. The function is either minimized or maximized over its first argument depending on the value of `maximum`.
- **interval** a vector containing the end-points of the interval to be searched for the minimum.
- **...** additional named or unnamed arguments to be passed to `f`.
- **lower** the lower end point of the interval to be searched.
- **upper** the upper end point of the interval to be searched.
- **maximum** logical. Should we maximize or minimize (the default)?
- **tol** the desired accuracy.

**Details**

Note that arguments after `...` must be matched exactly.

The method used is a combination of golden section search and successive parabolic interpolation, and was designed for use with continuous functions. Convergence is never much slower than that for a Fibonacci search. If `f` has a continuous second derivative which is positive at the minimum (which is not at `lower` or `upper`), then convergence is superlinear, and usually of the order of about 1.324.
The function \( f \) is never evaluated at two points closer together than
\[ \epsilon |x_0| + (\text{tol}/3), \]
where \( \epsilon \) is approximately \( \sqrt{\text{Machine}\$\text{double}\_eps} \) and \( x_0 \) is the final abscissa optimize().
If \( f \) is a unimodal function and the computed values of \( f \) are always unimodal when separated by at least \( \epsilon |x| + (\text{tol}/3) \), then \( x_0 \) approximates the abscissa of the global minimum of \( f \) on the interval lower, upper with an error less than \( \epsilon |x_0| + \text{tol} \).
If \( f \) is not unimodal, then optimize() may approximate a local, but perhaps non-global, minimum to the same accuracy.

The first evaluation of \( f \) is always at \( x_1 = a + (1 - \phi)(b - a) \) where \( (a, b) = (\text{lower, upper}) \) and \( \phi = (\sqrt{5} - 1)/2 = 0.61803.. \) is the golden section ratio. Almost always, the second evaluation is at \( x_2 = a + \phi(b - a) \). Note that a local minimum inside \([x_1, x_2]\) will be found as solution, even when \( f \) is constant in there, see the last example.

\( f \) will be called as \( f(x, \ldots) \) for a numeric value of \( x \).

The argument passed to \( f \) has special semantics and used to be shared between calls. The function should not copy it.

**Value**

A list with components minimum (or maximum) and objective which give the location of the minimum (or maximum) and the value of the function at that point.

**Source**

A C translation of Fortran code http://www.netlib.org/fmm/fmin.f (author(s) unstated) based on the Algol 60 procedure localmin given in the reference.

**References**

**See Also**

**Examples**

require(graphics)

\[
\begin{align*}
f &< - \text{function}(x, a) (x - a)^2 \\
x_{\text{min}} &< - \text{optimize}(f, \text{c}(0, 1), \text{tol} = 0.0001, a = 1/3) \\
x_{\text{min}}
\end{align*}
\]

```r
## See where the function is evaluated:
\text{optimize(}\text{function}(x) x^2*(\text{print}(x)-1), \text{lower} = 0, \text{upper} = 10)```

```r
## "wrong" solution with unlucky interval and piecewise constant \( f() \):
f <- \text{function}(x) \text{ifelse}(x > -1, \text{ifelse}(x < 4, \text{exp(-1/abs(x - 1))), 10), 10)
fp <- \text{function}(x) \{ \text{print}(x); f(x) \} 
plot(f, -2.5, \text{ylim} = 0:1, \text{col} = 2) 
\text{optimize}(fp, \text{c(-4, 20)}) ## doesn't see the minimum 
\text{optimize}(fp, \text{c(-7, 20)}) ## ok
```
ordering or Labels of the Leaves in a Dendrogram

Description

These functions return the order (index) or the "label" attribute for the leaves in a dendrogram. These indices can then be used to access the appropriate components of any additional data.

Usage

order.dendrogram(x)

## S3 method for class 'dendrogram'
labels(object, ...)

Arguments

x, object  a dendrogram (see as.dendrogram).

...  additional arguments

Details

The indices or labels for the leaves in left to right order are retrieved.

Value

A vector with length equal to the number of leaves in the dendrogram is returned. From r <- order.dendrogram(), each element is the index into the original data (from which the dendrogram was computed).

Author(s)

R. Gentleman (order.dendrogram) and Martin Maechler (labels.dendrogram).

See Also

reorder.dendrogram.

Examples

set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
hc$order
dd <- as.dendrogram(hc)
order.dendrogram(dd) ## the same:
stopifnot(hc$order == order.dendrogram(dd))

d2 <- as.dendrogram(hclust(dist(USArrests)))
labels(d2) ## in this case the same as
stopifnot(identical(labels(d2),
                   rownames(USArrests)[order.dendrogram(d2)]))
p.adjust

Adjust P-values for Multiple Comparisons

Description

Given a set of p-values, returns p-values adjusted using one of several methods.

Usage

p.adjust(p, method = p.adjust.methods, n = length(p))

p.adjust.methods

# c("holm", "hochberg", "hommel", "bonferroni", "BH", "BY",
# "fdr", "none")

Arguments

p numeric vector of p-values (possibly with NAs). Any other R is coerced by as.numeric.
method correction method
n number of comparisons, must be at least length(p); only set this (to non-default) when you know what you are doing!

Details

The adjustment methods include the Bonferroni correction ("bonferroni") in which the p-values are multiplied by the number of comparisons. Less conservative corrections are also included by Holm (1979) ("holm"), Hochberg (1988) ("hochberg"), Hommel (1988) ("hommel"), Benjamini & Hochberg (1995) ("BH" or its alias "fdr"), and Benjamini & Yekutieli (2001) ("BY"), respectively. A pass-through option ("none") is also included. The set of methods are contained in the p.adjust.methods vector for the benefit of methods that need to have the method as an option and pass it on to p.adjust.

The first four methods are designed to give strong control of the family-wise error rate. There seems no reason to use the unmodified Bonferroni correction because it is dominated by Holm’s method, which is also valid under arbitrary assumptions.

Hochberg’s and Hommel’s methods are valid when the hypothesis tests are independent or when they are non-negatively associated (Sarkar, 1998; Sarkar and Chang, 1997). Hommel’s method is more powerful than Hochberg’s, but the difference is usually small and the Hochberg p-values are faster to compute.

The "BH" (aka "fdr") and "BY" method of Benjamini, Hochberg, and Yekutieli control the false discovery rate, the expected proportion of false discoveries amongst the rejected hypotheses. The false discovery rate is a less stringent condition than the family-wise error rate, so these methods are more powerful than the others.

Note that you can set n larger than length(p) which means the unobserved p-values are assumed to be greater than all the observed p for "bonferroni" and "holm" methods and equal to 1 for the other methods.

Value

A numeric vector of corrected p-values (of the same length as p, with names copied from p).
References

See Also

*pairwise.* functions such as `pairwise.t.test`.

Examples

```r
require(graphics)
set.seed(123)
x <- rnorm(50, mean = c(rep(0, 25), rep(3, 25)))
p <- 2*pnorm(sort(-abs(x)))

round(p, 3)
round(p.adjust(p, 3)
round(p.adjust(p, "BH"), 3)

## or all of them at once (dropping the "fdr" alias):
p.adj <- sapply(p.adjust.M, function(meth) p.adjust(p, meth))
p.adj.60 <- sapply(p.adjust.M, function(meth) p.adjust(p, meth, n = 60))
stopifnot(identical(p.adj[, "none"], p), p.adj <= p.adj.60)
round(p.adj, 3)
## or a bit nicer:
noquote(apply(p.adj, 2, format.pval, digits = 3))

## and a graphic:
matplot(p, p.adj, ylab="p.adjust(p, meth)", type = "l", asp = 1, lty = 1:6,
main = "P-value adjustments")
legend(0.7, 0.6, p.adjust.M, col = 1:6, lty = 1:6)

## Can work with NA's:
```

pairwise.prop.test

pairwise.prop.test(x, n, p.adjust.method = p.adjust.methods, ...)

Arguments

x Vector of counts of successes or a matrix with 2 columns giving the counts of successes and failures, respectively.

n Vector of counts of trials; ignored if x is a matrix.

p.adjust.method Method for adjusting p values (see p.adjust)

... Additional arguments to pass to prop.test

Value

Object of class "pairwise.htest"

See Also

prop.test, p.adjust

Examples

smokers <- c( 83, 90, 129, 70 )
patients <- c( 86, 93, 136, 82 )
pairwise.prop.test(smokers, patients)
pairwise.t.test  Pairwise t tests

Description

Calculate pairwise comparisons between group levels with corrections for multiple testing

Usage

pairwise.t.test(x, g, p.adjust.method = p.adjust.methods,
    pool.sd = !paired, paired = FALSE,
    alternative = c("two.sided", "less", "greater"),
    ...
)

Arguments

x  response vector.

  g  grouping vector or factor.

  p.adjust.method  Method for adjusting p values (see p.adjust).

  pool.sd  switch to allow/disallow the use of a pooled SD

  paired  a logical indicating whether you want paired t-tests.

  alternative  a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less".

  ...  additional arguments to pass to t.test.

Details

The pool.sd switch calculates a common SD for all groups and uses that for all comparisons (this can be useful if some groups are small). This method does not actually call t.test, so extra arguments are ignored. Pooling does not generalize to paired tests so pool.sd and paired cannot both be TRUE.

Only the lower triangle of the matrix of possible comparisons is being calculated, so setting alternative to anything other than "two.sided" requires that the levels of g are ordered sensibly.

Value

Object of class "pairwise.htest"

See Also

t.test, p.adjust

Examples

attach(airquality)
Month <- factor(Month, labels = month.abb[5:9])
pairwise.t.test(Ozone, Month)
pairwise.t.test(Ozone, Month, p.adj = "bonf")
pairwise.t.test(Ozone, Month, pool.sd = FALSE)
detach()
pairwise.table

Tabulate p values for pairwise comparisons

Description

Creates table of p values for pairwise comparisons with corrections for multiple testing.

Usage

pairwise.table(compare.levels, level.names, p.adjust.method)

Arguments

compare.levels Function to compute (raw) p value given indices i and j
level.names Names of the group levels
p.adjust.method Method for multiple testing adjustment

Details

Functions that do multiple group comparisons create separate compare.levels functions (assumed to be symmetrical in i and j) and passes them to this function.

Value

Table of p values in lower triangular form.

See Also

pairwise.t.test, et al.

pairwise.wilcox.test

Pairwise Wilcoxon Rank Sum Tests

Description

Calculate pairwise comparisons between group levels with corrections for multiple testing.

Usage

pairwise.wilcox.test(x, g, p.adjust.method = p.adjust.methods,
paired = FALSE, ...)

Arguments

x response vector.
g grouping vector or factor.
p.adjust.method method for adjusting p values (see p.adjust).
paired a logical indicating whether you want a paired test.
... additional arguments to pass to wilcox.test.
Details

Extra arguments that are passed on to `wilcox.test` may or may not be sensible in this context. In particular, only the lower triangle of the matrix of possible comparisons is being calculated, so setting `alternative` to anything other than "two.sided" requires that the levels of `g` are ordered sensibly.

Value

Object of class "pairwise.htest"

See Also

`wilcox.test.p.adjust`

Examples

```R
attach(airquality)
Month <- factor(Month, labels = month.abb[5:9])
# These give warnings because of ties:
pairwise.wilcox.test(Ozone, Month)
pairwise.wilcox.test(Ozone, Month, p.adj = "bonf")
detach()
```
The confidence interval plotted in `plot.acf` is based on an uncorrelated series and should be treated with appropriate caution. Using `ci.type = "ma"` may be less potentially misleading.

See Also

`acf` which calls `plot.acf` by default.

Examples

```r
require(graphics)

z4 <- ts(matrix(rnorm(400), 100, 4), start = c(1961, 1), frequency = 12)
z7 <- ts(matrix(rnorm(700), 100, 7), start = c(1961, 1), frequency = 12)
acf(z4)
acf(z7, max.mfrow = 7)  # squeeze onto 1 page
acf(z7) # multi-page
```

Description

The plot method for density objects.

Usage

```r
## S3 method for class 'density'
plot(x, main = NULL, xlab = NULL, ylab = "Density", type = "l",
     zero.line = TRUE, ...)```
plot.HoltWinters

Arguments

- **x**: An object of class "HoltWinters".
- **predicted.values** (optional): Predicted values as returned by `predict.HoltWinters`.
- **intervals** (optional): If `TRUE`, the prediction intervals are plotted (default).
- **separator** (optional): If `TRUE`, a separating line between fitted and predicted values is plotted (default).
- **col, lty** (optional): Color/line type of original data (default: black solid).
- **col.predicted, lty.predicted** (optional): Color/line type of fitted and predicted values (default: red solid).
- **col.intervals, lty.intervals** (optional): Color/line type of prediction intervals (default: blue solid).
- **col.separator, lty.separator** (optional): Color/line type of observed/predicted values separator (default: black dashed).

Value

None.

See Also

density.

Description

Produces a chart of the original time series along with the fitted values. Optionally, predicted values (and their confidence bounds) can also be plotted.

Usage

```r
## S3 method for class 'HoltWinters'
plot(x, predicted.values = NA, intervals = TRUE,
     separator = TRUE, col = 1, col.predicted = 2,
     col.intervals = 4, col.separator = 1, lty = 1,
     lty.predicted = 1, lty.intervals = 1, lty.separator = 3,
     ylab = "Observed / Fitted",
     main = "Holt-Winters filtering",
     ylim = NULL, ...)
```

Arguments

- **x**: Object of class "HoltWinters"
- **predicted.values**: Predicted values as returned by `predict.HoltWinters`.
- **intervals**: If `TRUE`, the prediction intervals are plotted (default).
- **separator**: If `TRUE`, a separating line between fitted and predicted values is plotted (default).
- **col, lty**: Color/line type of original data (default: black solid).
- **col.predicted, lty.predicted**: Color/line type of fitted and predicted values (default: red solid).
- **col.intervals, lty.intervals**: Color/line type of prediction intervals (default: blue solid).
- **col.separator, lty.separator**: Color/line type of observed/predicted values separator (default: black dashed).

**plot.isoreg**  
*Plot Method for isoreg Objects*

**Description**

The `plot` and `lines` method for R objects of class `isoreg`.

**Usage**

```r
## S3 method for class 'isoreg'
plot(x, plot.type = c("single", "row.wise", "col.wise"),
     main = paste("Isotonic regression", deparse(x$call)),
     xlab = "x", ylab = "y",
     par.fit = list(col = "red", cex = 1.5, pch = 13, lwd = 1.5),
     mar = if (both) 0.1 + c(3.5, 2.5, 1, 1) else par("mar"),
     mgp = if (both) c(1.6, 0.7, 0) else par("mgp"),
     grid = if length(x$x) < 12, ...)

## S3 method for class 'isoreg'
lines(x, col = "red", lwd = 1.5,
      do.points = FALSE, cex = 1.5, pch = 13, ...)
```
Arguments

- **x**: an `isoreg` object.
- **plot.type**: character indicating which type of plot is desired. The first (default) only draws the data and the fit, where the others add a plot of the cumulative data and fit.
- **main**: main title of plot, see `title`.
- **main2**: title for second (cumulative) plot.
- **xlab, ylab**: x- and y- axis annotation.
- **par.fit**: a list of arguments (for `points` and `lines`) for drawing the fit.
- **mar, mgp**: graphical parameters, see `par`, mainly for the case of two plots.
- **grid**: logical indicating if grid lines should be drawn. If true, `grid()` is used for the first plot, where as vertical lines are drawn at ‘touching’ points for the cumulative plot.
- **do.points**: for `lines()`: logical indicating if the step points should be drawn as well (and as they are drawn in `plot()`).
- **col, lwd, cex, pch**: graphical arguments for `lines()`, where `cex` and `pch` are only used when `do.points` is TRUE.
- **...**: further arguments passed to and from methods.

See Also

- `isoreg` for computation of `isoreg` objects.

Examples

```r
require(graphics)

utils::example(isoreg) # for the examples there

plot(y3, main = "simple plot(.) + lines(isoreg")
lines(ir3)

# 'same' plot as above, "proving" that only ranks of 'x' are important
plot(isoreg(2^c(1:9), c(1,0,4,3,3,5,4,2,0)), plot.type = "row", log = "x")

plot(ir3, plot.type = "row", ylab = "y3")
plot(isoreg(y3 - 4), plot.t="r", ylab = "y3 - 4")
plot(ir4, plot.type = "ro", ylab = "y4", xlab = "x = 1:n")

# experiment a bit with these (C-c C-j):
plot(isoreg(sample(9), y3), plot.type = "row")
plot(isoreg(sample(9), y3), plot.type = "col.wise")

plot(ir <- isoreg(sample(10), sample(10, replace = TRUE)),
plot.type = "r")
```

plot.isoreg
plot.lm

Plot Diagnostics for an lm Object

Description

Six plots (selectable by which) are currently available: a plot of residuals against fitted values, a Scale-Location plot of $\sqrt{|\text{residuals}|}$ against fitted values, a Normal Q-Q plot, a plot of Cook’s distances versus row labels, a plot of residuals against leverages, and a plot of Cook’s distances against leverage/(1-leverage). By default, the first three and 5 are provided.

Usage

```r
## S3 method for class 'lm'
plot(x, which = c(1:3, 5),
caption = list("Residuals vs Fitted", "Normal Q-Q",
"Scale-Location", "Cook's distance",
"Residuals vs Leverage",
expression("Cook's dist vs Leverage " * h[ii] / (1 - h[ii]))),
panel = if(add.smooth) panel.smooth else points,
sub.caption = NULL, main = "",
ask = prod(par("mfcol")) < length(which) && dev.interactive(),
..., id.n = 3, labels.id = names(residuals(x)), cex.id = 0.75,
qqline = TRUE, cook.levels = c(0.5, 1.0),
add.smooth =getOption("add.smooth"), label.pos = c(4,2),
cex.caption = 1)
```

Arguments

- **x**: lm object, typically result of lm or glm.
- **which**: if a subset of the plots is required, specify a subset of the numbers 1:6.
- **caption**: captions to appear above the plots; character vector or list of valid graphics annotations, see as.graphicsAnnot. Can be set to "" or NA to suppress all captions.
- **panel**: panel function. The useful alternative to points, panel.smooth can be chosen by add.smooth = TRUE.
- **sub.caption**: common title—above the figures if there are more than one; used as sub (s$plot) otherwise. If NULL, as by default, a possible abbreviated version of deparse(x$call) is used.
- **main**: title to each plot—in addition to caption.
- **ask**: logical; if TRUE, the user is asked before each plot, see par(ask=.).
- **...**: other parameters to be passed through to plotting functions.
- **id.n**: number of points to be labelled in each plot, starting with the most extreme.
- **labels.id**: vector of labels, from which the labels for extreme points will be chosen. NULL uses observation numbers.
- **cex.id**: magnification of point labels.
- **qqline**: logical indicating if a qqline() should be added to the normal Q-Q plot.
cook.levels levels of Cook’s distance at which to draw contours.

add.smooth logical indicating if a smoother should be added to most plots; see also panel above.

label.pos positioning of labels, for the left half and right half of the graph respectively, for plots 1-3.

cex.caption controls the size of caption.

Details

sub.caption—by default the function call—is shown as a subtitle (under the x-axis title) on each plot when plots are on separate pages, or as a subtitle in the outer margin (if any) when there are multiple plots per page.

The ‘Scale-Location’ plot, also called ‘Spread-Location’ or ‘S-L’ plot, takes the square root of the absolute residuals in order to diminish skewness ($\sqrt{|E|}$) is much less skewed than $|E|$ for Gaussian zero-mean $E$).

The ‘S-L’, the Q-Q, and the Residual-Leverage plot, use standardized residuals which have identical variance (under the hypothesis). They are given as $R_i/(s\times\sqrt{1-h_{ii}})$ where $h_{ii}$ are the diagonal entries of the hat matrix, \texttt{influence()}$\hat{\text{h}}$ (see also \texttt{hat}), and where the Residual-Leverage plot uses standardized Pearson residuals ($\texttt{residuals.glm(type = "pearson")}$) for $R[i]$.

The Residual-Leverage plot shows contours of equal Cook’s distance, for values of \texttt{cook.levels} (by default 0.5 and 1) and omits cases with leverage one with a warning. If the leverages are constant (as is typically the case in a balanced \texttt{aov} situation) the plot uses factor level combinations instead of the leverages for the x-axis. (The factor levels are ordered by mean fitted value.)

In the Cook’s distance vs leverage/(1-leverage) plot, contours of standardized residuals that are equal in magnitude are lines through the origin. The contour lines are labelled with the magnitudes.

Examples

```r
require(graphics)

## Analysis of the life-cycle savings data
## given in Belsley, Kuh and Welsch.
lm.SR <- lm(sr ~ pop15 + pop75 + dpi + ddpi, data = LifeCycleSavings)
plot(lm.SR)

## 4 plots on 1 page;
## allow room for printing model formula in outer margin:
par(mfrow = c(2, 2), oma = c(0, 0, 2, 0))
plot(lm.SR)
plot(lm.SR, id.n = NULL)  # no id's
plot(lm.SR, id.n = 5, labels.id = NULL)  # 5 id numbers

## Was default in R <= 2.1.x:
## Cook's distances instead of Residual-Leverage plot
plot(lm.SR, which = 1:4)

## Fit a smooth curve, where applicable:
plot(lm.SR, panel = panel.smooth)
## Gives a smoother curve
plot(lm.SR, panel = function(x, y) panel.smooth(x, y, span = 1))

par(mfrow = c(2,1))  # same oma as above
plot(lm.SR, which = 1:2, sub.caption = "Saving Rates, n=50, p=5")
```

Description

Plot ridge functions for projection pursuit regression fit.

Usage

```r
## S3 method for class 'ppr'
plot(x, ask, type = "o", ...)  
```

Arguments

- `x` A fit of class "ppr" as produced by a call to ppr.
- `ask` the graphics parameter ask: see `par` for details. If set to TRUE will ask between the plot of each cross-section.
- `type` the type of line to draw
- `...` further graphical parameters

Value

None
Side Effects

A series of plots are drawn on the current graphical device, one for each term in the fit.

See Also

ppr, par

Examples

```r
require(graphics)

with(rock, {
  area1 <- area/10000; peri1 <- peri/10000
  par(mfrow = c(3,2)) # maybe: , pty = "s")
  rock.ppr <- ppr(log(perm) ~ area1 + peri1 + shape,
                  data = rock, nterms = 2, max.terms = 5)
  plot(rock.ppr, main = "ppr(log(perm)~ , nterms=2, max.terms=5")
  plot(update(rock.ppr, bass = 5), main = "update(..., bass = 5")
  plot(update(rock.ppr, sm.method = "gcv", gcvpen = 2),
       main = "update(..., sm.method="gcv", gcvpen=2")
})
```

plot.profile.nls  

Plot a profile.nls Object

Description

Displays a series of plots of the profile t function and interpolated confidence intervals for the parameters in a nonlinear regression model that has been fit with nls and profiled with profile.nls.

Usage

```r
## S3 method for class 'profile.nls'
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100,
     absVal = TRUE, ylab = NULL, lty = 2, ...)
```

Arguments

- `x` an object of class "profile.nls"
- `levels` levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually `conf` is used instead of giving `levels` explicitly.
- `conf` a numeric vector of confidence levels for profile-based confidence intervals on the parameters. Defaults to `c(0.99, 0.95, 0.90, 0.80, 0.50)`.
- `absVal` a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile t. Defaults to TRUE.
- `lty` the line type to be used for axis and dropped lines.
- `ylab, ...` other arguments to the `plot.default` function can be passed here (but not `xlab`, `xlim`, `ylim` nor `type`).
The plots are produced in a set of hard-coded colours, but as these are coded by number their effect can be changed by setting the `palette`. Colour 1 is used for the axes and 4 for the profile itself. Colours 3 and 6 are used for the axis line at zero and the horizontal/vertical lines dropping to the axes.

### Examples
```r
require(graphics)

# obtain the fitted object
fm1 <- nls(demand ~ SSasympOrig(Time, A, lrc), data = BOD)
# get the profile for the fitted model
pr1 <- profile(fm1, alpha = 0.05)
opar <- par(mfrow = c(2,2), oma = c(1.1, 0, 1.1, 0), las = 1)
plot(pr1, conf = c(95, 90, 80, 50)/100)
plot(pr1, conf = c(95, 90, 80, 50)/100, absVal = FALSE)
mtext("Confidence intervals based on the profile sum of squares",
     side = 3, outer = TRUE)
mtext("BOD data - confidence levels of 50%, 80%, 90% and 95%",
     side = 1, outer = TRUE)
par(opar)
```

### Description
Plotting method for objects of class "spec". For multivariate time series it plots the marginal spectra of the series or pairs plots of the coherency and phase of the cross-spectra.

### Usage
```r
## S3 method for class 'spec'
plot(x, add = FALSE, ci = 0.95, log = c("yes", "dB", "no"),
     xlab = "frequency", ylab = NULL, type = "1",
     ci.col = "blue", ci.lty = 3,
     main = NULL, sub = NULL,
     plot.type = c("marginal", "coherency", "phase"),
     ...)
```
plot.spec

...)

plot.spec.phase(x, ci = 0.95,
    xlab = "frequency", ylab = "phase",
    ylim = c(-pi, pi), type = "l",
    main = NULL, ci.col = "blue", ci.lty = 3, ...)

plot.spec.coherency(x, ci = 0.95,
    xlab = "frequency",
    ylab = "squared coherency",
    ylim = c(0, 1), type = "l",
    main = NULL, ci.col = "blue", ci.lty = 3, ...)

Arguments

x
    an object of class "spec".

add
    logical. If TRUE, add to already existing plot. Only valid for plot.type = "marginal".

ci
    coverage probability for confidence interval. Plotting of the confidence bar/limits is omitted unless ci is strictly positive.

log
    If "dB", plot on log10 (decibel) scale (as S-PLUS), otherwise use conventional log scale or linear scale. Logical values are also accepted. The default is "yes" unless options(ts.S.compact = TRUE) has been set, when it is "dB". Only valid for plot.type = "marginal".

xlab
    the x label of the plot.

ylab
    the y label of the plot. If missing a suitable label will be constructed.

type
    the type of plot to be drawn, defaults to lines.

ci.col
    colour for plotting confidence bar or confidence intervals for coherency and phase.

ci.lty
    line type for confidence intervals for coherency and phase.

main
    overall title for the plot. If missing, a suitable title is constructed.

sub
    a sub title for the plot. Only used for plot.type = "marginal". If missing, a description of the smoothing is used.

plot.type
    For multivariate time series, the type of plot required. Only the first character is needed.

ylim, ...
    Graphical parameters.

spectrum
Method of the generic `plot` for `stepfun` objects and utility for plotting piecewise constant functions.

### Usage

```r
## S3 method for class 'stepfun'
plot(x, xval, xlim, ylim = range(c(y, Fn.knots)),
     xlab = "x", ylab = "f(x)", main = NULL,
     add = FALSE, verticals = TRUE, do.points = (n < 1000),
     pch = par("pch"), col = par("col"),
     col.points = col, cex.points = par("cex"),
     col.hor = col, col.vert = col,
     lty = par("lty"), lwd = par("lwd"), ...)

## S3 method for class 'stepfun'
lines(x, ...)
```

### Arguments

- `x`: an R object inheriting from "stepfun".
- `xval`: numeric vector of abscissa values at which to evaluate `x`. Defaults to `knots(x)` restricted to `xlim`.
- `xlim, ylim`: limits for the plot region: see `plot.window`. Both have sensible defaults if omitted.
- `xlab, ylab`: labels for x and y axis.
- `main`: main title.
- `add`: logical; if TRUE only add to an existing plot.
- `verticals`: logical; if TRUE, draw vertical lines at steps.
- `do.points`: logical; if TRUE, also draw points at the (`xlim` restricted) knot locations. Default is true, for sample size < 1000.
- `pch`: character; point character if `do.points`.
- `col`: default color of all points and lines.
- `col.points`: character or integer code; color of points if `do.points`.
- `cex.points`: numeric; character expansion factor if `do.points`.
- `col.hor`: color of horizontal lines.
- `col.vert`: color of vertical lines.
- `lty, lwd`: line type and thickness for all lines.
- `...`: further arguments of `plot(.)`, or if(`add`) `segments(.)`. 

---

**plot.stepfun**

*Plot Step Functions*

---

**Description**

Method of the generic `plot` for `stepfun` objects and utility for plotting piecewise constant functions.
Value

A list with two components

\[ t \] abscissa (x) values, including the two outermost ones.

\[ y \] y values ‘in between’ the \( t[] \).

Author(s)

See Also

ecdf for empirical distribution functions as special step functions, approxfun and splinefun.

Examples

```r
require(graphics)

y0 <- c(1,2,4,3)
sfun0 <- stepfun(1:3, y0, f = 0)
sfun.2 <- stepfun(1:3, y0, f = .2)
sfun1 <- stepfun(1:3, y0, right = TRUE)

tt <- seq(0, 3, by = 0.1)
op <- par(mfrow = c(2,2))
plot(sfun0); plot(sfun0, xval = tt, add = TRUE, col.hor = "bisque")
plot(sfun.2); plot(sfun.2, xval = tt, add = TRUE, col = "orange") # all colors
plot(sfun1); lines(sfun1, xval = tt, col.hor = "coral")

# This is revealing:
plot(sfun0, verticals = FALSE,
main = "stepfun(x, y0, f=f) for f = 0, .2, 1")
for(i in 1:3)
  lines(list(sfun0, sfun.2, stepfun(1:3, y0, f = i))[[i]], col = i)
legend(2.5, 1.9, paste("f =", c(0, .2, 1)), col = 1:3, lty = 1, y.intersp = 1)
par(op)

# Extend and/or restrict 'viewport':
plot(sfun0, xlim = c(0,5), ylim = c(0, 3.5),
main = "plot(stepfun(*), xlim= ., ylim = .)")

### this works too (automatic call to ecdf(.)):
plot.stepfun(rt(50, df = 3), col.vert = "gray20")
```

Description

Plotting method for objects inheriting from class "ts".
Usage

```r
### S3 method for class 'ts'
plot(x, y = NULL, plot.type = c("multiple", "single"),
     xy.labels, xy.lines, panel = lines, nc, yax.flip = FALSE,
     mar.multi = c(0, 5.1, 0, if(yax.flip) 5.1 else 2.1),
     oma.multi = c(6, 0, 5, 0), axes = TRUE, ...)

### S3 method for class 'ts'
lines(x, ...)
```

Arguments

- `x`, `y`  
  time series objects, usually inheriting from class "ts".

- `plot.type`  
  for multivariate time series, should the series by plotted separately (with a common time axis) or on a single plot?

- `xy.labels`  
  logical, indicating if `text()` labels should be used for an x-y plot, or character, supplying a vector of labels to be used. The default is to label for up to 150 points, and not for more.

- `xy.lines`  
  logical, indicating if `lines` should be drawn for an x-y plot. Defaults to the value of `xy.labels` if that is logical, otherwise to `TRUE`.

- `panel`  
  a function(x, col, bg, pch, type, ...) which gives the action to be carried out in each panel of the display for `plot.type = "multiple"`. The default is `lines`.

- `nc`  
  the number of columns to use when `type = "multiple"`. Defaults to 1 for up to 4 series, otherwise to 2.

- `yax.flip`  
  logical indicating if the y-axis (ticks and numbering) should flip from side 2 (left) to 4 (right) from series to series when `type = "multiple"`.

- `mar.multi`, `oma.multi`  
  the (default) `par` settings for `plot.type = "multiple"`. Modify with care!

- `axes`  
  logical indicating if x- and y- axes should be drawn.

- `...`  
  additional graphical arguments, see `plot`, `plot.default` and `par`.

Details

If `y` is missing, this function creates a time series plot, for multivariate series of one of two kinds depending on `plot.type`.

If `y` is present, both `x` and `y` must be univariate, and a scatter plot `y ~ x` will be drawn, enhanced by using `text` if `xy.labels` is `TRUE` or character, and `lines` if `xy.lines` is `TRUE`.

See Also

- `ts` for basic time series construction and access functionality.

Examples

```r
require(graphics)

### Multivariate
z <- ts(matrix(rt(200 * 8, df = 3), 200, 8),
       start = c(1961, 1), frequency = 12)
```
The Poisson Distribution

Description

Density, distribution function, quantile function and random generation for the Poisson distribution with parameter \( \lambda \).

Usage

\[
dpois(x, \lambda, \log = \text{FALSE}) \\
p pois(q, \lambda, \text{lower.tail = TRUE}, \log.p = \text{FALSE}) \\
q pois(p, \lambda, \text{lower.tail = TRUE}, \log.p = \text{FALSE}) \\
r pois(n, \lambda)
\]

Arguments

- \( x \) vector of (non-negative integer) quantiles.
- \( q \) vector of quantiles.
- \( p \) vector of probabilities.
- \( n \) number of random values to return.
- \( \lambda \) vector of (non-negative) means.
- \( \log, \log.p \) logical; if TRUE, probabilities \( p \) are given as \( \log(p) \).
- \( \text{lower.tail} \) logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).
Details

The Poisson distribution has density

\[ p(x) = \frac{\lambda^x e^{-\lambda}}{x!} \]

for \( x = 0, 1, 2, \ldots \). The mean and variance are \( E(X) = Var(X) = \lambda \).

If an element of \( x \) is not integer, the result of \( \text{dpois} \) is zero, with a warning. \( p(x) \) is computed using Loader’s algorithm, see the reference in \( \text{dbinom} \).

The quantile is right continuous: \( \text{qpois}(p, \lambda) \) is the smallest integer \( x \) such that \( P(X \leq x) \geq p \).

Setting \( \text{lower.tail} = \text{FALSE} \) allows to get much more precise results when the default, \( \text{lower.tail} = \text{TRUE} \) would return 1, see the example below.

Value

dpois gives the (log) density, ppois gives the (log) distribution function, qpois gives the quantile function, and rpois generates random deviates.

Invalid \( \lambda \) will result in return value NaN, with a warning.

The length of the result is determined by \( n \) for rpois, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than \( n \) are recycled to the length of the result. Only the first elements of the logical parameters are used.

Source

dpois uses C code contributed by Catherine Loader (see \( \text{dbinom} \)).
ppois uses \( \text{pgamma} \).
qpois uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.
rpois uses

See Also

\( \text{Distributions} \) for other standard distributions, including \( \text{dbinom} \) for the binomial and \( \text{dnbinom} \) for the negative binomial distribution.

\( \text{poisson.test} \).

Examples

```
require(graphics)

-log(dpois(0:7, lambda = 1) * gamma(1+ 0:7)) # == 1
Ni <- rpois(50, lambda = 4); table(factor(Ni, 0:max(Ni)))
1 - ppois(10*(15:25), lambda = 100) # becomes 0 (cancellation)
ppois(10*(15:25), lambda = 100, lower.tail = FALSE) # no cancellation
```
Description

Performs an exact test of a simple null hypothesis about the rate parameter in Poisson distribution, or for the ratio between two rate parameters.

Usage

poisson.test(x, T = 1, r = 1,
    alternative = c("two.sided", "less", "greater"),
    conf.level = 0.95)

Arguments

x number of events. A vector of length one or two.
T time base for event count. A vector of length one or two.
r hypothesized rate or rate ratio
alternative indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter.
conf.level confidence level for the returned confidence interval.

Details

Confidence intervals are computed similarly to those of binom.test in the one-sample case, and using binom.test in the two sample case.

Value

A list with class "htest" containing the following components:

statistic the number of events (in the first sample if there are two.)
parameter the corresponding expected count
p.value the p-value of the test.
conf.int a confidence interval for the rate or rate ratio.
estimate the estimated rate or rate ratio.
null.value the rate or rate ratio under the null, r.
alternative a character string describing the alternative hypothesis.
method the character string "Exact Poisson test" or "Comparison of Poisson rates" as appropriate.
data.name a character string giving the names of the data.
Note

The rate parameter in Poisson data is often given based on a “time on test” or similar quantity (person-years, population size, or expected number of cases from mortality tables). This is the role of the \( t \) argument.

The one-sample case is effectively the binomial test with a very large \( n \). The two sample case is converted to a binomial test by conditioning on the total event count, and the rate ratio is directly related to the odds in that binomial distribution.

See Also

`binom.test`

Examples

### These are paraphrased from data sets in the ISwR package

```r
## SMR, Welsh Nickel workers
poisson.test(137, 24.19893)
```

```r
## eba1977, compare Fredericia to other three cities for ages 55-59
poisson.test(c(11, 6+8+7), c(800, 1038+1050+878))
```

---

**poly**

**Compute Orthogonal Polynomials**

Description

Returns or evaluates orthogonal polynomials of degree 1 to degree over the specified set of points \( x \). These are all orthogonal to the constant polynomial of degree 0. Alternatively, evaluate raw polynomials.

Usage

```r
poly(x, ..., degree = 1, coefs = NULL, raw = FALSE)
polym(..., degree = 1, raw = FALSE)
```

```r
## S3 method for class 'poly'
predict(object, newdata, ...)
```

Arguments

- `x, newdata`: a numeric vector at which to evaluate the polynomial. \( x \) can also be a matrix. Missing values are not allowed in \( x \).
- `degree`: the degree of the polynomial. Must be less than the number of unique points if \( raw = \) TRUE.
- `coefs`: for prediction, coefficients from a previous fit.
- `raw`: if true, use raw and not orthogonal polynomials.
- `object`: an object inheriting from class "poly", normally the result of a call to `poly` with a single vector argument.
- `...`: further vectors.
- `predict.poly`: arguments to be passed to or from other methods.
Details

Although formally degree should be named (as it follows . . . ), an unnamed second argument of length 1 will be interpreted as the degree.

The orthogonal polynomial is summarized by the coefficients, which can be used to evaluate it via the three-term recursion given in Kennedy & Gentle (1980, pp. 343–4), and used in the predict part of the code.

Value

For poly with a single vector argument:
A matrix with rows corresponding to points in x and columns corresponding to the degree, with attributes “degree” specifying the degrees of the columns and (unless raw = TRUE) “coefs” which contains the centering and normalization constants used in constructing the orthogonal polynomials. The matrix has given class c(“poly”, “matrix”).

Other cases of poly and polym, and predict.poly: a matrix.

Note

This routine is intended for statistical purposes such as contr.poly: it does not attempt to orthogonalize to machine accuracy.

References

See Also

contr.poly.
cars for an example of polynomial regression.

Examples

od <- options(digits = 3) # avoid too much visual clutter
(z <- poly(1:10, 3))
predict(z, seq(2, 4, 0.5))
zapsmall(poly(seq(4, 6, 0.5), 3, coefs = attr(z, "coefs")))

zapsmall(poly(1:4, c(1, 4:6), degree = 3)) # or just poly()
zapsmall(poly(cbind(1:4, c(1, 4:6)), degree = 3))
options(od)

power

Create a Power Link Object

Description

Creates a link object based on the link function \( \eta = \mu^\lambda \).
power.anova.test

Usage
power(lambda = 1)

Arguments
lambda a real number.

Details
If lambda is non-positive, it is taken as zero, and the log link is obtained. The default lambda = 1 gives the identity link.

Value
A list with components linkfun, linkinv, mu.eta, and valideta. See make.link for information on their meaning.

References

See Also
make.link, family
To raise a number to a power, see Arithmetic.
To calculate the power of a test, see various functions in the stats package, e.g., power.t.test.

Examples
power()
quasi(link = power(1/3))[c("linkfun", "linkinv")]

power.anova.test

Power Calculations for Balanced One-Way Analysis of Variance Tests

Description
Compute power of test or determine parameters to obtain target power.

Usage
power.anova.test(groups = NULL, n = NULL,
between.var = NULL, within.var = NULL,
sig.level = 0.05, power = NULL)
Arguments

groups: Number of groups
n: Number of observations (per group)
between.var: Between group variance
within.var: Within group variance
sig.level: Significance level (Type I error probability)
power: Power of test (1 minus Type II error probability)

Details

Exactly one of the parameters groups, n, between.var, power, within.var, and sig.level must be passed as NULL, and that parameter is determined from the others. Notice that sig.level has non-NULL default so NULL must be explicitly passed if you want it computed.

Value

Object of class “power.anova.test”, a list of the arguments (including the computed one) augmented with method and note elements.

Note

uniroot is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.

Author(s)

Claus Ekstrøm

See Also

anova, lm, uniroot

Examples

```r
power.anova.test(groups = 4, n = 5, between.var = 1, within.var = 3)
# Power = 0.3535594

power.anova.test(groups = 4, between.var = 1, within.var = 3, power = .80)
# n = 11.92613

## Assume we have prior knowledge of the group means:
groupmeans <- c(120, 130, 140, 150)
power.anova.test(groups = length(groupmeans),
                 between.var = var(groupmeans),
                 within.var = 500, power = .90) # n = 15.18834
```
Description

Compute power of test, or determine parameters to obtain target power.

Usage

```
power.prop.test(n = NULL, p1 = NULL, p2 = NULL, sig.level = 0.05,
power = NULL,
alternative = c("two.sided", "one.sided"),
strict = FALSE)
```

Arguments

- **n**: Number of observations (per group)
- **p1**: probability in one group
- **p2**: probability in other group
- **sig.level**: Significance level (Type I error probability)
- **power**: Power of test (1 minus Type II error probability)
- **alternative**: One- or two-sided test
- **strict**: Use strict interpretation in two-sided case

Details

Exactly one of the parameters `n`, `p1`, `p2`, `power`, and `sig.level` must be passed as NULL, and that parameter is determined from the others. Notice that `sig.level` has a non-NULL default so NULL must be explicitly passed if you want it computed.

If `strict = TRUE` is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.

Value

Object of class "power.htest", a list of the arguments (including the computed one) augmented with method and note elements.

Note

`uniroot` is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given. If one of them is computed `p1 < p2` will hold, although this is not enforced when both are specified.

Author(s)

Peter Dalgaard. Based on previous work by Claus Ekstrom

prop.test.unirroot

Examples

```r
power.prop.test(n = 50, p1 = .50, p2 = .75)
power.prop.test(p1 = .50, p2 = .75, power = .90)
power.prop.test(n = 50, p1 = .5, power = .90)
```

power.t.test  

**Power calculations for one and two sample t tests**

Description

Compute power of test, or determine parameters to obtain target power.

Usage

```r
power.t.test(n = NULL, delta = NULL, sd = 1, sig.level = 0.05,
             power = NULL,
             type = c("two.sample", "one.sample", "paired"),
             alternative = c("two.sided", "one.sided"),
             strict = FALSE)
```

Arguments

- `n` Number of observations (per group)
- `delta` True difference in means
- `sd` Standard deviation
- `sig.level` Significance level (Type I error probability)
- `power` Power of test (1 minus Type II error probability)
- `type` Type of t test
- `alternative` One- or two-sided test
- `strict` Use strict interpretation in two-sided case

Details

Exactly one of the parameters `n`, `delta`, `power`, `sd`, and `sig.level` must be passed as `NULL`, and that parameter is determined from the others. Notice that the last two have non-NULL defaults so `NULL` must be explicitly passed if you want to compute them.

If `strict = TRUE` is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.

Value

Object of class "power.htest", a list of the arguments (including the computed one) augmented with method and note elements.
Note

unir®®t is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.

Author(s)

Peter Dalgaard. Based on previous work by Claus Ekstrøm

t.test.unirroot

Examples

```r
power.t.test(n = 20, delta = 1)
power.t.test(power = .90, delta = 1)
power.t.test(power = .90, delta = 1, alternative = "one.sided")
```

Description

Computes the Phillips-Perron test for the null hypothesis that \( x \) has a unit root against a stationary alternative.

Usage

```r
PP.test(x, lshort = TRUE)
```

Arguments

\( x \) a numeric vector or univariate time series.

\( lshort \) a logical indicating whether the short or long version of the truncation lag parameter is used.

Details

The general regression equation which incorporates a constant and a linear trend is used and the corrected t-statistic for a first order autoregressive coefficient equals one is computed. To estimate \( \sigma^2 \) the Newey-West estimator is used. If \( lshort \) is TRUE, then the truncation lag parameter is set to \( \text{trunc}(4 + (n/100)^{0.25}) \), otherwise \( \text{trunc}(12 + (n/100)^{0.25}) \) is used. The p-values are interpolated from Table 4.2, page 103 of Banerjee et al. (1993).

Missing values are not handled.
Value

A list with class "htest" containing the following components:

- `statistic` the value of the test statistic.
- `parameter` the truncation lag parameter.
- `p.value` the p-value of the test.
- `method` a character string indicating what type of test was performed.
- `data.name` a character string giving the name of the data.

Author(s)

A. Trapletti

References

Examples

```r
x <- rnorm(1000)
PP.test(x)
y <- cumsum(x) # has unit root
PP.test(y)
```

Description

Generates the sequence of probability points \((1:m - a)/(m + (1-a)\cdot a)\) where \(m\) is either \(n\), if `length(n)==1`, or `length(n)`.

Usage

```r
ppoints(n, a = ifelse(n <= 10, 3/8, 1/2))
```

Arguments

- `n` either the number of points generated or a vector of observations.
- `a` the offset fraction to be used: typically in \((0, 1)\).
Details

If $0 < a < 1$, the resulting values are within $(0, 1)$ (excluding boundaries). In any case, the resulting sequence is symmetric in $[0, 1]$, i.e., $p + \text{rev}(p) = 1$.

ppoints() is used in qqplot and qnorm to generate the set of probabilities at which to evaluate the inverse distribution.

The choice of $a$ follows the documentation of the function of the same name in Becker et al (1988), and appears to have been motivated by results from Blom (1958) on approximations to expect normal order statistics (see also quantile).

References

See Also

qqplot, qnorm.

Examples

```r
ppoints(4) # the same as ppoints(1:4)
ppoints(10)
ppoints(10, a = 1/2)
```

ppr

*Projection Pursuit Regression*

Description

Fit a projection pursuit regression model.

Usage

```r
ppr(x, ...)  

## S3 method for class 'formula'
ppr(formula, data, weights, subset, na.action,  
    contrasts = NULL, ..., model = FALSE)

## Default S3 method:
ppr(x, y, weights = rep(1, n),  
    ww = rep(1, q), nterms, max.terms = nterms, optlevel = 2,  
    sm.method = c("supsmu", "spline", "gcvspine"),  
    bass = 0, span = 0, df = 5, gcpen = 1, ...)
```
Arguments

- **formula**: a formula specifying one or more numeric response variables and the explanatory variables.
- **x**: numeric matrix of explanatory variables. Rows represent observations, and columns represent variables. Missing values are not accepted.
- **y**: numeric matrix of response variables. Rows represent observations, and columns represent variables. Missing values are not accepted.
- **nterms**: number of terms to include in the final model.
- **data**: a data frame (or similar: see `model.frame`) from which variables specified in `formula` are preferentially to be taken.
- **weights**: a vector of weights $w_i$ for each case.
- **ww**: a vector of weights for each response, so the fit criterion is the sum over case $i$ and responses $j$ of $w_i \cdot (y_{ij} - \hat{fit}_{ij})^2$ divided by the sum of $w_i$.
- **subset**: an index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
- **na.action**: a function to specify the action to be taken if NAs are found. The default action is given by `getOption("na.action")`. (NOTE: If given, this argument must be named.)
- **contrasts**: the contrasts to be used when any factor explanatory variables are coded.
- **max.terms**: maximum number of terms to choose from when building the model.
- **optlevel**: integer from 0 to 3 which determines the thoroughness of an optimization routine in the SMART program. See the ‘Details’ section.
- **sm.method**: the method used for smoothing the ridge functions. The default is to use Friedman’s super smoother `supsmu`. The alternatives are to use the smoothing spline code underlying `smooth.spline`, either with a specified (equivalent) degrees of freedom for each ridge functions, or to allow the smoothness to be chosen by GCV.
- **bass**: super smoother bass tone control used with automatic span selection (see `supsmu`); the range of values is 0 to 10, with larger values resulting in increased smoothing.
- **span**: super smoother span control (see `supsmu`). The default, 0, results in automatic span selection by local cross validation. `span` can also take a value in (0, 1].
- **df**: if `sm.method` is "spline" specifies the smoothness of each ridge term via the requested equivalent degrees of freedom.
- **gcvpen**: if `sm.method` is "gcvspine" this is the penalty used in the GCV selection for each degree of freedom used.
- **...**: arguments to be passed to or from other methods.
- **model**: logical. If true, the model frame is returned.

Details

The basic method is given by Friedman (1984), and is essentially the same code used by S-PLUS’s `ppreg`. This code is extremely sensitive to the compiler used.

The algorithm first adds up to `max.terms` ridge terms one at a time; it will use less if it is unable to find a term to add that makes sufficient difference. It then removes the least important term at each step until `nterms` terms are left.
The levels of optimization (argument optlevel) differ in how thoroughly the models are refitted during this process. At level 0 the existing ridge terms are not refitted. At level 1 the projection directions are not refitted, but the ridge functions and the regression coefficients are. Levels 2 and 3 refit all the terms and are equivalent for one response; level 3 is more careful to re-balance the contributions from each regressor at each step and so is a little less likely to converge to a saddle point of the sum of squares criterion.

Value

A list with the following components, many of which are for use by the method functions.

call the matched call
p the number of explanatory variables (after any coding)
q the number of response variables
mu the argument nterms
m1 the argument max.terms
go the overall residual (weighted) sum of squares for the selected model
go the overall residual (weighted) sum of squares against the number of terms, up to max. terms. Will be invalid (and zero) for less than nterms.
df the argument df
edf if sm.method is "spline" or "gcvsp" the equivalent number of degrees of freedom for each ridge term used.
xnames the names of the explanatory variables
ynames the names of the response variables
alpha a matrix of the projection directions, with a column for each ridge term
beta a matrix of the coefficients applied for each response to the ridge terms: the rows are the responses and the columns the ridge terms
yb the weighted means of each response
ys the overall scale factor used: internally the responses are divided by ys to have unit total weighted sum of squares.
fitted.values the fitted values, as a matrix if q > 1.
residuals the residuals, as a matrix if q > 1.
smod internal work array, which includes the ridge functions evaluated at the training set points.
model (only if model = TRUE) the model frame.

Source

Friedman (1984): converted to double precision and added interface to smoothing splines by B. D. Ripley, originally for the MASS package.

Usage

prcomp(x, ...)

## S3 method for class 'formula'
prcomp(formula, data = NULL, subset, na.action, ...)

## Default S3 method:
prcomp(x, retx = TRUE, center = TRUE, scale. = FALSE,
tol = NULL, ...)

## S3 method for class 'prcomp'
predict(object, newdata, ...)

Arguments

- **formula**: a formula with no response variable, referring only to numeric variables.
- **data**: an optional data frame (or similar: see `model.frame`) containing the variables in the formula formula. By default the variables are taken from `environment(formula)`.
- **subset**: an optional vector used to select rows (observations) of the data matrix x.
- **na.action**: a function which indicates what should happen when the data contain NAs. The default is set by the `na.action` setting of `options`, and is `na.fail` if that is unset. The `factory-fresh` default is `na.omit`.
- **...**: arguments passed to or from other methods. If x is a formula one might specify `scale.` or `tol`.
- **x**: a numeric or complex matrix (or data frame) which provides the data for the principal components analysis.
- **retx**: a logical value indicating whether the rotated variables should be returned.
- **center**: a logical value indicating whether the variables should be shifted to be zero centered. Alternately, a vector of length equal the number of columns of x can be supplied. The value is passed to `scale`.
- **scale.**: a logical value indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is `FALSE` for consistency with S, but in general scaling is advisable. Alternatively, a vector of length equal the number of columns of x can be supplied. The value is passed to `scale`.
- **tol**: a value indicating the magnitude below which components should be omitted. (Components are omitted if their standard deviations are less than or equal to `tol` times the standard deviation of the first component.) With the default null setting, no components are omitted. Other settings for `tol` could be `tol = 0` or `tol = sqrt(.Machine$double.eps)`, which would omit essentially constant components.
- **object**: Object of class inheriting from "prcomp"
- **newdata**: An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, newdata must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order.
Details

The calculation is done by a singular value decomposition of the (centered and possibly scaled) data matrix, not by using `eigen` on the covariance matrix. This is generally the preferred method for numerical accuracy. The `print` method for these objects prints the results in a nice format and the plot method produces a scree plot.

Unlike `princomp`, variances are computed with the usual divisor $N - 1$.

Note that `scale = TRUE` cannot be used if there are zero or constant (for `center = TRUE`) variables.

Value

`prcomp` returns a list with class "`prcomp`" containing the following components:

- `sdev` the standard deviations of the principal components (i.e., the square roots of the eigenvalues of the covariance/correlation matrix, though the calculation is actually done with the singular values of the data matrix).
- `rotation` the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). The function `princomp` returns this in the element `loadings`.
- `x` if `retx` is true the value of the rotated data (the centred (and scaled if requested) data multiplied by the `rotation` matrix) is returned. Hence, `cov(x)` is the diagonal matrix $\text{diag}(\text{sdev}^2)$. For the formula method, `napredict()` is applied to handle the treatment of values omitted by the `na.action`.

- `center`, `scale` the centering and scaling used, or `FALSE`.

Note

The signs of the columns of the rotation matrix are arbitrary, and so may differ between different programs for PCA, and even between different builds of R.

## the variances of the variables in the
## USArrests data vary by orders of magnitude, so scaling is appropriate
prcomp(USArrests)  # inappropriate
prcomp(USArrests, scale = TRUE)
prcomp(~ Murder + Assault + Rape, data = USArrests, scale = TRUE)
plot(prcomp(USArrests))
summary(prcomp(USArrests, scale = TRUE))
biplot(prcomp(USArrests, scale = TRUE))
```
predict

Model Predictions

Description

predict is a generic function for predictions from the results of various model fitting functions. The function invokes particular methods which depend on the class of the first argument.

Usage

predict (object, ...)

Arguments

object: a model object for which prediction is desired.
...

Details

Most prediction methods which are similar to those for linear models have an argument newdata specifying the first place to look for explanatory variables to be used for prediction. Some considerable attempts are made to match up the columns in newdata to those used for fitting, for example that they are of comparable types and that any factors have the same level set in the same order (or can be transformed to be so).

Time series prediction methods in package stats have an argument n.ahead specifying how many time steps ahead to predict.

Many methods have a logical argument se.fit saying if standard errors are to be returned.

Value

The form of the value returned by predict depends on the class of its argument. See the documentation of the particular methods for details of what is produced by that method.

References

See Also

SafePrediction for prediction from polynomial and spline fits.

Examples

```r
require(utils)

## All the "predict" methods found
## NB most of the methods in the standard packages are hidden.
for(fn in methods("predict"))
  try({
    f <- eval(substitute(getAnywhere(fn)$objs[[1]], list(fn = fn))
    cat(fn, ":\n\t", deparse(args(f)), "\n")
  }, silent = TRUE)
```

predict.Arima  
**Forecast from ARIMA fits**

Description

Forecast from models fitted by `arima`.

Usage

```r
## S3 method for class 'Arima'
predict(object, n.ahead = 1, newxreg = NULL, se.fit = TRUE, ...)```

Arguments

- `object` The result of an `arima` fit.
- `n.ahead` The number of steps ahead for which prediction is required.
- `newxreg` New values of `xreg` to be used for prediction. Must have at least `n.ahead` rows.
- `se.fit` Logical: should standard errors of prediction be returned?
- `...` arguments passed to or from other methods.

Details

Finite-history prediction is used, via `KalmanForecast`. This is only statistically efficient if the MA part of the fit is invertible, so `predict.Arima` will give a warning for non-invertible MA models.

The standard errors of prediction exclude the uncertainty in the estimation of the ARMA model and the regression coefficients. According to Harvey (1993, pp. 58–9) the effect is small.

Value

A time series of predictions, or if `se.fit = TRUE`, a list with components `pred`, the predictions, and `se`, the estimated standard errors. Both components are time series.

References

predict.glm

Description

Obtains predictions and optionally estimates standard errors of those predictions from a fitted generalized linear model object.

Usage

## S3 method for class 'glm'
predict(object, newdata = NULL,
         type = c("link", "response", "terms"),
         se.fit = FALSE, dispersion = NULL, terms = NULL,
         na.action = na.pass, ...)

Arguments

- **object**: a fitted object of class inheriting from "glm".
- **newdata**: optionally, a data frame in which to look for variables with which to predict. If omitted, the fitted linear predictors are used.
- **type**: the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and type = "response" gives the predicted probabilities. The "terms" option returns a matrix giving the fitted values of each term in the model formula on the linear predictor scale.
  - The value of this argument can be abbreviated.
- **se.fit**: logical switch indicating if standard errors are required.
- **dispersion**: the dispersion of the GLM fit to be assumed in computing the standard errors. If omitted, that returned by summary applied to the object is used.
- **terms**: with type = "terms" by default all terms are returned. A character vector specifies which terms are to be returned
- **na.action**: function determining what should be done with missing values in newdata. The default is to predict NA.
- **...**: further arguments passed to or from other methods.
Details

If `newdata` is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the residuals, whereas if `na.action = na.exclude` they will appear (in predictions and standard errors), with residual value NA. See also `napredict`.

Value

If `se.fit = FALSE`, a vector or matrix of predictions. For type = "terms" this is a matrix with a column per term, and may have an attribute "constant".

If `se.fit = TRUE`, a list with components

- `fit` Predictions, as for `se.fit = FALSE`.
- `se.fit` Estimated standard errors.
- `residual.scale` A scalar giving the square root of the dispersion used in computing the standard errors.

Note

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

    sex = factor(rep("F", length(ld)), levels = levels(sex)),
    type = "response")))
```
predict.HoltWinters

**Description**

Computes predictions and prediction intervals for models fitted by the Holt-Winters method.

**Usage**

```r
## S3 method for class 'HoltWinters'
predict(object, n.ahead = 1, prediction.interval = FALSE,
        level = 0.95, ...)```

**Arguments**

- `object`: An object of class `HoltWinters`.
- `n.ahead`: Number of future periods to predict.
- `prediction.interval`: logical. If TRUE, the lower and upper bounds of the corresponding prediction intervals are computed.
- `level`: Confidence level for the prediction interval.
- `...`: arguments passed to or from other methods.

**Value**

A time series of the predicted values. If prediction intervals are requested, a multiple time series is returned with columns `fit`, `lwr` and `upr` for the predicted values and the lower and upper bounds respectively.

**Author(s)**

p <- predict(m, 50, prediction.interval = TRUE)
plot(m, p)
```
predict.lm

Predict method for Linear Model Fits

Description

Predicted values based on linear model object.

Usage

```r
## S3 method for class 'lm'
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf,
        interval = c("none", "confidence", "prediction"),
        level = 0.95, type = c("response", "terms"),
        terms = NULL, na.action = na.pass,
        pred.var = res.var/weights, weights = 1, ...)
```

Arguments

- `object`: Object of class inheriting from "lm"
- `newdata`: An optional data frame in which to look for variables with which to predict. If omitted, the fitted values are used.
- `se.fit`: A switch indicating if standard errors are required.
- `scale`: Scale parameter for std.err. calculation.
- `df`: Degrees of freedom for scale.
- `interval`: Type of interval calculation.
- `level`: Tolerance/confidence level.
- `type`: Type of prediction (response or model term).
- `terms`: If `type = "terms"`, which terms (default is all terms), a character vector.
- `na.action`: function determining what should be done with missing values in `newdata`. The default is to predict NA.
- `pred.var`: the variance(s) for future observations to be assumed for prediction intervals. See 'Details'.
- `weights`: variance weights for prediction. This can be a numeric vector or a one-sided model formula. In the latter case, it is interpreted as an expression evaluated in `newdata`.
- `...`: further arguments passed to or from other methods.

Details

`predict.lm` produces predicted values, obtained by evaluating the regression function in the frame `newdata` (which defaults to `model.frame(object)`). If the logical `se.fit` is `TRUE`, standard errors of the predictions are calculated. If the numeric argument `scale` is set (with optional `df`), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting `intervals` specifies computation of confidence or prediction (tolerance) intervals at the specified `level`, sometimes referred to as narrow vs. wide intervals.

If the fit is rank-deficient, some of the columns of the design matrix will have been dropped. Prediction from such a fit only makes sense if `newdata` is contained in the same subspace as the original data. That cannot be checked accurately, so a warning is issued.
If `newdata` is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit are handled is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the predictions, whereas if `na.action = na.exclude` they will appear (in predictions, standard errors or interval limits), with value NA. See also `napredict`.

The prediction intervals are for a single observation at each case in `newdata` (or by default, the data used for the fit) with error variance(s) `pred.var`. This can be a multiple of `res.var`, the estimated value of $\sigma^2$: the default is to assume that future observations have the same error variance as those used for fitting. If `weights` is supplied, the inverse of this is used as a scale factor. For a weighted fit, if the prediction is for the original data frame, `weights` defaults to the weights used for the model fit, with a warning since it might not be the intended result. If the fit was weighted and `newdata` is given, the default is to assume constant prediction variance, with a warning.

### Value

`predict.lm` produces a vector of predictions or a matrix of predictions and bounds with column names `fit`, `lwr`, and `upr` if `interval` is set. For `type = "terms"` this is a matrix with a column per term and may have an attribute "constant".

If `se.fit` is TRUE, a list with the following components is returned:

- `fit` vector or matrix as above
- `se.fit` standard error of predicted means
- `residual.scale` residual standard deviations
- `df` degrees of freedom for residual

### Note

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

Notice that prediction variances and prediction intervals always refer to future observations, possibly corresponding to the same predictors as used for the fit. The variance of the residuals will be smaller.

Strictly speaking, the formula used for prediction limits assumes that the degrees of freedom for the fit are the same as those for the residual variance. This may not be the case if `res.var` is not obtained from the fit.

The model fitting function `lm`, `predict`. 

`SafePrediction` for prediction from polynomial and spline fits.

### Examples

```r
require(graphics)

## Predictions
x <- rnorm(15)
y <- x + rnorm(15)
predict(lm(y ~ x))
new <- data.frame(x = seq(-3, 3, 0.5))
predict(lm(y ~ x), new, se.fit = TRUE)
```
pred.w.plim <- predict(lm(y ~ x), new, interval = "prediction")
pred.w.clim <- predict(lm(y ~ x), new, interval = "confidence")
matplot(new$x, cbind(pred.w.clim, pred.w.plim[,1]),
        lty = c(1,2,2,3,3), type = "l", ylab = "predicted y")

## Prediction intervals, special cases
## The first three of these throw warnings
w <- 1 + x^2
fit <- lm(y ~ x)
wfit <- lm(y ~ x, weights = w)
predict(fit, interval = "prediction")
predict(wfit, interval = "prediction")
predict(wfit, new, interval = "prediction", weights = (new$x)^2)
predict(wfit, new, interval = "prediction", weights = -x^2)

##-- From aov(.) example ---- predict(. terms)
npk.aov <- aov(yield ~ block + N*P*K, npk)
(termL <- attr(terms(npk.aov), "term.labels"))
(pt <- predict(npk.aov, type = "terms"))
pt. <- predict(npk.aov, type = "terms", terms = termL[1:4])
stopifnot(all.equal(pt[,1:4], pt.,
               check.attr = FALSE, tol = 1e-12))

---

**predict.loess**

*Predict Loess Curve or Surface*

**Description**

Predictions from a loess fit, optionally with standard errors.

**Usage**

```r
## S3 method for class 'loess'
predict(object, newdata = NULL, se = FALSE,
         na.action = na.pass, ...)
```

**Arguments**

- **object**: an object fitted by loess.
- **newdata**: an optional data frame in which to look for variables with which to predict, or a matrix or vector containing exactly the variables needed for prediction. If missing, the original data points are used.
- **se**: should standard errors be computed?
- **na.action**: function determining what should be done with missing values in data frame newdata. The default is to predict NA.
- **...**: arguments passed to or from other methods.
Details

The standard errors calculation is slower than prediction.

When the fit was made using `surface = "interpolate"` (the default), `predict.loess` will not extrapolate – so points outside an axis-aligned hypercube enclosing the original data will have missing (NA) predictions and standard errors.

The default for `na.action` prior to R 2.12.0 was `na.omit`.

Value

If `se = FALSE`, a vector giving the prediction for each row of `newdata` (or the original data). If `se = TRUE`, a list containing components

- `fit` the predicted values.
- `se` an estimated standard error for each predicted value.
- `residual.scale` the estimated scale of the residuals used in computing the standard errors.
- `df` an estimate of the effective degrees of freedom used in estimating the residual scale, intended for use with t-based confidence intervals.

If `newdata` was the result of a call to `expand.grid`, the predictions (and s.e.'s if requested) will be an array of the appropriate dimensions.

Predictions from infinite inputs will be NA since `loess` does not support extrapolation.

Note

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

Author(s)

B. D. Ripley, based on the `closs` package of Cleveland, Grosse and Shyu.

See Also

`loess`

Examples

```r
  cars.lo <- loess(dist ~ speed, cars)
predict(cars.lo, data.frame(speed = seq(5, 30, 1)), se = TRUE)
  # to get extrapolation
cars.lo2 <- loess(dist ~ speed, cars,
  control = loess.control(surface = "direct"))
predict(cars.lo2, data.frame(speed = seq(5, 30, 1)), se = TRUE)
```
**predict.nls**

*Predicting from Nonlinear Least Squares Fits*

**Description**

`predict.nls` produces predicted values, obtained by evaluating the regression function in the frame `newdata`. If the logical `se.fit` is TRUE, standard errors of the predictions are calculated. If the numeric argument `scale` is set (with optional `df`), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting `interval` specifies computation of confidence or prediction (tolerance) intervals at the specified level.

At present `se.fit` and `interval` are ignored.

**Usage**

```r
## S3 method for class 'nls'
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf,
          interval = c("none", "confidence", "prediction"),
          level = 0.95, ...)
```

**Arguments**

- `object` An object that inherits from class `nls`.
- `newdata` A named list or data frame in which to look for variables with which to predict. If `newdata` is missing the fitted values at the original data points are returned.
- `se.fit` A logical value indicating if the standard errors of the predictions should be calculated. Defaults to FALSE. At present this argument is ignored.
- `scale` A numeric scalar. If it is set (with optional `df`), it is used as the residual standard deviation in the computation of the standard errors, otherwise this information is extracted from the model fit. At present this argument is ignored.
- `df` A positive numeric scalar giving the number of degrees of freedom for the `scale` estimate. At present this argument is ignored.
- `interval` A character string indicating if prediction intervals or a confidence interval on the mean responses are to be calculated. At present this argument is ignored.
- `level` A numeric scalar between 0 and 1 giving the confidence level for the intervals (if any) to be calculated. At present this argument is ignored.
- `...` Additional optional arguments. At present no optional arguments are used.

**Value**

`predict.nls` produces a vector of predictions. When implemented, `interval` will produce a matrix of predictions and bounds with column names `fit`, `lwr`, and `upr`. When implemented, if `se.fit` is TRUE, a list with the following components will be returned:

- `fit` vector or matrix as above
- `se.fit` standard error of predictions
- `residual.scale` residual standard deviations
- `df` degrees of freedom for residual
predict.smooth.spline

Note
Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

predict.smooth.spline  Predict from Smoothing Spline Fit

Description
Predict a smoothing spline fit at new points, return the derivative if desired. The predicted fit is linear beyond the original data.

Usage
## S3 method for class 'smooth.spline'
predict(object, x, deriv = 0, ...)

Arguments

object  a fit from smooth.spline.
x  the new values of x.
deriv  integer; the order of the derivative required.
...  further arguments passed to or from other methods.

Value
A list with components

x  The input x.
y  The fitted values or derivatives at x.

lines(pp <- predict(cars.spl, xx, deriv = d), col = "red")

  points(kn, pp$y[i.kn], pch = 3, col = "dark red")
  abline(h = 0, lty = 3, col = "gray")
}
detach(); par(op)
```

---

**preplot**

*Pre-computations for a Plotting Object*

**Description**

Compute an object to be used for plots relating to the given model object.

**Usage**

```
preplot(object, ...)
```

**Arguments**

- `object` a fitted model object.
- `...` additional arguments for specific methods.
**Details**

Only the generic function is currently provided in base R, but some add-on packages have methods. Principally here for S compatibility.

**Value**

An object set up to make a plot that describes object.

---

**princomp**

*Principal Components Analysis*

**Description**

princomp performs a principal components analysis on the given numeric data matrix and returns the results as an object of class princomp.

**Usage**

```r
princomp(x, ...)  

## S3 method for class 'formula'
princomp(formula, data = NULL, subset, na.action, ...)

## Default S3 method:
princomp(x, cor = FALSE, scores = TRUE, covmat = NULL, subset = rep(TRUE, nrow(as.matrix(x))), ...)

## S3 method for class 'princomp'
predict(object, newdata, ...)
```

**Arguments**

- `formula`: a formula with no response variable, referring only to numeric variables.
- `data`: an optional data frame (or similar: see `model.frame`) containing the variables in the formula formula. By default the variables are taken from environment(formula).
- `subset`: an optional vector used to select rows (observations) of the data matrix x.
- `na.action`: a function which indicates what should happen when the data contain NAs. The default is set by the `na.action` setting of `options`, and is `na.fail` if that is unset. The ‘factory-fresh’ default is `na.omit`.
- `x`: a numeric matrix or data frame which provides the data for the principal components analysis.
- `cor`: a logical value indicating whether the calculation should use the correlation matrix or the covariance matrix. (The correlation matrix can only be used if there are no constant variables.)
- `scores`: a logical value indicating whether the score on each principal component should be calculated.
princomp

covmat  a covariance matrix, or a covariance list as returned by \texttt{cov.wt} (and \texttt{cov.mve} or \texttt{cov.mcd} from package \textit{MASS}). If supplied, this is used rather than the covariance matrix of \texttt{x}.

... arguments passed to or from other methods. If \texttt{x} is a formula one might specify \texttt{cor} or \texttt{scores}.

object  Object of class inheriting from "princomp"

newdata  An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, \texttt{newdata} must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order.

Details

princomp is a generic function with "formula" and "default" methods.
The calculation is done using \texttt{eigen} on the correlation or covariance matrix, as determined by \texttt{cor}. This is done for compatibility with the S-PLUS result. A preferred method of calculation is to use \texttt{svd} on \texttt{x}, as is done in \texttt{prcomp}.

Note that the default calculation uses divisor \texttt{N} for the covariance matrix.
The \texttt{print} method for these objects prints the results in a nice format and the \texttt{plot} method produces a scree plot (\texttt{screeplot}). There is also a \texttt{biplot} method.

If \texttt{x} is a formula then the standard NA-handling is applied to the scores (if requested): see \texttt{napredict}.

princomp only handles so-called R-mode PCA, that is feature extraction of variables. If a data matrix is supplied (possibly via a formula) it is required that there are at least as many units as variables. For Q-mode PCA use \texttt{prcomp}.

Value

princomp returns a list with class "princomp" containing the following components:

- \texttt{sdev}  the standard deviations of the principal components.
- \texttt{loadings}  the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). This is of class "loadings": see \texttt{loadings} for its \texttt{print} method.
- \texttt{center}  the means that were subtracted.
- \texttt{scale}  the scalings applied to each variable.
- \texttt{n.obs}  the number of observations.
- \texttt{scores}  if \texttt{scores} = \texttt{TRUE}, the scores of the supplied data on the principal components. These are non-null only if \texttt{x} was supplied, and if \texttt{covmat} was also supplied if it was a covariance list. For the formula method, \texttt{napredict()} is applied to handle the treatment of values omitted by the \texttt{na.action}.
- \texttt{call}  the matched call.
- \texttt{na.action}  If relevant.

Note

The signs of the columns of the loadings and scores are arbitrary, and so may differ between different programs for PCA, and even between different builds of \texttt{R}.

Examples

```r
require(graphics)

## The variances of the variables in the
## USAreasts data vary by orders of magnitude, so scaling is appropriate
(pc.cr <- princomp(USArrests))  # inappropriate
princomp(USArrests, cor = TRUE)  # == prcomp(USArrests, scale=TRUE)

## Similar, but different:
## The standard deviations differ by a factor of sqrt(49/50)

summary(pc.cr <- princomp(USArrests, cor = TRUE))
loadings(pc.cr)  # note that blank entries are small but not zero
plot(pc.cr)  # shows a screeplot.
biplot(pc.cr)

## Formula interface
princomp(~ ., data = USArrests, cor = TRUE)

## NA-handling
USArrests[1, 2] <- NA
pc.cr <- princomp(~ Murder + Assault + UrbanPop,  
                  data = USArrests, na.action = na.exclude, cor = TRUE)

pc.cr$scores[1:5, ]

## (Simple) Robust PCA:
## Classical:
(pc.cl <- princomp(stackloss))
## Robust:
(pc.rob <- princomp(stackloss, covmat = MASS::cov.rob(stackloss))
```

---

**print.power.htest**  
*Print method for power calculation object*

**Description**

Print object of class "power.htest" in nice layout.

**Usage**

```r
## S3 method for class 'power.htest'
print(x, ...)
```
Arguments

x Object of class "power.h.test".
...

Details

A power.h.test object is just a named list of numbers and character strings, supplemented with method and note elements. The method is displayed as a title, the note as a footnote, and the remaining elements are given in an aligned ‘name = value’ format.

Value

none

Author(s)

Peter Dalgaard

print.ts

Printing Time-Series Objects

Description

Print method for time series objects.

Usage

### S3 method for class 'ts'
print(x, calendar, ...)
printCoefmat

Print Coefficient Matrices

Description

Utility function to be used in higher-level print methods, such as those for summary.lm, summary.glm and anova. The goal is to provide a flexible interface with smart defaults such that often, only x needs to be specified.

Usage

printCoefmat(x, digits = max(3, getOption("digits") - 2),
    signif.stars = getOption("show.signif.stars"),
    signif.legend = signif.stars,
    dig.tst = max(1, min(5, digits - 1)),
    cs.ind = 1L:k, tst.ind = k + 1L,
    zap.ind = integer(), P.values = NULL,
    has.Pvalue = nc >= 4L &&
        substr(colnames(x)[nc], 1L, 3L) == "Pr",
    eps.Pvalue = .Machine$double.eps,
    na.print = "NA", ...)

Arguments

x a numeric matrix like object, to be printed.
digits minimum number of significant digits to be used for most numbers.
signif.stars logical; if TRUE, P-values are additionally encoded visually as ‘significance stars’ in order to help scanning of long coefficient tables. It defaults to the \show{signif.stars} slot of \code{options}.
signif.legend logical; if TRUE, a legend for the ‘significance stars’ is printed provided \code{signif.stars} is \code{TRUE}.
dig.tst minimum number of significant digits for the test statistics, see \code{tst.ind}.
cs.ind indices (integer) of column numbers which are (like) coefficients and standard errors to be formatted together.
tst.ind indices (integer) of column numbers for test statistics.
zap.ind indices (integer) of column numbers which should be formatted by \code{zapsmall}, i.e., by ‘zapping’ values close to 0.
P.values logical or \code{NULL}; if \code{TRUE}, the last column of \code{x} is formatted by \code{format.pval} as P values. If \code{P.values = NULL}, the default, it is set to \code{TRUE} only if \code{options("show.coef.PValue")} is \code{TRUE} and \code{x} has at least 4 columns and the last column name of \code{x} starts with \code{"Pr"}.
has.Pvalue logical; if \code{TRUE}, the last column of \code{x} contains P values; in that case, it is printed if and only if \code{P.values} (above) is true.
eps.Pvalue number, ...
na.print a character string to code \code{NA} values in printed output.
... further arguments for \code{print}.
Value
Invisibly returns its argument, x.

```r
cmat <- cbind(rnorm(3, 10), sqrt(rchisq(3, 12)))
cmat <- cbind(cmat, cmat[, 1]/cmat[, 2])
cmat <- cbind(cmat, 2*pnorm(-cmat[, 3]))
colnames(cmat) <- c("Estimate", "Std.Err", "Z value", "Pr(>|z|)"

printCoefmat(cmat[, 1:3])
printCoefmat(cmat)
op <- options(show.coef.Pvalues = FALSE)
printCoefmat(cmat, digits = 2)
printCoefmat(cmat, digits = 2, P.values = TRUE)
options(op) # restore
```

profile | Generic Function for Profiling Models

Description
Investigates behavior of objective function near the solution represented by fitted.
See documentation on method functions for further details.

Usage
```r
profile(fitted, ...)
```

Arguments
- fitted: the original fitted model object.
- ...: additional parameters. See documentation on individual methods.

Value
A list with an element for each parameter being profiled. See the individual methods for further details.

See Also
profile.nls, profile.glm in package MASS,
For profiling R code, see Rprof.
Method for Profiling nls Objects

Description

Investigates the profile log-likelihood function for a fitted model of class "nls".

Usage

```r
## S3 method for class 'nls'
profile(fitted, which = 1:npar, maxpts = 100, alphamax = 0.01,
delta.t = cutoff/5, ...)
```

Arguments

- `fitted`: the original fitted model object.
- `which`: the original model parameters which should be profiled. This can be a numeric or character vector. By default, all non-linear parameters are profiled.
- `maxpts`: maximum number of points to be used for profiling each parameter.
- `alphamax`: highest significance level allowed for the profile t-statistics.
- `delta.t`: suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.
- `...`: further arguments passed to or from other methods.

Details

The profile t-statistics is defined as the square root of change in sum-of-squares divided by residual standard error with an appropriate sign.

Value

A list with an element for each parameter being profiled. The elements are data-frames with two variables

- `par.vals`: a matrix of parameter values for each fitted model.
- `tau`: the profile t-statistics.

---

proj

Projections of Models

Description

proj returns a matrix or list of matrices giving the projections of the data onto the terms of a linear model. It is most frequently used for aov models.

Usage

proj(object, ...)  

## S3 method for class 'aov'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)

## S3 method for class 'aovlist'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)

## Default S3 method:
proj(object, onedf = TRUE, ...)

## S3 method for class 'lm'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)

Arguments

object An object of class "lm" or a class inheriting from it, or an object with a similar structure including in particular components qr and effects.

onedf A logical flag. If TRUE, a projection is returned for all the columns of the model matrix. If FALSE, the single-column projections are collapsed by terms of the model (as represented in the analysis of variance table).

unweighted.scale

... Swallow and ignore any other arguments.

Details

A projection is given for each stratum of the object, so for aov models with an Error term the result is a list of projections.
Value

A projection matrix or (for multi-stratum objects) a list of projection matrices.

Each projection is a matrix with a row for each observations and either a column for each term (\texttt{one}df = \texttt{FALSE}) or for each coefficient (\texttt{one}df = \texttt{TRUE}). Projection matrices from the default method have orthogonal columns representing the projection of the response onto the column space of the \( Q \) matrix from the QR decomposition. The fitted values are the sum of the projections, and the sum of squares for each column is the reduction in sum of squares from fitting that column (after those to the left of it).

The methods for \texttt{lm} and \texttt{aov} models add a column to the projection matrix giving the residuals (the projection of the data onto the orthogonal complement of the model space).

Strictly, when \texttt{one}df = \texttt{FALSE} the result is not a projection, but the columns represent sums of projections onto the columns of the model matrix corresponding to that term. In this case the matrix does not depend on the coding used.

Author(s)

The design was inspired by the S function of the same name described in Chambers \textit{et al.} (1992).

proj(npk.aovE)
\end{verbatim}
prop.test

Test of Equal or Given Proportions

Description

prop.test can be used for testing the null that the proportions (probabilities of success) in several groups are the same, or that they equal certain given values.

Usage

prop.test(x, n, p = NULL,
  alternative = c("two.sided", "less", "greater"),
  conf.level = 0.95, correct = TRUE)

Arguments

x  
a vector of counts of successes, a one-dimensional table with two entries, or a two-dimensional table (or matrix) with 2 columns, giving the counts of successes and failures, respectively.

n  
a vector of counts of trials; ignored if x is a matrix or a table.

p  
a vector of probabilities of success. The length of p must be the same as the number of groups specified by x, and its elements must be greater than 0 and less than 1.

alternative  
a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter. Only used for testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.

conf.level  
confidence level of the returned confidence interval. Must be a single number between 0 and 1. Only used when testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.

correct  
a logical indicating whether Yates’ continuity correction should be applied where possible.

Details

Only groups with finite numbers of successes and failures are used. Counts of successes and failures must be nonnegative and hence not greater than the corresponding numbers of trials which must be positive. All finite counts should be integers.

If p is NULL and there is more than one group, the null tested is that the proportions in each group are the same. If there are two groups, the alternatives are that the probability of success in the first group is less than, not equal to, or greater than the probability of success in the second group, as specified by alternative. A confidence interval for the difference of proportions with confidence level as specified by conf.level and clipped to \([-1, 1]\) is returned. Continuity correction is used only if it does not exceed the difference of the sample proportions in absolute value. Otherwise, if there are more than 2 groups, the alternative is always "two.sided", the returned confidence interval is NULL, and continuity correction is never used.

If there is only one group, then the null tested is that the underlying probability of success is p, or .5 if p is not given. The alternative is that the probability of success is less than, not equal to, or greater than p or 0.5, respectively, as specified by alternative. A confidence interval for the
underlying proportion with confidence level as specified by \texttt{conf.level} and clipped to \([0,1]\) is returned. Continuity correction is used only if it does not exceed the difference between sample and null proportions in absolute value. The confidence interval is computed by inverting the score test. Finally, if \(p\) is given and there are more than 2 groups, the null tested is that the underlying probabilities of success are those given by \(p\). The alternative is always "two.sided", the returned confidence interval is \texttt{NULL}, and continuity correction is never used.

**Value**

A list with class "htest" containing the following components:

\begin{itemize}
\item \texttt{statistic} \quad \text{the value of Pearson's chi-squared test statistic.}
\item \texttt{parameter} \quad \text{the degrees of freedom of the approximate chi-squared distribution of the test statistic.}
\item \texttt{p.value} \quad \text{the p-value of the test.}
\item \texttt{estimate} \quad \text{a vector with the sample proportions \(x/n\).}
\item \texttt{conf.int} \quad \text{a confidence interval for the true proportion if there is one group, or for the difference in proportions if there are 2 groups and \(p\) is not given, or \texttt{NULL} otherwise. In the cases where it is not \texttt{NULL}, the returned confidence interval has an asymptotic confidence level as specified by \texttt{conf.level}, and is appropriate to the specified alternative hypothesis.}
\item \texttt{null.value} \quad \text{the value of \(p\) if specified by the null, or \texttt{NULL} otherwise.}
\item \texttt{alternative} \quad \text{a character string describing the alternative.}
\item \texttt{method} \quad \text{a character string indicating the method used, and whether Yates' continuity correction was applied.}
\item \texttt{data.name} \quad \text{a character string giving the names of the data.}
\end{itemize}

**References**

\texttt{binom.test} for an \texttt{exact} test of a binomial hypothesis.

**Examples**

\begin{verbatim}
heads <- rbinom(1, size = 100, prob = .5)
prop.test(heads, 100)  # continuity correction TRUE by default
prop.test(heads, 100, correct = FALSE)
\end{verbatim}

\# Data from Fleiss (1981), p. 139.
\# H0: The null hypothesis is that the four populations from which
\# the patients were drawn have the same true proportion of smokers.
\# A: The alternative is that this proportion is different in at
\# least one of the populations.
prop.trend.test

Description

Performs chi-squared test for trend in proportions, i.e., a test asymptotically optimal for local alternatives where the log odds vary in proportion with score. By default, score is chosen as the group numbers.

Usage

```r
prop.trend.test(x, n, score = seq_along(x))
```

Arguments

- `x` Number of events
- `n` Number of trials
- `score` Group score

Value

An object of class "htest" with title, test statistic, p-value, etc.

Note

This really should get integrated with prop.test

Author(s)

Peter Dalgaard

See Also

- `prop.test`

Examples

```r
smokers <- c(83, 90, 129, 70)
patients <- c(86, 93, 136, 82)
prop.test(smokers, patients)
prop.trend.test(smokers, patients)
prop.trend.test(smokers, patients, c(0,0,0,1))
```
**Quantile-Quantile Plots**

**Description**

`qqnorm` is a generic function the default method of which produces a normal QQ plot of the values in `y`. `qqline` adds a line to a “theoretical”, by default normal, quantile-quantile plot which passes through the `probs` quantiles, by default the first and third quartiles.

`qqplot` produces a QQ plot of two datasets.

Graphical parameters may be given as arguments to `qqnorm`, `qqplot` and `qqline`.

**Usage**

```r
qqnorm(y, ...)  # Default S3 method:
qqnorm(y, ylim, main = "Normal Q-Q Plot",
      xlab = "Theoretical Quantiles", ylab = "Sample Quantiles",
      plot.it = TRUE, datax = FALSE, ...)

qqline(y, datax = FALSE, distribution = qnorm,
       probs = c(0.25, 0.75), qtype = 7, ...)

qqplot(x, y, plot.it = TRUE, xlab = deparse(substitute(x)),
       ylab = deparse(substitute(y)), ...)
```

**Arguments**

- `x`, `y`:
  - `x`: The first sample for `qqplot`.
  - `y`: The second or only data sample.
- `xlab`, `ylab`, `main`:
  - `xlab`, `ylab`:
    - `xlab`, `ylab` plot labels. The `xlab` and `ylab` refer to the `y` and `x` axes respectively if `datax = TRUE`.
- `plot.it`:
  - `plot.it` logical. Should the result be plotted?
- `datax`:
  - `datax` logical. Should data values be on the `x`-axis?
- `distribution`:
  - `distribution` quantile function for reference theoretical distribution.
- `probs`:
  - `probs` numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.
- `qtype`:
  - `qtype` the type of quantile computation used in `quantile`.
- `ylim`, `...`:
  - `ylim`, `...` graphical parameters.

**Value**

For `qqnorm` and `qqplot`, a list with components

- `x`:
  - `x` The `x` coordinates of the points that were/would be plotted.
- `y`:
  - `y` The original `y` vector, i.e., the corresponding `y` coordinates including `NAs`. 
References

See Also

`ppoints`, used by `qqnorm` to generate approximations to expected order statistics for a normal distribution.

Examples

```r
require(graphics)

y <- rt(200, df = 5)
qqnorm(y); qline(y, col = 2)
qqplot(y, rt(300, df = 5))

qqnorm(precip, ylab = "Precipitation [in/yr] for 70 US cities")
## "Q-Q-Chisquare" : ------------------------------
y <- rchisq(500, df = 3)
## Q-Q plot for Chi^2 data against true theoretical distribution:
qqplot(chisq(ppoints(500), df = 3), y,
       main = expression("Q-Q plot for" ~ \{chisq\}[nu == 3]))
qline(y, distribution = function(p) chisq(p, df = 3),
      prob = c(0.1, 0.6), col = 2)
mtext("qline(*, dist = chisq(. , df=3), prob = c(0.1, 0.6))")
```

quade.test

**Quade Test**

Description

Performs a Quade test with unreplicated blocked data.

Usage

```
quade.test(y, ...)  
```

Arguments

- `y` either a numeric vector of data values, or a data matrix.
- `groups` a vector giving the group for the corresponding elements of `y` if this is a vector; ignored if `y` is a matrix. If not a factor object, it is coerced to one.
- `blocks` a vector giving the block for the corresponding elements of `y` if this is a vector; ignored if `y` is a matrix. If not a factor object, it is coerced to one.
formulaa formula of the form \( a \sim b \mid c \), where \( a \), \( b \) and \( c \) give the data values and corresponding groups and blocks, respectively.
data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formulaa. By default the variables are taken from environment(formula).
subset an optional vector specifying a subset of observations to be used.
na.action a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").

Details

quade.test can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in \( y \) for each combination of levels of groups and blocks) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of blocks, the location parameter of \( y \) is the same in each of the groups.

If \( y \) is a matrix, groups and blocks are obtained from the column and row indices, respectively. NA's are not allowed in groups or blocks; if \( y \) contains NA's, corresponding blocks are removed.

Value

A list with class "htest" containing the following components:

- statistic the value of Quade’s F statistic.
- parameter a vector with the numerator and denominator degrees of freedom of the approximate F distribution of the test statistic.
- p.value the p-value of the test.
- method the character string "Quade test".
- data.name a character string giving the names of the data.

quantile

Sample Quantiles

Description

The generic function quantile produces sample quantiles corresponding to the given probabilities. The smallest observation corresponds to a probability of 0 and the largest to a probability of 1.

Usage

quantile(x, ...)

## Default S3 method:
quantile(x, probs = seq(0, 1, 0.25), na.rm = FALSE,
         names = TRUE, type = 7, ...)

Arguments

x numeric vector whose sample quantiles are wanted, or an object of a class for which a method has been defined (see also ‘details’). NA and NaN values are not allowed in numeric vectors unless na.rm is TRUE.

probs numeric vector of probabilities with values in [0, 1]. (Values up to ‘2e-14’ outside that range are accepted and moved to the nearby endpoint.)

na.rm logical; if true, any NA and NaN's are removed from x before the quantiles are computed.

names logical; if true, the result has a names attribute. Set to FALSE for speedup with many probs.

type an integer between 1 and 9 selecting one of the nine quantile algorithms detailed below to be used.

... further arguments passed to or from other methods.

Details

A vector of length length(probs) is returned; if names = TRUE, it has a names attribute.

NA and NaN values in probs are propagated to the result.

The default method works with classed objects sufficiently like numeric vectors that sort and (not needed by types 1 and 3) addition of elements and multiplication by a number work correctly. Note that as this is in a namespace, the copy of sort in base will be used, not some S4 generic of that name. Also note that that is no check on the ‘correctly’, and so e.g. quantile can be applied to complex vectors which (apart from ties) will be ordered on their real parts.

There is a method for the date-time classes (see “POSIXt”). Types 1 and 3 can be used for class "Date" and for ordered factors.
Types

quantile returns estimates of underlying distribution quantiles based on one or two order statistics from the supplied elements in x at probabilities in probs. One of the nine quantile algorithms discussed in Hyndman and Fan (1996), selected by type, is employed.

All sample quantiles are defined as weighted averages of consecutive order statistics. Sample quantiles of type \( i \) are defined by:

\[
Q_i(p) = (1 - \gamma)x_j + \gamma x_{j+1}
\]

where \( 1 \leq i \leq 9 \), \( \frac{i-1}{n} \leq p < \frac{i}{n} \), \( x_j \) is the \( j \)th order statistic, \( n \) is the sample size, the value of \( \gamma \) is a function of \( j = \lfloor np + m \rfloor \) and \( g = np + m - j \), and \( m \) is a constant determined by the sample quantile type.

Discontinuous sample quantile types 1, 2, and 3

For types 1, 2 and 3, \( Q_i(p) \) is a discontinuous function of \( p \), with \( m = 0 \) when \( i = 1 \) and \( i = 2 \), and \( m = -1/2 \) when \( i = 3 \).

Type 1 Inverse of empirical distribution function. \( \gamma = 0 \) if \( g = 0 \), and 1 otherwise.

Type 2 Similar to type 1 but with averaging at discontinuities. \( \gamma = 0.5 \) if \( g = 0 \), and 1 otherwise.

Type 3 SAS definition: nearest even order statistic. \( \gamma = 0 \) if \( g = 0 \) and \( j \) is even, and 1 otherwise.

Continuous sample quantile types 4 through 9

For types 4 through 9, \( Q_i(p) \) is a continuous function of \( p \), with \( \gamma = g \) and \( m \) given below. The sample quantiles can be obtained equivalently by linear interpolation between the points \((p_k, x_k)\) where \( x_k \) is the \( k \)th order statistic. Specific expressions for \( p_k \) are given below.

Type 4 \( m = 0 \). \( p_k = k/n \). That is, linear interpolation of the empirical cdf.

Type 5 \( m = 1/2 \). \( p_k = k/n + 0.5/n \). That is a piecewise linear function where the knots are the values midway through the steps of the empirical cdf. This is popular amongst hydrologists.

Type 6 \( m = p \). \( p_k = k/n \). Thus \( p_k = E[F(x_k)] \). This is used by Minitab and by SPSS.

Type 7 \( m = 1 - p \). \( p_k = k/n \). In this case, \( p_k = \text{mode}[F(x_k)] \). This is used by S.

Type 8 \( m = (p + 1)/3 \). \( p_k = k/n + 1/3 \). Then \( p_k \approx \text{median}[F(x_k)] \). The resulting quantile estimates are approximately median-unbiased regardless of the distribution of \( x \).

Type 9 \( m = p/4 + 3/8 \). \( p_k = k/n + 1/8 \). The resulting quantile estimates are approximately unbiased for the expected order statistics if \( x \) is normally distributed.

Further details are provided in Hyndman and Fan (1996) who recommended type 8. The default method is type 7, as used by S and by R < 2.0.0.

r2table

**Random 2-way Tables with Given Marginals**

Description

Generate random 2-way tables with given marginals using Patefield’s algorithm.

Usage

r2table(n, r, c)

Arguments

n

a non-negative numeric giving the number of tables to be drawn.

r

a non-negative vector of length at least 2 giving the row totals, to be coerced to integer. Must sum to the same as c.

c

a non-negative vector of length at least 2 giving the column totals, to be coerced to integer.

Value

A list of length n containing the generated tables as its components.

References

Examples

## Fisher's Tea Drinker data.

```r
teaTasting <- matrix(c(3, 1, 1, 3), nrow = 2, 
  dimnames = list(Guess = c("Milk", "Tea"),
                  Truth = c("Milk", "Tea")))
```

## Simulate permutation test for independence based on the maximum
## Pearson residuals (rather than their sum).

```r
rowTotals <- rowSums(teaTasting)
colTotals <- colSums(teaTasting)
noOfCases <- sum(rowTotals)
expected <- outer(rowTotals, colTotals, "*") / noOfCases
maxSqResid <- function(x) max((x - expected) ^ 2 / expected)
simMaxSqResid <- 
  sapply(r2dtable(1000, rowTotals, colTotals), maxSqResid)
sum(simMaxSqResid >= maxSqResid(teaTasting)) / 1000
```

## Fisher's exact test gives p = 0.4857 ...

---

**Manipulate Flat Contingency Tables**

**Description**

Read, write and coerce 'flat' contingency tables.

**Usage**

```r
read.ftable(file, sep = "", quote = "\", 
  row.var.names, col.vars, skip = 0)
write.ftable(x, file = "", quote = TRUE, append = FALSE, 
  digits = getOption("digits"), ...)
```

## S3 method for class 'ftable'

```r
format(x, quote = TRUE, digits = getOption("digits"), 
  method = c("non.compact", "row.compact", 
            "col.compact", "compact"),
  lsep = " | ", ...)
```

## S3 method for class 'ftable'

```r
print(x, digits = getOption("digits"), ...)
```

**Arguments**

- `file` either a character string naming a file or a connection which the data are to be read from or written to. "" indicates input from the console for reading and output to the console for writing.
- `sep` the field separator string. Values on each line of the file are separated by this string.
- `quote` a character string giving the set of quoting characters for `read.ftable`; to disable quoting altogether, use `quote=""`. For `write.table`, a logical indicating whether strings in the data will be surrounded by double quotes.
read.ftable

row.var.names a character vector with the names of the row variables, in case these cannot be
determined automatically.
col.vars a list giving the names and levels of the column variables, in case these cannot be
determined automatically.
skip the number of lines of the data file to skip before beginning to read data.
x an object of class "ftable".
append logical. If TRUE and file is the name of a file (and not a connection or "|cmd"),
the output from write.ftable is appended to the file. If FALSE, the contents of
file will be overwritten.
digits an integer giving the number of significant digits to use for (the cell entries of)
x.
method string specifying how the "ftable" object is formatted (and printed if used
as in write.ftable() or the print method). Available methods are (see the
examples):
"non.compact" the default representation of an "ftable" object.
"row.compact" a row-compact version without empty cells below the column
labels.
"col.compact" a column-compact version without empty cells to the right of
the row labels.
"compact" a row- and column-compact version. This may imply a row and a
column label sharing the same cell. They are then separated by the string
sep.
sep only for method = "compact", the separation string for row and column labels.
... further arguments to be passed to or from methods; for write() and print(),
notably arguments such as method, passed to format().

Details

read.ftable reads in a flat-like contingency table from a file. If the file contains the written
representation of a flat table (more precisely, a header with all information on names and levels of
column variables, followed by a line with the names of the row variables), no further arguments are
needed. Similarly, flat tables with only one column variable the name of which is the only entry
in the first line are handled automatically. Other variants can be dealt with by skipping all header
information using skip, and providing the names of the row variables and the names and levels of
the column variable using row.var.names and col.vars, respectively. See the examples below.

Note that flat tables are characterized by their ‘ragged’ display of row (and maybe also column)
labels. If the full grid of levels of the row variables is given, one should instead use read.table to
read in the data, and create the contingency table from this using xtabs.

write.ftable writes a flat table to a file, which is useful for generating ‘pretty’ ASCII representa-
tions of contingency tables. Different versions are available via the method argument, which may
be useful, for example, for constructing LaTeX tables.

cat("Intercourse",
    "Race Gender Yes No",
    "White Male 43 134",
    "Female 26 149",
    "Black Male 29 23",
    "Female 22 36",
    file = file)
file.show(file)
ft1 <- read.ftable(file)
unlink(file)

## Agresti (1990), page 297, Table 8.16.
## Almost o.k., but misses the name of the row variable.
file <- tempfile()
cat("\"Tonsil Size\"",
    "\"Not Enl." \"Enl." \"Greatly Enl.\",
    "Noncarriers 497 560 269",
    "Carriers 19 29 24",
    file = file)
file.show(file)
ft <- read.ftable(file, skip = 2,
    row.var.names = "Status",
    col.vars = list("Tonsil Size" =
        c("Not Enl.", "Enl.", "Greatly Enl.")))}
ft
unlink(file)

ft22 <- ftable(Titanic, row.vars = 2:1, col.vars = 4:3)
write.ftable(ft22, quote = FALSE)
write.ftable(ft22, quote = FALSE, method="row.compact")
write.ftable(ft22, quote = FALSE, method="col.compact")
write.ftable(ft22, quote = FALSE, method="compact")
```

### Description

Draws rectangles around the branches of a dendrogram highlighting the corresponding clusters. First the dendrogram is cut at a certain level, then a rectangle is drawn around selected branches.

### Usage

```r
rect.hclust(tree, k = NULL, which = NULL, x = NULL, h = NULL,
    border = 2, cluster = NULL)
```
Arguments

```
  tree
  k, h
  which, x
  border
  cluster
```

- **tree**: an object of the type produced by `hclust`.
- **k, h**: Scalar. Cut the dendrogram such that either exactly k clusters are produced or by cutting at height h.
- **which, x**: A vector selecting the clusters around which a rectangle should be drawn. which selects clusters by number (from left to right in the tree), x selects clusters containing the respective horizontal coordinates. Default is `which = 1:k`.
- **border**: Vector with border colors for the rectangles.
- **cluster**: Optional vector with cluster memberships as returned by `cutree(hclust.obj, k = k)`. Can be specified for efficiency if already computed.

Value

(Invisibly) returns a list where each element contains a vector of data points contained in the respective cluster.

See Also

`hclust`, `identify.hclust`.

Examples

```
require(graphics)

hca <- hclust(dist(USArrests))
plot(hca)
rect.hclust(hca, k = 3, border = "red")
x <- rect.hclust(hca, h = 50, which = c(2,7), border = 3:4)
x
```

---

**relevel**

Reorder Levels of Factor

Description

The levels of a factor are re-ordered so that the level specified by `ref` is first and the others are moved down. This is useful for `contr.treatment` contrasts which take the first level as the reference.

Usage

```
relevel(x, ref, ...)
```

Arguments

- **x**: An unordered factor.
- **ref**: The reference level.
- **...**: Additional arguments for future methods.
**reorder.default**

**Value**

A factor of the same length as x.

**See Also**

factor, contr.treatment, levels, reorder.

**Examples**

```r
warpbreaks$tension <- relevel(warpbreaks$tension, ref = "M")
summary(lm(breaks ~ wool + tension, data = warpbreaks))
```

---

**order Levels of a Factor**

**Description**

reorder is a generic function. The "default" method treats its first argument as a categorical variable, and reorders its levels based on the values of a second variable, usually numeric.

**Usage**

reorder(x, ...)

## Default S3 method:
reorder(x, X, FUN = mean, ..., 
    order = is.ordered(x))

**Arguments**

- **x**: An atomic vector, usually a factor (possibly ordered). The vector is treated as a categorical variable whose levels will be reordered. If x is not a factor, its unique values will be used as the implicit levels.
- **X**: a vector of the same length as x, whose subset of values for each unique level of x determines the eventual order of that level.
- **FUN**: a function whose first argument is a vector and returns a scalar, to be applied to each subset of x determined by the levels of x.
- **...**: optional: extra arguments supplied to FUN
- **order**: logical, whether return value will be an ordered factor rather than a factor.

**Value**

A factor or an ordered factor (depending on the value of order), with the order of the levels determined by FUN applied to X grouped by x. The levels are ordered such that the values returned by FUN are in increasing order. Empty levels will be dropped.

Additionally, the values of FUN applied to the subsets of X (in the original order of the levels of x) is returned as the "scores" attribute.
Author(s)
Deepayan Sarkar <deepayan.sarkar@r-project.org>

See Also
reorder.dendrogram, levels, relevel.

Examples

```r
require(graphics)

bymedian <- with(InsectSprays, reorder(spray, count, median))
boxplot(count ~ bymedian, data = InsectSprays,
    xlab = "Type of spray", ylab = "Insect count",
    main = "InsectSprays data", varwidth = TRUE,
    col = "lightgray")
```

Description
A method for the generic function reorder.

There are many different orderings of a dendrogram that are consistent with the structure imposed. This function takes a dendrogram and a vector of values and reorders the dendrogram in the order of the supplied vector, maintaining the constraints on the dendrogram.

Usage

```r
## S3 method for class 'dendrogram'
reorder(x, wts, agglo.FUN = sum, ...)
```

Arguments

- `x`: the (dendrogram) object to be reordered
- `wts`: numeric weights (arbitrary values) for reordering.
- `agglo.FUN`: a function for weights agglomeration, see below.
- `...`: additional arguments

Details
Using the weights `wts`, the leaves of the dendrogram are reordered so as to be in an order as consistent as possible with the weights. At each node, the branches are ordered in increasing weights where the weight of a branch is defined as \( f(w_j) \) where \( f \) is agglo.FUN and \( w_j \) is the weight of the \( j \)-th sub branch.

Value
A dendrogram where each node has a further attribute value with its corresponding weight.
Author(s)
R. Gentleman and M. Maechler

See Also
reorder.

rev.dendrogram which simply reverses the nodes' order; heatmap, cophenetic.

Examples

```r
require(graphics)
set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
dd <- as.dendrogram(hc)
dd.reorder <- reorder(dd, 10:1)
plot(dd, main = "random dendrogram 'dd'")

op <- par(mfcol = 1:2)
plot(dd.reorder, main = "reorder(dd, 10:1)")
plot(reorder(dd, 10:1, agglo.FUN = mean), main = "reorder(dd, 10:1, mean)")
par(op)
```

<table>
<thead>
<tr>
<th>replications</th>
<th>Number of Replications of Terms</th>
</tr>
</thead>
</table>

Description

Returns a vector or a list of the number of replicates for each term in the formula.

Usage

`replications(formula, data = NULL, na.action)`

Arguments

- `formula`: a formula or a terms object or a data frame.
- `data`: a data frame used to find the objects in `formula`.
- `na.action`: function for handling missing values. Defaults to a `na.action` attribute of `data`, then a setting of the option `na.action`, or `na.fail` if that is not set.

Details

If `formula` is a data frame and `data` is missing, `formula` is used for `data` with the formula `~ ..`. Any character vectors in the formula are coerced to factors.
Value

A vector or list with one entry for each term in the formula giving the number(s) of replications for each level. If all levels are balanced (have the same number of replications) the result is a vector, otherwise it is a list with a component for each terms, as a vector, matrix or array as required.

A test for balance is `!is.list(replications(formula, data))`.

Author(s)

The design was inspired by the S function of the same name described in Chambers et al. (1992).

```

---

**reshape**

*Reshape Grouped Data*

**Description**

This function reshapes a data frame between ‘wide’ format with repeated measurements in separate columns of the same record and ‘long’ format with the repeated measurements in separate records.

**Usage**

```r
reshape(data, varying = NULL, v.names = NULL, timevar = "time",
idvar = "id", ids = 1:NROW(data),
times = seq_along(varying[[1]]),
drop = NULL, direction, new.row.names = NULL,
sep = ",",
split = if (sep == "") {
  list(regexp = "[A-Za-z][0-9]", include = TRUE)
} else {
  list(regexp = sep, include = FALSE, fixed = TRUE)}
```
Arguments

data
varying
data frame
names of sets of variables in the wide format that correspond to single variables in long format (‘time-varying’). This is canonically a list of vectors of variable names, but it can optionally be a matrix of names, or a single vector of names. In each case, the names can be replaced by indices which are interpreted as referring to names(data). See ‘Details’ for more details and options.
v.names
names of variables in the long format that correspond to multiple variables in the wide format. See ‘Details’.
timevar
the variable in long format that differentiates multiple records from the same group or individual. If more than one record matches, the first will be taken (with a warning).
idvar
Names of one or more variables in long format that identify multiple records from the same group/individual. These variables may also be present in wide format.
ids
the values to use for a newly created idvar variable in long format.
times
the values to use for a newly created timevar variable in long format. See ‘Details’.
drop
a vector of names of variables to drop before reshaping.
direction
character string, either "wide" to reshape to wide format, or "long" to reshape to long format.
new.row.names
character or NULL: a non-null value will be used for the row names of the result.
sep
A character vector of length 1, indicating a separating character in the variable names in the wide format. This is used for guessing v.names and times arguments based on the names in varying. If sep == "", the split is just before the first numeral that follows an alphabetic character. This is also used to create variable names when reshaping to wide format.
split
A list with three components, regexp, include, and (optionally) fixed. This allows an extended interface to variable name splitting. See ‘Details’.

Details

The arguments to this function are described in terms of longitudinal data, as that is the application motivating the functions. A ‘wide’ longitudinal dataset will have one record for each individual with some time-constant variables that occupy single columns and some time-varying variables that occupy a column for each time point. In ‘long’ format there will be multiple records for each individual, with some variables being constant across these records and others varying across the records. A ‘long’ format dataset also needs a ‘time’ variable identifying which time point each record comes from and an ‘id’ variable showing which records refer to the same person.

If the data frame resulted from a previous reshape then the operation can be reversed simply by reshape(a). The direction argument is optional and the other arguments are stored as attributes on the data frame.

If direction = "wide" and no varying or v.names arguments are supplied it is assumed that all variables except idvar and timevar are time-varying. They are all expanded into multiple variables in wide format.
If direction = "long" the varying argument can be a vector of column names (or a corresponding index). The function will attempt to guess the v.names and times from these names. The default is variable names like x.1, x.2, where sep = "." specifies to split at the dot and drop it from the name. To have alphabetic followed by numeric times use sep = "".

Variable name splitting as described above is only attempted in the case where varying is an atomic vector, if it is a list or a matrix, v.names and times will generally need to be specified, although they will default to, respectively, the first variable name in each set, and sequential times.

Also, guessing is not attempted if v.names is given explicitly. Notice that the order of variables in varying is like x.1.y.1.x.2.y.2.

The split argument should not usually be necessary. The split$regexp component is passed to either strsplit or regexpr, where the latter is used if split$include is TRUE, in which case the splitting occurs after the first character of the matched string. In the strsplit case, the separator is not included in the result, and it is possible to specify fixed-string matching using split$fixed.

Value

The reshaped data frame with added attributes to simplify reshaping back to the original form.

See Also

stack, aperm; relist for reshaping the result of unlist.

Examples

```r
summary(Indometh)

wide <- reshape(Indometh, v.names = "conc", idvar = "Subject",
               timevar = "time", direction = "wide")

reshape(wide, direction = "long")
reshape(wide, idvar = "Subject", varying = list(2:12),
       v.names = "conc", direction = "long")

## times need not be numeric
df <- data.frame(id = rep(1:4, rep(2,4)),
                 visit = I(rep(c("Before","After"), 4)),
                 x = rnorm(4), y = runif(4))

df
reshape(df, timevar = "visit", idvar = "id", direction = "wide")
## warns that y is really varying
reshape(df, timevar = "visit", idvar = "id", direction = "wide", v.names = "x")

## unbalanced 'long' data leads to NA fill in 'wide' form
df2 <- df[1:7, ]
df2
reshape(df2, timevar = "visit", idvar = "id", direction = "wide")

## Alternative regular expressions for guessing names
df3 <- data.frame(id = 1:4, age = c(40,50,60,50), dose1 = c(1,2,1,2),
                  dose2 = c(2,1,2,1), dose4 = c(3,3,3,3))
reshape(df3, direction = "long", varying = 3:5, sep = "")

## an example that isn't longitudinal data
```
residuals

residuals <- as.data.frame(state.x77)
long <- reshape(residuals, idvar = "state", ids = row.names(residuals),
times = names(state.x77), timevar = "Characteristic",
  varying = list(names(state.x77)), direction = "long")
reshape(long, direction = "wide")
reshape(long, direction = "wide", new.row.names = unique(long$state))

## multiple id variables
df3 <- data.frame(school = rep(1:3, each = 4), class = rep(9:10, 6),
  time = rep(c(1,1,2,2), 3), score = rnorm(12))
wide <- reshape(df3, idvar = c("school","class"), direction = "wide")
reshape(wide)

residuals Residuals

Description

residuals is a generic function which extracts model residuals from objects returned by modeling functions.

The abbreviated form resid is an alias for residuals. It is intended to encourage users to access object components through an accessor function rather than by directly referencing an object slot.

All object classes which are returned by model fitting functions should provide a residuals method. (Note that the method is for ‘residuals’ and not ‘resid’.)

Methods can make use of naresid methods to compensate for the omission of missing values. The default, nls and smooth.spline methods do.

Usage

residuals(object, ...)
resid(object, ...)

Arguments

object an object for which the extraction of model residuals is meaningful.

... other arguments.

Value

Residuals extracted from the object object.

References

Runmed — Running Medians — Robust Scatter Plot Smoothing

Description

Compute running medians of odd span. This is the ‘most robust’ scatter plot smoothing possible. For efficiency (and historical reason), you can use one of two different algorithms giving identical results.

Usage

runmed(x, k, endrule = c("median", "keep", "constant"),
       algorithm = NULL, print.level = 0)

Arguments

x numeric vector, the ‘dependent’ variable to be smoothed.

k integer width of median window; must be odd. Turlach had a default of
     k <- 1 + 2 * min((n-1)%/% 2, ceiling(0.1*n)). Use k = 3 for
     ‘minimal’ robust smoothing eliminating isolated outliers.

endrule character string indicating how the values at the beginning and the end (of the
     data) should be treated.

"keep" keeps the first and last \(k_2\) values at both ends, where \(k_2\) is the half-
     bandwidth \(k_2 \approx k \%\% 2, i.e., y[j] = x[j] for j \in \{1, \ldots, k_2; n - k_2 +
     1, \ldots, n\}\);

"constant" copies median(y[1:k2]) to the first values and analogously for
     the last ones making the smoothed ends constant;

"median" the default, smooths the ends by using symmetrical medians of sub-
     sequently smaller bandwidth, but for the very first and last value where
     Tukey’s robust end-point rule is applied, see smoothEnds.

algorithm character string (partially matching “Turlach” or “Stuetzle”) or the default
     NULL, specifying which algorithm should be applied. The default choice depends
     on \(n = \text{length}(x)\) and \(k\) where “Turlach” will be used for larger problems.

print.level integer, indicating verbosity of algorithm; should rarely be changed by aver-
     age users.

Details

Apart from the end values, the result \(y = \text{runmed}(x, k)\) simply has
\(y[j] = \text{median}(x[(j-k2):(j+k2)])\) (\(k = 2k2+1\)), computed very efficiently.

The two algorithms are internally entirely different:

"Turlach" is the Härdle–Steiger algorithm (see Ref.) as implemented by Berwin Turlach. A
     tree algorithm is used, ensuring performance \(O(n \log k)\) where \(n = \text{length}(x)\) which is
     asymptotically optimal.

See Also

coefficients, fitted.values, glm, lm.
influence.measures for standardized (rstandard) and studentized (rstudent) residuals.
"Stuetzle" is the (older) Stuetzle–Friedman implementation which makes use of median updating when one observation enters and one leaves the smoothing window. While this performs as $O(n \times k)$ which is slower asymptotically, it is considerably faster for small $k$ or $n$.

Currently long vectors are only supported for algorithm = "Stuetzle".

Value

vector of smoothed values of the same length as x with an attribute k containing (the ‘oddified’) k.

Author(s)

Martin Maechler <maechler@stat.math.ethz.ch>, based on Fortran code from Werner Stuetzle and S-PLUS and C code from Berwin Turlach.

References

See Also

smoothEnds which implements Tukey’s end point rule and is called by default from runmed(*, endrule = "median"). smooth uses running medians of 3 for its compound smoothers.

Examples

require(graphics)
utils::example(nhtemp)
myNHT <- as.vector(nhtemp)
plot(myNHT, type = "b", ylim = c(48, 60), main = "Running Medians Example")
lines(runmed(myNHT, 7), col = "red")

## special: multiple y values for one x
plot(cars, main = "'cars' data and runmed(dist, 3)"
lines(cars, col = "light gray", type = "c")
with(cars, lines(speed, runmed(dist, k = 3), col = 2))

## nice quadratic with a few outliers
y <- ys <- (-20:20)^2
y [c(1,10,21,41)] <- c(150, 30, 400, 450)
all(y == runmed(y, 1)) # 1-neighbourhood ==> interpolation
plot(y) # lines(y, lwd = .1, col = "light gray")
lines(lowess(seq(y), y, f = 0.3), col = "brown")
lines(runmed(y, 7), lwd = 2, col = "blue")
lines(runmed(y, 11), lwd = 2, col = "red")
## Description

Generate \( n \) random matrices, distributed according to the Wishart distribution with parameters \( \Sigma \) and \( df \), \( W_p(\Sigma, m) \), \( m = df \), \( \Sigma = \Sigma \).

### Usage

```r
rWishart(n, df, Sigma)
```

### Arguments

- \( n \): integer sample size.
- \( df \): numeric parameter, “degrees of freedom”.
- \( Sigma \): positive definite \((p \times p)\) “scale” matrix, the matrix parameter of the distribution.

### Details

If \( X_1, \ldots, X_m, X_i \in \mathbb{R}^p \) is a sample of \( m \) independent multivariate Gaussians with mean (vector) \( 0 \), and covariance matrix \( \Sigma \), the distribution of \( M = X'X \) is \( W_p(\Sigma, m) \).

Consequently, the expectation of \( M \) is

\[
E[M] = m \times \Sigma.
\]

Further, if \( Sigma \) is scalar \((p = 1)\), the Wishart distribution is a scaled chi-squared \((\chi^2)\) distribution with \( df \) degrees of freedom, \( W_1(\sigma^2, m) = \sigma^2 \chi^2_m \).

The component wise variance is

\[
\text{Var}(M_{ij}) = m(\Sigma_{ij}^2 + \Sigma_{ii} \Sigma_{jj}).
\]

### Value

A numeric \texttt{array}, say \( R \), of dimension \( p \times p \times n \), where each \( R[, , i] \) is a positive definite matrix, a realization of the Wishart distribution \( W_p(\Sigma, m) \), \( m = df \), \( \Sigma = \Sigma \).

Examples

```r
## Artificial
S <- toeplitz((10:1)/10)
set.seed(11)
R <- rWishart(1000, 20, S)
dim(R) # 10 10 1000
mR <- apply(R, 1:2, mean) # E[ Wish(S, 20) ] = 20 * S
stopifnot(all.equal(mR, 20*S, tol = .009))

## See Details, the variance is
Va <- 20*(S*2 + tcrossprod(diag(S))
VR <- apply(R, 1:2, var)
stopifnot(all.equal(VR, Va, tol = 1/16))
```

`scatter.smooth`  
*Scatter Plot with Smooth Curve Fitted by Loess*

Description

Plot and add a smooth curve computed by `loess` to a scatter plot.

Usage

```r
scatter.smooth(x, y = NULL, span = 2/3, degree = 1,
                 family = c("symmetric", "gaussian"),
                 xlab = NULL, ylab = NULL,
                 ylim = range(y, pred$y, na.rm = TRUE),
                 evaluation = 50, ..., lpars = list())

loess.smooth(x, y, span = 2/3, degree = 1,
              family = c("symmetric", "gaussian"), evaluation = 50, ...)
```

Arguments

- `x, y` the x and y arguments provide the x and y coordinates for the plot. Any reasonable way of defining the coordinates is acceptable. See the function `xy.coords` for details.
- `span` smoothness parameter for `loess`.
- `degree` degree of local polynomial used.
- `family` if "gaussian" fitting is by least-squares, and if `family = "symmetric"` a re-descending M estimator is used.
- `xlab` label for x axis.
screeplot

... label for y axis.
... the y limits of the plot.
... number of points at which to evaluate the smooth curve.
... For scatter.smooth(), graphical parameters, passed to plot() only. For
... loess.smooth, control parameters passed to loess.control.
... a list of arguments to be passed to lines().

Details

loess.smooth is an auxiliary function which evaluates the loess smooth at evaluation equally
spaced points covering the range of x.

Value

For scatter.smooth, none.

For loess.smooth, a list with two components, x (the grid of evaluation points) and y (the smoothed
values at the grid points).

See Also

loess; smoothScatter for scatter plots with smoothed density color representation.

Examples

require(graphics)

with(cars, scatter.smooth(speed, dist))
## or with dotted thick smoothed line results :
with(cars, scatter.smooth(speed, dist, lpars =
list(col = "red", lwd = 3, lty = 3)))

Description

screeplot.default plots the variances against the number of the principal component. This is
also the plot method for classes "princomp" and "prcomp".

Usage

## Default S3 method:
screeplot(x,npcs = min(10, length(x$dev)),
 type = c("barplot", "lines"),
 main = deparse(substitute(x)), ...)

Screeplots

Screeplots
**Arguments**

- **x**: an object containing a sdev component, such as that returned by `princomp()` and `prcomp()`.
- **npcs**: the number of components to be plotted.
- **type**: the type of plot.
- **main, ...**: graphics parameters.

**References**

**See Also**

- `princomp` and `prcomp`.

**Examples**

```r
require(graphics)

## The variances of the variables in the
## USArrests data vary by orders of magnitude, so scaling is appropriate
(pc.cr <- princomp(USArrests, cor = TRUE)) # inappropriate
screepplot(pc.cr)

fit <- princomp(covmat = Harman74.cor)
screepplot(fit)
screepplot(fit, npcs = 24, type = "lines")
```

---

### `sd`

**Standard Deviation**

**Description**

This function computes the standard deviation of the values in `x`. If `na.rm` is `TRUE` then missing values are removed before computation proceeds.

**Usage**

```r
sd(x, na.rm = FALSE)
```

**Arguments**

- **x**: a numeric vector or an `R` object which is coercible to one by `as.vector(x, "numeric")`.
- **na.rm**: logical. Should missing values be removed?
Details

Like \texttt{var} this uses denominator $n - 1$.

The standard deviation of a zero-length vector (after removal of NAs if \texttt{na.rm = TRUE}) is not defined and gives an error. The standard deviation of a length-one vector is \texttt{NA}.

Prior to R 2.14.0, \texttt{sd(dfrm)} worked directly for a \texttt{data.frame dfrm}. This is now defunct and you are expected to use \texttt{sapply(dfrm, sd)}.

See Also

\texttt{var} for its square, and \texttt{mad}, the most robust alternative.

Examples

\texttt{sd(1:2)^2}

---

\texttt{se.contrast} \hspace{1cm} \textit{Standard Errors for Contrasts in Model Terms}

Description

Returns the standard errors for one or more contrasts in an \texttt{aov} object.

Usage

\texttt{se.contrast(object, \ldots)}

### S3 method for class \texttt{'aov'}

\texttt{se.contrast(object, contrast.obj,}
\begin{verbatim}
coef = contr.helmert(ncol(contrast))[1, 1],
data = NULL, \ldots)
\end{verbatim}

Arguments

\begin{itemize}
\item \textbf{object} \hspace{1cm} A suitable fit, usually from \texttt{aov}.
\item \textbf{contrast.obj} \hspace{1cm} The contrasts for which standard errors are requested. This can be specified via a list or via a matrix. A single contrast can be specified by a list of logical vectors giving the cells to be contrasted. Multiple contrasts should be specified by a matrix, each column of which is a numerical contrast vector (summing to zero).
\item \textbf{coef} \hspace{1cm} used when \texttt{contrast.obj} is a list; it should be a vector of the same length as the list with zero sum. The default value is the first Helmert contrast, which contrasts the first and second cell means specified by the list.
\item \textbf{data} \hspace{1cm} The data frame used to evaluate \texttt{contrast.obj}.
\item \ldots \hspace{1cm} further arguments passed to or from other methods.
\end{itemize}
Details

Contrasts are usually used to test if certain means are significantly different; it can be easier to use `se.contrast` than compute them directly from the coefficients.

In multistratum models, the contrasts can appear in more than one stratum, in which case the standard errors are computed in the lowest stratum and adjusted for efficiencies and comparisons between strata. (See the comments in the note in the help for `aov` about using orthogonal contrasts.) Such standard errors are often conservative.

Suitable matrices for use with `coef` can be found by calling `contrasts` and indexing the columns by a factor.

Value

A vector giving the standard errors for each contrast.

See Also

`contrasts`, `model.tables`

Examples

```r
N <- c(0,1,0,1,1,1,0,0,0,1,0,1,1,0,1,0,1,0,1,0,0,0,1,0,1,1,0,0,1,0,0)

cont2 <- c(-1, 1)[B] * c(-1, 1)[C]/32
colSums(cont1*Yield)  # values of the contrasts
se.contrast(fit, as.matrix(cont1))
## Not run: # comparison with lme
library(lme)
fit2 <- lme(Yield ~ A + B*C, random = -1 | Block, data = aovdat)
summary(fit2)$tTable  # same estimates, similar (but smaller) se's.
## End(Not run)

---

### selfStart

**Construct Self-starting Nonlinear Models**

#### Description

Construct self-starting nonlinear models.

#### Usage

```r
selfStart(model, initial, parameters, template)
```

#### Arguments

- **model**: a function object defining a nonlinear model or a nonlinear formula object of the form `~expression`.
- **initial**: a function object, taking three arguments: `mCall`, `data`, and `LHS`, representing, respectively, a matched call to the function `model`, a data frame in which to interpret the variables in `mCall`, and the expression from the left-hand side of the model formula in the call to `nls`. This function should return initial values for the parameters in `model`.
- **parameters**: a character vector specifying the terms on the right hand side of `model` for which initial estimates should be calculated. Passed as the `namevec` argument to the `deriv` function.
- **template**: an optional prototype for the calling sequence of the returned object, passed as the `function.arg` argument to the `deriv` function. By default, a template is generated with the covariates in `model` coming first and the parameters in `model` coming last in the calling sequence.
selfStart

Details

This function is generic; methods functions can be written to handle specific classes of objects.

Value

A function object of class "selfStart", for the formula method obtained by applying deriv to the right hand side of the model formula. An initial attribute (defined by the initial argument) is added to the function to calculate starting estimates for the parameters in the model automatically.

Author(s)

José Pinheiro and Douglas Bates

---

**setNames** Set the Names in an Object

**Description**

This is a convenience function that sets the names on an object and returns the object. It is most useful at the end of a function definition where one is creating the object to be returned and would prefer not to store it under a name just so the names can be assigned.

**Usage**

```r
setNames(object = nm, nm)
```

**Arguments**

- `object` an object for which a `names` attribute will be meaningful
- `nm` a character vector of names to assign to the object

**Value**

An object of the same sort as `object` with the new names assigned.

**Author(s)**

Douglas M. Bates and Saikat DebRoy

**See Also**

- `unname` for removing names.

**Examples**

```r
setNames(1:3, c("foo", "bar", "baz") )
# this is just a short form of
tmp <- 1:3
names(tmp) <- c("foo", "bar", "baz")
tmp

## special case of character vector, using default
setNames(nm = c("First", "2nd"))
```
shapiro.test

Shapiro-Wilk Normality Test

Description
Performs the Shapiro-Wilk test of normality.

Usage
shapiro.test(x)

Arguments
x a numeric vector of data values. Missing values are allowed, but the number of non-missing values must be between 3 and 5000.

Value
A list with class "htest" containing the following components:

statistic the value of the Shapiro-Wilk statistic.
p.value an approximate p-value for the test. This is said in Royston (1995) to be adequate for p.value < 0.1.
method the character string "Shapiro-Wilk normality test".
data.name a character string giving the name(s) of the data.

Source
The algorithm used is a C translation of the Fortran code described in Royston (1995) and found at http://lib.stat.cmu.edu/apstat/R94. The calculation of the p value is exact for n = 3, otherwise approximations are used, separately for 4 ≤ n ≤ 11 and n ≥ 12.

References

See Also
qqnorm for producing a normal quantile-quantile plot.

Examples
shapiro.test(rnorm(100, mean = 5, sd = 3))
shapiro.test(runif(100, min = 2, max = 4))
Description
Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon Signed Rank statistic obtained from a sample with size \( n \).

Usage

\[
\begin{align*}
\text{dsignrank}(x, n, \log = \text{FALSE}) \\
\text{psignrank}(q, n, \text{lower.tail} = \text{TRUE}, \log.p = \text{FALSE}) \\
\text{qsignrank}(p, n, \text{lower.tail} = \text{TRUE}, \log.p = \text{FALSE}) \\
\text{rsignrank}(\text{nn}, n)
\end{align*}
\]

Arguments

- \( x, q \): vector of quantiles.
- \( p \): vector of probabilities.
- \( \text{nn} \): number of observations. If \( \text{length(nn)} > 1 \), the length is taken to be the number required.
- \( n \): number(s) of observations in the sample(s). A positive integer, or a vector of such integers.
- \( \log, \log.p \): logical; if TRUE, probabilities \( p \) are given as \( \log(p) \).
- \( \text{lower.tail} \): logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details
This distribution is obtained as follows. Let \( x \) be a sample of size \( n \) from a continuous distribution symmetric about the origin. Then the Wilcoxon signed rank statistic is the sum of the ranks of the absolute values \( x[i] \) for which \( x[i] \) is positive. This statistic takes values between 0 and \( n(n + 1)/2 \), and its mean and variance are \( n(n + 1)/4 \) and \( n(n + 1)(2n + 1)/24 \), respectively.

If either of the first two arguments is a vector, the recycling rule is used to do the calculations for all combinations of the two up to the length of the longer vector.

Value
\text{dsignrank} gives the density, \text{psignrank} gives the distribution function, \text{qsignrank} gives the quantile function, and \text{rsignrank} generates random deviates.

The length of the result is determined by \( \text{nn} \) for \text{rsignrank}, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than \( \text{nn} \) are recycled to the length of the result. Only the first elements of the logical parameters are used.

Author(s)
Kurt Hornik; efficiency improvement by Ivo Ugrina.
simulate

See Also

wilcox.test to calculate the statistic from data, find p values and so on.

Distributions for standard distributions, including dwilcox for the distribution of two-sample Wilcoxon rank sum statistic.

Examples

require(graphics)

par(mfrow = c(2,2))
for(n in c(4:5,10,40)) {
  x <- seq(0, n*(n+1)/2, length = 501)
  plot(x, dsignrank(x, n = n), type = "l",
       main = paste0("dsignrank(x, n = ", n, ", ")
  }

Simulate Responses

Description

Simulate one or more responses from the distribution corresponding to a fitted model object.

Usage

simulate(object, nsim = 1, seed = NULL, ...)

Arguments

object an object representing a fitted model.
nsim number of response vectors to simulate. Defaults to 1.
seed an object specifying if and how the random number generator should be initialized ("seeded").

For the "lm" method, either NULL or an integer that will be used in a call to set.seed before simulating the response vectors. If set, the value is saved as the "seed" attribute of the returned value. The default, NULL will not change the random generator state, and return .Random.seed as the "seed" attribute, see 'Value'.

... additional optional arguments.

Details

This is a generic function. Consult the individual modeling functions for details on how to use this function.

Package stats has a method for "lm" objects which is used for lm and glm fits. There is a method for fits from glm.nb in package MASS, and hence the case of negative binomial families is not covered by the "lm" method.

The methods for linear models fitted by lm or glm(family = "gaussian") assume that any weights which have been supplied are inversely proportional to the error variance. For other GLMs
the (optional) simulate component of the family object is used—there is no appropriate simulation method for ‘quasi’ models as they are specified only up to two moments.

For binomial and Poisson GLMs the dispersion is fixed at one. Integer prior weights \( w_i \) can be interpreted as meaning that observation \( i \) is an average of \( w_i \) observations, which is natural for binomials specified as proportions but less so for a Poisson, for which prior weights are ignored with a warning.

For a gamma GLM the shape parameter is estimated by maximum likelihood (using function `gamma.shape` in package MASS). The interpretation of weights is as multipliers to a basic shape parameter, since dispersion is inversely proportional to shape.

For an inverse gaussian GLM the model assumed is \( IG(\mu_i, \lambda w_i) \) (see \url{http://en.wikipedia.org/wiki/Inverse_Gaussian_distribution}) where \( \lambda \) is estimated by the inverse of the dispersion estimate for the fit. The variance is \( \mu_i^3/(\lambda w_i) \) and hence inversely proportional to the prior weights. The simulation is done by function `rinvgauss` from the SuppDists package, which must be installed.

**Value**

Typically, a list of length `nsim` of simulated responses. Where appropriate the result can be a data frame (which is a special type of list).

For the "lm" method, the result is a data frame with an attribute "seed". If argument `seed` is NULL, the attribute is the value of `.Random.seed` before the simulation was started; otherwise it is the value of the argument with a "kind" attribute with value as.list(RNGkind()).

**See Also**

RNG about random number generation in R, fitted.values and residuals for related methods; glm, lm for model fitting.

There are further examples in the ‘simulate.R’ tests file in the sources for package stats.

**Examples**

```r
x <- 1:5
mod1 <- lm(c(1:3, 7, 6) ~ x)
S1 <- simulate(mod1, nsim = 4)
## repeat the simulation:
.Random.seed <- attr(S1, "seed")
identical(S1, simulate(mod1, nsim = 4))

S2 <- simulate(mod1, nsim = 200, seed = 101)
rowMeans(S2) # should be about the same as fitted(mod1)

## repeat identically:
(sseed <- attr(S2, "seed")) # seed; RNGkind as attribute
stopifnot(identical(S2, simulate(mod1, nsim = 200, seed = sseed)))

## To be sure about the proper RNGkind, e.g., after
RNGversion("2.7.0")
## first set the RNG kind, then simulate
do.call(RNGkind, attr(sseed, "kind"))
identical(S2, simulate(mod1, nsim = 200, seed = sseed))

## Binomial GLM examples
Tukey’s (Running Median) Smoothing

Description

Tukey’s smoother, 3RS3R, 3RSS, 3R, etc.

Usage

smooth(x, kind = c("3RS3R", "3RSS", "3RSR", "3R", "3", "S"),
       twiceit = FALSE, endrule = "Tukey", do.ends = FALSE)

Arguments

x  a vector or time series
kind a character string indicating the kind of smoother required; defaults to "3RS3R".
twiceit logical, indicating if the result should be ‘twiced’. Twicing a smoother $S(y)$ means $S(y) + S(y - S(y))$, i.e., adding smoothed residuals to the smoothed values. This decreases bias (increasing variance).
endrule a character string indicating the rule for smoothing at the boundary. Either "Tukey" (default) or "copy".
do.ends logical, indicating if the 3-splitting of ties should also happen at the boundaries (ends). This is only used for kind = "S".

Details

3 is Tukey’s short notation for running medians of length 3,
3R stands for Repeated 3 until convergence, and
S for Splitting of horizontal stretches of length 2 or 3.
Hence, 3RS3R is a concatenation of 3R, S and 3R, 3RSS similarly, whereas 3RSR means first 3R and then ($S$ and 3) Repeated until convergence – which can be bad.

Value

An object of class “tukeysround” (which has print and summary methods) and is a vector or time series containing the smoothed values with additional attributes.
**Note**

S and S-PLUS use a different (somewhat better) Tukey smoother in `smooth(*)`. Note that there are other smoothing methods which provide rather better results. These were designed for hand calculations and may be used mainly for didactical purposes.

Since R version 1.2, `smooth` *does* really implement Tukey's end-point rule correctly (see argument `endrule`).

`kind = "3RS"` has been the default till R-1.1, but it can have very bad properties, see the examples.

Note that repeated application of `smooth(*)` does smooth more, for the "3RS*" kinds.

**References**

**See Also**

`runmed` for running medians; `lowess` and `loess`; `supsmu` and `smooth.spline`.

**Examples**

```r
require(graphics)
## see also  demo(smooth) !

x1 <- c(4, 1, 3, 6, 6, 4, 1, 6, 2, 4, 2) # very artificial
(x3R <- smooth(x1, "3R")) # 2 iterations of "3"
smooth(x3R, kind = "S")

sm.3RS <- function(x, ...) 
  smooth(smooth(x, "3R", ...), "S", ...)

y <- c(1, 1, 19:1)
plot(y, main = "Misbehaviour of \"3RS\"", col.main = 3)
lines(sm.3RS(y))
lines(smooth(y))
lines(smooth(y, "3RS"), col = 3, lwd = 2) # the horror

x <- c(8:10, 10, 0, 0, 9, 9)
plot(x, main = "Breakdown of 3R and S and hence 3RSS")
matlines(cbind(smooth(x, "3R"), smooth(x, "S"), smooth(x, "3RSS"), smooth(x)))

presidents[is.na(presidents)] <- 0 # silly
summary(sm3 <- smooth(presidents, "3R"))
summary(sm2 <- smooth(presidents,"3RSS"))
summary(sm <- smooth(presidents))

all.equal(c(sm2), c(smooth(sm3, "S"), "S")) # 3RSS == 3R S S
all.equal(c(sm), c(smooth(sm3, "S"), "3R")) # 3RS3R == 3R S 3R

plot(presidents, main = "Smooth(presidents, *) : 3R and default 3RS3R")
lines(sm3, col = 3, lwd = 1.5)
lines(sm, col = 2, lwd = 1.25)
```
smooth.spline

**Fit a Smoothing Spline**

**Description**

Fits a cubic smoothing spline to the supplied data.

**Usage**

smooth.spline(x, y = NULL, w = NULL, df, spar = NULL,
   cv = FALSE, all.knots = FALSE, nknots = NULL,
   keep.data = TRUE, df.offset = 0, penalty = 1,
   control.spar = list(), tol = 1e-6 * IQR(x))

**Arguments**

- **x**: a vector giving the values of the predictor variable, or a list or a two-column matrix specifying x and y.
- **y**: responses. If y is missing or NULL, the responses are assumed to be specified by x, with x the index vector.
- **w**: optional vector of weights of the same length as x; defaults to all 1.
- **df**: the desired equivalent number of degrees of freedom (trace of the smoother matrix).
- **spar**: smoothing parameter, typically (but not necessarily) in (0, 1]. The coefficient λ of the integral of the squared second derivative in the fit (penalized log likelihood) criterion is a monotone function of spar, see the details below.
- **cv**: ordinary (TRUE) or 'generalized' cross-validation (GCV) when FALSE; setting it to NA skips the evaluation of leverages and any score.
- **all.knots**: if TRUE, all distinct points in x are used as knots. If FALSE (default), a subset of x[i] is used, specifically x[j] where the nknots indices are evenly spaced in 1:n, see also the next argument nknots.
- **nknots**: integer giving the number of knots to use when all.knots = FALSE. Per default, this is less than n, the number of unique x values for n > 49.
- **keep.data**: logical specifying if the input data should be kept in the result. If TRUE (as per default), fitted values and residuals are available from the result.
- **df.offset**: allows the degrees of freedom to be increased by df.offset in the GCV criterion.
- **penalty**: the coefficient of the penalty for degrees of freedom in the GCV criterion.
- **control.spar**: optional list with named components controlling the root finding when the smoothing parameter spar is computed, i.e., missing or NULL, see below.

**Note** that this is partly experimental and may change with general spar computation improvements!

- **low**: lower bound for spar; defaults to -1.5 (used to implicitly default to 0 in R versions earlier than 1.4).
- **high**: upper bound for spar; defaults to +1.5.
- **tol**: the absolute precision (tolerance) used; defaults to 1e-4 (formerly 1e-3).
**smooth.spline**

- **eps:** the relative precision used; defaults to 2e-8 (formerly 0.00244).
- **trace:** logical indicating if iterations should be traced.
- **maxit:** integer giving the maximal number of iterations; defaults to 500.

Note that spar is only searched for in the interval \([low, high]\).

- **tol**
  A tolerance for same-ness of the \(x\) values. The values are binned into bins of size \(t\) and values which fall into the same bin are regarded as the same. Must be strictly positive (and finite).

**Details**

Neither \(x\) nor \(y\) are allowed to containing missing or infinite values.

The \(x\) vector should contain at least four distinct values. ‘Distinct’ here is controlled by \(tol\): values which are regarded as the same are replaced by the first of their values and the corresponding \(y\) and \(w\) are pooled accordingly.

The computational \(\lambda\) used (as a function of \(s = \text{spar}\)) is \(\lambda = r * 256^{3s-1}\) where \(r = \text{tr}(X'WX)/\text{tr}(\Sigma)\), \(\Sigma\) is the matrix given by \(\Sigma_{ij} = \int B_{i}'(t)B_{j}'(t)dt\), \(X\) is given by \(X_{ij} = B_{j}(x_{i})\), \(W\) is the diagonal matrix of weights (scaled such that its trace is \(n\), the original number of observations) and \(B_{k}(.)\) is the \(k\)-th B-spline.

Note that with these definitions, \(f_{i} = f(x_{i})\), and the B-spline basis representation \(f = Xc\) (i.e., \(c\) is the vector of spline coefficients), the penalized log likelihood is \(L = (y - f)W(y - f) + \lambda e' \Sigma e\), and hence \(c\) is the solution of the (ridge regression) \((X'WX + \lambda \Sigma)c = X'Wy\).

If spar is missing or NULL, the value of df is used to determine the degree of smoothing. If both are missing, leave-one-out cross-validation (ordinary or ‘generalized’ as determined by \(cv\)) is used to determine \(\lambda\). Note that from the above relation, spar is \(s = s_{0} + 0.0601* \log\lambda\), which is intentionally different from the S-PLUS implementation of smooth.spline (where spar is proportional to \(\lambda\)). In R’s (\(\log\lambda\)) scale, it makes more sense to vary spar linearly.

Note however that currently the results may become very unreliable for spar values smaller than about -1 or -2. The same may happen for values larger than 2 or so. Don’t think of setting spar or the controls low and high outside such a safe range, unless you know what you are doing!

The ‘generalized’ cross-validation method will work correctly when there are duplicated points in \(x\). However, it is ambiguous what leave-one-out cross-validation means with duplicated points, and the internal code uses an approximation that involves leaving out groups of duplicated points. \(cv = \text{TRUE}\) is best avoided in that case.

**Value**

An object of class "smooth.spline" with components

- **x**
  the distinct \(x\) values in increasing order, see the ‘Details’ above.
- **y**
  the fitted values corresponding to \(x\).
- **w**
  the weights used at the unique values of \(x\).
- **yin**
  the \(y\) values used at the unique \(y\) values.

**data**

only if keep.data = TRUE: itself a list with components \(x\), \(y\) and \(w\) of the same length. These are the original \((x_{i}, y_{i}, w_{i}), i = 1, \ldots, n\), values where data\(\times\)x may have repeated values and hence be longer than the above \(x\) component; see details.

**lev**

when \(cv\) was not NA) leverages, the diagonal values of the smoother matrix.
smooth.spline

cv.crit: cross-validation score, ‘generalized’ or true, depending on cv.
pen.crit: penalized criterion
crit: the criterion value minimized in the underlying .Fortran routine ‘ss1vrg’.
df: equivalent degrees of freedom used. Note that (currently) this value may become quite imprecise when the true df is between 1 and 2.
spar: the value of spar computed or given.
lambda: the value of λ corresponding to spar, see the details above.
iparms: named integer(3) vector where ..$ipars["iter"] gives number of spar computing iterations used.
fit: list for use by predict.smooth.spline, with components
knot: the knot sequence (including the repeated boundary knots).
k: number of coefficients or number of ‘proper’ knots plus 2.
coef: coefficients for the spline basis used.
min, range: numbers giving the corresponding quantities of x.
call: the matched call.

Note
The default all.knots = FALSE and nknots = NULL entails using only $O(n^{0.2})$ knots instead of $n$ for $n > 49$. This cuts speed and memory requirements, but not drastically anymore since R version 1.5.1 where it is only $O(n_k) + O(n)$ where $n_k$ is the number of knots. In this case where not all unique x values are used as knots, the result is not a smoothing spline in the strict sense, but very close unless a small smoothing parameter (or large df) is used.

Author(s)
R implementation by B. D. Ripley and Martin Maechler (spar/lambda, etc).

Source
This function is based on code in the GAMFIT Fortran program by T. Hastie and R. Tibshirani (http://lib.stat.cmu.edu/general/), which makes use of spline code by Finbarr O’Sullivan. Its design parallels the smooth.spline function of Chambers & Hastie (1992).

References

See Also
predict.smooth.spline for evaluating the spline and its derivatives.
smoothEnds

**Description**

Smooth end points of a vector `y` using subsequently smaller medians and Tukey’s end point rule at the very end. (of odd span).

**Usage**

`smoothEnds(y, k = 3)`
smoothEnds

Arguments

y  dependent variable to be smoothed (vector).
k  width of largest median window; must be odd.

Details

smoothEnds is used to only do the ‘end point smoothing’, i.e., change at most the observations closer to the beginning/end than half the window k. The first and last value are computed using Tukey’s end point rule, i.e., $\text{sm}[1] = \text{median}(y[1], \text{sm}[2], 3*\text{sm}[2] - 2*\text{sm}[3])$.

Value

vector of smoothed values, the same length as y.

Author(s)

Martin Maechler

`runmed(*)`, `endrule = "median"`) which calls smoothEnds()

Examples

```r
require(graphics)
y <- ys <- (-20:20)^2
y [c(1,10,21,41)] <- c(100, 30, 400, 470)
s7k <- runmed(y, 7, endrule = "keep")
s7. <- runmed(y, 7, endrule = "const")
s7m <- runmed(y, 7)
col3 <- c("midnightblue","blue","steelblue")
plot(y, main = "Running Medians -- runmed(*, k=7, end.rule = X)")
matlines(chind(s7k, s7, s7m), lwd = 1.5, lty = 1, col = col3)
legend(1, 470, paste("endrule", c("keep","constant","median"), sep = " "),
       col = col3, lwd = 1.5, lty = 1)
stopifnot(identical(s7m, smoothEnds(s7k, 7)))
```
Create a sortedxyData Object

Description
This is a constructor function for the class of sortedxyData objects. These objects are mostly used in the initial function for a self-starting nonlinear regression model, which will be of the selfStart class.

Usage
sortedxyData(x, y, data)

Arguments
- **x**: a numeric vector or an expression that will evaluate in data to a numeric vector
- **y**: a numeric vector or an expression that will evaluate in data to a numeric vector
- **data**: an optional data frame in which to evaluate expressions for x and y, if they are given as expressions

Value
A sortedxyData object. This is a data frame with exactly two numeric columns, named x and y. The rows are sorted so the x column is in increasing order. Duplicate x values are eliminated by averaging the corresponding y values.

Author(s)
José Pinheiro and Douglas Bates

See Also
selfStart, NLSstClosestX, NLSstLfAsymptote, NLSstRtAsymptote

Examples
```r
dnaseNR <- DNase[ DNase$Run == "2", ]
sortedxyData( expression(log(conc)), expression(density), DNase )
```

Estimate Spectral Density of a Time Series from AR Fit

Description
Fits an AR model to x (or uses the existing fit) and computes (and by default plots) the spectral density of the fitted model.

Usage
spec.ar(x, n.freq, order = NULL, plot = TRUE, na.action = na.fail, method = "yule-walker", ...)

Arguments

- **x**: A univariate (not yet:or multivariate) time series or the result of a fit by `ar`.
- **n.freq**: The number of points at which to plot.
- **order**: The order of the AR model to be fitted. If omitted, the order is chosen by AIC.
- **plot**: Plot the periodogram?
- **na.action**: NA action function.
- **method**: Method for `ar` fit.
- **...**: Graphical arguments passed to `plot.spec`.

Value

An object of class "spec". The result is returned invisibly if `plot` is true.

Warning

Some authors, for example Thomson (1990), warn strongly that AR spectra can be misleading.

Note

The multivariate case is not yet implemented.

References

See Also

`ar`, `spectrum`.

Examples

```r
require(graphics)
spec.ar(lh)
spec.ar(ldeaths)
spec.ar(ldeaths, method = "burg")
spec.ar(log(lynx))
spec.ar(log(lynx), method = "burg", add = TRUE, col = "purple")
spec.ar(log(lynx), method = "mle", add = TRUE, col = "forest green")
spec.ar(log(lynx), method = "ols", add = TRUE, col = "blue")
```
**Description**

`spec.pgram` calculates the periodogram using a fast Fourier transform, and optionally smooths the result with a series of modified Daniell smoothers (moving averages giving half weight to the end values).

**Usage**

```r
spec.pgram(x, spans = NULL, kernel, taper = 0.1,
          pad = 0, fast = TRUE, demean = FALSE, detrend = TRUE,
          plot = TRUE, na.action = na.fail, ...)
```

**Arguments**

- `x` : univariate or multivariate time series.
- `spans` : vector of odd integers giving the widths of modified Daniell smoothers to be used to smooth the periodogram.
- `kernel` : alternatively, a kernel smoother of class "tskernel".
- `taper` : specifies the proportion of data to taper. A split cosine bell taper is applied to this proportion of the data at the beginning and end of the series.
- `pad` : proportion of data to pad. Zeros are added to the end of the series to increase its length by the proportion `pad`.
- `fast` : logical; if `TRUE`, pad the series to a highly composite length.
- `demean` : logical. If `TRUE`, subtract the mean of the series.
- `detrend` : logical. If `TRUE`, remove a linear trend from the series. This will also remove the mean.
- `plot` : plot the periodogram?
- `na.action` : NA action function.
- `...` : graphical arguments passed to `plot.spec`.

**Details**

The raw periodogram is not a consistent estimator of the spectral density, but adjacent values are asymptotically independent. Hence a consistent estimator can be derived by smoothing the raw periodogram, assuming that the spectral density is smooth.

The series will be automatically padded with zeros until the series length is a highly composite number in order to help the Fast Fourier Transform. This is controlled by the `fast` and not the `pad` argument.

The periodogram at zero is in theory zero as the mean of the series is removed (but this may be affected by tapering): it is replaced by an interpolation of adjacent values during smoothing, and no value is returned for that frequency.
Value

A list object of class "spec" (see \texttt{spectrum}) with the following additional components:

- \texttt{kernel} The kernel argument, or the kernel constructed from spans.
- \texttt{df} The distribution of the spectral density estimate can be approximated by a (scaled) chi square distribution with \texttt{df} degrees of freedom.
- \texttt{bandwidth} The equivalent bandwidth of the kernel smoother as defined by Bloomfield (1976, page 201).
- \texttt{taper} The value of the taper argument.
- \texttt{pad} The value of the pad argument.
- \texttt{detrend} The value of the detrend argument.
- \texttt{demean} The value of the demean argument.

The result is returned invisibly if \texttt{plot} is true.

spectrum(ideaths, spans = c(5,7))
spectrum(mdeaths, spans = c(3,3))
spectrum(fdeaths, spans = c(3,3))

## bivariate example
mfdeaths.spc <- spec.pgram(ts.union(mdeaths, fdeaths), spans = c(3,3))
# plots marginal spectra: now plot coherency and phase
plot(mfdeaths.spc, plot.type = "coherency")
plot(mfdeaths.spc, plot.type = "phase")

## now impose a lack of alignment
mfdeaths.spc <- spec.pgram(ts.intersect(mdeaths, lag(fdeaths, 4)),
                           spans = c(3,3), plot = FALSE)
plot(mfdeaths.spc, plot.type = "coherency")
plot(mfdeaths.spc, plot.type = "phase")
```
spec.taper

Taper a Time Series by a Cosine Bell

Description
Apply a cosine-bell taper to a time series.

Usage
spec.taper(x, p = 0.1)

Arguments
x A univariate or multivariate time series
p The proportion to be tapered at each end of the series, either a scalar (giving the proportion for all series) or a vector of the length of the number of series (giving the proportion for each series).

Details
The cosine-bell taper is applied to the first and last \( p[i] \) observations of time series \( x[, i] \).

Value
A new time series object.

See Also
spec.pgram, cpgram
The *spectrum* function estimates the spectral density of a time series.

Usage

spectrum(x, ..., method = c("pgram", "ar"))

Arguments

x
A univariate or multivariate time series.

method
String specifying the method used to estimate the spectral density. Allowed methods are "pgram" (the default) and "ar".

Further arguments to specific spec methods or plot.spec.

Details

*spectrum* is a wrapper function which calls the methods *spec.pgram* and *spec.ar*.

The spectrum here is defined with scaling $1/\text{frequency}(x)$, following S-PLUS. This makes the spectral density a density over the range $(-\text{frequency}(x)/2, +\text{frequency}(x)/2]$, whereas a more common scaling is $2\pi$ and range $(-0.5, 0.5]$ (e.g., Bloomfield) or 1 and range $(-\pi, \pi]$.

If available, a confidence interval will be plotted by plot.spec: this is asymmetric, and the width of the centre mark indicates the equivalent bandwidth.

Value

An object of class "spec", which is a list containing at least the following components:

- **freq**: vector of frequencies at which the spectral density is estimated. (Possibly approximate Fourier frequencies.) The units are the reciprocal of cycles per unit time (and not per observation spacing): see ‘Details’ below.
- **spec**: Vector (for univariate series) or matrix (for multivariate series) of estimates of the spectral density at frequencies corresponding to *freq*.
- **coh**: NULL for univariate series. For multivariate time series, a matrix containing the *squared* coherency between different series. Column $i + (j - 1) \times (j - 2)/2$ of *coh* contains the squared coherency between columns $i$ and $j$ of *x*, where $i < j$.
- **phase**: NULL for univariate series. For multivariate time series a matrix containing the cross-spectrum phase between different series. The format is the same as *coh*.
- **series**: The name of the time series.
- **snames**: For multivariate input, the names of the component series.
- **method**: The method used to calculate the spectrum.

The result is returned invisibly if plot is true.
Note
The default plot for objects of class "spec" is quite complex, including an error bar and default title, subtitle and axis labels. The defaults can all be overridden by supplying the appropriate graphical parameters.

---

**splinefun**  

**Interpolating Splines**

**Description**
Perform cubic (or Hermite) spline interpolation of given data points, returning either a list of points obtained by the interpolation or a function performing the interpolation.
splinefun

Usage

splinefun(x, y = NULL,
    method = c("fmm", "periodic", "natural", "monoH.FC", "hyman"),
    ties = mean)

spline(x, y = NULL, n = 3*length(x), method = "fmm",
    xmin = min(x), xmax = max(x), xout, ties = mean)

splinefunH(x, y, m)

Arguments

x, y vectors giving the coordinates of the points to be interpolated. Alternatively a
single plotting structure can be specified: see xy.coords.
y must be increasing or decreasing for method = "hyman".

m (for splinefunH()): vector of slopes $m_i$ at the points $(x_i, y_i)$; these together
determine the Hermite “spline” which is piecewise cubic, (only) once differentiable continuously.

method specifies the type of spline to be used. Possible values are "fmm", "natural", "periodic", "monoH.FC" and "hyman".

n if xout is left unspecified, interpolation takes place at $n$ equally spaced points
spanning the interval $[xmin, xmax]$.

xmin, xmax left-hand and right-hand endpoint of the interpolation interval (when xout is
unspecified).

xout an optional set of values specifying where interpolation is to take place.

ties Handling of tied x values. Either a function with a single vector argument returning a single number result or the string "ordered".

Details

The inputs can contain missing values which are deleted, so at least one complete $(x, y)$ pair is
required. If method = "fmm", the spline used is that of Forsythe, Malcolm and Moler (an exact
cubic is fitted through the four points at each end of the data, and this is used to determine the end conditions). Natural splines are used when method = "natural", and periodic splines when
method = "periodic".

The method "monoH.FC" computes a monotone Hermite spline according to the method of Fritsch
and Carlson. It does so by determining slopes such that the Hermite spline, determined by
$(x_i, y_i, m_i)$, is monotone (increasing or decreasing) iff the data are.

Method "hyman" computes a monotone cubic spline using Hyman filtering of an method = "fmm"
fit for strictly monotonic inputs. (Added in R 2.15.2.)

These interpolation splines can also be used for extrapolation, that is prediction at points outside
the range of x. Extrapolation makes little sense for method = "fmm"; for natural splines it is linear
using the slope of the interpolating curve at the nearest data point.

Value

spline returns a list containing components x and y which give the ordinates where interpolation
took place and the interpolated values.

splinefun returns a function with formal arguments x and deriv, the latter defaulting to zero. This
function can be used to evaluate the interpolating cubic spline (deriv = 0), or its derivatives (deriv = 1,2,3)
splinefun

= 1, 2, 3) at the points x, where the spline function interpolates the data points originally specified. It uses data stored in its environment when it was created, the details of which are subject to change.

Warning

The value returned by splinefun contains references to the code in the current version of R: it is not intended to be saved and loaded into a different R session. This is safer in R >= 3.0.0.

SSasymp

Self-Starting Nls Asymptotic Regression Model

Description

This selfStart model evaluates the asymptotic regression function and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters Asym, R0, and lrc for a given set of data.

Usage

SSasymp(input, Asym, R0, lrc)

Arguments

input  
a numeric vector of values at which to evaluate the model.

Asym  
a numeric parameter representing the horizontal asymptote on the right side (very large values of input).

R0  
a numeric parameter representing the response when input is zero.

lrc  
a numeric parameter representing the natural logarithm of the rate constant.

Value

a numeric vector of the same length as input. It is the value of the expression Asym*(R0-Asym)*exp(-exp(lrc)*input). If all of the arguments Asym, R0, and lrc are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

SSasymp( Lob.329$age, 100, -8.5, -3.2 ) # response only
Asym <- 100
resp0 <- -8.5
lrc <- -3.2
SSasymp( Lob.329$age, Asym, resp0, lrc ) # response and gradient
getInitial(height ~ SSasymp( age, Asym, resp0, lrc ), data = Lob.329)
## Initial values are in fact the converged values
fml <- nls(height ~ SSasymp( age, Asym, resp0, lrc ), data = Lob.329)
summary(fml)
```

Description

This `selfStart` model evaluates an alternative parametrization of the asymptotic regression function and the gradient with respect to those parameters. It has an `initial` attribute that creates initial estimates of the parameters `Asym`, `lrc`, and `c0`.

Usage

```r
SSasympOff(input, Asym, lrc, c0)
```

Arguments

- **input**: a numeric vector of values at which to evaluate the model.
- **Asym**: a numeric parameter representing the horizontal asymptote on the right side (very large values of `input`).
- **lrc**: a numeric parameter representing the natural logarithm of the rate constant.
- **c0**: a numeric parameter representing the input for which the response is zero.

Value

A numeric vector of the same length as `input`. It is the value of the expression `Asym*(1 - exp(-exp(lrc)*(input - c0)))`. If all of the arguments `Asym`, `lrc`, and `c0` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

fml <- nls(uptake ~ SSasympOff(conc, Asym, lrc, c0), data = CO2.Qn1)
summary(fml)

Description

This `selfStart` model evaluates the asymptotic regression function through the origin and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters `Asym` and `lrc` for a given set of data.

Usage

`SSasympOrig(input, Asym, lrc)`

Arguments

- `input`  a numeric vector of values at which to evaluate the model.
- `Asym`  a numeric parameter representing the horizontal asymptote.
- `lrc`  a numeric parameter representing the natural logarithm of the rate constant.

Value

a numeric vector of the same length as `input`. It is the value of the expression `Asym*(1 - exp(-exp(lrc)*input))`. If all of the arguments `Asym` and `lrc` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

getInitial(height ~ SSasymOrig(age, Asym, lrc), data = Lob.329)
## Initial values are in fact the converged values
fml <- nls(height ~ SSasymOrig(age, Asym, lrc), data = Lob.329)
summary(fml)
```

Description

This selfStart model evaluates the biexponential model function and its gradient. It has an initial attribute that creates initial estimates of the parameters \( A_1, \ln r_1, A_2, \) and \( \ln r_2 \).

Usage

```r
SSbiexp(input, A1, lrc1, A2, lrc2)
```

Arguments

- **input**: a numeric vector of values at which to evaluate the model.
- **A1**: a numeric parameter representing the multiplier of the first exponential.
- **lrc1**: a numeric parameter representing the natural logarithm of the rate constant of the first exponential.
- **A2**: a numeric parameter representing the multiplier of the second exponential.
- **lrc2**: a numeric parameter representing the natural logarithm of the rate constant of the second exponential.

Value

A numeric vector of the same length as `input`. It is the value of the expression \( A_1 \cdot e^{\ln r_1 \cdot \text{input}} + A_2 \cdot e^{\ln r_2 \cdot \text{input}} \). If all of the arguments `A1`, `lrc1`, `A2`, and `lrc2` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSD Matrix and Estimated Variance Matrix in Multivariate Models

Description

Functions to compute matrix of residual sums of squares and products, or the estimated variance matrix for multivariate linear models.

Usage

# S3 method for class 'mlm'
SSD(object, ...)

# S3 methods for class 'SSD' and 'mlm'
estVar(object, ...)

Arguments

object object of class "mlm", or "SSD" in the case of estVar.
... Unused

Value

SSD() returns a list of class "SSD" containing the following components

SSD The residual sums of squares and products matrix
df Degrees of freedom
call Copied from object

estVar returns a matrix with the estimated variances and covariances.

*Self-Starting Nls Four-Parameter Logistic Model*

**Description**

This `selfStart` model evaluates the four-parameter logistic function and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters `A`, `B`, `xmid`, and `scal` for a given set of data.

**Usage**

`SSfpl(input, A, B, xmid, scal)`

**Arguments**

- `input` a numeric vector of values at which to evaluate the model.
- `A` a numeric parameter representing the horizontal asymptote on the left side (very small values of `input`).
- `B` a numeric parameter representing the horizontal asymptote on the right side (very large values of `input`).
- `xmid` a numeric parameter representing the input value at the inflection point of the curve. The value of `SSfpl` will be midway between `A` and `B` at `xmid`.
- `scal` a numeric scale parameter on the input axis.

**Value**

a numeric vector of the same length as `input`. It is the value of the expression \( A + (B - A) / (1 + \exp((xmid - input) / scal)) \). If all of the arguments `A`, `B`, `xmid`, and `scal` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSgompertz Self-Starting Nls Gompertz Growth Model

Description
This selfStart model evaluates the Gompertz growth model and its gradient. It has an initial attribute that creates initial estimates of the parameters Asym, b2, and b3.

Usage
SSgompertz(x, Asym, b2, b3)

Arguments

  x a numeric vector of values at which to evaluate the model.

  Asym a numeric parameter representing the asymptote.

  b2 a numeric parameter related to the value of the function at x = 0

  b3 a numeric parameter related to the scale the x axis.

Value

  a numeric vector of the same length as input. It is the value of the expression Asym*exp(-b2+b3*x). If all of the arguments Asym, b2, and b3 are names of objects the gradient matrix with respect to these names is attached as an attribute named gradient.

### SSlogis

**Self-Starting Nls Logistic Model**

**Description**

This `selfStart` model evaluates the logistic function and its gradient. It has an initial attribute that creates initial estimates of the parameters `Asym`, `xmid`, and `scal`.

**Usage**

`SSlogis(input, Asym, xmid, scal)`

**Arguments**

- `input`: A numeric vector of values at which to evaluate the model.
- `Asym`: A numeric parameter representing the asymptote.
- `xmid`: A numeric parameter representing the `x` value at the inflection point of the curve. The value of `SSlogis` will be `Asym/2` at `xmid`.
- `scal`: A numeric scale parameter on the `input` axis.

**Value**

A numeric vector of the same length as `input`. It is the value of the expression `Asym/(1+exp((xmid-input)/scal))`. If all of the arguments `Asym`, `xmid`, and `scal` are names of objects the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSmicmen

Self-Starting Nls Michaelis-Menten Model

Description

This selfStart model evaluates the Michaelis-Menten model and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters \( V_m \) and \( K \).

Usage

    SSmicmen(input, Vm, K)

Arguments

- `input`: a numeric vector of values at which to evaluate the model.
- `Vm`: a numeric parameter representing the maximum value of the response.
- `K`: a numeric parameter representing the input value at which half the maximum response is attained. In the field of enzyme kinetics this is called the Michaelis parameter.

Value

a numeric vector of the same length as `input`. It is the value of the expression \( V_m \times \text{input} / (K + \text{input}) \). If both the arguments `Vm` and `K` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSweibull

Self-Starting Nls Weibull Growth Curve Model

Description

This selfStart model evaluates the Weibull model for growth curve data and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters Asym, Drop, 1rc, and pwr for a given set of data.

Usage

SSweibull(x, Asym, Drop, 1rc, pwr)

Arguments

- **x**: a numeric vector of values at which to evaluate the model.
- **Asym**: a numeric parameter representing the horizontal asymptote on the right side (very small values of x).
- **Drop**: a numeric parameter representing the change from Asym to the y intercept.
- **1rc**: a numeric parameter representing the natural logarithm of the rate constant.
- **pwr**: a numeric parameter representing the power to which x is raised.

Details

This model is a generalization of the SSasym model in that it reduces to SSasym when pwr is unity.

Value

a numeric vector of the same length as x. It is the value of the expression Asym-Drop*exp(-exp(1rc)*x^pwr). If all of the arguments Asym, Drop, 1rc, and pwr are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

**start**

Encode the Terminal Times of Time Series

Description

Extract and encode the times the first and last observations were taken. Provided only for compatibility with S version 2.

Usage

```r
start(x, ...)  
end(x, ...)
```

Arguments

- `x` a univariate or multivariate time-series, or a vector or matrix.
- `...` extra arguments for future methods.

Details

These are generic functions, which will use the `tsp` attribute of `x` if it exists. Their default methods decode the start time from the original time units, so that for a monthly series 1995.5 is represented as `c(1995, 7)`. For a series of frequency `f`, time `n+i/f` is presented as `c(n, i+1)` (even for `i = 0` and `f = 1`).

Warning

The representation used by `start` and `end` has no meaning unless the frequency is supplied.

ts, time, tsp.
GLM Anova Statistics

Description

This is a utility function, used in lm and glm methods for anova(..., test != NULL) and should not be used by the average user.

Usage

```r
stat.anova(table, test = c("Rao", "LRT", "Chisq", "F", "Cp"),
           scale, df.scale, n)
```

Arguments

- `table`: numeric matrix as results from `anova.glm(..., test = NULL)`.
- `test`: a character string, matching one of "Rao", "LRT", "Chisq", "F" or "Cp".
- `scale`: a residual mean square or other scale estimate to be used as the denominator in an F test.
- `df.scale`: degrees of freedom corresponding to `scale`.
- `n`: number of observations.

Value

A matrix which is the original `table`, augmented by a column of test statistics, depending on the `test` argument.

References

See Also

`anova.lm`, `anova.glm`.

Examples

```r
###-- Continued from '?glm':

print(ag <- anova(glm.D93))
stat.anova(ag$table, test = "Cp",
          scale = sum(resid(glm.D93, "pearson")^2)/4,
          df.scale = 4, n = 9)
```
Description

These functions are provided for compatibility with older versions of \texttt{R} only, and may be defunct as soon as the next release.

Usage

\texttt{plot\_clus}(tree, hang = 0.1, unit = FALSE, level = FALSE, hmin = 0, square = TRUE, labels = NULL, plot. = TRUE, axes = TRUE, frame.plot = FALSE, ann = TRUE, main = "", sub = NULL, xlab = NULL, ylab = "Height")

Arguments

tree
an object of the type produced by \texttt{hclust}.

hang
The fraction of the plot height by which labels should hang below the rest of the plot. A negative value will cause the labels to hang down from 0.

unit
logical. If true, the splits are plotted at equally-spaced heights rather than at the height in the object.

labels
A character vector of labels for the leaves of the tree. By default the row names or row numbers of the original data are used. If \texttt{labels = FALSE} no labels at all are plotted.

axes, frame.plot, ann
logical flags as in \texttt{plot.default}.

main, sub, xlab, ylab
character strings for \texttt{title}. \texttt{sub} and \texttt{xlab} have a non-NULL default when there’s a \texttt{tree$call}.

... Further graphical arguments. E.g. \texttt{cex} controls the size of the labels (if plotted) in the same way as \texttt{text}.

hmin
numeric. All heights less than \texttt{hmin} are regarded as being \texttt{hmin}: this can be used to suppress detail at the bottom of the tree.

level, square, plot.
unimplemented arguments for S-PLUS compatibility.

Details

\texttt{plot\_clus} is a deprecated wrapper for the \texttt{plot} method for \texttt{hclust}, provided long ago for S-PLUS compatibility.

See Also

\texttt{Deprecated}
**Description**

Select a formula-based model by AIC.

**Usage**

```r
step(object, scope, scale = 0,
     direction = c("both", "backward", "forward"),
     trace = 1, keep = NULL, steps = 1000, k = 2, ...)
```

**Arguments**

- `object`: an object representing a model of an appropriate class (mainly "lm" and "glm"). This is used as the initial model in the stepwise search.
- `scope`: defines the range of models examined in the stepwise search. This should be either a single formula, or a list containing components `upper` and `lower`, both formulae. See the details for how to specify the formulae and how they are used.
- `scale`: used in the definition of the AIC statistic for selecting the models, currently only for `lm`, `aov` and `glm` models. The default value, 0, indicates the scale should be estimated: see `extractAIC`.
- `direction`: the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the `scope` argument is missing the default for `direction` is "backward".
- `trace`: if positive, information is printed during the running of `step`. Larger values may give more detailed information.
- `keep`: a filter function whose input is a fitted model object and the associated AIC statistic, and whose output is arbitrary. Typically `keep` will select a subset of the components of the object and return them. The default is not to keep anything.
- `steps`: the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.
- `k`: the multiple of the number of degrees of freedom used for the penalty. Only \( k = 2 \) gives the genuine AIC: \( k = \log(n) \) is sometimes referred to as BIC or SBC.
- `...`: any additional arguments to `extractAIC`.

**Details**

`step` uses `add1` and `drop1` repeatedly; it will work for any method for which they work, and that is determined by having a valid method for `extractAIC`. When the additive constant can be chosen so that AIC is equal to Mallows' \( C_p \), this is done and the tables are labelled appropriately.

The set of models searched is determined by the `scope` argument. The right-hand-side of its `lower` component is always included in the model, and right-hand-side of the model is included in the `upper` component. If `scope` is a single formula, it specifies the `upper` component, and the `lower` model is empty. If `scope` is missing, the initial model is used as the `upper` model.
Models specified by `scope` can be templates to update `object` as used by `update.formula`. So using `.` in a `scope` formula means 'what is already there', with `.^2` indicating all interactions of existing terms.

There is a potential problem in using `glm` fits with a variable `scale`, as in that case the deviance is not simply related to the maximized log-likelihood. The "glm" method for function `extractAIC` makes the appropriate adjustment for a `gaussian` family, but may need to be amended for other cases. (The `binomial` and `poisson` families have fixed `scale` by default and do not correspond to a particular maximum-likelihood problem for variable `scale`.)

**Value**

the stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the `keep=` argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding `lm`, `aov` and `survreg` fits, for example).

**Warning**

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and R's default of `na.action = na.omit` is used. We suggest you remove the missing values first.

Calls to the function `nobs` are used to check that the number of observations involved in the fitting process remains unchanged.

**Note**

This function differs considerably from the function in S, which uses a number of approximations and does not in general compute the correct AIC.

This is a minimal implementation. Use `stepAIC` in package `MASS` for a wider range of object classes.

**Author(s)**

B. D. Ripley: `step` is a slightly simplified version of `stepAIC` in package `MASS` (Venables & Ripley, 2002 and earlier editions).

The idea of a `step` function follows that described in Hastie & Pregibon (1992); but the implementation in R is more general.

**stepfun**

**Step Function Class**

**Description**

Given the vectors \((x_1, \ldots, x_n)\) and \((y_0, y_1, \ldots, y_n)\) (one value more!), \(\text{stepfun}(x, y, \ldots)\) returns an interpolating ‘step’ function, say \(fn\). I.e., \(fn(t) = c_i\) (constant) for \(t \in (x_i, x_{i+1})\) and at the abscissa values, if (by default) \(\text{right} = \text{FALSE}\), \(fn(x_i) = y_i\) and for \(\text{right} = \text{TRUE}\), \(fn(x_i) = y_{i-1}\), for \(i = 1, \ldots, n\).

The value of the constant \(c_i\) above depends on the ‘continuity’ parameter \(f\). For the default, \(\text{right} = \text{FALSE}\), \(f = 0\), \(fn\) is a \textit{cadlag} function, i.e., continuous at right, limit (‘the point’) at left. In general, \(c_i\) is interpolated in between the neighbouring \(y\) values, \(c_i = (1 - f) y_i + f \cdot y_{i+1}\). Therefore, for non-0 values of \(f\), \(fn\) may no longer be a proper step function, since it can be discontinuous from both sides, unless \(\text{right} = \text{TRUE}\), \(f = 1\) which is right-continuous.

**Usage**

```r
stepfun(x, y, f = as.numeric(right), ties = "ordered",
       right = FALSE)

is.stepfun(x)
knots(Fn, ...)
as.stepfun(x, ...)

## S3 method for class 'stepfun'
print(x, digits = getOption("digits") - 2, ...)

## S3 method for class 'stepfun'
summary(object, ...)
```

**Arguments**

- **x** numeric vector giving the knots or jump locations of the step function for \(\text{stepfun}\). For the other functions, \(x\) is as object below.
- **y** numeric vector one longer than \(x\), giving the heights of the function values between the \(x\) values.
- **f** a number between 0 and 1, indicating how interpolation outside the given \(x\) values should happen. See \texttt{approxfun}.
- **ties** Handling of tied \(x\) values. Either a function or the string "ordered". See \texttt{approxfun}.
right logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa.

Fn, object an R object inheriting from "stepfun".
digits number of significant digits to use, see print.

... potentially further arguments (required by the generic).

Value
A function of class "stepfun", say fn.
There are methods available for summarizing ("summary(.)"), representing ("print(.)") and plotting ("plot(.)", see plot.stepfun) "stepfun" objects.
The environment of fn contains all the information needed;
"x", "y" the original arguments
"n" number of knots (x values)
"f" continuity parameter
"yleft", "yright" the function values outside the knots
"method" (always == "constant", from approxfun(.)).
The knots are also available via knots(fn).

          identical(y0[-4], sfunlc(1:3))) # right = TRUE
Description

Decompose a time series into seasonal, trend and irregular components using loess, acronym STL.

Usage

\[
\text{stl}(x, \text{s.window}, \text{s.degree} = 0, \\
\quad \text{t.window} = \text{NULL}, \text{t.degree} = 1, \\
\quad \text{l.window} = \text{nextodd}(\text{period}), \text{l.degree} = \text{t.degree}, \\
\quad \text{s.jump} = \text{ceiling}(\text{s.window}/10), \\
\quad \text{t.jump} = \text{ceiling}(\text{t.window}/10), \\
\quad \text{l.jump} = \text{ceiling}(\text{l.window}/10), \\
\quad \text{robust} = \text{FALSE}, \\
\quad \text{inner} = \text{if}(\text{robust}) \ 1 \ \text{else} \ 2, \\
\quad \text{outer} = \text{if}(\text{robust}) \ 15 \ \text{else} \ 0, \\
\quad \text{na.action} = \text{na.fail})
\]

Arguments

- **x**: univariate time series to be decomposed. This should be an object of class "ts" with a frequency greater than one.
- **s.window**: either the character string "periodic" or the span (in lags) of the loess window for seasonal extraction, which should be odd. This has no default.
- **s.degree**: degree of locally-fitted polynomial in seasonal extraction. Should be zero or one.
- **t.window**: the span (in lags) of the loess window for trend extraction, which should be odd. If NULL, the default, \(\text{nextodd}(\text{ceiling}(1.5\times\text{period}) / (1-(1.5/\text{s.window})))\), is taken.
- **t.degree**: degree of locally-fitted polynomial in trend extraction. Should be zero or one.
- **l.window**: the span (in lags) of the loess window of the low-pass filter used for each subseries. Defaults to the smallest odd integer greater than or equal to \(\text{frequency}(x)\) which is recommended since it prevents competition between the trend and seasonal components. If not an odd integer its given value is increased to the next odd one.
- **l.degree**: degree of locally-fitted polynomial for the subseries low-pass filter. Must be 0 or 1.
- **s.jump**, **t.jump**, **l.jump**: integers at least one to increase speed of the respective smoother. Linear interpolation happens between every \(s.j ump\)th value.
- **robust**: logical indicating if robust fitting be used in the loess procedure.
- **inner**: integer; the number of ‘inner’ (backfitting) iterations; usually very few (2) iterations suffice.
- **outer**: integer; the number of ‘outer’ robustness iterations.
- **na.action**: action on missing values.
The seasonal component is found by loess smoothing the seasonal sub-series (the series of all January values, ...); if \( s \text{window} = \) "periodic" smoothing is effectively replaced by taking the mean. The seasonal values are removed, and the remainder smoothed to find the trend. The overall level is removed from the seasonal component and added to the trend component. This process is iterated a few times. The remainder component is the residuals from the seasonal plus trend fit.

Several methods for the resulting class "stl" objects, see, \texttt{plot.stl}.

**Value**

\texttt{stl} returns an object of class "stl" with components:

- \texttt{time.series} a multiple time series with columns seasonal, trend and remainder.
- \texttt{weights} the final robust weights (all one if fitting is not done robustly).
- \texttt{call} the matched call.
- \texttt{win} integer (length 3 vector) with the spans used for the "s", "t", and "l" smoothers.
- \texttt{deg} integer (length 3 vector) with the polynomial degrees for these smoothers.
- \texttt{jump} integer (length 3 vector) with the 'jumps' (skips) used for these smoothers.
- \texttt{ni} number of inner iterations
- \texttt{no} number of outer robustness iterations

**Note**

This is similar to but not identical to the \texttt{stl} function in S-PLUS. The remainder component given by S-PLUS is the sum of the trend and remainder series from this function.

require(graphics)

plot(stl(nottem, "per"))
plot(stl(nottem, s.window = 4, t.window = 50, t.jump = 1))
plot(stl(log(co2), s.window = 21))
supmary(stllc)
## linear trend, strict period.
plot(stl(log(co2), s.window = "per", t.window = 100))
```
stlmethods

Methods for STL Objects

Description

Methods for objects of class stl, typically the result of stl. The plot method does a multiple figure plot with some flexibility.

There are also (non-visible) print and summary methods.

Usage

```r
## S3 method for class 'stl'
plot(x, labels = colnames(X),
    set.pars = list(mar = c(0, 6, 0, 6), oma = c(6, 0, 4, 0),
                  tck = -0.01, mfrow = c(npplot, 1)),
    main = NULL, range.bars = TRUE, ...,
    col.range = "light gray")
```

Arguments

- `x` stl object.
- `labels` character of length 4 giving the names of the component time-series.
- `set.pars` settings for `par(.)` when setting up the plot.
- `main` plot main title.
- `range.bars` logical indicating if each plot should have a bar at its right side which are of equal heights in user coordinates.
- `...` further arguments passed to or from other methods.
- `col.range` colour to be used for the range bars, if plotted. Note this appears after `...` and so cannot be abbreviated.

See Also

`plot.ts` and `stl`, particularly for examples.
StructTS

**Description**

Fit a structural model for a time series by maximum likelihood.

**Usage**

\[
\text{StructTS}(x, \text{type} = \text{c("level", "trend", "BSM")}, \text{init} = \text{NULL}, \\
\quad \text{fixed} = \text{NULL}, \text{optim.control} = \text{NULL})
\]

**Arguments**

- **x**: a univariate numeric time series. Missing values are allowed.
- **type**: the class of structural model. If omitted, a BSM is used for a time series with frequency\(x\) > 1, and a local trend model otherwise.
- **init**: initial values of the variance parameters.
- **fixed**: optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in fixed will be varied. Probably most useful for setting variances to zero.
- **optim.control**: List of control parameters for optim. Method "L-BFGS-B" is used.

**Details**

*Structural time series* models are (linear Gaussian) state-space models for (univariate) time series based on a decomposition of the series into a number of components. They are specified by a set of error variances, some of which may be zero.

The simplest model is the *local level* model specified by type = "level". This has an underlying level \( \mu_t \) which evolves by

\[
\mu_{t+1} = \mu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)
\]

The observations are

\[
x_t = \mu_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)
\]

There are two parameters, \( \sigma_\xi^2 \) and \( \sigma_\epsilon^2 \). It is an ARIMA(0,1,1) model, but with restrictions on the parameter set.

The *local linear trend model*, type = "trend", has the same measurement equation, but with a time-varying slope in the dynamics for \( \mu_t \), given by

\[
\mu_{t+1} = \mu_t + \nu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)
\]

\[
\nu_{t+1} = \nu_t + \zeta_t, \quad \zeta_t \sim N(0, \sigma_\zeta^2)
\]

with three variance parameters. It is not uncommon to find \( \sigma_\zeta^2 = 0 \) (which reduces to the local level model) or \( \sigma_\xi^2 = 0 \), which ensures a smooth trend. This is a restricted ARIMA(0,2,2) model.

The *basic structural model*, type = "BSM", is a local trend model with an additional seasonal component. Thus the measurement equation is

\[
x_t = \mu_t + \gamma_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)
\]
where $\gamma_t$ is a seasonal component with dynamics

$$\gamma_{t+1} = -\gamma_t + \cdots + \gamma_{t-s+2} + \omega_t, \quad \omega_t \sim N(0, \sigma^2_{\omega})$$

The boundary case $\sigma^2_{\omega} = 0$ corresponds to a deterministic (but arbitrary) seasonal pattern. (This is sometimes known as the ‘dummy variable’ version of the BSM.)

Value

A list of class "StructTS" with components:

- **coef**  
  the estimated variances of the components.

- **loglik**  
  the maximized log-likelihood. Note that as all these models are non-stationary this includes a diffuse prior for some observations and hence is not comparable to `arima` nor different types of structural models.

- **loglik0**  
  the maximized log-likelihood with the constant used prior to R 3.0.0, for backwards compatibility.

- **data**  
  the time series $x$.

- **residuals**  
  the standardized residuals.

- **fitted**  
  a multiple time series with one component for the level, slope and seasonal components, estimated contemporaneously (that is at time $t$ and not at the end of the series).

- **call**  
  the matched call.

- **series**  
  the name of the series $x$.

- **code**  
  the convergence code returned by `optim`.

- **model, model0**  
  Lists representing the Kalman Filter used in the fitting. See `KalmanLike`.

- **xtsp**  
  the tsp attributes of $x$.

Note

Optimization of structural models is a lot harder than many of the references admit. For example, the `AirPassengers` data are considered in Brockwell & Davis (1996); their solution appears to be a local maximum, but nowhere near as good a fit as that produced by `StructTS`. It is quite common to find fits with one or more variances zero, and this can include $\sigma^2_{\omega}$.

optim.control = list(trace = TRUE))
```

summary.aov

Summarize an Analysis of Variance Model

Description

Summarize an analysis of variance model.

Usage

```r
## S3 method for class 'aov'
summary(object, intercept = FALSE, split, expand.split = TRUE, keep.zero.df = TRUE, ...)

## S3 method for class 'aovlist'
summary(object, ...)
```

Arguments

- `object`: An object of class "aov" or "aovlist".
- `intercept`: logical: should intercept terms be included?
- `split`: an optional named list, with names corresponding to terms in the model. Each component is itself a list with integer components giving contrasts whose contributions are to be summed.
- `expand.split`: logical: should the split apply also to interactions involving the factor?
- `keep.zero.df`: logical: should terms with no degrees of freedom be included?
- `...`: Arguments to be passed to or from other methods, for `summary.aovlist` including those for `summary.aov`. 

Value

An object of class c("summary.aov", "listof") or "summary.aovlist" respectively.

For fits with a single stratum the result will be a list of ANOVA tables, one for each response (even if there is only one response): the tables are of class "anova" inheriting from class "data.frame". They have columns "Df", "Sum Sq", "Mean Sq", as well as "F value" and "Pr(>F)" if there are non-zero residual degrees of freedom. There is a row for each term in the model, plus one for "Residuals" if there are any.

For multistratum fits the return value is a list of such summaries, one for each stratum.

Note

The use of expand.split = TRUE is little tested: it is always possible to set it to FALSE and specify exactly all the splits required.

See Also

aov, summary, model.tables, TukeyHSD

Examples

## For a simple example see example(aov)

# Cochran and Cox (1957, p.164)
# 3x3 factorial with ordered factors, each is average of 12.
CC <- data.frame(
    y = c(449, 413, 326, 409, 358, 291, 341, 278, 312)/12,
    P = ordered(gl(3, 3)), N = ordered(gl(3, 1, 9))
)
CC.aov <- aov(y ~ N * P, data = CC, weights = rep(12, 9))
summary(CC.aov)

# Split both main effects into linear and quadratic parts.
summary(CC.aov, split = list(N = list(L = 1, Q = 2),
    P = list(L = 1, Q = 2)))

# Split only the interaction
summary(CC.aov, split = list("N:P" = list(L.L = 1, Q = 2:4)))

# split on just one var
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)))
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)),
    expand.split = FALSE)
Usage

```r
## S3 method for class 'glm'
summary(object, dispersion = NULL, correlation = FALSE,
         symbolic.cor = FALSE, ...)

## S3 method for class 'summary.glm'
print(x, digits = max(3, getOption("digits") - 3),
      symbolic.cor = x$symbolic.cor,
      signif.stars = getOption("show.signif.stars"), ...)
```

Arguments

- `object`: an object of class "glm", usually, a result of a call to `glm`.
- `x`: an object of class "summary.glm", usually, a result of a call to `summary.glm`.
- `dispersion`: the dispersion parameter for the family used. Either a single numerical value or `NULL` (the default), when it is inferred from `object` (see 'Details').
- `correlation`: logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
- `digits`: the number of significant digits to use when printing.
- `symbolic.cor`: logical. If TRUE, print the correlations in a symbolic form (see `symnum`) rather than as numbers.
- `signif.stars`: logical. If TRUE, 'significance stars' are printed for each coefficient.
- `...`: further arguments passed to or from other methods.

Details

`print.summary.glm` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if `signif.stars` is TRUE. The `coefficients` component of the result gives the estimated coefficients and their estimated standard errors, together with their ratio. This third column is labelled `t ratio` if the dispersion is estimated, and `z ratio` if the dispersion is known (or fixed by the family). A fourth column gives the two-tailed p-value corresponding to the `t` or `z` ratio based on a Student `t` or Normal reference distribution. (It is possible that the dispersion is not known and there are no residual degrees of freedom from which to estimate it. In that case the estimate is NaN.)

Aliased coefficients are omitted in the returned object but restored by the `print` method. Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

The dispersion of a GLM is not used in the fitting process, but it is needed to find standard errors. If `dispersion` is not supplied or `NULL`, the dispersion is taken as 1 for the binomial and Poisson families, and otherwise estimated by the residual Chisquared statistic (calculated from cases with non-zero weights) divided by the residual degrees of freedom.

`summary` can be used with Gaussian `glm` fits to handle the case of a linear regression with known error variance, something not handled by `summary.lm`.

Value

`summary.glm` returns an object of class "summary.glm", a list with components

- `call`: the component from `object`. 
summary.lm

summary method for class "lm".

Usage

## S3 method for class 'lm'
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)

## S3 method for class 'summary.lm'
print(x, digits = max(3, getOption("digits") - 3),
       symbolic.cor = x$symbolic.cor,
       signif.stars = getOption("show.signif.stars"), ...)
summary.lm

Arguments

object an object of class "lm", usually, a result of a call to \texttt{lm}.
x an object of class "summary.lm", usually, a result of a call to \texttt{summary.lm}.
correlation logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
digits the number of significant digits to use when printing.
symbolic.cor logical. If TRUE, print the correlations in a symbolic form (see \texttt{symnum}) rather than as numbers.
signif.stars logical. If TRUE, ‘significance stars’ are printed for each coefficient.
... further arguments passed to or from other methods.

Details

\texttt{print.summary.lm} tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives ‘significance stars’ if \texttt{signif.stars} is TRUE.

Aliased coefficients are omitted in the returned object but restored by the \texttt{print} method.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print \texttt{summary(object)\$correlation} directly.

Value

The function \texttt{summary.lm} computes and returns a list of summary statistics of the fitted linear model given in \texttt{object}, using the components (list elements) "call" and "terms" from its argument, plus

residuals the weighted residuals, the usual residuals rescaled by the square root of the weights specified in the call to \texttt{lm}.
coefficients a \(p \times 4\) matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value. Aliased coefficients are omitted.
aliased named logical vector showing if the original coefficients are aliased.
sigma the square root of the estimated variance of the random error
\[
\sigma^2 = \frac{1}{n-p} \sum_i w_i R_i^2,
\]
where \(R_i\) is the i-th residual, \texttt{residuals[i]}.
df degrees of freedom, a 3-vector \((p, n - p, p^*)\), the first being the number of non-aliased coefficients, the last being the total number of coefficients.
fstatistic (for models including non-intercept terms) a 3-vector with the value of the F-statistic with its numerator and denominator degrees of freedom.
r.squared \(R^2\), the ‘fraction of variance explained by the model’, \[
R^2 = 1 - \frac{\sum_i R_i^2}{\sum_i (y_i - y^*)^2},
\]
where \(y^*\) is the mean of \(y_i\) if there is an intercept and zero otherwise.
adj.r.squared the above \(R^2\) statistic ‘adjusted’, penalizing for higher \(p\).
cov.unscaled a \(p \times p\) matrix of (unscaled) covariances of the \(\hat{\beta}_j, j = 1, \ldots, p\).
correlation the correlation matrix corresponding to the above \texttt{cov.unscaled}, if \texttt{correlation = TRUE} is specified.
symbolic.cor (only if correlation is true.) The value of the argument \texttt{symbolic.cor}.
na.action from \texttt{object}, if present there.
See Also

The model fitting function `lm, summary`. Function `coef` will extract the matrix of coefficients with standard errors, t-statistics and p-values.

Examples

```r
##-- Continuing the `lm(.)` example:
coef(lm.D90) # the bare coefficients
sl90 <- summary(lm.D90 <- lm(weight ~ group -1)) # omitting intercept
csl90

## model with *aliased* coefficient:
lm.D9 <- lm(weight ~ group + I(group != "Ctl"))
sl90 <- summary(lm.D90)
sl90. # shows the NA NA NA NA line
stopifnot(length(cc <- coef(lm.D90)) == 3, is.na(cc[3]),
         dim(coef(sl90)) == c(2,4), sl90$df == c(2,18,3))
```

### Summary Method for Multivariate Analysis of Variance

**Description**

A summary method for class "manova".

**Usage**

```r
## S3 method for class 'manova'
summary(object,
         test = c("Pillai", "Wilks", "Hotelling-Lawley", "Roy"),
         intercept = FALSE, tol = 1e-7, ...)
```

**Arguments**

- `object` An object of class "manova" or an `aov` object with multiple responses.
- `test` The name of the test statistic to be used. Partial matching is used so the name can be abbreviated.
- `intercept` logical. If `TRUE`, the intercept term is included in the table.
- `tol` tolerance to be used in deciding if the residuals are rank-deficient: see `qr`.
- `...` further arguments passed to or from other methods.

**Details**

The `summary.manova` method uses a multivariate test statistic for the summary table. Wilks’ statistic is most popular in the literature, but the default Pillai–Bartlett statistic is recommended by Hand and Taylor (1987).

The table gives a transformation of the test statistic which has approximately an F distribution. The approximations used follow S-PLUS and SAS (the latter apart from some cases of the Hotelling–Lawley statistic), but many other distributional approximations exist: see Anderson (1984) and
Krzanowski and Marriott (1994) for further references. All four approximate F statistics are the same when the term being tested has one degree of freedom, but in other cases that for the Roy statistic is an upper bound.

The tolerance tol is applied to the QR decomposition of the residual correlation matrix (unless some response has essentially zero residuals, when it is unscaled). Thus the default value guards against very highly correlated responses: it can be reduced but doing so will allow rather inaccurate results and it will normally be better to transform the responses to remove the high correlation.

Value

An object of class "summary.manova". If there is a positive residual degrees of freedom, this is a list with components

row.names The names of the terms, the row names of the stats table if present.
SS A named list of sums of squares and product matrices.
Eigenvalues A matrix of eigenvalues.
stats A matrix of the statistics, approximate F value, degrees of freedom and P value.

otherwise components row.names, SS and df (degrees of freedom) for the terms (and not the residuals).

Examples

```r
# Example on producing plastic film from Krzanowski (1998, p. 381)
tear <- c(6.5, 6.2, 5.8, 6.5, 6.5, 5.9, 7.2, 6.9, 6.1, 6.3,
          6.7, 6.6, 7.2, 7.1, 6.8, 7.1, 7.0, 7.2, 7.5, 7.6)
gloss <- c(9.5, 9.9, 9.6, 9.6, 9.2, 9.1, 10.0, 9.9, 9.5, 9.4,
           9.1, 9.3, 8.3, 8.4, 8.5, 9.2, 8.8, 9.7, 10.1, 9.2)
opacity <- c(4.4, 6.4, 3.0, 4.1, 0.8, 5.7, 2.0, 3.9, 1.9, 5.7,
             2.8, 4.1, 3.8, 1.6, 3.4, 8.4, 5.2, 6.9, 2.7, 1.9)
Y <- cbind(tear, gloss, opacity)
rate <- factor(gl(2,10), labels = c("Low", "High"))
additive <- factor(gl(2, 5, length = 20), labels = c("Low", "High"))

fit <- manova(Y ~ rate * additive)
summary.aov(fit)  # univariate ANOVA tables
summary(fit, test = "Wilks")  # ANOVA table of Wilks' lambda
summary(fit)  # same F statistics as single-df terms
```
Summary of Non-Linear Least-Squares Model Fits

**Description**

summary method for class "nls".

**Usage**

```r
## S3 method for class 'nls'
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)
## S3 method for class 'summary.nls'
print(x, digits = max(3,getOption("digits") - 3),
      symbolic.cor = x$symbolic.cor,
      signif.stars = getOption("show.signif.stars"), ...)
```

**Arguments**

- `object` an object of class "nls".
- `x` an object of class "summary.nls", usually the result of a call to `summary.nls`.
- `correlation` logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
- `digits` the number of significant digits to use when printing.
- `symbolic.cor` logical. If TRUE, print the correlations in a symbolic form (see `symnum`) rather than as numbers.
- `signif.stars` logical. If TRUE, 'significance stars' are printed for each coefficient.
- `...` further arguments passed to or from other methods.

**Details**

The distribution theory used to find the distribution of the standard errors and of the residual standard error (for t ratios) is based on linearization and is approximate, maybe very approximate.

`print.summary.nls` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if `signif.stars` is TRUE.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

**Value**

The function `summary.nls` computes and returns a list of summary statistics of the fitted model given in object, using the component "formula" from its argument, plus

- `residuals` the weighted residuals, the usual residuals rescaled by the square root of the weights specified in the call to `nls`.
- `coefficients` a p × 4 matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value.
sigma

the square root of the estimated variance of the random error

\[ \hat{\sigma}^2 = \frac{1}{n - p} \sum_i R_i^2, \]

where \( R_i \) is the \( i \)-th weighted residual.

df

degrees of freedom, a 2-vector \((p, n - p)\). (Here and elsewhere \( n \) omits observations with zero weights.)

cov.unscaled

a \( p \times p \) matrix of (unscaled) covariances of the parameter estimates.

correlation

the correlation matrix corresponding to the above cov.unscaled, if correlation = TRUE is specified and there are a non-zero number of residual degrees of freedom.

symbolic.cor

(only if correlation is true.) The value of the argument symbolic.cor.

summary(pc.cr <- princomp(USArrests, cor = TRUE))
print(summary(princomp(USArrests, cor = TRUE),
    loadings = TRUE, cutoff = 0.2), digits = 2)

supsmu Friedman’s SuperSmoother

Description

Smooth the (x, y) values by Friedman’s ‘super smoother’.

Usage

supsmu(x, y, wt, span = "cv", periodic = FALSE, bass = 0)

Arguments

x x values for smoothing
y y values for smoothing
wt case weights, by default all equal
span the fraction of the observations in the span of the running lines smoother, or "cv" to choose this by leave-one-out cross-validation.
periodic if TRUE, the x values are assumed to be in [0, 1] and of period 1.
bass controls the smoothness of the fitted curve. Values of up to 10 indicate increasing smoothness.

Details

supsmu is a running lines smoother which chooses between three spans for the lines. The running lines smoothers are symmetric, with \( k/2 \) data points each side of the predicted point, and values of \( k \) as \( 0.5 \times n, 0.2 \times n \) and \( 0.05 \times n \), where \( n \) is the number of data points. If span is specified, a single smoother with span \( \frac{n}{2} \) is used.

The best of the three smoothers is chosen by cross-validation for each prediction. The best spans are then smoothed by a running lines smoother and the final prediction chosen by linear interpolation.

The FORTRAN code says: “For small samples (\( n < 40 \)) or if there are substantial serial correlations between observations close in x-value, then a pre-specified fixed span smoother (span > 0) should be used. Reasonable span values are 0.2 to 0.4.”

Cases with non-finite values of x, y or wt are dropped, with a warning.

Value

A list with components

x the input values in increasing order with duplicates removed.
y the corresponding y values on the fitted curve.
symnum

ppr

Examples

require(graphics)

with(cars, {
p <- plot(speed, dist)
  lines(supsmu(speed, dist))
  lines(supsmu(speed, dist, bass = 7), lty = 2)
})

symnum

Symbolic Number Coding

Description

Symbolically encode a given numeric or logical vector or array. Particularly useful for visualization of structured matrices, e.g., correlation, sparse, or logical ones.

Usage

symnum(x, cutpoints = c(0.3, 0.6, 0.8, 0.9, 0.95),
  symbols = if(numeric.x) c(" ", ", ", ", ", "+", "x", "B")
  else c(".", "|"),
  legend = length(symbols) >= 3,
  na = "?", eps = 1e-5, numeric.x = is.numeric(x),
  corr = missing(cutpoints) && numeric.x,
  show.max = if(corr) "1", show.min = NULL,
  abbr.colnames = has.colnames,
  lower.triangular = corr && is.numeric(x) && is.matrix(x),
  diag.lower.tri = corr && !is.null(show.max))

Arguments

x numeric or logical vector or array.

cutpoints numeric vector whose values cutpoints[j] = c_j (after augmentation, see corr below) are used for intervals.

symbols character vector, one shorter than (the augmented, see corr below) cutpoints. symbols[j] = s_j are used as ‘code’ for the (half open) interval (c_j, c_{j+1}]. When numeric.x is FALSE, i.e., by default when argument x is logical, the default is c(" ", ", ", "+") (graphical 0 / 1 s).
legend logical indicating if a "legend" attribute is desired.
na character or logical. How NAs are coded. If na == FALSE, NAs are coded invisibly, including the "legend" attribute below, which otherwise mentions NA coding.
eps absolute precision to be used at left and right boundary.
numeric.x logical indicating if x should be treated as numbers, otherwise as logical.
corr logical. If TRUE, x contains correlations. The cutpoints are augmented by 0 and 1 and abs(x) is coded.
show.max if TRUE, or of mode character, the maximal cutpoint is coded especially.
show.min if TRUE, or of mode character, the minimal cutpoint is coded especially.
abbr.colnames logical, integer or NULL indicating how column names should be abbreviated (if they are); if NULL (or FALSE and x has no column names), the column names will all be empty, i.e., ""; otherwise if abbr.colnames is false, they are left unchanged. If TRUE or integer, existing column names will be abbreviated to abbreviate(x, minlength = abbr.colnames).
lower.triangular logical. If TRUE and x is a matrix, only the lower triangular part of the matrix is coded as non-blank.
diag.lower.tri logical. If lower.triangular and this are TRUE, the diagonal part of the matrix is shown.

Value
An atomic character object of class noquote and the same dimensions as x.

If legend is TRUE (as by default when there are more than two classes), the result has an attribute "legend" containing a legend of the returned character codes, in the form

\[ c_1 s_1 c_2 s_2 \ldots s_n c_{n+1} \]

where \( c_j \) = cutpoints[j] and \( s_j \) = symbols[j].

Note
The optional (mostly logical) arguments all try to use smart defaults. Specifying them explicitly may lead to considerably improved output in many cases.

Examples
ii <- setNames(0:8, 0:8)
symnum(ii, cut = 2*(0:4), sym = c(".", "-", "+", ":"))
symnum(ii, cut = 2*(0:4), sym = c(".", "-", "+", ":"), show.max = TRUE)
symnum(1:12 %% 3 == 0) # --> ":" = TRUE, "." = FALSE for logical
## Pascal's Triangle modulo 2 -- odd and even numbers:

```r	n <- 38
pascal <- t(sapply(0:n, function(n) round(choose(n, 0:n) %% 2)))
```

### Symbolic correlation matrices:

```r
symnum(cor(attitude), diag = FALSE)
symnum(cor(attitude), abbr. = NULL)
symnum(cor(attitude), abbr. = FALSE)
symnum(cor(attitude), abbr. = 2)
```

### `NA`'s:

```r
cm <- cor(matrix(rnorm(60), 10, 6)); cm[c(3,6), 2] <- NA
symnum(cm, show.max = NULL)
```

### Graphical P-values (aka "significance stars"):

```r
pval <- rev(sort(c(outter(1:6, 10^(-(1:3))))))
symp <- symnum(pval, corr = FALSE,
               cutpoints = c(0, .001, .01, .05, .1, 1),
symbols = c("***","**","*","","",""))
nocode(cbind(P.val = format(pval), Signif = symp))
```

---

### `t.test`

#### Description

Performs one and two sample t-tests on vectors of data.

#### Usage

```r
t.test(x, ...)
```

#### Arguments

- **x**: a (non-empty) numeric vector of data values.
y an optional (non-empty) numeric vector of data values.

alternative a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.

mu a number indicating the true value of the mean (or difference in means if you are performing a two sample test).

paired a logical indicating whether you want a paired t-test.

var.equal a logical variable indicating whether to treat the two variances as being equal. If TRUE then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used.

conf.level confidence level of the interval.

formula a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.

data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").

... further arguments to be passed to or from methods.

Details

The formula interface is only applicable for the 2-sample tests.

alternative = "greater" is the alternative that x has a larger mean than y.

If paired is TRUE then both x and y must be specified and they must be the same length. Missing values are silently removed (in pairs if paired is TRUE). If var.equal is TRUE then the pooled estimate of the variance is used. By default, if var.equal is FALSE then the variance is estimated separately for both groups and the Welch modification to the degrees of freedom is used.

If the input data are effectively constant (compared to the larger of the two means) an error is generated.

Value

A list with class "htest" containing the following components:

statistic the value of the t-statistic.

parameter the degrees of freedom for the t-statistic.

p.value the p-value for the test.

conf.int a confidence interval for the mean appropriate to the specified alternative hypothesis.

estimate the estimated mean or difference in means depending on whether it was a one-sample test or a two-sample test.

null.value the specified hypothesized value of the mean or mean difference depending on whether it was a one-sample test or a two-sample test.

alternative a character string describing the alternative hypothesis.

method a character string indicating what type of t-test was performed.

data.name a character string giving the name(s) of the data.

prop.test

Examples

require(graphics)

t.test(1:10, y = c(7:20)) # P = .00001855
t.test(1:10, y = c(7:20, 200)) # P = .1245 -- NOT significant anymore

## Classical example: Student's sleep data
plot(extra ~ group, data = sleep)
## Traditional interface
with(sleep, t.test(extra[group == 1], extra[group == 2]))
## Formula interface
t.test(extra ~ group, data = sleep)

---

TDist

**The Student t Distribution**

Description

Density, distribution function, quantile function and random generation for the t distribution with
**df** degrees of freedom (and optional non-centrality parameter **ncp**).

Usage

dt(x, df, ncp, log = FALSE)
pt(q, df, ncp, lower.tail = TRUE, log.p = FALSE)
qt(p, df, ncp, lower.tail = TRUE, log.p = FALSE)
rt(n, df, ncp)

Arguments

- **x, q** vector of quantiles.
- **p** vector of probabilities.
- **n** number of observations. If `length(n) > 1`, the length is taken to be the number required.
- **df** degrees of freedom (> 0, maybe non-integer). `df = Inf` is allowed.
- **ncp** non-centrality parameter δ; currently except for `rt()`, only for `abs(ncp) <= 37.62`. If omitted, use the central t distribution.
- **log, log.p** logical; if **TRUE**, probabilities **p** are given as `log(p)`.
- **lower.tail** logical; if **TRUE** (default), probabilities are **P**[X ≤ x], otherwise, **P**[X > x].
Details

The t distribution with df = ν degrees of freedom has density

\[ f(x) = \frac{\Gamma((\nu + 1)/2)}{\sqrt{\pi\nu}\Gamma(\nu/2)} \left(1 + \frac{x^2}{\nu}\right)^{-\frac{\nu+1}{2}} \]

for all real x. It has mean 0 (for ν > 1) and variance \( \frac{\nu}{\nu - 2} \) (for ν > 2).

The general non-central t with parameters (ν, δ) = (df, ncp) is defined as the distribution of

\[ T_\nu(\delta) := \frac{U + \delta}{\sqrt{V/\nu}} \]

where U and V are independent random variables, \( U \sim N(0,1) \) and \( V \sim \chi^2_\nu \) (see Chisquare).

The most used applications are power calculations for t-tests:

Let \( T = \frac{\bar{X} - \mu_0}{S/\sqrt{n}} \) where \( \bar{X} \) is the mean and S the sample standard deviation (sd) of \( X_1, X_2, \ldots, X_n \) which are i.i.d. \( N(\mu, \sigma^2) \) Then T is distributed as non-central t with df = n − 1 degrees of freedom and non-centrality parameter ncp = (μ − μ0)\sqrt{n}/σ.

Value

dt gives the density, pt gives the distribution function, qt gives the quantile function, and rt generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by n for rt, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than n are recycled to the length of the result. Only the first elements of the logical parameters are used.

Note

Supplying ncp = 0 uses the algorithm for the non-central distribution, which is not the same algorithm used if ncp is omitted. This is to give consistent behaviour in extreme cases with values of ncp very near zero.

The code for non-zero ncp is principally intended to be used for moderate values of ncp: it will not be highly accurate, especially in the tails, for large values.

Source

The central dt is computed via an accurate formula provided by Catherine Loader (see the reference in dbinom).

For the non-central case of dt, C code contributed by Claus Ekstrøm based on the relationship (for \( x \neq 0 \)) to the cumulative distribution.

For the central case of pt, a normal approximation in the tails, otherwise via pbeta.

For the non-central case of pt based on a C translation of

This computes the lower tail only, so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant.

For central qt, a C translation of

altered to take account of

The non-central case is done by inversion.

*Distributions* for other standard distributions, including *df* for the F distribution.

**Examples**

```r
require(graphics)

1 - pt(1:5, df = 1)
qt(.975, df = c(1:10,20,50,100,1000))

tt <- seq(0, 10, len = 21)
ncp <- seq(0, 6, len = 31)
ptn <- outer(tt, ncp, function(t, d) pt(t, df = 3, ncp = d))
t.tit <- "Non-central t - Probabilities"
image(tt, ncp, ptn, zlim = c(0,1), main = t.tit)
persp(tt, ncp, ptn, zlim = 0:1, r = 2, phi = 20, theta = 200, main = t.tit,      xlab = "t", ylab = "non-centrality parameter",      zlab = "Pr(T <= t)")

plot(function(x) dt(x, df = 3, ncp = 2), -3, 31, ylim = c(0, 0.32), main = "Non-central t - Density", yaxs = "i")
```

---

**termplot**

*Plot Regression Terms*

**Description**

Plots regression terms against their predictors, optionally with standard errors and partial residuals added.

**Usage**

```r
termplot(model, data = NULL, envir = environment(formula(model)),      partial.resid = FALSE, rug = FALSE,      terms = NULL, se = FALSE,      xlabs = NULL, ylabs = NULL, main = NULL,      col.term = 2, lwd.term = 1.5,      col.se = "orange", lty.se = 2, lwd.se = 1,      col.res = "gray", cex = 1, pch = par("pch"),
```

---

**termplot**
col.smth = "darkred", lty.smth = 2, span.smth = 2/3,
ask = dev.interactive() && nb.fig < n.tms,
use.factor.levels = TRUE, smooth = NULL, ylim = "common",
plot = TRUE, transform.x = FALSE, ...)

Arguments

model fitted model object
data data frame in which variables in model can be found
envir environment in which variables in model can be found
partial.resid logical; should partial residuals be plotted?
rug add rug plots (jittered 1-d histograms) to the axes?
terms which terms to plot (default NULL means all terms); a vector passed to
predict(..., term = "terms", terms = *)
se plot pointwise standard errors?
xBx
yBx
main logical, or vector of main titles; if TRUE, the model’s call is taken as main title,
NULL or FALSE mean no titles.
col.term, lwd.term color and line width for the ‘term curve’, see lines.
col.se, lty.se, lwd.se color, line type and line width for the ‘twice-standard-error curve’ when
se = TRUE.
col.res, cex, pch color, plotting character expansion and type for partial residuals, when
partial.resid = TRUE, see points.
ask logical; if TRUE, the user is asked before each plot, see par(ask=.).
use.factor.levels Should x-axis ticks use factor levels or numbers for factor terms?
smooth NULL or a function with the same arguments as panel.smooth to draw a smooth
through the partial residuals for non-factor terms
lty.smth, col.smth, span.smth Passed to smooth
ylim an optional range for the y axis, or "common" when a range sufficient for all the
plot will be computed, or "free" when limits are computed for each plot.
plot if set to FALSE plots are not produced: instead a list is returned containing the
data that would have been plotted.
transform.x logical vector; if an element (recycled as necessary) is TRUE, partial residuals
for the corresponding term are plotted against transformed values. The model
response is then a straight line, allowing a ready comparison against the data or
against the curve obtained from smooth-panel.smooth.
...
other graphical parameters.
Details

The model object must have a predict method that accepts type = \texttt{terms}, e.g., \texttt{glm} in the \texttt{stats} package, \texttt{coxph} and \texttt{survreg} in the \texttt{survival} package.

For the partial.resid = \texttt{TRUE} option model must have a \texttt{residuals} method that accepts type = "partial", which \texttt{lm} and \texttt{glm} do.

The data argument should rarely be needed, but in some cases \texttt{termplot} may be unable to reconstruct the original data frame. Using \texttt{na.action=na.exclude} makes these problems less likely.

Nothing sensible happens for interaction terms, and they may cause errors.

The plot = \texttt{FALSE} option is useful when some special action is needed, e.g. to overlay the results of two different models or to plot confidence bands.

Value

For plot = \texttt{FALSE}, a list with one element for each plot which would have been produced. Each element of the list is a data frame with variables \texttt{x}, \texttt{y}, and optionally the pointwise standard errors \texttt{se}. For continuous predictors \texttt{x} will contain the ordered unique values and for a factor it will be a factor containing one instance of each level. The list has attribute "constant" copied from the predicted terms object.

Otherwise, the number of terms, invisibly.

See Also

For (generalized) linear models, \texttt{plot.lm} and \texttt{predict.glm}.

Examples

```r
require(graphics)

had.splines <- "package:splines" %in% search()
if(!had.splines) rs <- require(splines)
x <- 1:100
z <- factor(rep(LETTERS[1:4], 25))
y <- rnorm(100, sin(x/10)+as.numeric(z))
model <- glm(y ~ ns(x, 6) + z)

par(mfrow = c(2,2)) ## 2 x 2 plots for same model:
termplot(model, main = paste("termplot( ", deparse(model$call)," ...)"))
termplot(model, rug = TRUE)
termplot(model, partial.resid = TRUE, se = TRUE, main = TRUE)
termplot(model, partial.resid = TRUE, smooth = panel.smooth, span.smth = 1/4)
if(!had.splines && rs) detach("package:splines")

if (require(MASS)) {
  hills.lm <- lm(log(time) ~ log(climb)+log(dist), data=hills)
termplot(hills.lm, partial.resid = TRUE, smooth = panel.smooth,
         terms = "log(dist)", main = "Original")
termplot(hills.lm, transform.x = TRUE, partial.resid = TRUE,
         terms = "log(dist)", main = "Transformed",
         smooth=panel.smooth)
}
```
terms

Model Terms

Description

The function terms is a generic function which can be used to extract terms objects from various kinds of R data objects.

Usage

terms(x, ...)

Arguments

x

object used to select a method to dispatch.

...

further arguments passed to or from other methods.

Details

There are methods for classes "aovlist", and "terms" "formula" (see terms.formula): the default method just extracts the terms component of the object, or failing that a "terms" attribute (as used by model.frame).

There are print and labels methods for class "terms": the latter prints the term labels (see terms.object).

Value

An object of class c("terms", "formula") which contains the terms representation of a symbolic model. See terms.object for its structure.

References

See Also

terms.object, terms.formula, lm, glm, formula.

terms.formula

Construct a terms Object from a Formula

Description

This function takes a formula and some optional arguments and constructs a terms object. The terms object can then be used to construct a model.matrix.
Usage

```r
## S3 method for class 'formula'
terms(x, specials = NULL, abb = NULL, data = NULL, neg.out = TRUE,
      keep.order = FALSE, simplify = FALSE, ..., 
      allowDotAsName = FALSE)
```

Arguments

- **x**: a formula.
- **specials**: which functions in the formula should be marked as special in the terms object? A character vector or NULL.
- **abb**: Not implemented in R.
- **data**: a data frame from which the meaning of the special symbol . can be inferred. It is unused if there is no . in the formula.
- **neg.out**: Not implemented in R.
- **keep.order**: a logical value indicating whether the terms should keep their positions. If FALSE the terms are reordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on. Effects of a given order are kept in the order specified.
- **simplify**: should the formula be expanded and simplified, the pre-1.7.0 behaviour?
- **...**: further arguments passed to or from other methods.
- **allowDotAsName**: normally . in a formula refers to the remaining variables contained in data. Exceptionally, . can be treated as a name for non-standard uses of formulae.

Details

Not all of the options work in the same way that they do in S and not all are implemented.

Value

A terms.object object is returned. The object itself is the re-ordered (unless keep.order = TRUE) formula. In all cases variables within an interaction term in the formula are re-ordered by the ordering of the "variables" attribute, which is the order in which the variables occur in the formula.

See Also

terms, terms.object

---

terms.object | Description of Terms Objects

Description

An object of class terms holds information about a model. Usually the model was specified in terms of a formula and that formula was used to determine the terms object.
Value

The object itself is simply the formula supplied to the call of \texttt{terms.formula}. The object has a number of attributes and they are used to construct the model frame:

- **factors**: A matrix of variables by terms showing which variables appear in which terms. The entries are 0 if the variable does not occur in the term, 1 if it does occur and should be coded by contrasts, and 2 if it occurs and should be coded via dummy variables for all levels (as when an intercept or lower-order term is missing). If there are no terms other than an intercept and offsets, this is \texttt{numeric(0)}.

- **term.labels**: A character vector containing the labels for each of the terms in the model, except for offsets. Note that these are after possible re-ordering of terms. Non-syntactic names will be quoted by backticks: this makes it easier to reconstruct the formula from the term labels.

- **variables**: A call to \texttt{list} of the variables in the model.

- **intercept**: Either 0, indicating no intercept is to be fit, or 1 indicating that an intercept is to be fit.

- **order**: A vector of the same length as \texttt{term.labels} indicating the order of interaction for each term.

- **response**: The index of the variable (in \texttt{variables}) of the response (the left hand side of the formula). Zero, if there is no response.

- **offset**: If the model contains offset terms there is an \texttt{offset} attribute indicating which variable(s) are offsets.

- **specials**: If a \texttt{specials} argument was given to \texttt{terms.formula} there is a \texttt{specials} attribute, a pairlist of vectors (one for each specified special function) giving numeric indices of the arguments of the list returned as the \texttt{variables} attribute which contain these special functions.

- **dataClasses**: optional. A named character vector giving the classes (as given by \texttt{NMFclass}) of the variables used in a fit.

The object has class \texttt{c("terms", "formula")}.

Note

These objects are different from those found in S. In particular there is no \texttt{formula} attribute: instead the object is itself a formula. (Thus, the mode of a terms object is different.)

Examples of the \texttt{specials} argument can be seen in the \texttt{aov} and \texttt{coxph} functions, the latter from package \texttt{survival}.

See Also

\texttt{terms, formula}.

Examples

```r
## use of specials (as used for gam() in packages mgcv and gam)
(tf <- terms(y ~ x + x:z + s(x), specials = "s"))
## Note that the "factors" attribute has variables as row names
## and term labels as column names, both as character vectors.
attr(tf, "specials")  # index 's' variable(s)
rownames(attr(tf, "factors"))[attr(tf, "specials")$s]
```
**time**

We can keep the order by

```r
terms(y ~ x + x:z + s(x), specials = "s", keep.order = TRUE)
```

---

**Sampling Times of Time Series**

**Description**

time creates the vector of times at which a time series was sampled.
cycle gives the positions in the cycle of each observation.
frequency returns the number of samples per unit time and deltat the time interval between observations (see ts).

**Usage**

time(x, ...)

## Default S3 method:
time(x, offset = 0, ...)

cycle(x, ...)
frequency(x, ...)
deltat(x, ...)

**Arguments**

- `x` a univariate or multivariate time-series, or a vector or matrix.
- `offset` can be used to indicate when sampling took place in the time unit. 0 (the default) indicates the start of the unit, 0.5 the middle and 1 the end of the interval.
- `...` extra arguments for future methods.

**Details**

These are all generic functions, which will use the tsp attribute of x if it exists. time and cycle have methods for class ts that coerce the result to that class.

**References**

**See Also**

ts, start, tsp, window.
date for clock time, system.time for CPU usage.

**Examples**

```r
require(graphics)

cycle(presidents)
# a simple series plot
plot(as.vector(time(presidents)), as.vector(presidents), type = "l")
```
\textit{toeplitz} \hspace{1cm} \textit{Form Symmetric Toeplitz Matrix}

\textbf{Description}

Forms a symmetric Toeplitz matrix given its first row.

\textbf{Usage}

\begin{verbatim}
  \texttt{toeplitz(x, ...)}
\end{verbatim}

\textbf{Arguments}

\begin{itemize}
  \item \texttt{x} \hspace{1cm} the first to form the Toeplitz matrix.
  \item \texttt{...} \hspace{1cm} potential further arguments (for methods); none here.
\end{itemize}

\textbf{Value}

The Toeplitz matrix.

\textbf{Author(s)}

A. Trapletti

\textbf{Examples}

\begin{verbatim}
  x <- 1:5
  toeplitz(x)
\end{verbatim}

\textit{ts} \hspace{1cm} \textit{Time-Series Objects}

\textbf{Description}

The function \texttt{ts} is used to create time-series objects.

\texttt{as.ts} and \texttt{is.ts} coerce an object to a time-series and test whether an object is a time series.

\textbf{Usage}

\begin{verbatim}
  ts(data = NA, start = 1, end = numeric(), frequency = 1,
      deltat = 1, ts.eps = getOption("ts.eps"), class = , names = )
  as.ts(x, ...)
  is.ts(x)
\end{verbatim}
**Arguments**

- **data**: a vector or matrix of the observed time-series values. A data frame will be coerced to a numeric matrix via `data.matrix`. (See also ‘Details’.)
- **start**: the time of the first observation. Either a single number or a vector of two integers, which specify a natural time unit and a (1-based) number of samples into the time unit. See the examples for the use of the second form.
- **end**: the time of the last observation, specified in the same way as `start`.
- **frequency**: the number of observations per unit of time.
- **deltat**: the fraction of the sampling period between successive observations; e.g., 1/12 for monthly data. Only one of `frequency` or `deltat` should be provided.
- **ts.eps**: time series comparison tolerance. Frequencies are considered equal if their absolute difference is less than `ts.eps`.
- **class**: class to be given to the result, or none if `NULL` or "none". The default is "ts" for a single series, c("mts", "ts", "matrix") for multiple series.
- **names**: a character vector of names for the series in a multiple series: defaults to the colnames of `data`, or `series Q`, `series R`, ....
- **x**: an arbitrary R object.
- **...**: arguments passed to methods (unused for the default method).

**Details**

The function `ts` is used to create time-series objects. These are vector or matrices with class of "ts" (and additional attributes) which represent data which has been sampled at equispaced points in time. In the matrix case, each column of the matrix `data` is assumed to contain a single (univariate) time series. Time series must have at least one observation, and although they need not be numeric there is very limited support for non-numeric series.

Class "ts" has a number of methods. In particular arithmetic will attempt to align time axes, and subsetting to extract subsets of series can be used (e.g., `EuStockMarkets[, "DAX"]`). However, subsetting the first (or only) dimension will return a matrix or vector, as will matrix subsetting. Subassignment can be used to replace values but not to extend a series (see `window`). There is a method for `t` that transposes the series as a matrix (a one-column matrix if a vector) and hence returns a result that does not inherit from class "ts".

The value of argument `frequency` is used when the series is sampled an integral number of times in each unit time interval. For example, one could use a value of 7 for `frequency` when the data are sampled daily, and the natural time period is a week, or 12 when the data are sampled monthly and the natural time period is a year. Values of 4 and 12 are assumed in (e.g.) `print` methods to imply a quarterly and monthly series respectively.

`as.ts` is generic. Its default method will use the `tsp` attribute of the object if it has one to set the start and end times and frequency.

`is.ts` tests if an object is a time series. It is generic: you can write methods to handle specific classes of objects, see `InternalMethods`.

**References**

See Also
tsp, frequency, start, end, time, window; print.ts, the print method for time series objects; plot.ts, the plot method for time series objects.

For other definitions of 'time series' (e.g., time-ordered observations) see the CRAN task view at http://cran.r-project.org/web/views/TimeSeries.html.

Examples

require(graphics)

```r
ts(1:10, frequency = 4, start = c(1959, 2)) # 2nd Quarter of 1959
print( ts(1:10, frequency = 7, start = c(12, 2)), calendar = TRUE)
# print.ts(.)
## Using July 1954 as start date:
gnp <- ts(cumsum(1 + round(rnorm(100), 2)),  
           start = c(1954, 7), frequency = 12)
plot(gnp) # using 'plot.ts' for time-series plot

## Multivariate
z <- ts(matrix(rnorm(300), 100, 3), start = c(1961, 1), frequency = 12)
class(z)
head(z) # as "matrix"
plot(z)
plot(z, plot.type = "single", lty = 1:3)

## A phase plot:
plot(nhtemp, c(nhtemp[-1], NA), cex = .8, col = "blue",  
     main = "Lag plot of New Haven temperatures")
## a clearer way to do this would be
## Not run:
plot(nhtemp, lag(nhtemp, 1), cex = .8, col = "blue",  
     main = "Lag plot of New Haven temperatures")

## End(Not run)
```

Methods for Time Series Objects

Description

Methods for objects of class "ts", typically the result of ts.

Usage

```r
## S3 method for class 'ts'
diff(x, lag = 1, differences = 1, ...)

## S3 method for class 'ts'
na.omit(object, ...)
```
Arguments

- **x**: an object of class "ts" containing the values to be differenced.
- **lag**: an integer indicating which lag to use.
- **differences**: an integer indicating the order of the difference.
- **object**: a univariate or multivariate time series.
- **...**: further arguments to be passed to or from methods.

Details

The `na.omit` method omits initial and final segments with missing values in one or more of the series. 'Internal' missing values will lead to failure.

Value

For the `na.omit` method, a time series without missing values. The class of object will be preserved.

See Also

- `diff`
- `na.omit`, `na.fail`, `na.contiguous`.

---

**ts.plot**

*Plot Multiple Time Series*

Description

Plot several time series on a common plot. Unlike `plot.ts` the series can have a different time bases, but they should have the same frequency.

Usage

```
 ts.plot(..., gpars = list())
```

Arguments

- **...**: one or more univariate or multivariate time series.
- **gpars**: list of named graphics parameters to be passed to the plotting functions. Those commonly used can be supplied directly in . . . .

Value

None.

Note

Although this can be used for a single time series, `plot` is easier to use and is preferred.

See Also

- `plot.ts`
Examples

```
require(graphics)

ts.plot(mdeaths, mdeaths, fdeaths,
       main=list(xlab="year", ylab="deaths", lty=c(1:3)))
```

**ts.union**

**Bind Two or More Time Series**

**Description**

Bind time series which have a common frequency. `ts.union` pads with NAs to the total time coverage, `ts.intersect` restricts to the time covered by all the series.

**Usage**

```
R> ts.intersect(..., dframe = FALSE)
R> ts.union(..., dframe = FALSE)
```

**Arguments**

- `...` two or more univariate or multivariate time series, or objects which can coerced to time series.
- `dframe` logical; if TRUE return the result as a data frame.

**Details**

As a special case, `...` can contain vectors or matrices of the same length as the combined time series of the time series present, as well as those of a single row.

**Value**

A time series object if `dframe` is FALSE, otherwise a data frame.

**See Also**

`cbind`.

**Examples**

```
ts.union(mdeaths, fdeaths)
cbind(mdeaths, fdeaths) # same as the previous line
ts.intersect(window(mdeaths, 1976), window(fdeaths, 1974, 1978))

sales1 <- ts.union(BJsales, lead = BJsales.lead)
ts.intersect(sales1, lead3 = lag(BJsales.lead, -3))
```
**tsdiag**  
*Diagnostic Plots for Time-Series Fits*

**Description**

A generic function to plot time-series diagnostics.

**Usage**

`tsdiag(object, gof.lag, ...)`

**Arguments**

- `object` a fitted time-series model
- `gof.lag` the maximum number of lags for a Portmanteau goodness-of-fit test
- `...` further arguments to be passed to particular methods

**Details**

This is a generic function. It will generally plot the residuals, often standardized, the autocorrelation function of the residuals, and the p-values of a Portmanteau test for all lags up to `gof.lag`.

The methods for `arima` and `StructTS` objects plots residuals scaled by the estimate of their (individual) variance, and use the Ljung–Box version of the portmanteau test.

**Value**

None. Diagnostics are plotted.

**See Also**

`arima, StructTS, Box.test`

**Examples**

```r
## Not run: require(graphics)

fit <- arima(1h, c(1,0,0))
tsdia(fit)

## see also examples(arima)

(fit <- StructTS(log10(JohnsonJohnson), type = "BSM"))
tsdia(fit)

## End(Not run)
```

tsp

Tsp Attribute of Time-Series-like Objects

Description

tsp returns the tsp attribute (or NULL). It is included for compatibility with S version 2. tsp<- sets the tsp attribute. hastsp ensures x has a tsp attribute, by adding one if needed.

Usage

tsp(x)
tsp(x) <- value
hasTsp(x)

Arguments

x   a vector or matrix or univariate or multivariate time-series.
value  a numeric vector of length 3 or NULL.

Details

The tsp attribute was previously described here as c(start(x), end(x), frequency(x)), but this is incorrect. It gives the start time in time units, the end time and the frequency.

Assignments are checked for consistency.

Assigning NULL which removes the tsp attribute and any "ts" (or "mts") class of x.

References

See Also

ts, time, start.

---

tsSmooth

Use Fixed-Interval Smoothing on Time Series

Description

Performs fixed-interval smoothing on a univariate time series via a state-space model. Fixed-interval smoothing gives the best estimate of the state at each time point based on the whole observed series.

Usage

tsSmooth(object, ...)

---
Tukey

Arguments

- object: a time-series fit. Currently only class "StructTS" is supported.
- ...: possible arguments for future methods.

Value

A time series, with as many dimensions as the state space and results at each time point of the original series. (For seasonal models, only the current seasonal component is returned.)

Author(s)

B. D. Ripley

References

See Also

KalmanSmooth, StructTS.

For examples consult AirPassengers, JohnsonJohnson and Nile.

Tukey

The Studentized Range Distribution

Description

Functions of the distribution of the studentized range, $R/s$, where $R$ is the range of a standard normal sample and $df \times s^2$ is independently distributed as chi-squared with $df$ degrees of freedom, see pchisq.

Usage

```r
ptukey(q, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
qtukey(p, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
```

Arguments

- q: vector of quantiles.
- p: vector of probabilities.
- nmeans: sample size for range (same for each group).
- df: degrees of freedom for $s$ (see below).
- nranges: number of groups whose maximum range is considered.
- log.p: logical; if TRUE, probabilities p are given as log(p).
- lower.tail: logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

If $n_g = nranges$ is greater than one, $R$ is the maximum of $n_g$ groups of nmeans observations each.
Value

ptukey gives the distribution function and qtukey its inverse, the quantile function.

The length of the result is the maximum of the lengths of the numerical parameters. The other numerical parameters are recycled to that length. Only the first elements of the logical parameters are used.

Note

A Legendre 16-point formula is used for the integral of ptukey. The computations are relatively expensive, especially for qtukey which uses a simple secant method for finding the inverse of ptukey. qtukey will be accurate to the 4th decimal place.

Source

qtukey is in part adapted from Odeh and Evans (1974).

References

See Also

Distributions for standard distributions, including pnorm and qnorm for the corresponding functions for the normal distribution.

Examples

```r
if(interactive())
  curve(ptukey(x, nm = 6, df = 5), from = -1, to = 8, n = 101)
  (ptt <- ptukey(0:10, 2, df = 5))
  (qtt <- qtukey(.95, 2, df = 2:11))
  ## The precision may be not much more than about 8 digits:
  summary(abs(.95 - ptukey(qtt, 2, df = 2:11)))
```

---

TukeyHSD

*Compute Tukey Honest Significant Differences*

Description

Create a set of confidence intervals on the differences between the means of the levels of a factor with the specified family-wise probability of coverage. The intervals are based on the Studentized range statistic, Tukey’s ‘Honest Significant Difference’ method.

Usage

TukeyHSD(x, which, ordered = FALSE, conf.level = 0.95, ...)

---
**TukeyHSD**

**Arguments**

- `x` A fitted model object, usually an `aov` fit.
- `which` A character vector listing terms in the fitted model for which the intervals should be calculated. Defaults to all the terms.
- `ordered` A logical value indicating if the levels of the factor should be ordered according to increasing average in the sample before taking differences. If `ordered` is true then the calculated differences in the means will all be positive. The significant differences will be those for which the lower end point is positive.
- `conf.level` A numeric value between zero and one giving the family-wise confidence level to use.
- `...` Optional additional arguments. None are used at present.

**Details**

When comparing the means for the levels of a factor in an analysis of variance, a simple comparison using t-tests will inflate the probability of declaring a significant difference when it is not in fact present. This because the intervals are calculated with a given coverage probability for each interval but the interpretation of the coverage is usually with respect to the entire family of intervals.

John Tukey introduced intervals based on the range of the sample means rather than the individual differences. The intervals returned by this function are based on this Studentized range statistics. The intervals constructed in this way would only apply exactly to balanced designs where there are the same number of observations made at each level of the factor. This function incorporates an adjustment for sample size that produces sensible intervals for mildly unbalanced designs.

If `which` specifies non-factor terms these will be dropped with a warning: if no terms are left this is an error.

In R 2.15.2 and earlier the results were `NA` for fits with `na.action` methods such as `na.exclude`.

**Value**

A list of class `c("multcomp", "TukeyHSD")`, with one component for each term requested in which. Each component is a matrix with columns `diff` giving the difference in the observed means, `lwr` giving the lower end point of the interval, `upr` giving the upper end point and `p` adj giving the p-value after adjustment for the multiple comparisons.

There are `print` and `plot` methods for class "TukeyHSD". The `plot` method does not accept `xlab`, `ylab` or main arguments and creates its own values for each plot.

**Author(s)**

Douglas Bates

`aov, qtukey, model.tables, glht` in package `multcomp`. 
Examples

```r
require(graphics)

summary(fm1 <- aov(breaks ~ wool + tension, data = warpbreaks))
TukeyHSD(fm1, "tension", ordered = TRUE)
plot(TukeyHSD(fm1, "tension"))
```

### Description

These functions provide information about the uniform distribution on the interval from min to max. `dunif` gives the density, `punif` gives the distribution function `qunif` gives the quantile function and `runif` generates random deviates.

### Usage

- `dunif(x, min = 0, max = 1, log = FALSE)`
- `punif(q, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)`
- `qunif(p, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)`
- `runif(n, min = 0, max = 1)`

### Arguments

- `x, q` vector of quantiles.
- `p` vector of probabilities.
- `n` number of observations. If `length(n) > 1`, the length is taken to be the number required.
- `min, max` lower and upper limits of the distribution. Must be finite.
- `log, log.p` logical; if `TRUE`, probabilities `p` are given as `log(p)`.
- `lower.tail` logical; if `TRUE` (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

### Details

If `min` or `max` are not specified they assume the default values of 0 and 1 respectively.

The uniform distribution has density

$$ f(x) = \frac{1}{max - min} $$

for $min \leq x \leq max$.

For the case of $u := min == max$, the limit case of $X \equiv u$ is assumed, although there is no density in that case and `dunif` will return `NaN` (the error condition).

`runif` will not generate either of the extreme values unless `max = min` or `max-min` is small compared to `min`, and in particular not for the default arguments.
uniroot

Value

dunif gives the density, punif gives the distribution function, qunif gives the quantile function, and runif generates random deviates.

The length of the result is determined by n for runif, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than n are recycled to the length of the result. Only the first elements of the logical parameters are used.

Note

The characteristics of output from pseudo-random number generators (such as precision and periodicity) vary widely. See .Random.seed for more information on R’s random number generation algorithms.

References

See Also

RNG about random number generation in R.
Distributions for other standard distributions.

Examples

```r
u <- runif(20)

## The following relations always hold :
punif(u) == u
dunif(u) == 1
var(runif(10000))    # ~ = 1/12 = .08333
```

Description

The function uniroot searches the interval from lower to upper for a root (i.e., zero) of the function f with respect to its first argument.

Usage

```r
uniroot(f, interval, ..., 
lower = min(interval), upper = max(interval),
f.lower = f(lower, ...), f.upper = f(upper, ...),
tol = .Machine$double.eps^0.25, maxiter = 1000)
```
Arguments

- `f` the function for which the root is sought.
- `interval` a vector containing the end-points of the interval to be searched for the root.
- `...` additional named or unnamed arguments to be passed to `f`.
- `lower`, `upper` the lower and upper end points of the interval to be searched.
- `f.lower`, `f.upper` the same as `f(upper)` and `f(lower)`, respectively. Passing these values from the caller where they are often known is more economical as soon as `f()` contains non-trivial computations.
- `tol` the desired accuracy (convergence tolerance).
- `maxiter` the maximum number of iterations.

Details

Note that arguments after `...` must be matched exactly.

Either `interval` or both `lower` and `upper` must be specified: the upper endpoint must be strictly larger than the lower endpoint. The function values at the endpoints must be of opposite signs (or zero).

The function uses Fortran subroutine ‘“zeroin”’ (from Netlib) based on algorithms given in the reference below. They assume a continuous function (which then is known to have at least one root in the interval).

Convergence is declared either if `f(x) == 0` or the change in `x` for one step of the algorithm is less than `tol` (plus an allowance for representation error in `x`).

If the algorithm does not converge in `maxiter` steps, a warning is printed and the current approximation is returned.

`f` will be called as `f(x, ...)` for a numeric value of `x`.

The argument passed to `f` has special semantics and used to be shared between calls. The function should not copy it.

Value

A list with at least four components: `root` and `f.root` give the location of the root and the value of the function evaluated at that point. `iter` and `estim.prec` give the number of iterations used and an approximate estimated precision for `root`. (If the root occurs at one of the endpoints, the estimated precision is NA.)

Further components may be added in future.

Source

Based on ‘zeroin.c’ in http://www.netlib.org/c/brent.shar.

polyroot for all complex roots of a polynomial; optimize, nlm.
Examples

```r
require(utils) # for str

## some platforms hit zero exactly on the first step:
## if so the estimated precision is 2/3.
f <- function(x, a) x - a
str(xmin <- uniroot(f, c(0, 1), tol = 0.0001, a = 1/3))

## handheld calculator example: fixed point of cos():
unroot(function(x) cos(x) - x, lower = -pi, upper = pi, tol = 1e-9)
str(unroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2,
tol = 0.0001))
str(unroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2,
tol = 1e-10))

## Find the smallest value x for which exp(x) > 0 (numerically):
r <- unroot(function(x) 1e80*exp(x) - 1e-300, c(-1000, 0), tol = 1e-15)
str(r, digits.d = 15) # around -745, depending on the platform.

exp(r$root) # = 0, but not for r$root * 0.999...
minexp <- r$root * (1 - 10*.Machine$double.eps)
exp(minexp) # typically denormalized
```

update

**Update and Re-fit a Model Call**

update will update and (by default) re-fit a model. It does this by extracting the call stored in the object, updating the call and (by default) evaluating that call. Sometimes it is useful to call `update` with only one argument, for example if the data frame has been corrected.

“Extracting the call” in `update()` and similar functions uses `getCall()` which itself is a (S3) generic function with a default method that simply gets x$call.

Because of this, `update()` will often work (via its default method) on new model classes, either automatically, or by providing a simple `getCall()` method for that class.

**Usage**

```r
update(object, ...)
## Default S3 method:
update(object, formula., ..., evaluate = TRUE)
```

**Arguments**

- `object`, `x` An existing fit from a model function such as `lm`, `glm` and many others.
- `formula.` Changes to the formula – see `update.formula` for details.
- `...` Additional arguments to the call, or arguments with changed values. Use name = NULL to remove the argument name.
- `evaluate` If true evaluate the new call else return the call.
Value

If `evaluate` = TRUE the fitted object, otherwise the updated call.

summary(lm.D9 <- update(lm.D9, . ~ - 1))
options(contrasts = c("contr.helmert", "contr.poly"))
update(lm.D9)
getCall(lm.D9)  # "through the origin"

options(oldcon)
```

Description

`update.formula` is used to update model formulae. This typically involves adding or dropping terms, but updates can be more general.

Usage

```r
## S3 method for class 'formula'
update(old, new, ...)
```

Arguments

- `old` a model formula to be updated.
- `new` a formula giving a template which specifies how to update.
- `...` further arguments passed to or from other methods.
Details

Either or both of old and new can be objects such as length-one character vectors which can be coerced to a formula via `as.formula`.

The function works by first identifying the left-hand side and right-hand side of the old formula. It then examines the new formula and substitutes the lhs of the old formula for any occurrence of `.` on the left of new, and substitutes the rhs of the old formula for any occurrence of `.` on the right of new. The result is then simplified via `terms.formula(simplify = TRUE).

Value

The updated formula is returned. The environment of the result is that of old.

See Also

`terms, model.matrix`.

Examples

```r
update(y ~ x, ~ . + x2) #> y ~ x + x2
update(y ~ x, log(.) ~ . ) #> log(y) ~ x
```

---

### var.test

**F Test to Compare Two Variances**

**Description**

Performs an F test to compare the variances of two samples from normal populations.

**Usage**

```r
var.test(x, y)
```

```r
## Default S3 method:
var.test(x, y, ratio = 1,
    alternative = c("two.sided", "less", "greater"),
    conf.level = 0.95, ...)
```

```r
## S3 method for class 'formula'
var.test(formula, data, subset, na.action, ...)
```

**Arguments**

- **x, y** numeric vectors of data values, or fitted linear model objects (inheriting from class "lm").
- **ratio** the hypothesized ratio of the population variances of x and y.
- **alternative** a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
- **conf.level** confidence level for the returned confidence interval.
a formula of the form lhs \sim rhs where lhs is a numeric variable giving the
data values and rhs a factor with two levels giving the corresponding groups.

data an optional matrix or data frame (or similar: see model.frame) containing
the variables in the formula formula. By default the variables are taken from
environment(formula).

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NAs. De-
defaults to getOption("na.action").

... further arguments to be passed to or from methods.

Details
The null hypothesis is that the ratio of the variances of the populations from which x and y were
drawn, or in the data to which the linear models x and y were fitted, is equal to ratio.

Value
A list with class "htest" containing the following components:

statistic the value of the F test statistic.
parameter the degrees of the freedom of the F distribution of the test statistic.
p.value the p-value of the test.
conf.int a confidence interval for the ratio of the population variances.
estimate the ratio of the sample variances of x and y.
null.value the ratio of population variances under the null.
alternative a character string describing the alternative hypothesis.
method the character string "F test to compare two variances".
data.name a character string giving the names of the data.

See Also

bartlett.test for testing homogeneity of variances in more than two samples from normal dis-
tributions; ansari.test and mood.test for two rank based (nonparametric) two-sample tests for
difference in scale.

Examples

x <- rnorm(50, mean = 0, sd = 2)
y <- rnorm(30, mean = 1, sd = 1)
var.test(x, y)  # Do x and y have the same variance?
var.test(lm(x ~ 1), lm(y ~ 1))  # The same.
Rotation Methods for Factor Analysis

Description

These functions ‘rotate’ loading matrices in factor analysis.

Usage

varimax(x, normalize = TRUE, eps = 1e-5)
promax(x, m = 4)

Arguments

x A loadings matrix, with \( p \) rows and \( k < p \) columns
m The power used the target for promax. Values of 2 to 4 are recommended.
normalize logical. Should Kaiser normalization be performed? If so the rows of \( x \) are re-scaled to unit length before rotation, and scaled back afterwards.
eps The tolerance for stopping: the relative change in the sum of singular values.

Details

These seek a ‘rotation’ of the factors \( x \) that aims to clarify the structure of the loadings matrix. The matrix \( T \) is a rotation (possibly with reflection) for varimax, but a general linear transformation for promax, with the variance of the factors being preserved.

Value

A list with components

loadings The ‘rotated’ loadings matrix, \( x \) \( \times \) \( \text{rotmat} \), of class "loadings".
rotmat The ‘rotation’ matrix.

References

See Also

factanal, Harman74.cor.
Examples

```r
## varimax with normalize = TRUE is the default
fa <- factanal(~., 2, data = swiss)
varimax(loadings(fa), normalize = FALSE)
promax(loadings(fa))
```

Description

Returns the variance-covariance matrix of the main parameters of a fitted model object.

Usage

```r
vcov(object, ...)
```

Arguments

- **object**: a fitted model object, typically. Sometimes also a `summary()` object of such a fitted model.
- **...**: additional arguments for method functions. For the `glm` method this can be used to pass a dispersion parameter.

Details

This is a generic function. Functions with names beginning in `vcov` will be methods for this function. Classes with methods for this function include: `lm`, `mlm`, `glm`, `nls`, `summary.lm`, `summary.glm`, `negbin`, `polr`, `r1m` (in package `MASS`), `multinom` (in package `nnet`) `gls`, `lme` (in package `nlme`), `coxph` and `survreg` (in package `survival`).

`vcov()` methods for summary objects allow more efficient and still encapsulated access when both `summary(mod)` and `vcov(mod)` are needed.

Value

A matrix of the estimated covariances between the parameter estimates in the linear or non-linear predictor of the model. This should have row and column names corresponding to the parameter names given by the `coef` method.
The Weibull Distribution

Description

Density, distribution function, quantile function and random generation for the Weibull distribution with parameters shape and scale.

Usage

dweibull(x, shape, scale = 1, log = FALSE)
pweibull(q, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
qweibull(p, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
rweibull(n, shape, scale = 1)

Arguments

- x, q: vector of quantiles.
- p: vector of probabilities.
- n: number of observations. If length(n) > 1, the length is taken to be the number required.
- shape, scale: shape and scale parameters, the latter defaulting to 1.
- log, log.p: logical; if TRUE, probabilities p are given as log(p).
- lower.tail: logical; if TRUE (default), probabilities are \( P[X ≤ x] \), otherwise, \( P[X > x] \).

Details

The Weibull distribution with shape parameter \( a \) and scale parameter \( σ \) has density given by

\[
f(x) = (a/σ)(x/σ)^{a-1} \exp(-(x/σ)^a)
\]

for \( x > 0 \). The cumulative distribution function is \( F(x) = 1 - \exp(-(x/σ)^a) \) on \( x > 0 \), the mean is \( E(X) = σΓ(1 + 1/a) \), and the \( Var(X) = σ^2(Γ(1 + 2/a) - (Γ(1 + 1/a))^2) \).

Value

dweibull gives the density, pweibull gives the distribution function, qweibull gives the quantile function, and rweibull generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by n for rweibull, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than n are recycled to the length of the result. Only the first elements of the logical parameters are used.

Note

The cumulative hazard \( H(t) = -\log(1 - F(t)) \) is

\[
-pweibull(t, a, b, lower = FALSE, log = TRUE)
\]

which is just \( H(t) = (t/b)^a \).
weighted.mean

Source

dpqweibull are calculated directly from the definitions. rweibull uses inversion.

References

See Also

Distributions for other standard distributions, including the Exponential which is a special case of the Weibull distribution.

Examples

    x <- c(0, rlnorm(50))
    all.equal(dweibull(x, shape = 1), dexp(x))
    all.equal(pweibull(x, shape = 1, scale = pi), pexp(x, rate = 1/pi))
    ## Cumulative hazard H(t):
    all.equal(pweibull(x, 2.5, pi, lower.tail = FALSE, log.p = TRUE),
              -(x/pi)^2.5, tol = 1e-15)
    all.equal(qweibull(x/11, shape = 1, scale = pi), qexp(x/11, rate = 1/pi))

---

weighted.mean

Weighted Arithmetic Mean

Description

Compute a weighted mean.

Usage

weighted.mean(x, w, ...)

## Default S3 method:
weighted.mean(x, w, ..., na.rm = FALSE)

Arguments

x
an object containing the values whose weighted mean is to be computed.

w
a numerical vector of weights the same length as x giving the weights to use for elements of x.

... arguments to be passed to or from methods.

na.rm
a logical value indicating whether NA values in x should be stripped before the computation proceeds.
Details

This is a generic function and methods can be defined for the first argument \( x \): apart from the default methods there are methods for the date-time classes "POSIXct", "POSIXlt", "difftime" and "Date". The default method will work for any numeric-like object for which \([\cdot]\), multiplication, division and \texttt{sum} have suitable methods, including complex vectors.

If \( w \) is missing then all elements of \( x \) are given the same weight, otherwise the weights coerced to numeric by \texttt{as.numeric} and normalized to sum to one (if possible: if their sum is zero or infinite the value is likely to be \texttt{NaN}).

Missing values in \( w \) are not handled specially and so give a missing value as the result. However, as from \( R \) 2.11.0 zero weights are handled specially and the corresponding \( x \) values are omitted from the sum.

Value

For the default method, a length-one numeric vector.

See Also

\texttt{mean}

Examples

```r
## GPA from Siegel 1994
wt <- c(5, 5, 4, 1)/15
x <- c(3.7, 3.3, 3.5, 2.8)
xm <- weighted.mean(x, wt)
```

---

\texttt{weighted.residuals} \quad \textit{Compute Weighted Residuals}

Description

Computed weighted residuals from a linear model fit.

Usage

\texttt{weighted.residuals(obj, drop0 = TRUE)}

Arguments

\begin{itemize}
  \item \texttt{obj} \quad \textit{R} object, typically of class \texttt{lm} or \texttt{glm}.
  \item \texttt{drop0} \quad \textit{logical}. If \texttt{TRUE}, drop all cases with \texttt{weights} \texttt{==} \texttt{0}.
\end{itemize}

Details

Weighted residuals are based on the deviance residuals, which for a \texttt{lm} fit are the raw residuals \( R_i \) multiplied by \( \sqrt{w_i} \), where \( w_i \) are the weights as specified in \texttt{lm}'s call.

Dropping cases with weights zero is compatible with \texttt{influence} and related functions.
weights

Value

Numeric vector of length \( n' \), where \( n' \) is the number of non-0 weights (\texttt{drop0 = TRUE}) or the number of observations, otherwise.

See Also

\texttt{residuals}, \texttt{lm.influence}, etc.

Examples

```r
## following on from example(lm)

all.equal(weighted.residuals(lm.D9),
          residuals(lm.D9))
x <- 1:10
w <- 0:9
y <- rnorm(x)
weighted.residuals(lmxy <- lm(y ~ x, weights = w))
weighted.residuals(lmxy, drop0 = FALSE)
```

Description

\texttt{weights} is a generic function which extracts fitting weights from objects returned by modeling functions.

Methods can make use of \texttt{napredict} methods to compensate for the omission of missing values. The default methods does so.

Usage

\texttt{weights(object, \ldots)}

Arguments

\begin{itemize}
\item \texttt{object} an object for which the extraction of model weights is meaningful.
\item \texttt{\ldots} other arguments passed to methods.
\end{itemize}

Value

Weights extracted from the object \texttt{object}: the default method looks for component "w\texttt{eights}" and if not \texttt{NULL} calls \texttt{napredict} on it.

References

See Also

\texttt{weights.glm}
wilcox.test

Description

Performs one- and two-sample Wilcoxon tests on vectors of data; the latter is also known as 'Mann-Whitney' test.

Usage

wilcox.test(x, ...)  

### Default S3 method:

wilcox.test(x, y = NULL,  
alternatives = c("two.sided", "less", "greater"),  
mu = 0, paired = FALSE, exact = NULL, correct = TRUE,  
conf.int = FALSE, conf.level = 0.95, ...)

### S3 method for class 'formula'

wilcox.test(formula, data, subset, na.action, ...)

Arguments

x     numeric vector of data values. Non-finite (e.g. infinite or missing) values will be omitted.
y  an optional numeric vector of data values: as with x non-finite values will be omitted.
alternative  a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
mu  a number specifying an optional parameter used to form the null hypothesis. See 'Details'.
paired  a logical indicating whether you want a paired test.
exact  a logical indicating whether an exact p-value should be computed.
correct  a logical indicating whether to apply continuity correction in the normal approximation for the p-value.
conf.int  a logical indicating whether a confidence interval should be computed.
conf.level  a confidence level of the interval.
formula  a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.
data  an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset  an optional vector specifying a subset of observations to be used.
na.action  a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").
...  further arguments to be passed to or from methods.
Details

The formula interface is only applicable for the 2-sample tests.

If only \( x \) is given, or if both \( x \) and \( y \) are given and paired is \text{TRUE}, a Wilcoxon signed rank test of the null that the distribution of \( x \) (in the one sample case) or of \( x - y \) (in the paired two sample case) is symmetric about \( \mu \) is performed.

Otherwise, if both \( x \) and \( y \) are given and paired is \text{FALSE}, a Wilcoxon rank sum test (equivalent to the Mann-Whitney test: see the Note) is carried out. In this case, the null hypothesis is that the distributions of \( x \) and \( y \) differ by a location shift of \( \mu \) and the alternative is that they differ by some other location shift (and the one-sided alternative “\textgreater\” is that \( x \) is shifted to the right of \( y \)).

By default (if \text{exact} is not specified), an exact p-value is computed if the samples contain less than 50 finite values and there are no ties. Otherwise, a normal approximation is used.

Optionally (if argument \text{conf.int} is true), a nonparametric confidence interval and an estimator for the pseudomedian (one-sample case) or for the difference of the location parameters \( x - y \) is computed. (The pseudomedian of a distribution \( F \) is the median of the distribution of \( (u + v)/2 \), where \( u \) and \( v \) are independent, each with distribution \( F \). If \( F \) is symmetric, then the pseudomedian and median coincide. See Hollander & Wolfe (1973), page 34.) Note that in the two-sample case the estimator for the difference in location parameters does \textit{not} estimate the difference in medians (a common misconception) but rather the median of the difference between a sample from \( x \) and a sample from \( y \).

If exact p-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations. These are continuity-corrected for the interval but \textit{not} the estimate (as the correction depends on the \text{alternative}).

With small samples it may not be possible to achieve very high confidence interval coverages. If this happens a warning will be given and an interval with lower coverage will be substituted.

Value

A list with class "htest" containing the following components:

- \text{statistic} the value of the test statistic with a name describing it.
- \text{parameter} the parameter(s) for the exact distribution of the test statistic.
- \text{p.value} the p-value for the test.
- \text{null.value} the location parameter \( \mu \).
- \text{alternative} a character string describing the alternative hypothesis.
- \text{method} the type of test applied.
- \text{data.name} a character string giving the names of the data.
- \text{conf.int} a confidence interval for the location parameter. (Only present if argument \text{conf.int} = \text{TRUE}.)
- \text{estimate} an estimate of the location parameter. (Only present if argument \text{conf.int} = \text{TRUE}.)

Warning

This function can use large amounts of memory and stack (and even crash R if the stack limit is exceeded) if \text{exact} = \text{TRUE} and one sample is large (several thousands or more).
The literature is not unanimous about the definitions of the Wilcoxon rank sum and Mann-Whitney tests. The two most common definitions correspond to the sum of the ranks of the first sample with the minimum value subtracted or not: R subtracts and S-PLUS does not, giving a value which is larger by \( m(m + 1)/2 \) for a first sample of size \( m \). (It seems Wilcoxon’s original paper used the unadjusted sum of the ranks but subsequent tables subtracted the minimum.)

R’s value can also be computed as the number of all pairs \( (x[i], y[j]) \) for which \( y[j] \) is not greater than \( x[i] \), the most common definition of the Mann-Whitney test.

**Wilcoxon**

**Distribution of the Wilcoxon Rank Sum Statistic**

Description

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon rank sum statistic obtained from samples with size \( m \) and \( n \), respectively.

Usage

dwilcoxon(x, m, n, log = FALSE)
pwilcoxon(q, m, n, lower.tail = TRUE, log.p = FALSE)
qwilcoxon(p, m, n, lower.tail = TRUE, log.p = FALSE)
rwilcoxon(nn, m, n)

Arguments

- **x, q**: vector of quantiles.
- **p**: vector of probabilities.
- **nn**: number of observations. If length(nn) > 1, the length is taken to be the number required.
- **m, n**: numbers of observations in the first and second sample, respectively. Can be vectors of positive integers.
- **log, log.p**: logical; if TRUE, probabilities p are given as log(p).
- **lower.tail**: logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

This distribution is obtained as follows. Let \( x \) and \( y \) be two random, independent samples of size \( m \) and \( n \). Then the Wilcoxon rank sum statistic is the number of all pairs \((x[i], y[j])\) for which \( y[j] \) is not greater than \( x[i] \). This statistic takes values between 0 and \( m \times n \), and its mean and variance are \( m \times n / 2 \) and \( m \times n \times (m + n + 1) / 12 \), respectively.

If any of the first three arguments are vectors, the recycling rule is used to do the calculations for all combinations of the three up to the length of the longest vector.

Value

dwilcoxon gives the density, pwilcoxon gives the distribution function, qwilcoxon gives the quantile function, and rwilcoxon generates random deviates.

The length of the result is determined by nn for rwilcoxon, and is the maximum of the lengths of the numerical parameters for the other functions.

The numerical parameters other than nn are recycled to the length of the result. Only the first elements of the logical parameters are used.
Warning

These functions can use large amounts of memory and stack (and even crash R if the stack limit is exceeded and stack-checking is not in place) if one sample is large (several thousands or more).

Note

S-PLUS uses a different (but equivalent) definition of the Wilcoxon statistic: see \texttt{wilcox.test} for details.

Author(s)

Kurt Hornik

Source

These are calculated via recursion, based on \texttt{cwilcox(k, m, n)}, the number of choices with statistic \textit{k} from samples of size \textit{m} and \textit{n}, which is itself calculated recursively and the results cached. Then \texttt{dwilcox} and \texttt{pwilcox} sum appropriate values of \texttt{cwilcox}, and \texttt{qwilcox} is based on inversion. \texttt{rwilcox} generates a random permutation of ranks and evaluates the statistic.

See Also

\texttt{wilcox.test} to calculate the statistic from data, find \textit{p} values and so on.

Distributions for standard distributions, including \texttt{dsignrank} for the distribution of the \textit{one-sample} Wilcoxon signed rank statistic.

Examples

require(graphics)

x <- -1:(4*6 + 1)
fX <- dwilcox(x, 4, 6)
Fx <- pwilcox(x, 4, 6)

layout(rbind(1,2), widths = 1, heights = c(3,2))
plot(x, fx, type = "h", col = "violet",
     main = "Probabilities (density) of Wilcoxon-Statist.(n=6, m=4)"
)
plot(x, Fx, type = "s", col = "blue",
     main = "Distribution of Wilcoxon-Statist.(n=6, m=4)"
)
abline(h = 0:1, col = "gray20", lty = 2)
layout(1) # set back

N <- 200
hist(U <- rwilcox(N, m = 4,n = 6), breaks = 0:25 - 1/2,
     border = "red", col = "pink", sub = paste("N =",N))
mtext("N * f(x), f() = true \"density\"", side = 3, col = "blue")
lines(x, N*fx, type = "h", col = "blue", lwd = 2)
points(x, N*fx, cex = 2)

## Better is a Quantile-Quantile Plot
qqplot(U, qr <- qwilcox((1: N - 1/2)/N, m = 4, n = 6),
     main = paste("Q-Q-Plot of empirical and theoretical quantiles",
                  "Wilcoxon Statistic. (m=4, n=6)", sep = "\n")
)n <- as.numeric(names(print(tU <- table(U))))
text(n+.2, n+.5, labels = tU, col = "red")
Time Windows

Description

window is a generic function which extracts the subset of the object x observed between the times start and end. If a frequency is specified, the series is then re-sampled at the new frequency.

Usage

window(x, ...)
## S3 method for class 'ts'
window(x, ...)
## Default S3 method:
window(x, start = NULL, end = NULL,
frequency = NULL, deltat = NULL, extend = FALSE, ...)

window(x, ...) <- value
## S3 replacement method for class 'ts'
window(x, start, end, frequency, deltat, ...) <- value

Arguments

x a time-series (or other object if not replacing values).
start the start time of the period of interest.
end the end time of the period of interest.
frequency, deltat the new frequency can be specified by either (or both if they are consistent).
extend logical. If true, the start and end values are allowed to extend the series. If false, attempts to extend the series give a warning and are ignored.
... further arguments passed to or from other methods.
value replacement values.

Details

The start and end times can be specified as for ts. If there is no observation at the new start or end, the immediately following (start) or preceding (end) observation time is used.

The replacement function has a method for ts objects, and is allowed to extend the series (with a warning). There is no default method.

Value

The value depends on the method. window.default will return a vector or matrix with an appropriate tsp attribute.

window.ts differs from window.default only in ensuring the result is a ts object.

If extend = TRUE the series will be padded with NAs if needed.
xtabs

Cross Tabulation

Description

Create a contingency table (optionally a sparse matrix) from cross-classifying factors, usually contained in a data frame, using a formula interface.

Usage

xtabs(formula = ~ ., data = parent.frame(), subset, sparse = FALSE,
na.action, exclude = c(NA, NaN), drop.unused.levels = FALSE)

Arguments

formula a formula object with the cross-classifying variables (separated by +) on the right hand side (or an object which can be coerced to a formula). Interactions are not allowed. On the left hand side, one may optionally give a vector or a matrix of counts; in the latter case, the columns are interpreted as corresponding to the levels of a variable. This is useful if the data have already been tabulated, see the examples below.
data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset an optional vector specifying a subset of observations to be used.
sparse logical specifying if the result should be a sparse matrix, i.e., inheriting from sparseMatrix. Only works for two factors (since there are no higher-order sparse array classes yet).
na.action a function which indicates what should happen when the data contain NAs.
exclude

a vector of values to be excluded when forming the set of levels of the classifying factors.

drop.unused.levels

a logical indicating whether to drop unused levels in the classifying factors. If this is FALSE and there are unused levels, the table will contain zero marginals, and a subsequent chi-squared test for independence of the factors will not work.

Details

There is a summary method for contingency table objects created by table or xtabs(*, sparse = FALSE), which gives basic information and performs a chi-squared test for independence of factors (note that the function chisq.test currently only handles 2-d tables).

If a left hand side is given in formula, its entries are simply summed over the cells corresponding to the right hand side; this also works if the lhs does not give counts.

For variables in formula which are factors, exclude must be specified explicitly; the default exclusions will not be used.

Value

By default, when sparse = FALSE, a contingency table in array representation of S3 class c("xtabs", "table"); with a "call" attribute storing the matched call.

When sparse = TRUE, a sparse numeric matrix, specifically an object of S4 class dgTMatrix from package Matrix.

See Also

table for traditional cross-tabulation, and as.data.frame.table which is the inverse operation of xtabs (see the DF example below).

sparseMatrix on sparse matrices in package Matrix.

Examples

## 'esoph' has the frequencies of cases and controls for all levels of
## the variables 'agegp', 'alcgp', and 'tobgp'.
xtabs(cbind(ncases, ncontrols) ~ ., data = esoph)
## Output is not really helpful ... flat tables are better:
table(xtabs(cbind(ncases, ncontrols) ~ ., data = esoph))
## In particular if we have fewer factors ...
table(xtabs(cbind(ncases, ncontrols) ~ agegp, data = esoph))

## This is already a contingency table in array form.
DF <- as.data.frame(UCBAmissions)
## Now 'DF' is a data frame with a grid of the factors and the counts
## in variable 'Freq'.
DF
## Nice for taking margins ...
xtabs(Freq ~ Gender + Admit, DF)
## And for testing independence ...
summary(xtabs(Freq ~ ., DF))

## Create a nice display for the warp break data.
warpbreaks$replicate <- rep(1:9, len = 54)
ftable(xtabs(breaks ~ wool + tension + replicate, data = warpbreaks))
### ---- Sparse Examples ----

```r
if(require("Matrix")) {
  ## similar to "nlme"s 'ergoStool':
  d.ergo <- data.frame(Type = paste0("T", rep(1:4, 9*4)),
                       Subj = gl(9, 4, 36*4))
  print(xtabs(~ Type + Subj, data = d.ergo)) # 4 replicates each
  set.seed(15) # a subset of cases:
  print(xtabs(~ Type + Subj, data = d.ergo[sample(36, 10), ], sparse = TRUE))

  ## Hypothetical two level setup:
  inner <- factor(sample(letters[1:25], 100, replace = TRUE))
  inout <- factor(sample(LETTERS[1:5], 25, replace = TRUE))
  fr <- data.frame(inner = inner, outer = inout[as.integer(inner)])
  print(xtabs(~ inner + outer, fr, sparse = TRUE))
}
```
Chapter 11

The stats4 package

stats4-package  Statistical Functions using S4 Classes

Description
Statistical Functions using S4 classes.

Details
This package contains functions and classes for statistics using the S version 4 class system.
The methods currently support maximum likelihood (function mle() returning class "mle"), including methods for logLik for use with AIC.

Author(s)
R Core Team and contributors worldwide
Maintainer: R Core Team <R-core@r-project.org>

coeq-methods  Methods for Function coef in Package stats4

Description
Extract the coefficient vector from "mle" objects.

Methods
signature(object = "ANY") Generic function: see coef.
signature(object = "mle") Extract the full coefficient vector (including any fixed coefficients) from the fit.
signature(object = "summary.mle") Extract the coefficient vector and standard errors from the summary of the fit.
confint-methods

Methods for Function confint in Package stats4

Description

Generate confidence intervals

Methods

signature(object = "ANY") Generic function: see confint.
signature(object = "mle") First generate profile and then confidence intervals from the profile.
signature(object = "profile.mle") Generate confidence intervals based on likelihood profile.

logLik-methods

Methods for Function logLik in Package stats4

Description

Extract the maximized log-likelihood from "mle" objects.

Methods

signature(object = "ANY") Generic function: see logLik.
signature(object = "mle") Extract log-likelihood from the fit.

Note

The mle method does not know about the number of observations unless nobs was specified on the call and so may not be suitable for use with BIC.

mle

Maximum Likelihood Estimation

Description

Estimate parameters by the method of maximum likelihood.

Usage

mle(minuslogl, start = formals(minuslogl), method = "BFGS", fixed = list(), nobs, ...)

Arguments

- `minuslogl` Function to calculate negative log-likelihood.
- `start` Named list. Initial values for optimizer.
- `method` Optimization method to use. See `optim`.
- `fixed` Named list. Parameter values to keep fixed during optimization.
- `nobs` optional integer: the number of observations, to be used for e.g. computing BIC.
- `...` Further arguments to pass to `optim`.

Details

The `optim` optimizer is used to find the minimum of the negative log-likelihood. An approximate covariance matrix for the parameters is obtained by inverting the Hessian matrix at the optimum.

Value

An object of class `mle-class`.

Note

Be careful to note that the argument is -log L (not -2 log L). It is for the user to ensure that the likelihood is correct, and that asymptotic likelihood inference is valid.

See Also

- `mle-class`

Examples

```r
## Avoid printing to unwarranted accuracy
od <- options(digits = 5)
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 8, 5, 4, 8)

## Easy one-dimensional MLE:
nLL <- function(lambda) -sum(stats::dpois(y, lambda, log = TRUE))
fit0 <- mle(nLL, start = list(lambda = 5), nobs = NROW(y))
# For ID, this is preferable:
fit1 <- mle(nLL, start = list(lambda = 5), nobs = NROW(y),
          method = "Brent", lower = 1, upper = 20)
stopifnot(nobs(fit0) == length(y))

## This needs a constrained parameter space: most methods will accept NA
ll <- function(ymax = 15, xhalf = 6) {
  if(ymax > 0 && xhalf > 0)
    -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
  else NA
}
(fit <- mle(ll, nobs = length(y)))
mle(ll, fixed = list(xhalf = 6))

## alternative using bounds on optimization
ll2 <- function(ymax = 15, xhalf = 6)
  -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
mle(ll2, method = "L-BFGS-B", lower = rep(0, 2))
```
mle-class

Class "mle" for Results of Maximum Likelihood Estimation

Description

This class encapsulates results of a generic maximum likelihood procedure.

Objects from the Class

Objects can be created by calls of the form new("mle", ...), but most often as the result of a call to mle.

Slots

- call: Object of class "language". The call to mle.
- coef: Object of class "numeric". Estimated parameters.
- fullcoef: Object of class "numeric". Fixed and estimated parameters.
- vcov: Object of class "matrix". Approximate variance-covariance matrix.
- min: Object of class "numeric". Minimum value of objective function.
- details: a "list", as returned from optim.
- minuslogl: Object of class "function". The negative loglikelihood function.
- nobs: "integer" of length one. The number of observations (often NA, when not set in call explicitly).
- method: Object of class "character". The optimization method used.
Methods

confint signature(object = "mle"): Confidence intervals from likelihood profiles.
logLik signature(object = "mle"): Extract maximized log-likelihood.
profile signature(fitted = "mle"): Likelihood profile generation.
nobs signature(object = "mle"): Number of observations, here simply accessing the nobs slot mentioned above.
show signature(object = "mle"): Display object briefly.
summary signature(object = "mle"): Generate object summary.
update signature(object = "mle"): Update fit.
vcov signature(object = "mle"): Extract variance-covariance matrix.

Description

Plot profile likelihoods for "mle" objects.

Usage

## S4 method for signature 'profile.mle,missing'
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100, nseg = 50,
     absVal = TRUE, ...)

Arguments

x
levels
conf
nseg
absVal

other arguments to the plot function can be passed here.

Methods

signature(x = "ANY", y = "ANY") Generic function: see plot.
signature(x = "profile.mle", y = "missing") Plot likelihood profiles for x.
Profile likelihood for "mle" objects.

Usage

```r
## S4 method for signature 'mle'
profile(fitted, which = 1:p, maxsteps = 100, alpha = 0.01,
       zmax = sqrt(qchisq(1 - alpha, 1L)), del = zmax/5,
       trace = FALSE, ...)
```

Arguments

- `fitted`: Object to be profiled.
- `which`: Optionally select subset of parameters to profile.
- `maxsteps`: Maximum number of steps to bracket \( z_{\text{max}} \).
- `alpha`: Significance level corresponding to \( z_{\text{max}} \), based on a Scheffe-style multiple testing interval. Ignored if \( z_{\text{max}} \) is specified.
- `zmax`: Cutoff for the profiled value of the signed root-likelihood.
- `del`: Initial stepsize on root-likelihood scale.
- `trace`: Logical. Print intermediate results.
- `...`: Currently unused.

Details

The profiling algorithm tries to find an approximately evenly spaced set of at least five parameter values (in each direction from the optimum) to cover the root-likelihood function. Some care is taken to try and get sensible results in cases of high parameter curvature. Notice that it may not always be possible to obtain the cutoff value, since the likelihood might level off.

Value

An object of class "profile.mle", see "profile.mle-class".

Methods

- `signature(fitted = "ANY")` Generic function: see `profile`.
- `signature(fitted = "mle")` Profile the likelihood in the vicinity of the optimum of an "mle" object.
profile.mle-class

Class "profile.mle"; Profiling information for "mle" object

Description

Likelihood profiles along each parameter of likelihood function

Objects from the Class

Objects can be created by calls of the form `new("profile.mle", ...)`, but most often by invoking `profile` on an "mle" object.

Slots

- `profile`: Object of class "list". List of profiles, one for each requested parameter. Each profile is a data frame with the first column called `z` being the signed square root of the -2 log likelihood ratio, and the others being the parameters with names prefixed by `par.vals`.

- `summary`: Object of class "summary.mle". Summary of object being profiled.

Methods

- `confint` signature(object = "profile.mle"): Use profile to generate approximate confidence intervals for parameters.

- `plot` signature(x = "profile.mle", y = "missing"): Plot profiles for each parameter.

See Also

- `mle, mle-class, summary.mle-class`

show-methods

Methods for Function show in Package stats4

Description

Show objects of classes `mle` and `summary.mle`
Methods for Function `summary` in Package `stats4`

**Description**

Summarize objects

**Methods**

- `signature(object = "ANY")` Generic function
- `signature(object = "mle")` Generate a summary as an object of class "summary.mle", containing estimates, asymptotic SE, and value of $-2 \log L$.

**summary.mle-class**  
Class "summary.mle", Summary of "mle" Objects

**Description**

Extract of "mle" object

**Objects from the Class**

Objects can be created by calls of the form `new("summary.mle", ...). but most often by invoking `summary` on an "mle" object. They contain values meant for printing by `show`.

**Slots**

- `call`: Object of class "language" The call that generated the "mle" object.
- `coef`: Object of class "matrix". Estimated coefficients and standard errors
- `m2logL`: Object of class "numeric". Minus twice the log likelihood.

**Methods**

- `show signature(object = "summary.mle")`: Pretty-prints object
- `coef signature(object = "summary.mle")`: Extracts the contents of the `coef` slot

**See Also**

`summary.mle`, `mle-class`
**update-methods**

Methods for Function `update` in Package `stats4`

**Description**

Update "mle" objects.

**Usage**

```r
## S4 method for signature 'mle'
update(object, ..., evaluate = TRUE)
```

**Arguments**

- `object` An existing fit.
- `...` Additional arguments to the call, or arguments with changed values. Use `name = NULL` to remove the argument name.
- `evaluate` If true evaluate the new call else return the call.

**Methods**

- `signature(object = "ANY")` Generic function: see `update`.
- `signature(object = "mle")` Update a fit.

**Examples**

```r
x <- 0:10
y <- c(26, 17, 13, 20, 5, 9, 8, 5, 4, 8)
ll <- function(ymax = 15, xhalf = 6)
  -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
fit <- mle(ll)
## note the recorded call contains ..1, a problem with S4 dispatch
update(fit, fixed = list(xhalf = 3))
```

---

**vcov-methods**

Methods for Function `vcov` in Package `stats4`

**Description**

Extract the approximate variance-covariance matrix from "mle" objects.

**Methods**

- `signature(object = "ANY")` Generic function: see `vcov`.
- `signature(object = "mle")` Extract the estimated variance-covariance matrix for the estimated parameters (if any).
Chapter 12

The tcltk package

---

tcltk-package  Tcl/Tk Interface

Description

Interface and language bindings to Tcl/Tk GUI elements.

Details

This package provides access to the platform-independent Tcl scripting language and Tk GUI elements. See TkWidgets for a list of supported widgets, TkWidgetcmds for commands to work with them, and references in those files for more.

The Tcl/Tk documentation is in the system man pages.

For a complete list of functions, use ls("package:tcltk").

Note that Tk will not be initialized if there is no DISPLAY variable set, but Tcl can still be used. This is most useful to allow the loading of a package which depends on tcltk in a session that does not actually use it (e.g. during installation).

Author(s)

R Core Team

Maintainer: R Core Team <R-core@r-project.org>

---

TclInterface  Low-level Tcl/Tk Interface

Description

These functions and variables provide the basic glue between R and the Tcl interpreter and Tk GUI toolkit. Tk windows may be represented via R objects. Tcl variables can be accessed via objects of class tclVar and the C level interface to Tcl objects is accessed via objects of class tclObj.
Usage

.Tcl(...)
.Tcl.objv(objv)
.Tcl.args(...)
.Tcl.args.objv(...)
.Tcl.callback(...)
.Tk.ID(win)
.Tk.newwin(ID)
.Tk.subwin(parent)
.TkRoot

tkdestroy(win)
is.tkwin(x)

tclvalue(x)
tclvalue(x) <- value

tclVar(init = "")
## S3 method for class 'tclVar'
as.character(x, ...)
## S3 method for class 'tclVar'
tclvalue(x)
## S3 replacement method for class 'tclVar'
tclvalue(x) <- value

tclArray()
## S3 method for class 'tclArray'
x[[...]]
## S3 replacement method for class 'tclArray'
x[[...]] <- value
## S3 method for class 'tclArray'
x$i
## S3 replacement method for class 'tclArray'
x$i <- value

## S3 method for class 'tclArray'
names(x)
## S3 method for class 'tclArray'
length(x)

tclObj(x)
tclObj(x) <- value
## S3 method for class 'tclVar'
tclObj(x)
## S3 replacement method for class 'tclVar'
tclObj(x) <- value

as.tclObj(x, drop = FALSE)
is.tclObj(x)

## S3 method for class 'tclObj'
as.character(x, ...)}
**Arguments**

- **objv**
  a named vector of Tcl objects
- **win**
  a window structure
- **x**
  an object
- **i**
  character or (unquoted) name
- **drop**
  logical. Indicates whether a single-element vector should be made into a simple
  Tcl object or a list of length one
- **value**
  For tclvalue assignments, a character string. For tc10bj assignments, an object
  of class tc10bj
- **ID**
  a window ID
- **parent**
  a window which becomes the parent of the resulting window
- **path**
  path to a directory containing Tcl packages
- **package**
  a Tcl package name
- **warn**
  logical. Warn if not found?
- **...**
  Additional arguments. See below.
- **init**
  initialization value

**Details**

Many of these functions are not intended for general use but are used internally by the commands that create and manipulate Tk widgets and Tcl objects. At the lowest level `.Tcl` sends a command as a text string to the Tcl interpreter and returns the result as an object of class tc10bj (see below). A newer variant `.Tcl.object` accepts arguments in the form of a named list of tc10bj objects.

`.Tcl.args` converts an R argument list of tag = value pairs to the Tcl \-option value style, thus enabling a simple translation between the two languages. To send a value with no preceding option flag to Tcl, just use an untagged argument. In the rare case one needs an option with no subsequent value tag = NULL can be used. Most values are just converted to character mode and inserted in
the command string, but window objects are passed using their ID string, and callbacks are passed via the result of .Tcl.callback. Tags are converted to option flags simply by prepending a `-`

`.Tcl.args.objv serves a similar purpose as .Tcl.args but produces a list of tc1obj objects suitable for passing to .Tcl.objv. The names of the list are converted to Tcl option style internally by .Tcl.objv.

Callbacks can be either atomic callbacks handled by .Tcl.callback or expressions. An expression is treated as a list of atomic callbacks, with the following exceptions: if an element is a name, it is first evaluated in the callers frame, and likewise if it is an explicit function definition; the break expression is translated directly to the Tcl counterpart. .Tcl.callback converts R functions and unevaluated calls to Tcl command strings. The argument must be either a function closure or an object of mode "call" followed by an environment. The return value in the first case is of the form R_call 0x408b94d4 in which the hexadecimal number is the memory address of the function. In the second case it will be of the form R_call_lang 0x8a959d0 0x819b6d0. For expressions, a sequence of similar items is generated, separated by semicolons.

`.Tcl.args takes special precautions to ensure that functions or calls will continue to exist at the specified address by assigning the callback into the relevant window environment (see below).

Tk windows are represented as objects of class tkwin which are lists containing a ID field and an env field which is an R environments, enclosed in the global environment. The value of the ID field is identical to the Tk window name. The env environment contains a parent variable and a num.subwin variable. If the window obtains sub-windows and callbacks, they are added as variables to the environment. .TkRoot is the top window with ID ".": this window is not displayed in order to avoid ill effects of closing it via window manager controls. The parent variable is undefined for .TkRoot.

.Tk.ID extracts the ID of a window. .Tk.newwin creates a new window environment with a given ID and .Tk.subwin creates a new window which is a sub-window of a given parent window.

tkdestroy destroys a window and also removes the reference to a window from its parent.

.is.tkwin can be used to test whether a given object is a window environment.

.tclVar creates a new Tcl variable and initializes it to init. An R object of class tclVar is created to represent it. Using as.character on the object returns the Tcl variable name. Accessing the Tcl variable from R is done using the tclvalue function, which can also occur on the left-hand side of assignments. If tclvalue is passed an argument which is not a tclVar object, then it will assume that it is a character string explicitly naming global Tcl variable. Tcl variables created by tclVar are uniquely named and automatically unset by the garbage collector when the representing object is no longer in use.

tclArray creates a new Tcl array and initializes it to the empty array. An R object of class tclArray and inheriting from class tclVar is created to represent it. You can access elements of the Tcl array using indexing with [ or $, which also allow replacement forms. Notice that Tcl arrays are associative by nature and hence unordered; indexing with a numeric index i refers to the element with the name as.character(i). Multiple indices are pasted together separated by commas to form a single name. You can query the length and the set of names in an array using methods for `length` and `names`, respectively; these cannot meaningfully be set so assignment forms exist only to print an error message.

It is possible to access Tcl’s ‘dual-ported’ objects directly, thus avoiding parsing and deparsing of their string representation. This works by using objects of class tc1obj. The string representation of such objects can be extracted (but not set) using tclvalue and conversion to vectors of mode "character", "double", "integer", "logical", and "raw" is performed using the standard coercion functions as.character, etc. Conversely, such vectors can be converted using as.tc1obj. There is an ambiguity as to what should happen for length one vectors, controlled by the drop argument; there are cases where the distinction matters to Tcl, although mostly it treats them equivalently. Notice that tclvalue and as.character differ on an object whose string representation
TclInterface has embedded spaces, the former is sometimes to be preferred, in particular when applied to the result of tclread, tkgetOpenFile, and similar functions. The as.raw method returns a raw vector or a list of raw vectors and can be used to return binary data from Tcl.

The object behind a tclVar object is extracted using tclobj(x) which also allows an assignment form, in which the right hand side of the assignment is automatically converted using as.tclobj. There is a print method for tclobj objects; it prints $<Tcl>$ followed by the string representation of the object. Notice that as.character on a tclVar object is the name of the corresponding Tcl variable and not the value.

Tcl packages can be loaded with tclRequire; it may be necessary to add the directory where they are found to the Tcl search path with addTclPath. The return value is a class "tclobj" object if it succeeds, or FALSE if it fails (when a warning is issued). To see the current search path as an R character vector, use

\[ \text{strsplit(tclvalue('auto_path'), " ")[[1]]} \]

Note

Strings containing unbalanced braces are currently not handled well in many circumstances.

capabilities("tcltk") to see if Tcl/Tk support was compiled into this build of R.

Examples

```r
## Not run:
## These cannot be run by example() but should be OK when pasted
## into an interactive R session with the tcltk package loaded
.Tcl("format \"%s\n\" \"Hello, World!\"\")
f <- function()cat("HI\n")
.Tcl.callback(f)
.Tcl.args(text = "Push!", command = f) # NB: Different address

xyzzy <- tclVar(7913)
tclvalue(xyzzy)
tclvalue(xyzzy) <- "foo"
as.character(xyzzy)
tcl("set", as.character(xyzzy))

top <- tkplevel() # a Tk widget, see Tk-widgets
ls(envir = top$env, all = TRUE)
ls(envir = .TkRoot$env, all = TRUE) # .Tcl.args put a callback ref in here

## End(Not run)
```
**tclServiceMode**

*Allow Tcl events to be serviced or not*

**Description**

This function controls or reports on the Tcl service mode, i.e. whether Tcl will respond to events.

**Usage**

```c
int tclServiceMode(int on = NULL);
```

**Arguments**

- `on` (logical): Whether event servicing is turned on.

**Details**

If called with `on = NULL` (the default), no change is made.

Note that this blocks all Tcl/Tk activity, including for widgets from other packages. It may be better to manage mapping of windows individually.

**Value**

The value of the Tcl service mode before the call.

**Examples**

```c
// see demo(tkcanvas) for an example
// Not run:
oldmode = tclServiceMode(FALSE);
// Do some work to create a nice picture.
// Nothing will be displayed until...
tclServiceMode(oldmode);

// End(Not run)
// another idea is to use tkwm.withdraw() ... tkwm.deiconify()
```

tkdialo(g(...)
tkpopu(p(...)

## File handling functions
tclfile.tail(...)
tclfile.dir(...)
tclreopen(...)
tclclose(...)
tclputs(...)
tclread(...)

Arguments

x        A window object
value    For tktitle assignments, a character string.
...      Handled via .Tcl.args

Details
tcl provides a generic interface to calling any Tk or Tcl command by simply running .Tcl.args.objv on the argument list and passing the result to .Tcl.objv. Most of the other commands simply call tcl with a particular first argument and sometimes also a second argument giving the subcommand.
tktitle and its assignment form provides an alternate interface to Tk's wm title
There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. With a few exceptions, the pattern is that Tk subcommands like pack configure are converted to function names like tkpack.configure, and Tcl subcommands are like tclfile.dir.

See Also

TclInterface, TkWidgets, TkWidgetcmds
Examples

```r
tk <- tkoplevel()
tkpack(ll <- tklabell(tt, text = "Heave"), 12 <- tklabell(tt, text = "Ho"))
tkpack.configure(ll, side = "left")

## Try stretching the window and then

tkdestroy(tt)

## End(Not run)
```

tkpager

Page file using Tk text widget

Description

This plugs into file.show, showing files in separate windows.

Usage

```r
tkpager(file, header, title, delete.file)
```

Arguments

- `file`: character vector containing the names of the files to be displayed
- `header`: headers to use for each file
- `title`: common title to use for the window(s). Pasted together with the header to form actual window title.
- `delete.file`: logical. Should file(s) be deleted after display?

Note

The "\b_" string used for underlining is currently quietly removed. The font and background colour are currently hardcoded to Courier and gray90.

See Also

`file.show`
**tkProgressBar**  
*Progress Bars via Tk*

**Description**
Put up a Tk progress bar widget.

**Usage**
```r
tkProgressBar(title = "R progress bar", label = "",  
               min = 0, max = 1, initial = 0, width = 300)
```

```r
getTkProgressBar(pb)
setTkProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'tkProgressBar'
close(con, ...)
```

**Arguments**
- `title`, `label`: character strings, giving the window title and the label on the dialog box respectively.
- `min`, `max`: (finite) numeric values for the extremes of the progress bar.
- `initial`, `value`: initial or new value for the progress bar.
- `width`: the width of the progress bar in pixels: the dialog box will be 40 pixels wider (plus frame).
- `pb`, `con`: an object of class "tkProgressBar".
- `...`: for consistency with the generic.

**Details**
- `tkProgressBar` will display a widget containing a label and progress bar.
- `setTkProgressBar` will update the value and for non-NULL values, the title and label (provided there was one when the widget was created). Missing (NA) and out-of-range values of `value` will be (silently) ignored.
- The progress bar should be closed when finished with.
- This will use the ttk::progressbar widget for Tk version 8.5 or later, otherwise R's copy of BWidget's `progressbar`.

**Value**
- For `tkProgressBar` an object of class "tkProgressBar".
- For `getTkProgressBar` and `setTkProgressBar`, a length-one numeric vector giving the previous value (invisibly for `setTkProgressBar`).

**See Also**
- `txtProgressBar`
Examples

```r
tp <- tkProgressBar("test progress bar", "Some information in %", 0, 100, 50)
Sys.sleep(0.5)
u <- c(0, sort(runif(20, 0, 100)), 100)
for(i in u) {
  Sys.sleep(0.1)
  info <- sprintf("%d%% done", round(i))
  setTkProgressBar(pb, i, sprintf("test (%s)", info), info)
}
Sys.sleep(5)
close(pb)
```

tkStartGUI

_Tcl/Tk GUI startup_

Description

Starts up the _Tcl/Tk_ GUI

Usage

tkStartGUI()

Details

Starts a GUI console implemented via a _Tk_ text widget. This should probably be called at most once per session. Also redefines the file pager (as used by _help_()) to be the _Tk_ pager.

Note

tkStartGUI() saves its evaluation environment as `.GUIenv`. This means that the user interface elements can be accessed in order to extend the interface. The three main objects are named `Term`, `Menu`, and `Toolbar`, and the various submenus and callback functions can be seen with `ls(envir = `.GUIenv`)`.

Peter Dalgaard

TkWidgetcmds

_Tk_ widget commands

Description

These functions interface to _Tk_ widget commands.
Usage

tkactivate(widget, ...)
tkaddd(widget, ...)
tkadddtag(widget, ...)
tkbbox(widget, ...)
tkcanvasx(widget, ...)
tkcanvasy(widget, ...)
tkcget(widget, ...)
tkcompare(widget, ...)
tkconfigure(widget, ...)
tkcoords(widget, ...)
tkcreate(widget, ...)
tkcurselection(widget, ...)
tkdchars(widget, ...)
tkdebug(widget, ...)
tkdelete(widget, ...)
tkdelta(widget, ...)
tkdeselct(widget, ...)
tkdlineinfo(widget, ...)
tktag(widget, ...)
tkdump(widget, ...)
tkentrycget(widget, ...)
tkentryconfigure(widget, ...)
tkffind(widget, ...)
tkflash(widget, ...)
tkfraction(widget, ...)
tkget(widget, ...)
tkgettags(widget, ...)
tkicursor(widget, ...)
tkidentify(widget, ...)
tkindex(widget, ...)
tkinsert(widget, ...)
tkinvoke(widget, ...)
tkitembind(widget, ...)
tkitemcget(widget, ...)
tkitemconfigure(widget, ...)
tkitemfocus(widget, ...)
tkitemlower(widget, ...)
tkitemraise(widget, ...)
tkitemscale(widget, ...)
tkmark.gravity(widget, ...)
tkmrk.names(widget, ...)
tkmrk.next(widget, ...)
tkmrk.previous(widget, ...)
tkmrk.set(widget, ...)
tkmrk.unset(widget, ...)
tkmv(widget, ...)
tknearest(widget, ...)
tkpost(widget, ...)
tkpostcascade(widget, ...)
tkpostscript(widget, ...)
tkscan.mark(widget, ...)

tkscan.dragto(widget, ...)
tksearch(widget, ...)
tksee(widget, ...)
tkselect(widget, ...)
tkselection.adjust(widget, ...)
tkselection.anchor(widget, ...)
tkselection.clear(widget, ...)
tkselection.from(widget, ...)
tkselection.includes(widget, ...)
tkselection.present(widget, ...)
tkselection.range(widget, ...)
tkselection.set(widget, ...)
tkselection.to(widget, ...)
tkset(widget, ...)
tksize(widget, ...)
tktoggle(widget, ...)
tktag.add(widget, ...)
tktag.bind(widget, ...)
tktag.cget(widget, ...)
tktag.configure(widget, ...)
tktag.delete(widget, ...)
tktag.lower(widget, ...)
tktag.names(widget, ...)
tktag.nextrange(widget, ...)
tktag.prevrange(widget, ...)
tktag.raise(widget, ...)
tktag.ranges(widget, ...)
tktag.remove(widget, ...)
tktype(widget, ...)
tkunpost(widget, ...)
tkwindow.cget(widget, ...)
tkwindow.configure(widget, ...)
tkwindow.create(widget, ...)
tkwindow.names(widget, ...)
tkxview(widget, ...)
tkxview.moveto(widget, ...)
tkxview.scroll(widget, ...)
tkyposition(widget, ...)
tkyview(widget, ...)
tkyview.moveto(widget, ...)
tkyview.scroll(widget, ...)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>widget</td>
<td>The widget this applies to</td>
</tr>
<tr>
<td>...</td>
<td>Handled via .Tcl.args</td>
</tr>
</tbody>
</table>

Details

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. Except for a few exceptions, the pattern is that Tcl widget commands possibly with subcommands like .a.b selection clear are converted to function names like tkselection.clear and the widget is given as the first argument.

tkinsert(txt.w, "0.0", "plot(1:10)"

# callback function
eval.txt <- function()
eval(parse(text = tclvalue(tkget(txt.w, "0.0", "end"))))
tkpack(but.w <- tkbutton(tt, text = "Submit", command = eval.txt))

## Try pressing the button, edit the text and when finished:
tkdestroy(tt)

## End(Not run)

<table>
<thead>
<tr>
<th>TkWidgets</th>
<th>Tk widgets</th>
</tr>
</thead>
</table>

Description

Create Tk widgets and associated R objects.

Usage

tkwidget(parent, type, ...)
tkbutton(parent, ...)
tkcanvas(parent, ...)
tkcheckbutton(parent, ...)
tkentry(parent, ...)
tktentry(parent, ...)
tkframe(parent, ...)
tklabel(parent, ...)
tklistbox(parent, ...)
tkmenuparent(parent, ...)
tkmtextbutton(parent, ...)
tkmessage(parent, ...)
tkradiobutton(parent, ...)
tkscale(parent, ...)
tkscrollbar(parent, ...)
tktext(parent, ...)
tktoplevel(parent = .TkRoot, ...)
ttkbutton(parent, ...)
ttkcheckbutton(parent, ...)
ttkcomboxbox(parent, ...)
ttkframe(parent, ...)
ttkimage(parent, ...)
ttklabel(parent, ...)
ttklabelframe(parent, ...)
ttkmenubutton(parent, ...)
ttknotebook(parent, ...)
ttkpanedwindow(parent, ...)
ttkprogressbar(parent, ...)
ttkradiobutton(parent, ...)
ttkscrollbar(parent, ...)
ttkseparator(parent, ...)
ttksizegrip(parent, ...)
ttktreeview(parent, ...)

Arguments

parent     Parent of widget window.
type       string describing the type of widget desired.
...         handled via .Tcl.args.

Details

These functions create Tk widgets. tkwidget creates a widget of a given type, the others simply call tkwidget with the respective type argument.

The functions starting ttk are for the themed widget set for Tk 8.5 or later. A tutorial can be found at http://www.tkdcs.com.

It is not possible to describe the widgets and their arguments in full. Please refer to the Tcl/Tk documentation.

See Also

TclInterface, TkCommands, TkWidgetcmds

Examples

## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
label.widget <- tklabel(tt, text = "Hello, World!")
button.widget <- tkbutton(tt, text = "Push",
command = function()cat("OW!\n"))
tkpack(label.widget, button.widget) # geometry manager
# see Tk-commands

## Push the button and then...

tkdestroy(tt)
## tk_choose.dir

### Choose a Folder Interactively

**Description**

Use a Tk widget to choose a directory interactively.

**Usage**

```r
tk_choose.dir(default = "", caption = "Select directory")
```

**Arguments**

- **default**: which directory to show initially.
- **caption**: the caption on the selection dialog.

**Value**

A length-one character vector, character NA if ‘Cancel’ was selected.

**See Also**

- `tk_choose.files`

**Examples**

```r
## Not run:
tk_choose.dir(getwd(), "Choose a suitable folder")

## End(Not run)
```
tk_choose.files  

Choose a List of Files Interactively

**Description**

Use a Tk file dialog to choose a list of zero or more files interactively.

**Usage**

```r
tk_choose.files(default = "", caption = "Select files",
                 multi = TRUE, filters = NULL, index = 1)
```

**Arguments**

- `default` which filename to show initially.
- `caption` the caption on the file selection dialog.
- `multi` whether to allow multiple files to be selected.
- `filters` two-column character matrix of filename filters.
- `index` unused.

**Details**

Unlike `file.choose`, `tk_choose.files` will always attempt to return a character vector giving a list of files. If the user cancels the dialog, then zero files are returned, whereas `file.choose` would signal an error.

The format of `filters` can be seen from the example. File patterns are specified via extensions, with "*" meaning any file, and "*" any file without an extension (a filename not containing a period). (Other forms may work on specific platforms.) Note that the way to have multiple extensions for one file type is to have multiple rows with the same name in the first column, and that whether the extensions are named in file chooser widget is platform-specific. **The format may change before release.**

**Value**

A character vector giving zero or more file paths.

**Note**

A bug in Tk 8.5.0–8.5.4 prevented multiple selections being used.

**See Also**

`file.choose`, `tk_choose.dir`

**Examples**

```r
Filters <- matrix(c("R code", ".R", "R code", ".s",
                    "Text", ".txt", "All files", ".*"),
                 4, 2, byrow = TRUE)
Filters
if(interactive()) tk_choose.files(filter = Filters)
```
tk_messageBox  

**Tk Message Box**

**Description**

An implementation of a generic message box using Tk

**Usage**

```r
tk_messageBox(type = c("ok", "okcancel", "yesno", "yesnocancel", "retrycancel", "aburtretrycancel"), message, caption = "", default = "", ...)
```

**Arguments**

- `type` character. The type of dialog box. It will have the buttons implied by its name.
- `message` character. The information field of the dialog box.
- `caption` character. The caption on the widget displayed.
- `default` character. The name of the button to be used as the default.
- `...` additional named arguments to be passed to the Tk function of this name. An example is `icon = "warning"`.

**Value**

A character string giving the name of the button pressed.

**See Also**

- `tkmessageBox` for a 'raw' interface.

---

tk_select.list  

**Select Items from a List**

**Description**

Select item(s) from a character vector using a Tk listbox.

**Usage**

```r
tk_select.list(choices, preselect = NULL, multiple = FALSE, title = NULL)
```

**Arguments**

- `choices` a character vector of items.
- `preselect` a character vector, or NULL. If non-null and if the string(s) appear in the list, the item(s) are selected initially.
- `multiple` logical: can more than one item be selected?
- `title` optional character string for window title, or NULL for no title.
Details

This is a version of select.list implemented as a Tk list box plus OK and Cancel buttons. There will be a scrollbar if the list is too long to fit comfortably on the screen.

The dialog box is modal, so a selection must be made or cancelled before the R session can proceed. Double-clicking on an item is equivalent to selecting it and then clicking OK.

If Tk is version 8.5 or later, themed widgets will be used.

Value

A character vector of selected items. If multiple is false and no item was selected (or Cancel was used), "" is returned. If multiple is true and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

See Also

select.list (a text version except on Windows and the OS X GUI), menu (whose graphics = TRUE mode uses this on most Unix-alikes).
Chapter 13

The tools package

tools-package    Tools for Package Development

Description
Tools for package development, administration and documentation.

Details
This package contains tools for manipulating R packages and their documentation.
For a complete list of functions, use library(help = "tools").

Author(s)
Kurt Hornik and Friedrich Leisch
Maintainer: R Core Team <R-core@r-project.org>

.print.via.format    Printing Utilities

Description
.print.via.format is a “prototype” print() method, useful, at least as a start, by a simple

print.<myS3class> <- .print.via.format

Usage
.print.via.format(x, ...)

Arguments
x       object to be printed.
...     optional further arguments, passed to format.
add_datalist

Value

x, invisibly (by invisible()), as print methods should.

See Also

The print generic; its default method print.default (used for many basic implicit classes such as "numeric", "character" and arrays of them, lists etc).

Examples

```r
## The function is simply defined as
function (x, ...) {
  writelines(format(x, ...))
  invisible(x)
}

## is used for simple print methods in R, and as prototype for new methods.
```

Description

The data() command with no arguments lists all the datasets available via data in attached packages, and to do so a per-package list is installed. Creating that list at install time can be slow for packages with huge datasets, and can be expedited by a supplying 'data/datalist' file.

Usage

```r
add_datalist(pkgpath, force = FALSE)
```

Arguments

- `pkgpath` The path to a (source) package.
- `force` logical: can an existing 'data/datalist' file be over-written?

Details

R CMD build will call this function to add a data list to packages with 1MB or more of data.

It is also helpful to give a 'data/datalist' file in packages whose datasets have many dependencies, including loading the packages itself (and maybe others).

See Also

- data.

The ‘Writing R Extensions’ manual.
assertCondition

Assuming Error Conditions

Description

When testing code, it is not sufficient to check that results are correct, but also that errors or warnings are signalled in appropriate situations. The functions described here provide a convenient facility for doing so. The three functions check that evaluating the supplied expression produces an error, a warning or one of a specified list of conditions, respectively. If the assertion fails, an error is signalled.

Usage

assertError(expr, verbose = FALSE)
assertWarning(expr, verbose = FALSE)
assertCondition(expr, ..., .exprString = , verbose = FALSE)

Arguments

- expr: an unevaluated \texttt{R} expression which will be evaluated via \texttt{tryCatch(expr, ...)}.
- \textsf{...}: character strings corresponding to the classes of the conditions that would satisfy the assertion; e.g., "error" or "warning". If none are specified, any condition will satisfy the assertion. See the details section.
- .exprString: The string to be printed corresponding to expr. By default, the actual expr will be deparsed. Will be omitted if the function is supplied with the actual expression to be tested. If assertCondition() is called from another function, with the actual expression passed as an argument to that function, supply the deparsed version.
- verbose: If \texttt{TRUE}, a message is printed when the condition is satisfied.

Details

assertCondition() uses the general condition mechanism to check all the conditions generated in evaluating expr. The occurrence of any of the supplied condition classes among these satisfies the assertion regardless of what other conditions may be signalled.

assertError() is a convenience function for asserting errors; it calls assertCondition().

assertWarning() asserts that a warning will be signalled, but \textit{not} an error, whereas assertCondition(expr, "warning") will be satisfied even if an error follows the warning. See the examples.

Value

If the assertion is satisfied, a list of all the condition objects signalled is returned, invisibly. See \texttt{conditionMessage} for the interpretation of these objects. Note that all conditions signalled during the evaluation are returned, whether or not they were among the requirements.

Author(s)

John Chambers and Martin Maechler
See Also

stop.warning; signalCondition, tryCatch.

Examples

```r
assertError(sqrt("abc"))
assertWarning(matrix(1:8, 4, 3))
assertCondition( ""-1 ) # ok, any condition would satisfy this

try( assertCondition(sqrt(2), "warning") )
## .. Failed to get warning in evaluating sqrt(2)
assertCondition(sqrt("abc"), "error") # ok
try( assertCondition(sqrt("abc"), "warning") )# -> error: had no warning
assertCondition(sqrt("abc"), "error")
## identical to assertError() call above

assertCondition(matrix(1:5, 2,3), "warning")
try( assertCondition(matrix(1:8, 4,3), "error") )
## .. Failed to get expected error ....

## either warning or worse:
assertCondition(matrix(1:8, 4,3), "error","warning") # OK
assertCondition(matrix(1:8, 4, 3), "warning") # OK

## when both are signalled:
ff <- function() { warning("my warning"); stop("my error") }
assertCondition(ff(), "warning")
## but assertWarning does not allow an error to follow
try(assertWarning(ff()))
assertCondition(ff(), "error") # ok
assertCondition(ff(), "error", "warning") # ok (quietly, catching warning)

## assert that assertC..() does not assert [and use *one* argument only]
assertCondition( assertCondition(sqrt(2 ), "warning") )
assertCondition( assertCondition(sqrt("abc"), "warning"), "error")
assertCondition( assertCondition(matrix(1:8, 4,3), "error"),
                  "error")
```

## bibstyle

Select or define a bibliography style.

Description

This function defines and registers styles for rendering `bibentry` objects into `Rd` format, for later conversion to text, HTML, etc.

Usage

```
bibstyle(style, envir, ..., .init = FALSE, .default = TRUE)
getBibStyle(all = FALSE)
```
bibstyle

Arguments

style   A character string naming the style.
envir   (optional) An environment holding the functions to implement the style.
...     Named arguments to add to the environment.
.init   Whether to initialize the environment from the default style "JSS".
.default Whether to set the specified style as the default style.
all     Whether to return the names of all registered styles.

Details

Rendering of bibentry objects may be done using routines modelled after those used by BibTeX. This function allows environments to be created and manipulated to contain those routines.

There are two ways to create a new style environment. The easiest is to set .init = TRUE, in which case the environment will be initialized with a copy of the default "JSS" environment. (This style is modelled after the 'jss.bst' style used by the Journal of Statistical Software.) Alternatively, the envir argument can be used to specify a completely new style environment.

To find the name of the default style, use getBibstyle(). To retrieve an existing style without setting it as the default, use bibstyle(style, .default = FALSE). To modify an existing style, specify style and some named entries via .... (Modifying the default "JSS" style is discouraged.) Setting style to NULL or leaving it missing will retrieve the default style, but modifications will not be allowed.

At a minimum, the environment should contain routines to render each of the 12 types of bibliographic entry supported by bibentry as well as several other routines described below. The former must be named formatArticle, formatBook, formatInbook, formatIncollection, formatInProceedings, formatManual, formatMastersthesis, formatMisc, formatPhdthesis, formatProceedings, formatTechreport and formatUnpublished. Each of these takes one argument, a single uncassed entry from the bibentry vector passed to the renderer, and should produce a single character vector (possibly containing newlines).

The other routines are as follows. sortKeys, a function to produce a sort key to sort the entries, is passed the original bibentry vector and should produce a sortable vector of the same length to define the sort order. Finally, the optional function cite should have the same argument list as utils:::cite, and should produce a citation to be used in text.

The format method for "bibentry" objects adds a field named ".index" to each entry after sorting and before formatting. This is a 1-based index within the complete object that can be used in styles that require numbering. Although the "JSS" style doesn't use numbers, it includes a fmtPrefix() stub function that may be used to display them. See the example below.

Value

bibstyle returns the environment which has been selected or created.
getBibstyle returns the name of the default style, or all style names.

.init = TRUE)
print(refs, .bibstyle = "unsorted")

Description

Run Swave (or other custom weave function) and texi2dvi on all vignettes of a package.

Usage

buildVignettes(package, dir, lib.loc = NULL, quiet = TRUE,
clean = TRUE, tangle = FALSE)

pkgVignettes(package, dir, subdirs = NULL, lib.loc = NULL,
output = FALSE, source = FALSE, check = FALSE)

Arguments

package a character string naming an installed package. If given, Swave files are searched in subdirectory 'doc'.

dir a character string specifying the path to a package’s root source directory. This subdirectory ‘vignettes’ (or if it does not exist ‘inst/doc’) is searched for Swave files.

lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.

quiet logical. Weave and run texi2pdf in quiet mode.

clean Remove all files generated by the build, even if there were copies there before.

tangle logical. Do tangle as well as weaving.
subdirs  a character vector of subdirectories of dir in which to look for vignettes. Ignored if package is used.

output   logical. If TRUE, the output filename for each vignette in the result.

source   logical. If TRUE, include the tangled output filename for each vignette in the result.

check    logical. If TRUE, check whether all files that have vignette-like filenames have an identifiable vignette engine. This may be a false positive if a file is not a vignette but has a filename matching a pattern defined by one of the vignette engines.

Details

buildVignettes is used by R CMD build and R CMD check to (re-)build vignette PDFs from their (typically Sweave) sources.

Value

buildVignettes is called for its side effect of creating the PDF versions of all vignettes, and if tangle = TRUE, extracting the R code.

pkgVignettes returns an object of class "pkgVignettes" if a vignette directory is found, otherwise NULL.

---

charsets  Conversion Tables between Character Sets

Description

charset_to_Unicode is a matrix of Unicode points with columns for the common 8-bit encodings.

Adobe_glyphs is a data frame which gives Adobe glyph names for Unicode points. It has two character columns, "adobe" and "unicode" (a 4-digit hex representation).

Usage

charset_to_Unicode
Adobe_glyphs

Details

charset_to_Unicode is an integer matrix of class c("noquote", "hexmode") so prints in hexadecimal. The mappings are those used by libiconv: there are differences in the way quotes and minus/hyphen are mapped between sources (and the postscript encoding files use a different mapping).

Adobe_glyphs include all the Adobe glyph names which correspond to single Unicode characters. It is sorted by Unicode point and within a point alphabetically on the glyph (there can be more than one name for a Unicode point). The data are in the file 'R_HOME/share/encodings/Adobe_glyphlist'.

Source

Examples

```r
## find Adobe names for ISOLatin2 chars.
latin2 <- charset_to_unicode[, "ISOLatin2"]
alnumcode <- as.numeric(paste0("0x", Adobe_glyphs$unicode))
keep <- alunicode %in% latin2
alnumcode <- alunicode[keep]
AAdobe <- Adobe_glyphs[keep, 1]
## first match
aLatin2 <- AAdobe[match(latin2, alunicode)]
## all matches
bLatin2 <- lapply(1:256, function(x) AAdobe[alnumcode == latin2[x]])
format(bLatin2, justify = "none")
```

---

**checkFF**  
**Check Foreign Function Calls**

**Description**

Performs checks on calls to compiled code from R code. Currently only checks whether the interface functions such as `.C` and `.Fortran` are called with a "NativeSymbolInfo" first argument or with argument PACKAGE specified, which is highly recommended to avoid name clashes in foreign function calls.

**Usage**

```
checkFF(package, dir, file, lib.loc = NULL, 
         verbose = getOption("verbose"))
```

**Arguments**

- `package` a character string naming an installed package. If given, the installed R code of the package is checked.
- `dir` a character string specifying the path to a package’s root source directory. This should contain the subdirectory ‘R’ (for R code). Only used if package is not given.
- `file` the name of a file containing R code to be checked. Used if neither package nor dir are given.
- `lib.loc` a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
- `verbose` a logical. If TRUE, additional diagnostics are printed (and the result is returned invisibly).

**Details**

Note that we can only check if the name argument is a symbol or a character string, not what class of object the symbol resolves to at run-time.

If the package has a namespace which contains a useDynLib directive, calls in top-level functions in the package are not reported as their symbols will be preferentially looked up in the DLL named in the first useDynLib directive.
checkMD5sums

This checks that calls with PACKAGE specified are to the same package, and reports separately those which are in base packages and those which are in other packages (and if those packages are specified in the 'DESCRIPTION' file).

Value

An object of class "checkFF".

There are format and print methods to display the information contained in such objects.

See Also

.C., Fortran, Foreign.

Examples

# order is pretty much random
checkFF(package = "stats", verbose = TRUE)

checkMD5sums Check and Create MD5 Checksum Files

Description

checkMD5sums checks the files against a file 'MD5'.

Usage

checkMD5sums(package, dir)

Arguments

package the name of an installed package

dir the path to the top-level directory of an installed package.

Details

The file 'MD5' which is created is in a format which can be checked by md5sum -c MD5 if a suitable command-line version of md5sum is available. (For Windows, one is supplied in the bundle at http://www.murdoch-sutherl land.com/Rtools.)

If dir is missing, an installed package of name package is searched for.

The private function tools:::installMD5sums is used to create MD5 files in the Windows build.

Value

checkMD5sums returns a logical, NA if there is no 'MD5' file to be checked.

See Also

md5sum
checkPoFiles  

Description

These functions compare formats embedded in English messages with translated strings to check for consistency. checkPoFile checks one file, while checkPoFiles checks all files for a specified language.

Usage

checkPoFile(f, strictPlural = FALSE)
checkPoFiles(language, dir = ".")

Arguments

- f: a character string giving a single filepath.
- strictPlural: whether to compare formats of singular and plural forms in a strict way.
- language: a character string giving a language code.
- dir: a path to a directory in which to check files.

Details

Part of R’s internationalization depends on translations of messages in ‘.po’ files. In these files an ‘English’ message taken from the R sources is followed by a translation into another language. Many of these messages are format strings for C or R sprintf and related functions. In these cases, the translation must give a compatible format or an error will be generated when the message is displayed.

The rules for compatibility differ between C and R in several ways. C supports several conversions not supported by R, namely c, u, p, n. It is allowed in C’s sprintf() function to have more arguments than are needed by the format string, but in R the counts must match exactly. R requires types of arguments to match, whereas C will do the display whether it makes sense or not.

These functions compromise on the testing as follows. The additional formats allowed in C are accepted, and all differences in argument type or count are reported. As a consequence some reported differences are not errors.

If the strictPlural argument is TRUE, then argument lists must agree exactly between singular and plural forms of messages; if FALSE, then translations only need to match one or the other of the two forms. When checkPoFiles calls checkPoFile, the strictPlural argument is set to TRUE for files with names starting ‘R-‘, and to FALSE otherwise.

Items marked as ‘fuzzy’ in the ‘.po’ file are not processed (as they are ignored by the message compiler).

If a difference is found, the translated string is checked for variant percent signs (e.g. the wide percent sign "\uff05"). Such signs will not be recognized as format specifiers, and are likely to be errors.

Value

Both functions return an object of S3 class "check_po_files". A print method is defined for this class to display a report on the differences.
checkRd

Author(s)
Duncan Murdoch

References
See the GNU gettext manual for the `.po` file format:

Examples
```r
## Not run:
checkPoFiles("de", "/path/to/R/src/directory")
## End(Not run)
```

---

checkRd

Check an Rd Object

Description
Check an help file or the output of the `parse_Rd` function.

Usage
```r
checkRd(Rd, defines = .Platform$OS.type, stages = "render",
unknownOK = TRUE, listOK = TRUE, ..., def_enc = FALSE)
```

Arguments
- `Rd` a filename or Rd object to use as input.
- `defines` string(s) to use in #ifdef tests.
- `stages` at which stage ("build", "install", or "render") should \Sexpr macros be executed? See the notes below.
- `unknownOK` unrecognized macros are treated as errors if FALSE, otherwise warnings.
- `listOK` unnecessary non-empty braces (e.g., around text, not as an argument) are treated as errors if FALSE, otherwise warnings.
- `...` additional parameters to pass to `parse_Rd` when Rd is a filename. One that is often useful is encoding.
- `def_enc` logical: has the package declared an encoding, so tests for non-ASCII text are suppressed?
checkRd performs consistency checks on an Rd file, confirming that required sections are present, etc.

It accepts a filename for an Rd file, and will use parse_Rd to parse it before applying the checks. If so, warnings from parse_Rd are collected, together with those from the internal function prepare_Rd, which does the ifdef and \Sexpr processing, drops sections that would not be rendered or are duplicated (and should not be) and removes empty sections.

An Rd object is passed through prepare_Rd, but it may already have been (and installed Rd objects have).

Warnings are given a ‘level’: those from prepare_Rd have level 0. These include

- All text must be in a section
- Only one tag name section is allowed: the first will be used
- Section name is unrecognized and will be dropped
- Dropping empty section name

checkRd itself can show

```
7Tag tag name not recognized
7\tabular format must be simple text
7Unrecognized \tabular format: ...
7Only \text{\textbf{\textit{1}}} columns allowed in this table
7Must have a tag name
7Only one tag name is allowed
7Tag tag name must not be empty
7\docType must be plain text
5Tag \method is only valid in \usage
5Tag \dontrun is only valid in \examples
5Tag tag name is invalid in a block name block
5Title of \section must be non-empty plain text
5\title content must be plain text
3Empty section tag name
3\synopsis will be removed in R 3.1.0
-1Non-ASCII contents without declared encoding
-1Non-ASCII contents in second part of \enc
-3Tag ... is not valid in a code block
-3Apparent non-ASCII contents without declared encoding
-3Apparent non-ASCII contents in second part of \enc
-3Unnecessary braces at...
-3 \method not valid outside a code block
```

and variations with \method replaced by \S3method or \S4method.

Note that both prepare_Rd and checkRd have tests for an empty section: that in checkRd is stricter (essentially that nothing is output).

Value

This may fail through an R error, but otherwise warnings are collected as returned as an object of class "checkRd", a character vector of messages. This class has a print method which only
prints unique messages, and has argument minlevel that can be used to select only more serious messages. (This is set to -1 in R CMD check.)

Possible fatal errors are those from running the parser (e.g. a non-existent file, unclosed quoted string, non-ASCII input without a specified encoding) or from prepare_Rd (multiple \Rdversion declarations, invalid \encoding or \docType or \name sections, and missing or duplicate \name or \title sections).

**checkRdaFiles**

Report on Details of Saved Images or Re-saves them

**Description**

This reports for each of the files produced by save the size, if it was saved in ASCII or XDR binary format, and if it was compressed (and if so in what format).

Usually such files have extension `.rda` or `.RData`, hence the name of the function.

**Usage**

checkRdaFiles(paths)

resaveRdaFiles(paths, compress = c("auto", "gzip", "bzip2", "xz"), compression_level)

**Arguments**

paths

A character vector of paths to save files. If this specifies a single directory, it is taken to refer to all `.rda` and `.RData` files in that directory.

compress, compression_level

type and level of compression: see save.

**Details**

compress = "auto" asks R to choose the compression and ignores compression_level. It will try "gzip", "bzip2" and if the "gzip" compressed size is over 10Kb, "xz" and choose the smallest compressed file (but with a 10% bias towards "gzip"). This can be slow.

**Value**

For checkRdaFiles, a data frame with rows names paths and columns

size numeric: file size in bytes, NA if the file does not exist.

ASCII logical: true for save(ASCII = TRUE), NA if the format is not that of an R save file.
compress character: type of compression. One of "gzip", "bzip2", "xz", "none" or "unknown" (which means that if this is an R save file it is from a later version of R).

version integer: the version of the save – usually 2 but 1 for very old files, and NA for other files.

Examples

```r
## Not run:
## from a package top-level source directory
dirs <- sort(Sys.glob(c("data/*.rda", "data/*.RData")))
(res <- checkRdaFiles(dirs))
## pick out some that may need attention
bad <- is.na(res$ASCII) | res$ASCII | (res<size > 1e4 & res$compress == "none")
res[bad, ]
## End(Not run)
```

checkTnF Check R Packages or Code for T/F

Description

Checks the specified R package or code file for occurrences of T or F, and gathers the expression containing these. This is useful as in R T and F are just variables which are set to the logicals TRUE and FALSE by default, but are not reserved words and hence can be overwritten by the user. Hence, one should always use TRUE and FALSE for the logicals.

Usage

```r
checkTnF(package, dir, file, lib.loc = NULL)
```

Arguments

- **package** a character string naming an installed package. If given, the installed R code and the examples in the documentation files of the package are checked. R code installed as an image file cannot be checked.
- **dir** a character string specifying the path to a package’s root source directory. This must contain the subdirectory ‘R’ (for R code), and should also contain ‘man’ (for documentation). Only used if package is not given. If used, the R code files and the examples in the documentation files are checked.
- **file** the name of a file containing R code to be checked. Used if neither package nor dir are given.
- **lib.loc** a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
Value

An object of class "checkTnF" which is a list containing, for each file where occurrences of T or F were found, a list with the expressions containing these occurrences. The names of the list are the corresponding file names.

There is a `print` method for nicely displaying the information contained in such objects.

---

**checkVignettes**  
*Check Package Vignettes*

---

**Description**

Check all `Sweave` files of a package by running `Sweave` and/or `Stangle` on them. All R source code files found after the tangling step are `source`ed to check whether all code can be executed without errors.

**Usage**

```r
checkVignettes(package, dir, lib.loc = NULL,  
tangle = TRUE, weave = TRUE, latex = FALSE,  
workdir = c("tmp", "src", "cur"),  
keepfiles = FALSE)
```

**Arguments**

- `package`  
a character string naming an installed package. If given, Sweave files are searched in subdirectory ‘doc’.

- `dir`  
a character string specifying the path to a package’s root source directory. This subdirectory ‘inst/doc’ is searched for Sweave files.

- `lib.loc`  
a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.

- `tangle`  
Perform a tangle and `source` the extracted code?

- `weave`  
Perform a weave?

- `latex`  
logical: if `weave` and `latex` are TRUE and there is no ‘Makefile’ in the vignettes directory, run the weaved files through `pdflatex`.

- `workdir`  
Directory used as working directory while checking the vignettes. If "tmp" then a temporary directory is created, this is the default. If "src" then the directory containing the vignettes itself is used, if "cur" then the current working directory of R is used.

- `keepfiles`  
Delete files in the temporary directory? This option is ignored when `workdir` != "tmp".
check_packages_in_dir

Details

A ‘vignette’ is a file in the package’s ‘inst/doc’ directory with extension ‘.Rnw’ (preferred), ‘.Snw’, ‘.Rtex’ or ‘.Stex’ (and lower-case versions are also accepted).

If tangle is true, this function runs Stangle to produce (one or more) R code files from each vignette, then sources each code file in turn.

If weave is true, the vignettes are run through Sweave, which will produce a ‘.tex’ file for each vignette. If latex is also true, \texttt{texi2pdf} is run on the ‘.tex’ files from those vignettes which did not give errors in the previous steps.

Value

An object of class "checkVignettes", which is a list with the error messages found during the tangle, source, weave and latex steps. There is a \texttt{print} method for displaying the information contained in such objects.

Note

Prior to R 2.13.0 this was the code used by \texttt{R CMD check}, but the latter is now more careful, running the code for each vignette in a separate \texttt{R} session.

check_packages_in_dir  Check Source Packages and Their Reverse Dependencies

Description

Check source packages in a given directory, optionally with their reverse dependencies.

Usage

\begin{verbatim}
check_packages_in_dir(dir,
    check_args = character(),
    check_args_db = list(),
    reverse = NULL,
    check_env = character(),
    xvfb = FALSE,
    Ncpus = getOption("Ncpus", 1L),
    clean = TRUE,
    ...
)
summarize_check_packages_in_dir_results(dir, all = TRUE)
summarize_check_packages_in_dir_timings(dir, all = FALSE,
    full = FALSE)
summarize_check_packages_in_dir_depends(dir, all = FALSE)
\end{verbatim}

Arguments

- \texttt{dir}: a character string giving the path to the directory with the source ‘.tar.gz’ files to be checked.
- \texttt{check_args}: a character vector with arguments to be passed to \texttt{R CMD check}, or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively.
check_packages_in_dir

- check_args_db: a named list of character vectors with arguments to be passed to R CMD check, with names the respective package names.
- reverse: a list with names partially matching "repos", "which", or "recursive", giving the repositories to use for locating reverse dependencies (default: getOption("repos")), the types of reverse dependencies (default: c("Depends", "Imports", "LinkingTo")), and indicating whether to also check reverse dependencies of reverse dependencies (and so on), or NULL (default), in which case no reverse dependencies are checked.
- check_env: a character vector of name=value strings to set environment variables for checking, or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively.
- xvfb: a logical indicating whether to perform checking inside a virtual framebuffer X server (Unix only), or a character vector of Xvfb options for doing so.
- Ncpus: the number of parallel processes to use for parallel installation and checking.
- clean: a logical indicating whether to remove the downloaded reverse dependency sources.
- ... currently not used.
- all: a logical indicating whether to also summarize the reverse dependencies checked.
- full: a logical indicating whether to also summarize check example timings (if available).

Details

check_packages_in_dir allows to conveniently check source package `.tar.gz` files in the given directory dir, along with their reverse dependencies as controlled by reverse.

If needed, the source `.tar.gz` files of the reverse dependencies to be checked as well are downloaded into dir (and removed at the end if clean is true). Next, all packages (additionally) needed for checking are installed to the ‘Library’ subdirectory of dir. Then, all `.tar.gz` files are checked using the given arguments and environment variables, with outputs and messages to files in the ‘Outputs’ subdirectory of dir. The ‘*Rcheck’ directories with the check results of the reverse dependencies are renamed by prefixing their base names with ‘rdepends_’.

Results and timings can conveniently be summarized using summarize_check_packages_in_dir_results and summarize_check_packages_in_dir_timings, respectively.

Installation and checking is performed in parallel if Ncpus is greater than one: this will use mclapply on Unix and parLapply on Windows.

Note

This functionality is still experimental: interfaces may change in future versions.
Check Code/Documentation Consistency

Description

Find inconsistencies between actual and documented ‘structure’ of R objects in a package. codoc compares names and optionally also corresponding positions and default values of the arguments of functions. codocClasses and codocData compare slot names of S4 classes and variable names of data sets, respectively.

Usage

codoc(package, dir, lib.loc = NULL, use.values = NULL, verbose =getOption("verbose"))
codocClasses(package, lib.loc = NULL)
codocData(package, lib.loc = NULL)

Arguments

- **package**: a character string naming an installed package.
- **dir**: a character string specifying the path to a package’s root source directory. This must contain the subdirectories ‘man’ with R documentation sources (in Rd format) and ‘R’ with R code. Only used if package is not given.
- **lib.loc**: a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
- **use.values**: if FALSE, do not use function default values when comparing code and docs. Otherwise, compare all default values if TRUE, and only the ones documented in the usage otherwise (default).
- **verbose**: a logical. If TRUE, additional diagnostics are printed.

Details

The purpose of codoc is to check whether the documented usage of function objects agrees with their formal arguments as defined in the R code. This is not always straightforward, in particular as the usage information for methods to generic functions often employs the name of the generic rather than the method.

The following algorithm is used. If an installed package is used, it is loaded (unless it is the base package), after possibly detaching an already loaded version of the package. Otherwise, if the sources are used, the R code files of the package are collected and sourced in a new environment. Then, the usage sections of the Rd files are extracted and parsed ‘as much as possible’ to give the formals documented. For interpreted functions in the code environment, the formals are compared between code and documentation according to the values of the argument use.values. Synopsis sections are used if present; their occurrence is reported if verbose is true.

If a package has a namespace both exported and unexported objects are checked, as well as registered S3 methods. (In the unlikely event of differences the order is exported objects in the package, registered S3 methods and finally objects in the namespace and only the first found is checked.)

Currently, the R documentation format has no high-level markup for the basic ‘structure’ of classes and data sets (similar to the usage sections for function synopses). Variable names for data frames
in documentation objects obtained by suitably editing 'templates' created by \texttt{prompt} are recognized by \texttt{codocData} and used provided that the documentation object is for a single data frame (i.e., only has one alias). \texttt{codocClasses} analogously handles slot names for classes in documentation objects obtained by editing shells created by \texttt{promptClass}.

Help files named ‘\texttt{pkgname\_defunct.Rd}’ for the appropriate \texttt{pkgname} are checked more loosely, as they may have undocumented arguments.

\textbf{Value}

codoc returns an object of class "codoc". Currently, this is a list which, for each Rd object in the package where an inconsistency was found, contains an element with a list of the mismatches (which in turn are lists with elements code and docs, giving the corresponding arguments obtained from the function’s code and documented usage).

codocClasses and \texttt{codocData} return objects of class "codocClasses" and "codocData", respectively, with a structure similar to class "codoc".

There are print methods for nicely displaying the information contained in such objects.

\textbf{Note}

The default for \texttt{use\_values} has been changed from \texttt{FALSE} to \texttt{NULL}, for \texttt{R} versions 1.9.0 and later.

\textbf{See Also}

\texttt{undoc, QC}

---

### compactPDF

#### Compact PDF Files

#### Description

Re-save PDF files (especially vignettes) more compactly. Support function for \texttt{R CMD build --compact-vignettes}.

#### Usage

\begin{verbatim}
compactPDF(paths, 
  qpdf = Sys.which(Sys.getenv("R_QPDF", "qpdf")), 
  gs_cmd = Sys.getenv("R_GSCMD", ""), 
  gs_quality = Sys.getenv("GS_QUALITY", "none"), 
  gs_extras = character())

## S3 method for class 'compactPDF'
format(x, ratio = 0.9, diff = 1e4, ...)
\end{verbatim}

#### Arguments

- \texttt{paths} A character vector of paths to PDF files, or a length-one character vector naming a directory, when all ‘.pdf’ files in that directory will be used.

- \texttt{qpdf} Character string giving the path to the \texttt{qpdf} command. If empty, \texttt{qpdf} will not be used.
gs_cmd

Character string giving the path to the GhostScript executable, if that is to be
used. On Windows this is the path to 'gswin32c.exe' or 'gswin64c.exe'. If "" (the default), the function will try to find a platform-specific path to GhostScript
where required.

gs_quality

A character string indicating the quality required: the options are "none" (so
GhostScript is not used), "printer" (300dpi), "ebook" (150dpi) and "screen"
(72dpi).

gs_extras

An optional character vector of further options to be passed to GhostScript.

x

An object of class "compactpdf".

ratio, diff

Limits for reporting: files are only reported whose sizes are reduced both by a
factor of ratio and by diff bytes.

Further arguments to be passed to or from other methods.

details

This by default makes use of qpdf, available from http://qpdf.sourceforge.net/ (including
as a Windows binary) and included with the CRAN Mac OS X distribution of R. If gs_cmd is
non-empty and gs_quality != "none", GhostScript will used first, then qpdf if it is available.
If gs_quality != "none" and gs_cmd is "", an attempt will be made to find a GhostScript
executable.

qpdf and/or gs_cmd are run on all PDF files found, and those which are reduced in size by at least
10% and 10Kb are replaced.

The strategy of our use of qpdf is to (losslessly) compress both PDF streams and objects.
GhostScript compresses streams and more (including downsampling and compressing embedded
images) and consequently is much slower and may lose quality (but can also produce much smaller
PDF files). However, quality "ebook" is perfectly adequate for screen viewing and printing on laser
printers.

Where PDF files are changed they will become PDF version 1.5 files: these have been supported by
Acrobat Reader since version 6 in 2003, so this is very unlikely to cause difficulties.

Stream compression is what most often has large gains: R’s pdf device prior to R 2.14.0 did not use
it, and older vignette PDFs often benefit from being re-generated. Most PDF documents are
generated with object compression, but this does not seem to be the default for MiKTeX’s pdflatex.
For some PDF files (and especially package vignettes), using GhostScript can dramatically reduce
the space taken by embedded images (often screenshots).

Where both GhostScript and qpdf are selected (when gs_quality != "none" and both executables
are found), they are run in that order and the size reductions apply to the total compression achieved.

Value

An object of class c("compactPDF", "data.frame"). This has two columns, the old and new
sizes in bytes for the files that were changed.

There are format and print methods: the latter passes ... to the format method, so will accept
ratio and diff arguments.

Note

The external tools used may change in future releases.

Versions of GhostScript 9.06 and later give several times better compression than 9.05 on some
vignettes in CRAN packages.
See Also

`resaveRdaFiles`.

Many other (and sometimes more effective) tools to compact PDF files are available, including Adobe Acrobat (not Reader). See the ‘Writing R Extensions’ manual.

delimMatch

**Delimited Pattern Matching**

**Description**

Match delimited substrings in a character vector, with proper nesting.

**Usage**

```r
delimMatch(x, delim = c("\", ")", syntax = "Rd")
```

**Arguments**

- **x**
  - a character vector.
- **delim**
  - a character vector of length 2 giving the start and end delimiters. Future versions might allow for arbitrary regular expressions.
- **syntax**
  - currently, always the string "Rd" indicating Rd syntax (i.e., '%' starts a comment extending till the end of the line, and '\ ' escapes). Future versions might know about other syntax, perhaps via 'syntax tables' allowing to flexibly specify comment, escape, and quote characters.

**Value**

An integer vector of the same length as `x` giving the starting position (in characters) of the first match, or −1 if there is none, with attribute "match.length" giving the length (in characters) of the matched text (or −1 for no match).

**See Also**

`regexpr` for ‘simple’ pattern matching.

**Examples**

```r
x <- c("\value{foo}", "function(bar)"

delimMatch(x)

delimMatch(x, c("\", ")"))
```
dependsOnPkgs  Find Reverse Dependencies

Description
Find ‘reverse’ dependencies of packages, that is those packages which depend on this one, and (optionally) so on recursively.

Usage
\begin{verbatim}
dependsOnPkgs(pkgs, 
  dependencies = c("Depends", "Imports", "LinkingTo"), 
  recursive = TRUE, lib.loc = NULL, 
  installed = 
  installed.packages(lib.loc, fields = "Enhances"))
\end{verbatim}

Arguments
- pkgs  a character vector of package names.
- dependencies  a character vector listing the types of dependencies, a subset of c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances"). Character string "all" is shorthand for that vector.
- recursive  logical: should reverse dependencies of reverse dependencies (and so on) be included?
- lib.loc  a character vector of \texttt{R} library trees, or \texttt{NULL} for all known trees (see \texttt{libPaths}).
- installed  a result of calling \texttt{installed.packages}.

Value
A character vector of package names, which does not include any from \texttt{pkgs}.

Examples
\begin{verbatim}
## there are few dependencies in a vanilla \texttt{R} installation:
## lattice may not be installed
dependsOnPkgs("lattice")
\end{verbatim}

encoded_text_to_latex  Translate non-ASCII Text to \LaTeX{} Escapes

Description
Translate non-ASCII characters in text to \LaTeX{} escape sequences.

Usage
\begin{verbatim}
encoded_text_to_latex(x, 
  encoding = c("latin1", "latin2", "latin9", 
              "UTF-8", "utf8"))
\end{verbatim}
encoded_text_to_latex

Arguments

- `x`: a character vector.
- `encoding`: the encoding to be assumed. "latin9" is officially ISO-8859-15 or Latin-9, but known as latin9 to LaTeX’s inputenc package.

Details

Non-ASCII characters in `x` are replaced by an appropriate LaTeX escape sequence, or '?' if there is no appropriate sequence.

Even if there is an appropriate sequence, it may not be supported by the font in use. Hyphen is mapped to '\-'.

Value

A character vector of the same length as `x`.

See Also

`iconv`

Examples

```r
x <- "fa\xe7ile"
encoded_text_to_latex(x, "latin1")
## Not run:
## create a tex file to show the upper half of 8-bit charsets
x <- as.raw(160:255), multiple = TRUE)
(x <- matrix(x, ncol = 16, byrow = TRUE))
xx <- x
xx[] <- encoded_text_to_latex(x, "latin1") # or latin2 or latin9
xx <- apply(xx, 1, paste, collapse = "&")
con <- file("test-encoding.tex", "w")
header <- c(
  "\documentclass{article},",
  "\usepackage[T1]{fontenc},",
  "\usepackage{rd},",
  "\begin{document},",
  "\begin{test}{test},",
  "\begin{Details}\relax",
  "\begin{tabular{cccccccccccccccc}{"",
trailer <- c("\"}`, "\end{Details}), "\end{document})"
writeLines(header, con)
writeLines(paste0(xx, "\"), con)
writeLines(trailer, con)
close(con)
## and some UTF-8 chars
x <- intToUtf8(as.integer(
  c(160:383,0x0192,0x02C6,0x02C7,0x02CA,0x02D8, 0x02D9, 0x02DD, 0x020C, 0x2018, 0x2019, 0x201C, 0x201D, 0x2020, 0x2022, 0x2026, 0x20AC),
multiple = TRUE))
x <- matrix(x, ncol = 16, byrow = TRUE)
xx <- x
xx[] <- encoded_text_to_latex(x, "UTF-8")
xx <- apply(xx, 1, paste, collapse = "&")
```

Utilities for listing files, and manipulating file paths.

Usage

```r
file_ext(x)
file_path_as_absolute(x)
file_path_sans_ext(x, compression = FALSE)
list_files_with_exts(dir, exts, all.files = FALSE, full.names = TRUE)
list_files_with_type(dir, type, all.files = FALSE, full.names = TRUE, OS_subdirs = .OS_type())
```

Arguments

- `x` character vector giving file paths.
- `compression` logical: should compression extension `.gz`, `.bz2` or `.xz` be removed first?
- `dir` a character string with the path name to a directory.
- `exts` a character vector of possible file extensions (excluding the leading dot).
- `all.files` a logical. If FALSE (default), only visible files are considered; if TRUE, all files are used.
- `full.names` a logical indicating whether the full paths of the files found are returned (default), or just the file names.
- `type` a character string giving the `type` of the files to be listed, as characterized by their extensions. Currently, possible values are "code" (R code), "data" (data sets), "demo" (demos), "docs" (R documentation), and "vignette" (vignettes).
- `OS_subdirs` a character vector with the names of OS-specific subdirectories to possibly include in the listing of R code and documentation files. By default, the value of the environment variable R_OSTYPE, or if this is empty, the value of `.Platform$OS.type`, is used.
getDepList

Details

file_ext returns the file (name) extensions (excluding the leading dot). (Only purely alphanumeric extensions are recognized.)

file_path_as_absolute turns a possibly relative file path absolute, performing tilde expansion if necessary. This is a wrapper for normalizePath. Currently, x must be a single existing path.

file_path_sans_ext returns the file paths without extensions (and the leading dot). (Only purely alphanumeric extensions are recognized.)

list_files_with_exts returns the paths or names of the files in directory dir with extension matching one of the elements of exts. Note that by default, full paths are returned, and that only visible files are used.

list_files_with_type returns the paths of the files in dir of the given 'type', as determined by the extensions recognized by R. When listing R code and documentation files, files in OS-specific subdirectories are included if present according to the value of OS_subdirs. Note that by default, full paths are returned, and that only visible files are used.

file.path, file.info, list.files

Examples

dir <- file.path(R.home(), "library", "stats")
list_files_with_exts(file.path(dir, "demo"), "R")
list_files_with_type(file.path(dir, "demo"), "demo") # the same
file_path_sans_ext(list.files(file.path(R.home("modules"))))

gDepList

Functions to Retrieve Dependency Information

Description

Given a dependency matrix, will create a DependsList object for that package which will include the dependencies for that matrix, which ones are installed, which unresolved dependencies were found online, which unresolved dependencies were not found online, and any R dependencies.

Usage

gDepList(depMtrx, instPkgs, recursive = TRUE, local = TRUE,
reduce = TRUE, lib.loc = NULL)

pkgDepends(pkg, recursive = TRUE, local = TRUE, reduce = TRUE,
lib.loc = NULL)

Arguments

depMtrx A dependency matrix as from package.dependencies
pkg The name of the package
instPkgs A matrix specifying all packages installed on the local system, as from installed.packages
The function `pkgdepends` is a convenience function which wraps `getDepList` and takes as input a package name. It will then query `installed.packages` and also generate a dependency matrix, calling `getDepList` with this information and returning the result.

These functions will retrieve information about the dependencies of the matrix, resulting in a `DependsList` object. This is a list with four elements:

- **Depends**: A vector of the dependencies for this package.
- **Installed**: A vector of the dependencies which have been satisfied by the currently installed packages.
- **Found**: A list representing the dependencies which are not in `Installed` but were found online. This list has element names which are the URLs for the repositories in which packages were found and the elements themselves are vectors of package names which were found in the respective repositories. If `local = TRUE`, the `Found` element will always be empty.
- **R**: Any R version dependencies.

If `recursive` is TRUE, any package that is specified as a dependency will in turn have its dependencies included (and so on), these are known as indirect dependencies. If `recursive` is FALSE, only the dependencies directly stated by the package will be used.

If `local` is TRUE, the system will only look at the user’s local install and not online to find unresolved dependencies.

If `reduce` is TRUE, the system will collapse the fields in the `DependsList` object such that a minimal set of dependencies are specified (for instance if there was `\texttt{`foo, foo (>= 1.0.0), foo (>= 1.3.0)'}`, it would only return `\texttt{`foo (>= 1.3.0)'}`).

**Value**

An object of class "DependsList".

**Author(s)**

Jeff Gentry

**See Also**

`installFoundDepends`

**Examples**

```r
pkgDepends("tools", local = FALSE)
```
**getVignetteInfo** Get information on installed vignettes.

Description
This function gets information on installed vignettes.

Usage
getVignetteInfo(package = NULL, lib.loc = NULL, all = TRUE)

Arguments
- **package**: Which package to look in, or NULL for all packages.
- **lib.loc**: Which library to look in.
- **all**: Whether to search all installed packages, or just attached packages.

Value
A matrix with columns
- **Package**: the name of the package
- **Dir**: the directory where the package is installed
- **Topic**: the name of the vignette
- **File**: the base filename of the source of the vignette
- **Title**: the title of the vignette
- **R**: the tangled R source from the vignette
- **PDF**: the PDF or HTML file for display

Note
The last column of the result is named PDF for historical reasons, but it may contain a filename of a PDF or HTML document.

See Also
pkgVignettes is a similar function that can work on an uninstalled package.

Examples
getVignetteInfo("grid")
**HTMLheader**

*Generate a standard HTML header for R help*

---

**Description**

This function generates the standard HTML header used on R help pages.

**Usage**

```r
HTMLheader(title = "R", logo = TRUE, up = NULL,
            top = file.path(Rhome, "doc/html/index.html"),
            Rhome = "",
            css = file.path(Rhome, "doc/html/R.css"),
            headerTitle = paste("R:\"", title),
            outputEncoding = "UTF-8")
```

**Arguments**

- `title`: The title to display and use in the HTML headers. Should have had any HTML escaping already done.
- `logo`: Whether to display the R logo after the title.
- `up`: Which page (if any) to link to on the “up” button.
- `top`: Which page (if any) to link to on the “top” button.
- `Rhome`: A relative path to the R home directory. See the ‘Details’.
- `css`: The relative URL for the Cascading Style Sheet.
- `headerTitle`: The title used in the headers.
- `outputEncoding`: The declared encoding for the whole page.

**Details**

The up and top links should be relative to the current page. The Rhome path default works with dynamic help; for static help, a relative path (e.g. ‘..../’) to it should be used.

**Value**

A character vector containing the lines of an HTML header which can be used to start a page in the R help system.

**Examples**

```r
cat(HTMLheader("This is a sample header"), sep="\n")
```
**HTMLLinks**

**Description**

Compute relative file paths for URLs to other package’s installed HTML documentation.

**Usage**

```r
findHTMLlinks(pkgDir = "", lib.loc = NULL, level = 0:2)
```

**Arguments**

- `pkgDir`: the top-level directory of an installed package. The default indicates no package.
- `lib.loc`: character vector describing the location of R library trees to scan: the default indicates `.libPaths()`.
- `level`: Which level(s) to include.

**Details**

`findHTMLlinks` tries to resolve links from one help page to another. It uses in decreasing priority

- The package in `pkgDir`: this is used when converting HTML help for that package (level 0).
- The base and recommended packages (level 1).
- Other packages found in the library trees specified by `lib.loc` in the order of the trees and alphabetically within a library tree (level 2).

**Value**

A named character vector of file paths, relative to the ‘html’ directory of an installed package. So these are of the form ‘".../.../somepkg/html/sometopic.html"’.

**Author(s)**

Duncan Murdoch, Brian Ripley

---

**installFoundDepends**

*A function to install unresolved dependencies*

**Description**

This function will take the `Found` element of a `pkgDependsList` object and attempt to install all of the listed packages from the specified repositories.

**Usage**

```r
installFoundDepends(depPkgList, ...)
```
make_translations_pkg

Arguments

```r
depPkgsList A found element from a pkgDependsList object
...
Arguments to pass on to install.packages
```

Details

This function takes as input the found list from a pkgDependsList object. This list will have element names being URLs corresponding to repositories and the elements will be vectors of package names. For each element, `install.packages` is called for that URL to install all packages listed in the vector.

Author(s)

Jeff Gentry

See Also

pkgDepends, install.packages

Examples

```r
### Set up a temporary directory to install packages to
tmp <- tempfile()
dir.create(tmp)

pDL <- pkgDepends("tools", local = FALSE)
installFoundDepends(pDL$Found, destdir = tmp)
```

make_translations_pkg  Package the Current Translations in the R sources

Description

A utility for R Core members to prepare a package of updated translations.

Usage

```r
make_translations_pkg(srcdir, outDir = ".", append = "-1")
```

Arguments

```r
srcdir  The R source directory.
outDir   The directory into which to place the prepared package.
append   The suffix for the package version number, e.g. 3.0.0-1 will be the default in R 3.0.0.
```

Details

This extracts the translations in a current R source distribution and packages them as a source package called `translations` which can be distributed on CRAN and installed by `update.packages`. This allows e.g. the translations shipped in R 3.x.y to be updated to those currently in 'R-patched', even by a user without administrative privileges.

The package has a ‘Depends’ field which restricts it to versions 3.x.* for a single x.
**md5sum**  
*Compute MD5 Checksums*

**Description**
Compute the 32-byte MD5 checksums of one or more files.

**Usage**
md5sum(files)

**Arguments**
- **files** character. The paths of file(s) to be check-summed.

**Value**
A character vector of the same length as `files`, with names equal to `files`. The elements will be NA for non-existent or unreadable files, otherwise a 32-character string of hexadecimal digits.

On Windows all files are read in binary mode (as the `md5sum` utilities there do): on other OSes the files are read in the default way.

**See Also**
checkMD5sums

**Examples**
```r
as.vector(md5sum(dir(R.home(), pattern = "^COPY", full.names = TRUE)))
```

**package.dependencies**  
*Check Package Dependencies*

**Description**
Parses and checks the dependencies of a package against the currently installed version of R (and other packages).

**Usage**
```r
package.dependencies(x, check = FALSE, 
  depLevel = 
  c("Depends", "Imports", "Suggests"))
```

**Arguments**
- **x** A matrix of package descriptions as returned by `available.packages`.
- **check** If TRUE, return logical vector of check results. If FALSE, return parsed list of dependencies.
- **depLevel** Whether to look for Depends or Suggests level dependencies.
Details
Currently we only check if the package conforms with the currently running version of R. In the future we might add checks for inter-package dependencies.

update.packages

package_dependencies  Computations on the Dependency Hierarchy of Packages

Description
Find (recursively) dependencies or reverse dependencies of packages.

Usage
package_dependencies(packages = NULL, db,
which = c("Depends", "Imports", "LinkingTo"),
recursive = FALSE, reverse = FALSE)

Arguments
packages a character vector of package names.
db character matrix as from available.packages(), or data frame variants thereof. Alternatively, a package database like the one available from http://cran.R-project.org/web/packages/packages.rds.
which a character vector listing the types of dependencies, a subset of c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances"). Character string "all" is shorthand for that vector, character string "most" for the same vector without "Enhances".
recursive logical: should (reverse) dependencies of (reverse) dependencies (and so on) be included?
reverse logical: if FALSE (default), regular dependencies are calculated, otherwise reverse dependencies.

Value
Named list with one element for each package in argument packages, each consists of a character vector naming the (recursive) (reverse) dependencies of that package.
For given packages which are not found in the db, NULL entries are returned, as opposed to character(0) entries which indicate no dependencies.

See Also
dependsOnPkgs, and package_dependencies for checking dependencies
Examples

## Not run:
```
pdb <- available.packages()
deps <- package_dependencies(packages = "MASS", pdb,
    which = c("Depends", "Imports", "LinkingTo", "Suggests"),
    recursive = TRUE, reverse = TRUE)
length(deps$MASS)
## End(Not run)
```

**Description**

The `parseLatex` function parses LaTeX source, producing a structured object; `deparseLatex` reverses the process. The `latexToUtf8` function takes a LaTeX object, and processes a number of different macros to convert them into the corresponding UTF-8 characters.

**Usage**

```
parseLatex(text, filename = deparse(substitute(text)),
    verbose = FALSE,
    verbatim = c("verbatim", "verbatim*",
        "Sinput", "Soutput"))
deparseLatex(x, dropBraces = FALSE)
llatexToUtf8(x)
```

**Arguments**

- **text** A character vector containing LaTeX source code.
- **filename** A filename to use in syntax error messages.
- **verbose** If TRUE, print debug error messages.
- **verbatim** A character vector containing the names of LaTeX environments holding verbatim text.
- **x** A "LaTeX" object.
- **dropBraces** Drop unnecessary braces when displaying a "LaTeX" object.

**Details**

The parser does not recognize all legal LaTeX code, only relatively simple examples. It does not associate arguments with macros, that needs to be done after parsing, with knowledge of the definitions of each macro. The main intention for this function is to process simple LaTeX code used in bibliographic references, not fully general LaTeX documents.

Verbose text is allowed in two forms: the \verb macro (with single character delimiters), and environments whose names are listed in the \verbatim argument.
Value

The `parseLatex()` function returns a recursive object of class "LaTeX". Each of the entries in this object will have a "latex_tag" attribute identifying its syntactic role.

The `deparseLatex()` function returns a single element character vector, possibly containing embedded newlines.

The `latexToUtf8()` function returns a modified version of the "LaTeX" object that was passed to it.

Author(s)

Duncan Murdoch

Examples

```r
latex <- parseLatex("fa\\c{c}ile")
deparseLatex(latexToUtf8(latex))
```

Description

This function reads an R documentation (Rd) file and parses it, for processing by other functions.

Usage

```r
parse_Rd(file, srcfile = NULL, encoding = "unknown",
          verbose = FALSE, fragment = FALSE, warningCalls = TRUE)
# S3 method for class 'Rd'
print(x, deparse = FALSE, ...)
# S3 method for class 'Rd'
as.character(x, deparse = FALSE, ...)
```

Arguments

- `file`: A filename or text-mode connection. At present filenames work best.
- `srcfile`: NULL, or a "srcfile" object. See the ‘Details’ section.
- `encoding`: Encoding to be assumed for input strings.
- `verbose`: Logical indicating whether detailed parsing information should be printed.
- `fragment`: Logical indicating whether file represents a complete Rd file, or a fragment.
- `warningCalls`: Logical: should parser warnings include the call?
- `x`: An object of class Rd.
- `deparse`: If TRUE, attempt to reinstate the escape characters so that the resulting characters will parse to the same object.
- `...`: Further arguments to be passed to or from other methods.
pskill

Details

This function parses ‘Rd’ files according to the specification given in http://developer.r-project.org/parsed.pdf.

It generates a warning for each parse error and attempts to continue parsing. In order to continue, it is generally necessary to drop some parts of the file, so such warnings should not be ignored.

Value

parse_Rd returns an object of class "Rd". The internal format of this object is subject to change. The as.character() and print() methods defined for the class return character vectors and print them, respectively.

Files without a marked encoding are by default assumed to be in the native encoding. An alternate default can be set using the encoding argument. All text in files is translated to the UTF-8 encoding in the parsed object.

Rd2HTML for the converters that use the output of parse_Rd().

pskill Kill a Process

Description

pskill sends a signal to a process, usually to terminate it.

Usage

pskill(pid, signal = SIGTERM)

SIGHUP
SIGINT
SIGQUIT
SIGKILL
SIGTERM
SIGSTOP
SIGTSTP
SIGCHLD
SIGUSR1
SIGUSR2
Arguments

pid positive integers: one or more process IDs as returned by `Sys.getpid`.
signal integer, most often one of the symbolic constants.

Details

Signals are a C99 concept, but only a small number are required to be supported (of those listed, only SIGINT and SIGTERM). They are much more widely used on POSIX operating systems (which should define all of those listed here), which also support a `kill` system call to send a signal to a process, most often to terminate it. Function `pskill` provides a wrapper: it silently ignores invalid values of its arguments, including zero or negative pids.

In normal use on a Unix-alike, `Ctrl-C` sends SIGINT, `Ctrl-\` sends SIGQUIT and `Ctrl-Z` sends SIGTSTP: that and SIGSTOP suspend a process which can be resumed by SIGCONT.

The signals are small integers, but the actual numeric values are not standardized (and most do differ between OSes). The `sigJ` objects contain the appropriate integer values for the current platform (or `NA_INTEGER_` if the signal is not defined).

Only SIGINT and SIGKILL will be defined on Windows, and `pskill` will always use the Windows system call `TerminateProcess`.

Value

A logical vector of the same length as `pid`, `TRUE` (for success) or `FALSE`, invisibly.

See Also

Package `parallel` has several means to launch child processes which record the process IDs.

`psnice`

Examples

```r
## Not run:
pskill(c(237, 245), SIGKILL)

## End(Not run)
```

---

### psnice

*Get or Set the Priority (Niceness) of a Process*

Description

Get or set the ‘niceness’ of the current process, or one or more other processes.

Usage

```r
psnice(pid = Sys.getpid(), value = NA_integer_)
```

Arguments

- **pid** positive integers: the process IDs of one of more processes: defaults to the R session process.
- **value** The niceness to be set, or `NA` for an enquiry.
Details

POSIX operating systems have a concept of process priorities, usually from 0 to 39 (or 40) with 20 being a normal priority and (somewhat confusingly) larger numeric values denoting lower priority. To add to the confusion, there is a ‘niceness’ value, the amount by which the priority numerically exceeds 20 (which can be negative). Processes with high niceness will receive less CPU time than those with normal priority. On some OSes, processes with niceness +19 are only run when the system would otherwise be idle.

On many OSes utilities such as top report the priority and not the niceness. Niceness is used by the utility ‘/usr/bin/renice’ ‘/usr/bin/nice’ (and /usr/bin/renice -n) specifies an increment in niceness.

Only privileged users (usually super-users) can lower the niceness.

Windows has a slightly different concept of ‘priority classes’. We have mapped the idle priority to niceness 19, ‘below normal’ to 15, normal to 0, ‘above normal’ to -5 and ‘realtime’ to -10. Unlike Unix-alikes, a non-privileged user can increase the priority class on Windows (but using ‘realtime’ is inadvisable).

Value

An integer vector of previous niceness values, NA if unknown for any reason.

See Also

Various functions in package parallel create child processes whose priority may need to be changed. pskill.

Description

Functions for performing various quality checks.

Usage

checkDocFiles(package, dir, lib.loc = NULL)
checkDocStyle(package, dir, lib.loc = NULL)
checkReplaceFuns(package, dir, lib.loc = NULL)
checkS3methods(package, dir, lib.loc = NULL)

Arguments

package a character string naming an installed package.
dir a character string specifying the path to a package’s root source directory. This should contain the subdirectories ‘R’ (for R code) and ‘man’ with R documentation sources (in Rd format). Only used if package is not given.
lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
checkDocFiles checks, for all Rd files in a package, whether all arguments shown in the usage sections of the Rd file are documented in its arguments section. It also reports duplicated entries in the arguments section, and ‘over-documented’ arguments which are given in the arguments section but not in the usage. Note that the match is for the usage section and not a possibly existing synopsis section, as the usage is what gets displayed.

checkDocStyle investigates how (S3) methods are shown in the usages of the Rd files in a package. It reports the methods shown by their full name rather than using the Rd \method markup for indicating S3 methods. Earlier versions of R also reported about methods shown along with their generic, which typically caused problems for the documentation of the primary argument in the generic and its methods. With \method now being expanded in a way that class information is preserved, joint documentation is no longer necessarily a problem. (The corresponding information is still contained in the object returned by checkDocStyle.)

checkReplaceFuns checks whether replacement functions or S3/S4 replacement methods in the package R code have their final argument named value.

checkS3methods checks whether all S3 methods defined in the package R code have all arguments of the corresponding generic, with positional arguments of the generics in the same positions for the method. As an exception, the first argument of a formula method may be called formula even if this is not the name used by the generic. The rules when ... is involved are subtle: see the source code. Functions recognized as S3 generics are those with a call to UseMethod in their body, internal S3 generics (see InternalMethods), and S3 group generics (see Math). Possible dispatch under a different name is not taken into account. The generics are sought first in the given package, then in the base package and (currently) the packages graphics, stats, and utils added in R 1.9.0 by splitting the former base, and, if an installed package is tested, also in the loaded namespaces/packages listed in the package’s ‘DESCRIPTION’ Depends field.

If using an installed package, the checks needing access to all R objects of the package will load the package (unless it is the base package), after possibly detaching an already loaded version of the package.

Value

The functions return objects of class the same as the respective function names containing the information about problems detected. There are print methods for nicely displaying the information contained in such objects.
stylesheet = "R.css", ...)

Rd2txt(Rd, out = "", package = "", defines = .Platform$OS.type,
    stages = "render", outputEncoding = "",
    fragment = FALSE, options, ...)

Rd2latex(Rd, out = "", defines = .Platform$OS.type,
    stages = "render", outputEncoding = "ASCII",
    fragment = FALSE, ..., writeEncoding = TRUE)

Rd2ex(Rd, out = "", defines = .Platform$OS.type,
    stages = "render", outputEncoding = "UTF-8",
    commentDontrun = TRUE, ...)

Arguments

Rd a filename or Rd object to use as input.
out a filename or connection object to which to write the output.
package the package to list in the output.
defines string(s) to use in #ifdef tests.
stages at which stage ("build", "install", or "render") should \Sexpr macros be executed? See the notes below.
outputEncoding see the 'Encodings' section below.
dynamic logical: set links for render-time resolution by dynamic help system.
no_links logical: suppress hyperlinks to other help topics. Used by R CMD Rdconv.
fragment logical: should fragments of Rd files be accepted? See the notes below.
stylessheet character: a URL for a stylesheet to be used in the header of the HTML output page.

Links, Links2 NULL or a named (by topics) character vector of links, as returned by findHTMLlinks.
options An optional named list of options to pass to Rd2txt_options.
... additional parameters to pass to parse_Rd when Rd is a filename.
writeEncoding should \inputencoding lines be written in the file for non-ASCII encodings?
commentDontrun should \dontrun sections be commented out?

Details

These functions convert help documents: Rd2HTML produces HTML, Rd2txt produces plain text,
Rd2latex produces LaTeX. Rd2ex extracts the examples in the format used by example and R utilities.

Each of the functions accepts a filename for an Rd file, and will use parse_Rd to parse it before applying the conversions or checks.

The difference between arguments Link and Link2 is that links are looked in them in turn, so lazy-evaluation can be used to only do a second-level search for links if required.

Note that the default for Rd2latex is to output ASCII, including using the second option of \enc markup. This was chosen because use of UTF-8 in LaTeX requires version ‘2005/12/01’ or later, and even with that version the coverage of UTF-8 glyphs is not extensive (and not even as complete as Latin-1).
Rd2txt will format text paragraphs to a width determined by `width`, with appropriate margins. The default is to be close to the rendering in versions of R < 2.10.0.

Rd2txt will use directional quotes (see `sQuote`) if option "useFancyQuotes" is true (the default) and the current encoding is UTF-8.

Various aspects of formatting by `Rd2txt` are controlled by the options argument, documented with the `Rd2txt_options` function. Changes made using options are temporary, those made with `Rd2txt_options` are persistent.

When `fragment = TRUE`, the Rd file will be rendered with no processing of \Sexpr elements or conditional defines using `#ifdef` or `#ifndef`. Normally a fragment represents text within a section, but if the first element of the fragment is a section macro, the whole fragment will be rendered as a series of sections, without the usual sorting.

### Value

These functions are executed mainly for the side effect of writing the converted help page. Their value is the name of the output file (invisibly). For `Rd2latex`, the output name is given an attribute "latexEncoding" giving the encoding of the file in a form suitable for use with the LaTeX ‘inputenc’ package.

### Encodings

Rd files are normally intended to be rendered on a wide variety of systems, so care must be taken in the encoding of non-ASCII characters. In general, any such encoding should be declared using the ‘encoding’ section for there to be any hope of correct rendering.

For output, the `outputEncoding` argument will be used: `outputEncoding = ""` will choose the native encoding for the current system.

If the text cannot be converted to the `outputEncoding`, byte substitution will be used (see `iconv`): `Rd2latex` and `Rd2ex` give a warning.

### Note

The \Sexpr macro is a new addition to Rd files. It includes R code that will be executed at one of three times: build time (when a package’s source code is built into a tarball), install time (when the package is installed or built into a binary package), and render time (when the man page is converted to a readable format).

For example, this man page was:

1. built on 2014-03-03 at 06:03:23,
2. installed on 2014-03-03 at 06:03:23, and
3. rendered on 2014-03-03 at 06:06:40.

**Examples**

```r
## Not run:
## Simulate install and rendering of this page in HTML and text format:

Rd <- file.path("src/library/tools/man/Rd2HTML.Rd")

outfile <- tempfile(fileext = ".html")
browseURL(Rd2HTML(Rd, outfile, package = "tools",
    stages = c("install", "render")))

outfile <- tempfile(fileext = ".txt")
file.show(Rd2txt(Rd, outfile, package = "tools",
    stages = c("install", "render")))

checkRd(Rd) # A stricter test than Rd2HTML uses

## End(Not run)
```

---

**Rd2txt_options**  
*Set formatting options for text help*

---

**Description**

This function sets various options for displaying text help.

**Usage**

`Rd2txt_options(...)`

**Arguments**

`...`  
A list containing named options, or options passed as individual named arguments. See below for currently defined ones.

**Details**

This function persistently sets various formatting options for the `Rd2txt` function which is used in displaying text format help. Currently defined options are:

- `width` (default 80): The width of the output page.
- `minIndent` (default 10): The minimum indent to use in a list.
- `extraIndent` (default 4): The extra indent to use in each level of nested lists.
- `sectionIndent` (default 5): The indent level for a section.
- `sectionExtra` (default 2): The extra indentation for each nested section level.
- `itemBullet` (default "\* ", with the asterisk replaced by a Unicode bullet in UTF-8 and most Windows locales): The symbol to use as a bullet in itemized lists.
- `enumFormat` : A function to format item numbers in enumerated lists.
- `showURLs` (default FALSE): Whether to show URLs when expanding \href tags.
- `code_quote` (default TRUE): Whether to render `code` and similar with single quotes.
- `underline_titles` default TRUE): Whether to render section titles with underlines (via backspacing).
Value

If called with no arguments, returns all option settings in a list. Otherwise, it changes the named settings and invisibly returns their previous values.

---

Rdiff Difference R Output Files

Description

Given two R output files, compute differences ignoring headers, footers and some other differences.

Usage

Rdiff(from, to, useDiff = FALSE, forEx = FALSE,
nullPointers = TRUE, Log = FALSE)

Arguments

from, to filepaths to be compared
useDiff should diff always be used to compare results?
forEx logical: extra pruning for ‘-Ex.Rout’ files to exclude the header.
nullPointers logical: should the displayed addresses of pointers be set to 0x00000000 before comparison?
Log logical: should the returned value include a log of differences found?
Details

The R startup banner and any timing information from R CMD BATCH are removed from both files, together with lines about loading packages. UTF-8 fancy quotes (see sQuote) and on Windows, Windows' so-called 'smart quotes', are mapped to a simple quote. Addresses of environments, compiled bytecode and other exotic types expressed as hex addresses (e.g. <environment: 0x12345678>) are mapped to 0x00000000. The files are then compared line-by-line. If there are the same number of lines and useDiff is false, a simple diff-like display of differences is printed (which ignores differences in consecutive spaces), otherwise diff -bw is called on the edited files. (This tries to ignore all differences in whitespace; note that flag `-w` is not required by POSIX but is supported by GNU, Solaris and FreeBSD versions.)

This can compare uncompressed PDF files, ignoring differences in creation and modification dates.

Value

If log is true, a list with components status (see below) and out, a character vector of descriptions of differences, possibly of zero length.

Otherwise, a status indicator, 0L if and only if no differences were found.

See Also

The shell script run as R CMD Rdiff.

---

**Rdindex**  
*Generate Index from Rd Files*

### Description

Print a 2-column index table with names and titles from given R documentation files to a given output file or connection. The titles are nicely formatted between two column positions (typically 25 and 72, respectively).

### Usage

```r
Rdindex(RdFiles, outFile = "", type = NULL,  
        width = 0.9 *getOption("width"), indent = NULL)
```

### Arguments

- **RdFiles**: a character vector specifying the Rd files to be used for creating the index, either by giving the paths to the files, or the path to a single directory with the sources of a package.
- **outFile**: a connection, or a character string naming the output file to print to. "" (the default) indicates output to the console.
- **type**: a character string giving the documentation type of the Rd files to be included in the index, or NULL (the default). The type of an Rd file is typically specified via the `\docType` tag; if type is "data", Rd files whose only keyword is datasets are included as well.
- **width**: a positive integer giving the target column for wrapping lines in the output.
- **indent**: a positive integer specifying the indentation of the second column. Must not be greater than `width/2`, and defaults to `width/3`. 
RdTextFilter

Select text in an Rd file.

Description

This function blanks out all non-text in an Rd file, for spell checking or other uses.

Usage

RdTextFilter(ifile, encoding = "unknown", keepSpacing = TRUE,
             drop = character(), keep = character())

Arguments

ifile An input file specified as a filename or connection, or an "Rd" object from parse_Rd.
encoding An encoding name to pass to parse_Rd.
keepSpacing Whether to try to leave the text in the same lines and columns as in the original file.
drop Additional sections of the Rd to drop.
keep Sections of the Rd file to keep.

Details

This function parses the Rd file, then walks through it, element by element. Items with tag "TEXT" are kept in the same position as they appeared in the original file, while other parts of the file are replaced with blanks, so a spell checker such as aspell can check only the text and report the position in the original file. (If keepSpacing is FALSE, blank filling will not occur, and text will not be output in its original location.)

By default, the tags \S3method, \S4method, \command, \docType, \email, \encoding, \file, \key-
word, \link, \linkS4class, \method, \pkg, and \var are skipped. Additional tags can be skipped by listing them in the drop argument; listing tags in the keep argument will stop them from being skipped. It is also possible to keep any of the c("R CODE", "COMMENT", "VER B") tags, which correspond to R-like code, comments, and verbatim text respectively, or to drop "TEXT".

Value

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Rd file.

Note

The filter attempts to merge text elements into single words when markup in the Rd file is used to highlight just the start of a word.

Duncan Murdoch
Rdutils

See Also

aspell, for which this is an acceptable filter.

---

Rdutils  Rd Utilities

Description

Utilities for computing on the information in Rd objects.

Usage

Rd_db(package, dir, lib.loc = NULL)

Arguments

dir

a character string specifying the path to a package's root source directory. This should contain the subdirectory 'man' with R documentation sources (in Rd format). Only used if package is not given.

lib.loc

a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.

Details

Rd_db builds a simple database of all Rd objects in a package, as a list of the results of running parse_Rd on the Rd source files in the package and processing platform conditionals.

See Also

parse_Rd

Examples

## Build the Rd db for the (installed) base package.
db <- Rd_db("base")

## Keyword metadata per Rd object.
keywords <- lapply(db, tools:::Rd_get_metadata, "keyword")
## Tabulate the keyword entries.
kw_table <- sort(table(unlist(keywords)))
## The 5 most frequent ones:
rev(kw_table)[1 : 5]
## The "most informative" ones:
kw_table[kw_table == 1]

## Concept metadata per Rd file.
concepts <- lapply(db, tools:::Rd_get_metadata, "concept")
## How many files already have \concept metadata?
sum(sapply(concepts, length) > 0)
## How many concept entries altogether?
length(unlist(concepts))
Description

Read item/description information from ‘00Index’-like files. Such files are description lists rendered in tabular form, and currently used for the ‘INDEX’ and ‘demo/00Index’ files of add-on packages.

Usage

read.00Index(file)

Arguments

file

the name of a file to read data values from. If the specified file is "", then input is taken from the keyboard (in this case input can be terminated by a blank line). Alternatively, file can be a connection, which will be opened if necessary, and if so closed at the end of the function call.

Value

A character matrix with 2 columns named "Item" and "Description" which hold the items and descriptions.

See Also

formatDL for the inverse operation of creating a 00Index-style file from items and their descriptions.

Description

Read/R’s ‘NEWS’ file or a similarly formatted one. This was an experimental feature added in R 2.4.0: as from R 2.12.0 the preferred format is ‘NEWS.Rd’.

Usage

readNEWS(file = file.path(R.home(), "NEWS"), trace = FALSE,
        chop = c("first", "1", "par1", "keepAll"))
checkNEWS(file = file.path(R.home(), "NEWS"))

Arguments

file

the name of the file which the data are to be read from. Alternatively, file can be a connection, which will be opened if necessary, and can also be a complete URL. For more details, see the file argument of read.table.

trace

logical indicating if the recursive reading should be traced, i.e., print what it is doing.

chop

a character string specifying how the news entries should be chopped; chop = "keepAll" saves the full entries.
Details

readNEWS() reads a pre-R-2.12.0-style ‘NEWS’ file; checkNEWS() checks for common errors in formatting. Currently it detects an incorrect number of spaces before the "o" item marker.

If non-ASCII characters are needed, the ‘NEWS’ file may be encoded in UTF-8 with a byte-order mark (BOM) at the beginning, which readNEWS() will recognize. Other encodings will display incorrectly on some systems. However, BOMs are discouraged on many systems and not all editors recognize them, so ‘NEWS’ files should normally be written in ASCII.

Value

readNEWS() returns an (S3) object of class "newstree"; effectively a list of lists which is a tree of NEWS entries.

checkNEWS() returns TRUE if no suspected errors are found, or prints a message for each suspected error and returns FALSE.

Note that this was only ever experimental and will be removed soon, since the NEWS-file format is no longer supported (but there are examples ‘NEWS.0’, ‘NEWS.1’ and perhaps in packages).

showNonASCII

Pick Out Non-ASCII Characters

Description

This function prints elements of a character vector which contain non-ASCII bytes, printing such bytes as a escape like ‘<fc>’.

Usage

showNonASCII(x)

showNonASCII(file)

Arguments

x a character vector.

file path to a file.

Details

This was originally written to help detect non-portable text in files in packages.

It prints all element of x which contain non-ASCII characters, preceded by the element number and with non-ASCII bytes highlighted via iconv(sub = "byte").

Value

The elements of x containing non-ASCII characters will be returned invisibly.
Examples

out <- c("fa\xE7ile test of showNonASCII():",
"\n\n\ndefaults",
"  This is a good line",
"  This has an \xfcm laut in it.",
"  OK again.",
")
f <- tempfile()
cat(out, file = f, sep = "\n")
showNonASCIIfile(f)
unlink(f)

---

startDynamicHelp  Start the Dynamic HTML Help System

Description

This function starts the internal help server, so that HTML help pages are rendered when requested.

Usage

startDynamicHelp(start = TRUE)

Arguments

start  logical: whether to start or shut down the dynamic help system.

Details

This function starts the internal HTTP server, which runs on the loopback interface (127.0.0.1). If `options("help.ports")` is set to a vector of integer values, `startDynamicHelp` will try those ports in order; otherwise, it tries up to 10 random ports to find one not in use. It can be disabled by setting the environment variable `R_DISABLE_HTTPD` to a non-empty value.

`startDynamicHelp` is called by functions that need to use the server, so would rarely be called directly by a user.

Note that `options(help_type = "html")` must be set to actually make use of HTML help, although it might be the default for an R installation.

If the server cannot be started or is disabled, `help.start` will be unavailable and requests for HTML help will give text help (with a warning).

The browser in use does need to be able to connect to the loopback interface: occasionally it is set to use a proxy for HTTP on all interfaces, which will not work – the solution is to add an exception for 127.0.0.1.

Value

The chosen port number is returned invisibly (which will be 0 if the server has been stopped).
See Also

`help.start` and `help(help_type = "html")` will attempt to start the HTTP server if required.

`Rd2HTML` is used to render the package help pages.

---

**SweaveTeXFilter**

---

**Strip R code out of Sweave file**

---

**Description**

This function blanks out code chunks and Noweb markup in an Sweave input file, for spell checking or other uses.

**Usage**

```
SweaveTeXFilter(ifile, encoding = "unknown")
```

**Arguments**

- `ifile` Input file or connection.
- `encoding` Text encoding to pass to `readLines`.

**Details**

This function blanks out all Noweb markup and code chunks from an Sweave input file, leaving behind the LaTeX source, so that a LaTeX-aware spelling checker can check it and report errors in their original locations.

**Value**

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Rd file.

**Author(s)**

Duncan Murdoch

**See Also**

`aspell`, for which this is used with `filter = "Sweave"`. 
testInstalledPackage  Test Installed Packages

Description
These functions allow an installed package to be tested, or all base and recommended packages.

Usage

```r
testInstalledPackage(pkg, lib.loc = NULL, outDir = ".",
  types = c("examples", "tests", "vignettes"),
  srcdir = NULL, Ropts = "")
```

```r
testInstalledPackages(outDir = ".", errorsAreFatal = TRUE,
  scope = c("both", "base", "recommended"),
  types = c("examples", "tests", "vignettes"),
  srcdir = NULL, Ropts = "")
```

```r
testInstalledBasic(scope = c("basic", "devel", "both"))
```

Arguments

- **pkg**: name of an installed package.
- **lib.loc**: library path(s) in which to look for the package. See `library`
- **outDir**: the directory into which to write the output files: this should already exist.
- **types**: type(s) of tests to be done.
- **errorsAreFatal**: logical: should testing terminate at the first error?
- **srcdir**: Optional directory to look for .save files.
- **Ropts**: Additional options such as `\~d valgrind` to be passed to `R CMD BATCH` when running examples or tests.
- **scope**: Which set(s) should be tested?

Details
These tests depend on having the package example files installed (which is the default). If package-specific tests are found in a ‘tests’ directory they can be tested: these are not installed by default, but will be if `R CMD INSTALL --install-tests` was used. Finally, the R code in any vignettes can be extracted and tested.

Package tests are run in a ‘pkg-tests’ subdirectory of `outDir`, and leave their output there. `testInstalledBasic` runs the basic tests, if installed. This should be run with `LC_COLLATE=C` set: the function tries to set this by it may not work on all OSes. For non-English locales it may be desirable to set environment variables `LANGUAGE` to ‘en’ and `LC_TIME` to ‘C’ to reduce the number of differences from reference results.

The package-specific tests for the base and recommended packages are not normally installed, but make `install-tests` is provided to do so (as well as the basic tests).

Value
Invisibly 0L for success, 1L for failure.
**texi2dvi**  

*Compile LaTeX Files*

**Description**

Run `latex` and `bibtex` until all cross-references are resolved and create either a dvi or a PDF file.

**Usage**

```
texi2dvi(file, pdf = FALSE, clean = FALSE, quiet = TRUE,  
texi2dvi = getOption("texi2dvi"),  
texinputs = NULL, index = TRUE)
```

```
texipdfe(file, clean = FALSE, quiet = TRUE,  
texi2dvi = getOption("texi2dvi"),  
texinputs = NULL, index = TRUE)
```

**Arguments**

- **file** character. Name of LaTeX source file.
- **pdf** logical. If TRUE, a PDF file is produced instead of the default dvi file (``texi2dvi`` command line option `--pdf`).
- **clean** logical. If TRUE, all auxiliary files created during the conversion are removed.
- **quiet** logical. No output unless an error occurs. Ignored if emulation (see the `texi2dvi` argument) is used.
- **texi2dvi** character (or NULL). Script or program used to compile a TeX file to dvi or PDF, respectively. The default (selected by "" or NULL) is to look for an executable on the path and otherwise emulate the script with `system` calls.
- **texinputs** NULL or a character vector of paths to add to the LaTeX and bibtex input search paths.
- **index** logical: should indices be prepared?

**Details**

`texipdfe` is a wrapper for the common case of `texi2dvi(pdf = TRUE)`.

Despite the name, this is used in `R` to compile LaTeX files, specifically those generated from vignettes. It ensures that the `"R_HOME/share/texmf"` directory is in the `TEXINPUTS` path, so `R` style files such as "Sweave" and "Rd" will be found. The TeX search path used is first the existing `TEXINPUTS` setting (or the current directory if unset), then elements of `texinputs`, then `"R_HOME/share/texmf"` and finally the default path. Analogous changes are made to `BIBINPUTS` and `BSTINPUTS` settings.

MiKTeX has a `texi2dvi` executable but no other Windows TeX installation that we know of does, so emulation is used on e.g. TeXLive installations on Windows.

Occasionally indices contain special characters which cause indexing to fail (particularly when using the `hyperref` TeX package) even on valid input. The argument `index = FALSE` is provided to allow package manuals to be made when this happens: it uses emulation.
Value

Invisible NULL. Used for the side effect of creating a dvi or PDF file in the current working directory (and maybe other files, especially if clean = FALSE).

Note

There are various versions of the texi2dvi script on Unix-alikes and quite a number of bugs have been seen, some of which this R wrapper works around.
One that was present with texi2dvi version 4.8 (as supplied on OS X) is that it will not work correctly for paths which contain spaces, nor if the absolute path to a file would contain spaces.
The three possible approaches all have their quirks. For example the Unix-alike texi2dvi script removes ancillary files that already exist but the other two approaches do not (and may get confused by such files).

Author(s)

Originally Achim Zeileis but largely rewritten by R-core.

---

toHTML

Display an object in HTML.

Description

This generic function generates a complete HTML page from an object.

Usage

toHTML(x, ...)  
## S3 method for class 'packageIQR'
toHTML(x, ...)  
## S3 method for class 'news_db'
toHTML(x, ...)

Arguments

x               An object to display.
...             Optional parameters for methods; the "packageIQR" and "news_db" methods pass these to HTMLheader.

Value

A character vector to display the object x. The "packageIQR" method is designed to display lists in the R help system.

See Also

HTMLheader

Examples

cat(toHTML(demo(package = "base")), sep = "\n")
tools-deprecated

Deprecated Objects in Package tools

Description

The functions or variables listed here are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

See Also

Deprecated, Defunct

toRd

Generic function to convert object to a fragment of Rd code.

Description

Methods for this function render their associated classes as a fragment of Rd code, which can then be rendered into text, HTML, or LaTeX.

Usage

toRd(obj, ...)

## S3 method for class 'bibentry'
toRd(obj, style = NULL, ...)

Arguments

obj

The object to be rendered.

style

The style to be used in converting a bibentry object.

...

Additional arguments used by methods.

Details

See bibstyle for a discussion of styles. The default style = NULL value gives the default style.

Value

Returns a character vector containing a fragment of Rd code that could be parsed and rendered. The default method converts obj to mode character, then escapes any Rd markup within it. The bibentry method converts an object of that class to markup appropriate for use in a bibliography.
Find Undocumented Objects

Description

Finds the objects in a package which are undocumented, in the sense that they are visible to the user (or data objects or S4 classes provided by the package), but no documentation entry exists.

Usage

undoc(package, dir, lib.loc = NULL)

Arguments

package a character string naming an installed package.
dir a character string specifying the path to a package's root source directory. This must contain the subdirectory 'man' with R documentation sources (in Rd format), and at least one of the 'R' or 'data' subdirectories with R code or data objects, respectively.
lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.

Details

This function is useful for package maintainers mostly. In principle, all user-level R objects should be documented.

The base package is special as it contains the primitives and these do not have definitions available at code level. We provide equivalent closures in environments .ArgsEnv and .GenericArgsEnv in the base package that are used for various purposes: undoc("base") checks that all the primitives that are not language constructs are prototyped in those environments and no others are.

Value

An object of class "undoc" which is a list of character vectors containing the names of the undocumented objects split according to documentation type.

There is a print method for nicely displaying the information contained in such objects.

update_pkg_po

Prepare Translations for a Package

Description

Prepare the ‘po’ directory of a package and compile and install the translations.

Usage

update_pkg_po(pkgdir, pkg = NULL, version = NULL, copyright, bugs)

Arguments

pkgdir The path to the package directory.
 pkg The package name: if NULL it is read from the package’s ‘DESCRIPTION’ file.
 version The package version: if NULL it is read from the package’s ‘DESCRIPTION’ file.
copyright, bugs optional character strings for the ‘Copyright’ and ‘Report-Msgid-Bugs-To’ details in the template files.

Details

This performs a series of steps to prepare or update messages in the package.

• If the package sources do not already have a ‘po’ directory, one is created.
• xgettext2pot is called to create/update a file ‘po/R-pkgname.pot’ containing the translatable messages in the package.
• All existing files in directory po with names ‘R-lang.po’ are updated from ‘R-pkgname.pot’. checkPoFile is called on the updated file, and if there are no problems the file is compiled and installed under ‘inst/po’.
• In a UTF-8 locale, a ‘translation’ ‘R-en@quot.pot’ is created with UTF-8 directional quotes, compiled and installed under ‘inst/po’.
• The remaining steps are done only if file ‘po/pkgname.pot’ already exists. The ‘src/*.c,cc,cpp,m,mm’ files in the package are examined to create a file ‘po/pkgname.pot’ containing the translatable messages in the C/C++ files. If there is a src/windows directory, files within it are also examined.
• All existing files in directory po with names ‘lang.po’ are updated from ‘pkgname.pot’. checkPoFile is called on the updated file, and if there are no problems the file is compiled and installed under ‘inst/po’.
• In a UTF-8 locale, a ‘translation’ ‘en@quot.pot’ is created with UTF-8 directional quotes, compiled and installed under ‘inst/po’.

Note that C/C++ messages are not automatically prepared for translation as they need to be explicitly marked for translation in the source files. Once that has been done, create an empty file ‘po/pkgname.pot’ in the package sources and run this function again.

pkg = "base" is special (and for use by R developers only): the C files are not in the package directory but in the main sources.
System requirements

This function requires the following tools from the GNU gettext tools: xgettext, msgmerge, msgfmt, msginit and msgconv. These are part of most Linux distributions and easily compiled from the sources on Unix-alikes (including OS X). Pre-compiled versions for Windows are available in http://www.stats.ox.ac.uk/pub/Rtools/goodies/gettext-tools.zip.

It will probably not work correctly for en@quote translations except in a UTF-8 locale, so these are skipped elsewhere.

xgettext2pot.

vignetteDepends

Retrieve Dependency Information for a Vignette

Description

Given a vignette name, will create a DependsList object that reports information about the packages the vignette depends on.

Usage

vignetteDepends(vignette, recursive = TRUE, reduce = TRUE,
local = TRUE, lib.loc = NULL)

Arguments

vignette  The path to the vignette source
recursive  Whether or not to include indirect dependencies
reduce    Whether or not to collapse all sets of dependencies to a minimal value
local     Whether or not to search only locally
lib.loc   What libraries to search in locally

Details

If recursive is TRUE, any package that is specified as a dependency will in turn have its dependencies included (and so on), these are known as indirect dependencies. If recursive is FALSE, only the dependencies directly named by the vignette will be used.

If local is TRUE, the system will only look at the user’s local machine and not online to find dependencies.

If reduce is TRUE, the system will collapse the fields in the DependsList object such that a minimal set of dependencies are specified (for instance if there was ‘foo, foo (>= 1.0.0), foo (>= 1.3.0)’, it would only return ‘foo (>= 1.3.0)’).

Value

An object of class "DependsList".
Author(s)
Jeff Gentry

pkgdepends

Examples
## This may not be installed
gridEx <- system.file("doc", "grid.Rnw", package = "grid")
vignetteDepends(gridEx)

vignetteEngine

Description
Vignettes are normally processed by Sweave, but package writers may choose to use a different engine (e.g. one provided by the knitr, noweb or R.rsp packages). This function is used by those packages to register their engines, and internally by R to retrieve them.

Usage
vignetteEngine(name, weave, tangle, pattern = NULL,
               package = NULL)

Arguments
  name          the name of the engine.
  weave         a function to convert vignette source files to LaTeX output.
  tangle        a function to convert vignette source files to R code.
  pattern       a regular expression pattern for the filenames handled by this engine, or NULL for the default pattern.
  package       the package registering the engine. By default, this is the package calling vignetteEngine.

Details
If weave is missing, vignetteEngine will return the currently registered engine matching name and package.

If weave is NULL, the specified engine will be deleted.

Other settings define a new engine. The weave and tangle functions must be defined with argument lists compatible with function(file, ...). Currently the ... arguments may include logical argument quiet and character argument encoding; others may be added in future. These are described in the documentation for Sweave and Stangle.

The weave and tangle functions should return the filename of the output file that has been produced. Currently the weave function, when operating on a file named '<name> <pattern>' must produce a file named '<name>[.]tex[|pdf|html]'. The '.tex' files will be processed by
write_PACKAGES

Generate PACKAGES files

Description

Generate 'PACKAGES' and 'PACKAGES.gz' files for a repository of source or Mac/Windows binary packages.

Usage

write_PACKAGES(dir = ".", fields = NULL,
type = c("source", "mac.binary", "win.binary"),
verbose = FALSE, unpacked = FALSE, subdirs = FALSE,
latestOnly = TRUE, addFiles = FALSE)
**write_PACKAGES**

**Arguments**

- **dir**
  - Character vector describing the location of the repository (directory including source or binary packages) to generate the `PACKAGES` and `PACKAGES.gz` files from and write them to.

- **fields**
  - a character vector giving the fields to be used in the `PACKAGES` and `PACKAGES.gz` files in addition to the default ones, or NULL (default). The default corresponds to the fields needed by `available.packages`: "Package", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "OS_type", "License" and "Archs". and those fields will always be included, plus the file name in field "File" if addFile = TRUE and the path to the subdirectory in field "Path" if subdirectories are used.

- **type**
  - Type of packages: currently source `.tar.gz` archives, and Mac or Windows binary (`.tgz` or `.zip`, respectively) packages are supported. Defaults to "win.binary" on Windows and to "source" otherwise.

- **verbose**
  - logical. Should packages be listed as they are processed?

- **unpacked**
  - a logical indicating whether the package contents are available in unpacked form or not (default).

- **subdirs**
  - either logical (to indicate if subdirectories should be included, recursively) or a character vector of name of subdirectories to include.

- **latestOnly**
  - logical: if multiple versions of a package are available should only the latest version be included?

- **addFiles**
  - logical: should the filenames be included as field "File" in the `PACKAGES` file.

**Details**

`write_PACKAGES` scans the named directory for R packages, extracts information from each package's `DESCRIPTION` file, and writes this information into the `PACKAGES` and `PACKAGES.gz` files.

Including non-latest versions of packages is only useful if they have less constraining version requirements, so for example `latestOnly = FALSE` could be used for a source repository when `foo_1.0` depends on `R >= 2.15.0` but `foo_0.9` is available which depends on `R >= 2.11.0`.

Support for repositories with subdirectories and hence for `subdirs != FALSE` was added in R 2.7.0: this depends on recording a "Path" field in the `PACKAGES` file.

Support for more general file names (e.g. other types of compression) via a "File" field in the `PACKAGES` file was added in R 2.10.0 and can be used by `download.packages`. If the file names are not of the standard form, use `addFiles = TRUE`.

`type = "win.binary"` uses `unz` connections to read all `DESCRIPTION` files contained in the (zipped) binary packages for Windows in the given directory `dir`, and builds files `PACKAGES` and `PACKAGES.gz` files from this information.

**Value**

Invisibly returns the number of packages described in the resulting `PACKAGES` and `PACKAGES.gz` files. If 0, no packages were found and no files were written.

**Note**

Processing `.tar.gz` archives to extract the `DESCRIPTION` files is quite slow.

This function can be useful on other OSes to prepare a repository to be accessed by Windows machines, so `type = "win.binary"` should work on all OSes.
xgettext

Extract Translatable Messages from R Files in a Package

Description

For each file in the ‘R’ directory (including system-specific subdirectories) of a package, extract the unique arguments passed to `step`, `warning`, `message`, `gettext`, and `gettextf`, or to `ngettext`.

Usage

```r
xgettext(dir, verbose = FALSE, asCall = TRUE)
xgettext(dir, verbose = FALSE)
xgettext2pot(dir, potFile, name = "R", version, bugs)
```

Arguments

- `dir` - the directory of a source package.
- `verbose` - logical: should each file be listed as it is processed?
- `asCall` - logical: if TRUE each argument is returned whole, otherwise the strings within each argument are extracted.
- `potFile` - name of po template file to be produced. Defaults to ‘R-pkgsname.pot’ where `pkgsname` is the basename of ‘dir’.
- `name`, `version`, `bugs` - as recorded in the template file: version defaults the version number of the currently running R, and bugs to "bugs.r-project.org".
Details

Leading and trailing white space (space, tab and linefeed) is removed for calls to gettext, gettextf, stop, warning, and message, as it is by the internal code that passes strings for translation.

We look to see if these functions were called with domain = NA and if so omit the call if asCall = TRUE: note that the call might contain a call to gettext which would be visible if asCall = FALSE.

xgettext2pot calls xgettext and then xngettext, and writes a PO template file for use with the GNU Gettext tools. This ensures that the strings for simple translation are unique in the file (as GNU Gettext requires), but does not do so for ngettext calls (and the rules are not stated in the Gettext manual, but msgfmt complains if there is duplication between the sets.).

If applied to the base package, this also looks in the ‘.R’ files in ‘R_HOME/share/R’.

Value

For xgettext, a list of objects of class "xgettext" (which has a print method), one per source file that potentially contains translatable strings.

For xngettext, a list of objects of class "xngettext", which are themselves lists of length-2 character strings.

Examples

```r
## Not run: ## in a source-directory build of R:
xgettext(file.path(R.home(), "src", "library", "splines"))

## End(Not run)
```

adist

Approximate String Distances

Description

Compute the approximate string distance between character vectors. The distance is a generalized
Levenshtein (edit) distance, giving the minimal possibly weighted number of insertions, deletions
and substitutions needed to transform one string into another.

Usage

adist(x, y = NULL, costs = NULL, counts = FALSE, fixed = TRUE,
     partial = !fixed, ignore.case = FALSE, useBytes = FALSE)
Arguments

- **x**: a character vector. Long vectors are not supported.
- **y**: a character vector, or NULL (default) indicating taking x as y.
- **costs**: a numeric vector or list with names partially matching ‘insertions’, ‘deletions’ and ‘substitutions’ giving the respective costs for computing the Levenshtein distance, or NULL (default) indicating using unit cost for all three possible transformations.
- **counts**: a logical indicating whether to optionally return the transformation counts (numbers of insertions, deletions and substitutions) as the “counts” attribute of the return value.
- **fixed**: a logical. If TRUE (default), the x elements are used as string literals. Otherwise, they are taken as regular expressions and partial = TRUE is implied (corresponding to the approximate string distance used by `agrep` with fixed = FALSE).
- **partial**: a logical indicating whether the transformed x elements must exactly match the complete y elements, or only substrings of these. The latter corresponds to the approximate string distance used by `agrep` (by default).
- **ignore.case**: a logical. If TRUE, case is ignored for computing the distances.
- **useBytes**: a logical. If TRUE distance computations are done byte-by-byte rather than character-by-character.

Details

The (generalized) Levenshtein (or edit) distance between two strings s and t is the minimal possibly weighted number of insertions, deletions and substitutions needed to transform s into t (so that the transformation exactly matches t). This distance is computed for partial = FALSE, currently using a dynamic programming algorithm (see, e.g., [http://en.wikipedia.org/wiki/Levenshtein_distance](http://en.wikipedia.org/wiki/Levenshtein_distance)) with space and time complexity $O(mn)$, where $m$ and $n$ are the lengths of s and t, respectively. Additionally computing the transformation sequence and counts is $O(max(m,n))$.

The generalized Levenshtein distance can also be used for approximate (fuzzy) string matching, in which case one finds the substring of t with minimal distance to the pattern s (which could be taken as a regular expression, in which case the principle of using the leftmost and longest match applies), see, e.g., [http://en.wikipedia.org/wiki/Approximate_string_matching](http://en.wikipedia.org/wiki/Approximate_string_matching). This distance is computed for partial = TRUE using ‘tre’ by Ville Laurikari ([http://http://laurikari.net/tre/](http://http://laurikari.net/tre/)) and corresponds to the distance used by `agrep`. In this case, the given cost values are coerced to integer.

Note that the costs for insertions and deletions can be different, in which case the distance between s and t can be different from the distance between t and s.

Value

A matrix with the approximate string distances of the elements of x and y, with rows and columns corresponding to x and y, respectively.

If counts is TRUE, the transformation counts are returned as the "counts" attribute of this matrix, as a 3-dimensional array with dimensions corresponding to the elements of x, the elements of y, and the type of transformation (insertions, deletions and substitutions), respectively. Additionally, if partial = FALSE, the transformation sequences are returned as the "trafos" attribute of the return value, as character strings with elements ‘M’, ‘I’, ‘D’ and ‘S’ indicating a match, insertion, deletion and substitution, respectively. If partial = TRUE, the offsets (positions of the first and last element) of the matched substrings are returned as the "offsets" attribute of the return value (with both offsets −1 in case of no match).
See Also

agrep for approximate string matching (fuzzy matching) using the generalized Levenshtein distance.

Examples

```r
adist("kitten", "sitting")
## To see the transformation counts for the Levenshtein distance:
drop(attr(adist("kitten", "sitting", counts = TRUE), "counts"))
## To see the transformation sequences:
attr(adist(c("kitten", "sitting"), counts = TRUE), "trafos")

## Cf. the examples for agrep:
adist("lasy", "1 lazy 2")
## For a "partial approximate match" (as used for agrep):
adist("lasy", "1 lazy 2", partial = TRUE)
```

---

**alarm**

*Alert the User*

### Description

Gives an audible or visual signal to the user.

### Usage

```r
alarm()
```

### Details

alarm() works by sending a \a character to the console. On most platforms this will ring a bell, beep, or give some other signal to the user (unless standard output has been redirected).

It attempts to flush the console (see flush.console).

### Value

No useful value is returned.

### Examples

```r
alarm()
```
Description

`apropos()` returns a character vector giving the names of all objects in the search list matching `what`. `find()` is a different user interface to the same task.

Usage

`apropos(what, where = FALSE, ignore.case = TRUE, mode = "any")`

`find(what, mode = "any", numeric = FALSE, simple.words = TRUE)`

Arguments

- `what`: character string with name of an object, or more generally a regular expression to match against.
- `where`, `numeric`: a logical indicating whether positions in the search list should also be returned.
- `ignore.case`: logical indicating if the search should be case-insensitive, `TRUE` by default. Note that in R versions prior to 2.5.0, the default was implicitly `ignore.case = FALSE`.
- `mode`: character; if not "any", only objects whose `mode` equals `mode` are searched.
- `simple.words`: logical; if `TRUE`, the `what` argument is only searched as whole word.

Details

If `mode` != "any" only those objects which are of mode `mode` are considered. If `where` is `TRUE`, the positions in the search list are returned as the names attribute.

`find` is a different user interface for the same task as `apropos`. However, by default (`simple.words == TRUE`), only full words are searched with `grep(fixed = TRUE)`.

Value

For `apropos` character vector, sorted by name, possibly with names giving the (numerical) positions on the search path.

For `find`, either a character vector of environment names, or for `numeric = TRUE`, a numerical vector of positions on the search path, with names giving the names of the corresponding environments.

Author(s)

Kurt Hornik and Martin Maechler (May 1997).

See Also

`glob2rx` to convert wildcard patterns to regular expressions.

`objects` for listing objects from one place, `help.search` for searching the help system, `search` for the search path.
aregexec

Examples

require(stats)

## Not run: apropos("lm")
 apropos("GLM") # more than a dozen
## that may include internal objects starting '.__Ca__' if
## methods is attached
 apropos("GLM", ignore.case = FALSE) # not one
 apropos("lq")

cor <- 1:pi
 find("cor") #> "GlobalEnv"  "package:stats"
 find("cor", numeric = TRUE) # numbers with these names
 find("cor", numeric = TRUE, mode = "function") # only the second one
 rm(cor)

## Not run: apropos(".", mode="list") # a long list

# need a DOUBLE backslash '\\' (in case you don't see it anymore)
 apropos("\\[")

## Not run: # everything
 length(apropos("."))

# those starting with 'pr'
 apropos("pr")

# the 1-letter things
 apropos(".\$")

# the 1-2-letter things
 apropos("..?\$")

# the 2-to-4 letter things
 apropos("..{2,4}\$")

# the 8-and-more letter things
 apropos("..{8}\$")
table(nchar(apropos("..{8}\$")))

## End(Not run)

---

aregexec Approximate String Match Positions

Description

Determine positions of approximate string matches.

Usage

aregexec(pattern, text, max.distance = 0.1, costs = NULL,
         ignore.case = FALSE, fixed = FALSE, useBytes = FALSE)
Arguments

pattern a non-empty character string or a character string containing a regular expression (for fixed = FALSE) to be matched. Coerced by as.character to a string if possible.

text character vector where matches are sought. Coerced by as.character to a character vector if possible.

max.distance maximum distance allowed for a match. See agrep.

costs cost of transformations. See agrep.

ignore.case a logical. If TRUE, case is ignored for computing the distances.

fixed If TRUE, the pattern is matched literally (as is). Otherwise (default), it is matched as a regular expression.

useBytes a logical. If TRUE comparisons are byte-by-byte rather than character-by-character.

Details

aregexec provides a different interface to approximate string matching than agrep (along the lines of the interfaces to exact string matching provided by regexec and grep).

Note that by default, agrep performs literal matches, whereas aregexec performs regular expression matches.

See agrep and adist for more information about approximate string matching and distances.

Comparisons are byte-by-byte if pattern or any element of text is marked as "bytes".

Value

A list of the same length as text, each element of which is either $-1$ if there is no match, or a sequence of integers with the starting positions of the match and all substrings corresponding to parenthesized subexpressions of pattern, with attribute "match.length" an integer vector giving the lengths of the matches (or $-1$ for no match).

See Also

regmatches for extracting the matched substrings.

Examples

```r
## Cf. the examples for agrep.
x <- c("1 lazy", "1", "1 LAZY")
aregexec("laysy", x, max.distance = 2)
aregexec("(lay)(sy)", x, max.distance = 2)
aregexec("(lay)(sy)", x, max.distance = 2, ignore.case = TRUE)
m <- aregexec("(lay)(sy)", x, max.distance = 2)
regmatches(x, m)
```
**aspe**ll

**Spell Check Interface**

**Description**

Spell check given files via Aspell, Hunspell or Ispell.

**Usage**

```r
aspe\text{ll}(files, filter, control = \text{list()}, encoding = "unknown",
program = \text{NULL}, dictionaries = \text{character()})
```

**Arguments**

- **files**: a character vector with the names of files to be checked.
- **filter**: an optional filter for processing the files before spell checking, given as either a function (with formals \text{ifile} and \text{encoding}), or a character string specifying a built-in filter, or a list with the name of a built-in filter and additional arguments to be passed to it. See **Details** for available filters. If missing or \text{NULL}, no filtering is performed.
- **control**: a list or character vector of control options for the spell checker.
- **encoding**: the encoding of the files. Recycled as needed.
- **program**: a character string giving the name (if on the system path) or full path of the spell check program to be used, or \text{NULL} (default). By default, the system path is searched for \text{aspell}, \text{hunspell} and \text{ispell} (in that order), and the first one found is used.
- **dictionaries**: a character vector of names or file paths of additional R level dictionaries to use. Elements with no path separator specify R system dictionaries (in subdirectory \text{'share/dictionaries'} of the R home directory). The file extension (currently, only \text{'.rds'}) can be omitted.

**Details**

The spell check programs employed must support the so-called Ispell pipe interface activated via command line option `-\text{a}`. In addition to the programs, suitable dictionaries need to be available. See \url{http://aspell.net}, \url{http://hunspell.sourceforge.net/} and \url{http://lasr.cs.ucla.edu/geoff/ispell.html}, respectively, for obtaining the Aspell, Hunspell and (International) Ispell programs and dictionaries.

The currently available built-in filters are "\text{Rd}" (corresponding to \text{RdTextFilter}), "\text{Sweave}" (corresponding to \text{SweaveTextFilter}), "\text{R}", "\text{pot}" and "\text{dcf}".

Filter "\text{R}" is for R code and extracts the message string constants in calls to \text{message}, \text{warning}, \text{stop}, \text{packageStartupMessage}, \text{gettext}, \text{gettextf}, and \text{ngettext} (the unnamed string constants for the first five, and \text{fmt} and \text{msg1/msg2} string constants, respectively, for the latter two). Filter "\text{pot}" is for message string catalog \text{\'\text{pot}'} files. Both have an argument \text{ignore} allowing to give regular expressions for parts of message strings to be ignored for spell checking: e.g., using "^[\s\t]" ignores all text inside single quotes.

Filter "\text{dcf}" is for files in Debian Control File format. The fields to keep can be controlled by argument \text{keep} (a character vector with the respective field names). By default, 'Title' and 'Description' fields are kept.
The print method has for the objects returned by aspell an indent argument controlling the indentation of the positions of possibly mis-spelled words. The default is 2; Emacs users may find it useful to use an indentation of 0 and visit output in grep-mode. It also has a verbose argument: when this is true, suggestions for replacements are shown as well.

It is possible to employ additional R level dictionaries. Currently, these are files with extension `.rds’ obtained by serializing character vectors of word lists using saveRDS. If such dictionaries are employed, they are combined into a single word list file which is then used as the spell checker’s personal dictionary (option ‘--p’): hence, the default personal dictionary is not used in this case.

Value

A data frame inheriting from aspell (which has a useful print method) with the information about possibly mis-spelled words.

See Also

aspell-utils for utilities for spell checking packages.

Package Aspell on Omegahat (http://www.omegahat.org/Aspell) for a fine-grained R interface to the Aspell library.

Examples

```r
## Not run:
## To check all Rd files in a directory, (additionally) skipping the
## \references sections.
files <- Sys.glob("*.Rd")
aspell(files, filter = list("Rd", drop = "\references"))

## To check all Sweave files
files <- Sys.glob(c("*.Rnw", "*.Snw", "*.rnw", "*.snw"))
aspell(files, filter = "Sweave", control = "-t")

## To check all Texinfo files (Aspell only)
files <- Sys.glob("*.texi")
aspell(files, control = "--mode=texinfo")

## End(Not run)

## List the available R system dictionaries.
Sys.glob(file.path(R.home("share"), "dictionaries", "*.rds"))
```

Description

Utilities for spell checking packages via Aspell, Hunspell or Ispell.
Usage

aspell_package_Rd_files(dir, drop = c("\author", "\references"),
control = list(), program = NULL,
dictionaries = character())
aspell_package_vignettes(dir,
control = list(), program = NULL,
dictionaries = character())
aspell_package_R_files(dir, ignore = character(), control = list(),
program = NULL, dictionaries = character())
aspell_package_C_files(dir, ignore = character(), control = list(),
program = NULL, dictionaries = character())
aspell_write_personal_dictionary_file(x, out, language = "en",
program = NULL)

Arguments

dir
  a character string specifying the path to a package’s root directory.
drop
  a character vector naming additional Rd sections to drop when selecting text via
  RdTextFilter.
control
  a list or character vector of control options for the spell checker.
program
  a character string giving the name (if on the system path) or full path of the
  spell check program to be used, or NULL (default). By default, the system path
  is searched for aspell, hunspell and ispell (in that order), and the first one
  found is used.
dictionaries
  a character vector of names or file paths of additional R level dictionaries to use.
  See aspell.
ignore
  a character vector with regular expressions to be replaced by blanks when filter-
  ing the message strings.
x
  a character vector, or the result of a call to aspell().
out
  a character string naming the personal dictionary file to write to.
language
  a character string indicating a language as used by Aspell.

Details

Functions aspell_package_Rd_files, aspell_package_vignettes,
aspell_package_R_files and aspell_package_C_files perform spell checking on the
Rd files, vignettes, R files, and C-level messages of the package with root directory dir. They
determine the respective files, apply the appropriate filters, and run the spell checker.
See aspell for details on filters.
The C-level message string are obtained from the ‘po/PACKAGE.pot’ message catalog file, with
PACKAGEx the basename of dir. See the section on “C-level messages” in “Writing R Extensions”
for more information.
When using Aspell, the vignette checking skips parameters and/or options of commands \Sexpr,
\citet, \code, \pkg, \proglang and \samp. Further commands can be skipped by adding --add-tex-
command options to the control argument. E.g., to skip both option and parameter of \mycmd,
add --add-tex-command="\mycmd op".
Suitable values for control, program, dictionaries, drop and ignore can also be specified using
a package defaults file which should go as ‘defaults.R’ into the .aspell subdirectory of dir,
and provides defaults via assignments of suitable named lists, e.g.,
vignettes <- list(control = "--add-tex-command='mycmd op'")

for vignettes (when using Aspell) and similarly assigning to Rd_files, R_files and C_files for Rd files, R files and C level message defaults.

Maintainers of packages using both English and American spelling will find it convenient to pass control options '--master=en_US' and '--add-extra-dicts=en_GB' to Aspell and control options '-d en_US, en_GB' to Hunspell (provided that the corresponding dictionaries are installed).

Older versions of R had no support for R level dictionaries, and hence provided the function aspell_write_personal_dictionary_file to create (spell check) program-specific personal dictionary files from words to be accepted. The new mechanism is to use R level dictionaries, i.e., '.rds' files obtained by serializing character vectors of such words using saveRDS. For such dictionaries specified via the package defaults mechanism, elements with no path separator can be R system dictionaries or dictionaries in the '.aspell' subdirectory.

**available.packages**  
List Available Packages at CRAN-like Repositories

### Description

available.packages returns a matrix of details corresponding to packages currently available at one or more repositories. The current list of packages is downloaded over the internet (or copied from a local mirror).

### Usage

```r
available.packages(  
  contriburl =  
    contrib.url(getOption("repos"), type),  
    method, fields = NULL,  
    type = getOption("pkgType"),  
    filters = NULL
)
```

### Arguments

- `contriburl`  
  URL(s) of the `contrib` sections of the repositories. Specify this argument only if your repository mirror is incomplete, e.g., because you burned only the `contrib` section on a CD.

- `method`  
  download method, see `download.file`.

- `type`  
  character string, indicate which type of packages: see `install.packages`.

- `fields`  
  a character vector giving the fields to extract from the `PACKAGES` file(s) in addition to the default ones, or NULL (default). Unavailable fields result in NA values.

- `filters`  
  a character vector or list or NULL (default). See ‘Details’.
available.packages

Details

The list is either copied from a local mirror (specified by a ‘file://’ URI) or downloaded. If downloaded, the list is cached for the R session in a per-repository file in `tempdir()` with a name like `repos_http%3a%2f%2fcran.r-project.org%2fsr%2fcontrib.rds`

By default, the report includes only packages whose version and OS requirements are met by the running version of R, and only gives information on the latest versions of packages.

Argument filters can be used to select which of the packages on the repositories are reported. It is called with its default value (NULL) by functions such as `install.packages`: this value corresponds to `getOption("available_packages_filters")` and to `c("R_version", "OS_type", "subarch", "duplicates")` if that is unset or set to NULL.

The built-in filters are

"R_version" exclude packages whose R version requirements are not met

"OS_type" exclude packages whose OS requirement is incompatible with this version of R: that is exclude Windows-only packages on a Unix-alike platform and vice versa.

"subarch" for binary packages, exclude those with compiled code that is not available for the current sub-architecture, e.g. exclude packages only compiled for 32-bit Windows on a 64-bit Windows R.

"duplicates" only report the latest version where more than one version is available, and only report the first-named repository (in contriburl) with the latest version if that is in more than one repository.

"license/FOSS" include only packages for which installation can proceed solely based on packages which can be verified as Free or Open Source Software (FOSS, e.g., https://en.wikipedia.org/wiki/FOSS) employing the available license specifications. Thus both the package and any packages that it depends on to load need to be known to be FOSS.

Note that this does depend on the repository supplying license information.

"license/restricts_use" include only packages for which installation can proceed solely based on packages which are guaranteed not to restrict use.

"CRAN" use CRAN versions in preference to versions from other repositories (even if these have a higher version number).

If all the filters are from this set they can be specified as a character vector; otherwise filters should be a list with elements which are character strings, user-defined functions or add = TRUE

User-defined filters are functions which take a single argument, a matrix of the form returned by `available.packages`, and return a matrix consisting of a subset of the rows of the argument.

The special ‘filter’ add = TRUE appends the other elements of the filter list to the default filters.

Value

A matrix with one row per package, row names the package names and column names including "Package", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "File" and "Repository". Additional columns can be specified using the fields argument.

Where provided by the repository, fields "OS_type", "License", "License_is_FOSS", "License_restricts_use", "Archs", "MD5sum" and "NeedsCompilation" are reported for use by the filters and package management tools, including `install.packages`.

install.packages, download.packages, contrib.url.

The 'R Installation and Administration' manual for how to set up a repository.

Examples

```r
## Not run:
## restrict install.packages() (etc) to known-to-be-FOSS packages
options(available_packages_filters =
  c("R_version", "OS_type", "subarch", "duplicates", "license/FOSS"))
## or
options(available_packages_filters = list(add = TRUE, "license/FOSS"))
## End(Not run)
```

Description

Run R non-interactively with input from infile and send output (stdout/stderr) to another file.

Usage

```r
R CMD BATCH [options] infile [outfile]
```

Arguments

- `infile` the name of a file with R code to be executed.
- `options` a list of R command line options, e.g., for setting the amount of memory available and controlling the load/save process. If `infile` starts with a `'-', use `--'` as the final option. The default options are `--restore --save --no-readline`.
  (Without `--no-readline` on Windows.)
- `outfile` the name of a file to which to write output. If not given, the name used is that of `infile`, with a possible `'.R'` extension stripped, and `'.Rout'` appended.

Details

Use `R CMD BATCH --help` to be reminded of the usage.

By default, the input commands are printed along with the output. To suppress this behavior, add `options(echo = FALSE)` at the beginning of `infile`, or use option `--slave`.

The `infile` can have end of line marked by LF or CRLF (but not just CR), and files with an incomplete last line (missing end of line (EOL) mark) are processed correctly.

A final expression `proc.time()` will be executed after the input script unless the latter calls `q(runLast = FALSE)` or is aborted. This can be suppressed by the option `--no-timing`.

Additional options can be set by the environment variable `R_BATCH_OPTIONS`: these come after the default options (see the description of the `options` argument) and before any options given on the command line.
Note

Unlike Splus BATCH on a Unix-alike, this does not run the \texttt{R} process in the background. In most shells,

\texttt{R CMD BATCH [options] infile [outfile] \&}

will do so.

\begin{description}
\item[bibentry] \textit{Bibliography Entries}
\end{description}

\section*{Description}

Functionality for representing and manipulating bibliographic information in enhanced \texttt{BibTeX} style.

\section*{Usage}

\begin{verbatim}
bibentry(bibtpe, textVersion = NULL, header = NULL, footer = NULL,
    key = NULL, ..., other = list(),
    mheader = NULL, mfooter = NULL)
\end{verbatim}

\begin{verbatim}
## S3 method for class 'bibentry'
print(x, style = "text", .bibstyle, ...)
\end{verbatim}

\section*{Arguments}

\begin{itemize}
\item[bibtype] a character string with a \texttt{BibTeX} entry type. See \textbf{Entry Types} for details.
\item[textVersion] a character string with a text representation of the reference to optionally be employed for printing.
\item[header] a character string with optional header text.
\item[footer] a character string with optional footer text.
\item[key] a character string giving the citation key for the entry.
\item[... for bibentry: arguments of the form \texttt{tag=value} giving the fields of the entry, with \texttt{tag} and \texttt{value} the name and value of the field, respectively. Arguments with empty values are dropped. See \textbf{Entry Fields} for details.
\item[other] a list of arguments as in \ldots (useful in particular for fields named the same as formals of \texttt{bibentry}).
\item[mheader] a character string with optional "outer" header text.
\item[mfooter] a character string with optional "outer" footer text.
\item[x] an object inheriting from class "bibentry".
\item[style] an optional character string specifying the print style. If present, must be a unique abbreviation (with case ignored) of the available styles, see \textbf{Details}.
\item[.bibstyle] a character string naming a bibliography style.
\end{itemize}
Details

The bibentry objects created by bibentry can represent an arbitrary positive number of references. One can use c() to combine bibentry objects, and hence in particular build a multiple reference object from single reference ones. Alternatively, one can use bibentry to directly create a multiple reference object by “vectorizing” the given arguments, i.e., use character vectors instead of character strings.

The print method for bibentry objects provides a choice between seven different styles: plain text (style "text"), BibTeX ("Bibtex"), a mixture of plain text and BibTeX as traditionally used for citations ("citation"), HTML ("html"), LaTeX ("latex"), R code ("R"), and a simple copy of the textVersion elements (style "textVersion"). The "text", "html" and "latex" styles make use of the .bibstyle argument using the bibstyle function. When printing bibentry objects in citation style, a header/footer for each item can be displayed as well as a mheader/mfooter for the whole vector of references.

The print method is based on a format method which provides the same styles, and for formatting as R code a choice between giving a character vector with one bibentry() call for each bibentry (as commonly used in 'CITATION' files), or a character string with one collapsed call, obtained by combining the individual calls with c() if there is more than one bibentry. This can be controlled by setting the option collapse to FALSE (default) or TRUE, respectively. (Printing in R style always collapses to a single call.) Further, for the "citation" style, format()'s optional argument citation.bibtex.max (with default getOption("citation.bibtex.max") which defaults to 1) determines for up to how many citation bibentries text style is shown together with with bibtex, automatically.

It is possible to subscript bibentry objects by their keys (which are used for character subscripts if the names are NULL).

There is also a toBibTex method for direct conversion to BibTeX.

Value

bibentry produces an object of class "bibentry".

Entry Types

bibentry creates "bibentry" objects, which are modeled after BibTeX entries. The entry should be a valid BibTeX entry type, e.g.,

Article: An article from a journal or magazine.
InBook: A part of a book, which may be a chapter (or section or whatever) and/or a range of pages.
InCollection: A part of a book having its own title.
InProceedings: An article in a conference proceedings.
Misc: Use this type when nothing else fits.
Proceedings: The proceedings of a conference.
TechReport: A report published by a school or other institution, usually numbered within a series.
Unpublished: A document having an author and title, but not formally published.
Entry Fields

The \ldots argument of \texttt{bibentry} can be any number of \LaTeX\ fields, including

- \texttt{address}: The address of the publisher or other type of institution.
- \texttt{author}: The name(s) of the author(s), either as a character string in the format described in the \LaTeX\ book, or a \texttt{person} object.
- \texttt{booktitle}: Title of a book, part of which is being cited.
- \texttt{chapter}: A chapter (or section or whatever) number.
- \texttt{editor}: Name(s) of editor(s), same format as \texttt{author}.
- \texttt{institution}: The publishing institution of a technical report.
- \texttt{journal}: A journal name.
- \texttt{note}: Any additional information that can help the reader. The first word should be capitalized.
- \texttt{number}: The number of a journal, magazine, technical report, or of a work in a series.
- \texttt{pages}: One or more page numbers or range of numbers.
- \texttt{publisher}: The publisher’s name.
- \texttt{school}: The name of the school where a thesis was written.
- \texttt{series}: The name of a series or set of books.
- \texttt{title}: The work’s title.
- \texttt{volume}: The volume of a journal or multi-volume book.
- \texttt{year}: The year of publication.

\texttt{person}

Examples

```r
## R reference
rref <- bibentry(
  bibtype = "Manual",
  title = "R: A Language and Environment for Statistical Computing",
  author = person("R Core Team"),
  organization = "R Foundation for Statistical Computing",
  address = "Vienna, Austria",
  year = 2013,
  url = "http://www.R-project.org/"
)

## Different printing styles
print(rref)
print(rref, style = "Bibtex")
print(rref, style = "citation")
print(rref, style = "html")
print(rref, style = "latex")
print(rref, style = "R")

## References for boot package and associated book
bref <- c(
  bibentry(
    bibtype = "Manual",
    title = "boot: Bootstrap R (S-PLUS) Functions",
    author = person("A. C. Davison"))
)```
The `browseEnv` function opens a browser with list of objects currently in `sys.frame()` environment.

```r
author = c(
  person("Angelo", "Canty", role = "aut",
    comment = "S original"),
  person(c("Brian", "D."), "Ripley", role = c("aut", "tr1", "cre"),
    comment = "R port, author of parallel support",
    email = "ripley@stats.ox.ac.uk"))
)
year = "2012",
note = "R package version 1.3-4",
url = "http://CRAN.R-project.org/package=boot",
key = "boot-package"
)

bibentry(
  bibtpe = "Book",
  title = "Bootstrap Methods and Their Applications",
  author = as.person("Anthony C. Davison [aut], David V. Hinkley [aut]"),
  year = "1997",
  publisher = "Cambridge University Press",
  address = "Cambridge",
  isbn = "0-521-57391-2",
  url = "http://statwww.epfl.ch/davison/BMA/",
  key = "boot-book"
)
)

## Combining and subsetting
c(rref, bref)
bref[2]
bref["boot-book"]

## Extracting fields
bref$author
bref[1]$author

## Convert to BibTeX
toBibTeX(bref)

## Format in R style
## One bibentry() call for each bibentry:
writeLines(paste(format(bref, "R"), collapse = "\n\n"))
## One collapsed call:
writeLines(format(bref, "R", collapse = TRUE))
```
Usage

browseEnv(envir = .GlobalEnv, pattern,
          excludepatt = "[^last]\.warning",
          html = .Platform$GUI != "AQUA",
          expanded = TRUE, properties = NULL,
          main = NULL, debugMe = FALSE)

Arguments

envir an environment the objects of which are to be browsed.
pattern a regular expression for object subselection is passed to the internal ls() call.
excludepatt a regular expression for dropping objects with matching names.
html is used to display the workspace on a HTML page in your favorite browser. The default except when running from R.app on OS X.
expanded whether to show one level of recursion. It can be useful to switch it to FALSE if your workspace is large. This option is ignored if html is set to FALSE.
properties a named list of global properties (of the objects chosen) to be showed in the browser; when NULL (as per default), user, date, and machine information is used.
main a title string to be used in the browser; when NULL (as per default) a title is constructed.
debugMe logical switch; if true, some diagnostic output is produced.

Details

Very experimental code: displays a static HTML page on all platforms except R.app on OS X. Only allows one level of recursion into object structures.

It can be generalized. See sources for details. Most probably, this should rather work through using the ‘tkWidget’ package (from www.Bioconductor.org).

Examples

if(interactive()) {
  ## create some interesting objects :
  ofa <- ordered(4:1)
  ex1 <- expression(1+ 0:9)
  ex3 <- expression(u, v, l+ 0:9)
  example(factor, echo = FALSE)
  example(table, echo = FALSE)
  example(ftime, echo = FALSE)
  example(lm, echo = FALSE, ask = FALSE)
  example(str, echo = FALSE)

  ## and browse them:
  browseEnv()

  ## a (simple) function’s environment:

browseURL

Load URL into a WWW Browser

Description

Load a given URL into a WWW browser.

Usage

browseURL(url, browser =getOption("browser"),
encodeIfNeeded = FALSE)

Arguments

url a non-empty character string giving the URL to be loaded.
browser a non-empty character string giving the name of the program to be used as
hypertext browser. It should be in the PATH, or a full path specified. Alternatively,
an R function to be called to invoke the browser.
Under Windows NULL is also allowed (and is the default), and implies that the
file association mechanism will be used.
encodeIfNeeded Should the URL be encoded by GURLencode before passing to the browser? This
is not needed (and might be harmful) if the browser program/function itself
does encoding, and can be harmful for 'file://' URLs on some systems and
for 'http://' URLs passed to some CGI applications. Fortunately, most URLs
do not need encoding.

Details

The default browser is set by option "browser", in turn set by the environment variable R_BROWSER
which is by default set in file `R_HOME/etc/Renviron` to a choice made manually or automati-
cally when R was configured. (See Startup for where to override that default value.) To suppress
showing URLs altogether, use the value "false".

If browser supports remote control and R knows how to perform it, the URL is opened in any al-
ready running browser or a new one if necessary. This mechanism currently is available for browsers
which support the "-remote openURL(...)" interface (which includes Mozilla >= 0.9.5 and
Mozilla Firefox), Galeon, KDE konqueror (via kfmclient) and the GNOME interface to Mozilla.
Note that the type of browser is determined from its name, so this mechanism will only be used if
the browser is installed under its canonical name.

Because "-remote" will use any browser displaying on the X server (whatever machine it is running
on), the remote control mechanism is only used if DISPLAY points to the local host. This may not
allow displaying more than one URL at a time from a remote host.

It is the caller's responsibility to encode url if necessary (see GURLencode). This can be tricky for
file URLs, where the format accepted can depend on the browser and OS.

To suppress showing URLs altogether, set browser = "false".
Examples

```r
# Not run: # for KDE users who want to open files in a new tab
options(browser = "kfmclient newTab")
browseURL("http://www.r-project.org")

# End(Not run)
```

browseVignettes  List Vignettes in an HTML Browser

Description
List available vignettes in an HTML browser with links to PDF, LaTeX/noweb source, and (tangled) R code (if available).

Usage

```r
browseVignettes(package = NULL, lib.loc = NULL, all = TRUE)
```

## S3 method for class 'browseVignettes'
```r
print(x, ...)```

Arguments

- **package**: a character vector with the names of packages to search through, or `NULL` in which "all" packages (as defined by argument `all`) are searched.
- **lib.loc**: a character vector of directory names of R libraries, or `NULL`. The default value of `NULL` corresponds to all libraries currently known.
- **all**: logical; if `TRUE` search all available packages in the library trees specified by `lib.loc`, and if `FALSE`, search only attached packages.
- **x**: Object of class `browseVignettes`.
- **...**: Further arguments, ignored by the `print` method.

Details
Function `browseVignettes` returns an object of the same class; the print method displays it as an HTML page in a browser (using `browseURL`).

See Also

`browseURL`, `vignette`

Examples

```r
# Not run:
# List vignettes from all *attached* packages
browseVignettes(all = FALSE)

# List vignettes from a specific package
browseVignettes("grid")

# End(Not run)
```
Description

Invokes an editor or email program to write a bug report or opens a web page for bug submission. Some standard information on the current version and configuration of R are included automatically.

Usage

```
bug.report(subject = "", address,
            file = "R.bug.report", package = NULL, lib.loc = NULL,
            ...)```

Arguments

- `subject` Subject of the email.
- `address` Recipient’s email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed).
- `file` filename to use (if needed) for setting up the email.
- `package` Optional character vector naming a single package which is the subject of the bug report.
- `lib.loc` A character vector describing the location of R library trees in which to search for the package, or NULL. The default value of NULL corresponds to all libraries currently known.
- `...` additional named arguments such as `method` and `ccaddress` to pass to `create.post`.

Details

If package is NULL or a base package, this opens the R bugs tracker at http://bugs.r-project.org/.

If package is specified, it is assumed that the bug report is about that package, and parts of its ‘DESCRIPTION’ file are added to the standard information. If the package has a `BugReports` field in the `DESCRIPTION` file, that URL will be opened using `browseURL`, otherwise an email directed to the package maintainer will be generated using `create.post`.

Value

Nothing useful.

When is there a bug?

If R executes an illegal instruction, or dies with an operating system error message that indicates a problem in the program (as opposed to something like “disk full”), then it is certainly a bug.

Taking forever to complete a command can be a bug, but you must make certain that it was really R’s fault. Some commands simply take a long time. If the input was such that you KNOW it should have been processed quickly, report a bug. If you don’t know whether the command should take a long time, find out by looking in the manual or by asking for assistance.
If a command you are familiar with causes an R error message in a case where its usual definition ought to be reasonable, it is probably a bug. If a command does the wrong thing, that is a bug. But be sure you know for certain what it ought to have done. If you aren’t familiar with the command, or don’t know for certain how the command is supposed to work, then it might actually be working right. Rather than jumping to conclusions, show the problem to someone who knows for certain.

Finally, a command’s intended definition may not be best for statistical analysis. This is a very important sort of problem, but it is also a matter of judgement. Also, it is easy to come to such a conclusion out of ignorance of some of the existing features. It is probably best not to complain about such a problem until you have checked the documentation in the usual ways, feel confident that you understand it, and know for certain that what you want is not available. The mailing list r-devel@r-project.org is a better place for discussions of this sort than the bug list.

If you are not sure what the command is supposed to do after a careful reading of the manual this indicates a bug in the manual. The manual’s job is to make everything clear. It is just as important to report documentation bugs as program bugs.

If the online argument list of a function disagrees with the manual, one of them must be wrong, so report the bug.

How to report a bug

When you decide that there is a bug, it is important to report it and to report it in a way which is useful. What is most useful is an exact description of what commands you type, from when you start R until the problem happens. Always include the version of R, machine, and operating system that you are using; type version in R to print this. To help us keep track of which bugs have been fixed and which are still open please send a separate report for each bug.

The most important principle in reporting a bug is to report FACTS, not hypotheses or categorizations. It is always easier to report the facts, but people seem to prefer to strain to posit explanations and report them instead. If the explanations are based on guesses about how R is implemented, they will be useless; we will have to try to figure out what the facts must have been to lead to such speculations. Sometimes this is impossible. But in any case, it is unnecessary work for us.

For example, suppose that on a data set which you know to be quite large the command data.frame(x, y, z, monday, tuesday) never returns. Do not report that data.frame fails for large data sets. Perhaps it fails when a variable name is a day of the week. If this is so then when we got your report we would try out the data.frame command on a large data set, probably with no day of the week variable name, and not see any problem. There is no way in the world that we could guess that we should try a day of the week variable name.

Or perhaps the command fails because the last command you used was a method that had a bug causing R’s internal data structures to be corrupted and making the data.frame command fail from then on. This is why we need to know what other commands you have typed (or read from your startup file).

It is very useful to try and find simple examples that produce apparently the same bug, and somewhat useful to find simple examples that might be expected to produce the bug but actually do not. If you want to debug the problem and find exactly what caused it, that is wonderful. You should still report the facts as well as any explanations or solutions.

Invoking R with the ‘--vanilla’ option may help in isolating a bug. This ensures that the site profile and saved data files are not read.

A bug report can be generated using the function bug.report(). For reports on R this will open the Web page at http://bugs.R-project.org/: for a contributed package it will open the package’s bug tracker Web page or help you compose an email to the maintainer.

Bug reports on contributed packages should not be sent to the R bug tracker: rather make use of the package argument.

capture.output

Send Output to a Character String or File

Description

Evaluates its arguments with the output being returned as a character string or sent to a file. Related to sink in the same way that with is related to attach.

Usage

capture.output(..., file = NULL, append = FALSE)

Arguments

... Expressions to be evaluated.
file A file name or a connection, or NULL to return the output as a character vector. If the connection is not open, it will be opened initially and closed on exit.
append logical. If file a file name or unopened connection, append or overwrite?

Details

An attempt is made to write output as far as possible to file if there is an error in evaluating the expressions, but for file = NULL all output will be lost.

Value

A character string (if file = NULL), or invisible NULL.

See Also

sink.textConnection

Examples

require(stats)
glmout <- capture.output(example(glm))
glmout[1:5]
capture.output(1+1, 2+2)
capture.output(1+1; 2+2)
## Not run:
## on Unix with enscript available
ps <- pipe("enscript -o tempout.ps","w")
chooseBioCmirror

Description
Interact with the user to choose a Bioconductor mirror.

Usage
chooseBioCmirror(graphics =getOption("menu.graphics"), ind = NULL)

Arguments
- graphics: logical. If true, use a graphical list: on Windows or the OS X GUI use a list box, and on a Unix-alike if package tcltk and an X server are available, use a Tk widget. Otherwise use a text menu.
- ind: Optional numeric value giving which entry to select.

Details
This sets the option "BioC_mirror": it needs to be used before a call to setRepositories.
In addition to the Bioconductor master site (in Seattle, USA), there currently are mirrors in Bethesda (USA), Dortmund (Germany), Bergen (Norway) and Cambridge (UK).

Value
None: this function is invoked for its side effect of updating options("BioC_mirror").

See Also
setRepositories, chooseCRANmirror.

chooseCRANmirror

Description
Interact with the user to choose a CRAN mirror.

Usage
chooseCRANmirror(graphics =getOption("menu.graphics"), ind = NULL)
getCRANmirrors(all = FALSE, local.only = FALSE)
Arguments

- **graphics** Logical. If true, use a graphical list: on Windows or the OS X GUI use a list box, and on a Unix-alike if package `tcltk` and an X server are available, use a Tk widget. Otherwise use a text menu.
- **ind** Optional numeric value giving which entry to select.
- **all** Logical, get all known mirrors or only the ones flagged as OK.
- **local.only** Logical, try to get most recent list from CRAN or use file on local disk only.

Details

A list of mirrors is stored in file `R_HOME/doc/CRAN_mirrors.csv`, but first an on-line list of current mirrors is consulted, and the file copy used only if the on-line list is inaccessible.

This function was originally written to support a Windows GUI menu item, but is also called by `contrib.url` if it finds the initial dummy value of `options("repos")`.

Value

None for `chooseCRANmirror()`, this function is invoked for its side effect of updating `options("repos")`.

`getCRANmirrors()` returns a data frame with mirror information.

See Also

- `setRepositories`, `chooseBioCmirror`, `contrib.url`.

---

citation

### Citing R and R Packages in Publications

How to cite R and R packages in publications.

Usage

- `citation(package = "base", lib.loc = NULL, auto = NULL)`
- `readCitationFile(file, meta = NULL)`

Arguments

- **package** a character string with the name of a single package. An error occurs if more than one package name is given.
- **lib.loc** a character vector with path names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.
- **auto** a logical indicating whether the default citation auto-generated from the package `DESCRIPTION` metadata should be used or not, or NULL (default), indicating that a `CITATION` file is used if it exists, or an object of class "packageDescription" with package metadata (see below).
- **file** a file name.
- **meta** a list of package metadata as obtained by `packageDescription`, or NULL (the default).
Details

The R core development team and the very active community of package authors have invested a lot of time and effort in creating R as it is today. Please give credit where credit is due and cite R and R packages when you use them for data analysis.

Execute function `citation()` for information on how to cite the base R system in publications. If the name of a non-base package is given, the function either returns the information contained in the `CITATION` file of the package or auto-generates citation information. In the latter case the package `DESCRIPTION` file is parsed, the resulting citation object may be arbitrarily bad, but is quite useful (at least as a starting point) in most cases.

In R >= 2.14.0, one can use a `Authors@R` field in `DESCRIPTION` to provide (R code giving) a `person` object with a refined, machine-readable description of the package “authors” (in particular specifying their precise roles). Only those with an author role will be included in the auto-generated citation.

If only one reference is given, the print method for the object returned by `citation()` shows both a text version and a BibTeX entry for it, if a package has more than one reference then only the text versions are shown. The BibTeX versions can be obtained using function `toBibTeX()` (see the examples below).

The `CITATION` file of an R package should be placed in the `inst` subdirectory of the package source. The file is an R source file and may contain arbitrary R commands including conditionals and computations. Function `readCitationFile()` is used by `citation()` to extract the information in `CITATION` files. The file is sourced by the R parser in a temporary environment and all resulting bibliographic objects (specifically, of class "bibentry") are collected.

Traditionally, the `CITATION` file contained zero or more calls to `citHeader`, then one or more calls to `citEntry`, and finally zero or more calls to `citFooter`, where in fact `citHeader` and `citFooter` are simply wrappers to `paste`, with their ... argument passed on to `paste` as is. R 2.12.0 adds a new "bibentry" class for improved representation and manipulation of bibliographic information (in fact, the old mechanism is implemented using the new one), and one can write `CITATION` files using the unified `bibentry` interface. Such files are not usable with versions of R prior to 2.12.0.

In R >= 2.14.0, one can include an auto-generated package citation in the `CITATION` file via `citation(auto = meta)`. `readCitationFile` makes use of the Encoding element (if any) of `meta` to determine the encoding of the file.

Value

An object inheriting from class "bibentry".

See Also

`bibentry`

Examples

```r
## the basic R reference
citation()

## references for a package -- might not have these installed
if(nchar(system.file(package = "lattice"))) citation("lattice")
if(nchar(system.file(package = "foreign"))) citation("foreign")

## extract the bibtext entry from the return value
```
\texttt{x <- citation()}
\texttt{toBibtex(x)}

\begin{description}
\item[cite] \textit{Cite a bibliography entry.}
\end{description}

\textbf{Description}

Cite a \texttt{bibentry} object in text. The \texttt{cite()} function uses the \texttt{cite()} function from the default \texttt{bibstyle} if present, or \texttt{citeNatbib()} if not. \texttt{citeNatbib()} uses a style similar to that used by the \LaTeX{} package \texttt{natbib}.

\textbf{Usage}

\begin{verbatim}
cite(keys, bib, ...) citeNatbib(keys, bib, textual = FALSE, before = NULL, after = NULL,
mode = c("authoryear", "numbers", "super"),
abbreviate = TRUE, longnamesfirst = TRUE,
bibpunct = c("", ",", ";", ",", ",", ",", previous)
\end{verbatim}

\textbf{Arguments}

\begin{itemize}
\item \texttt{keys} \quad A character vector of keys of entries to cite. May contain multiple keys in a single entry, separated by commas.
\item \texttt{bib} \quad A \texttt{"bibentry"} object containing the list of documents in which to find the keys.
\item \texttt{...} \quad Additional arguments to pass to the \texttt{cite()} function for the default style.
\item \texttt{textual} \quad Produce a “textual” style of citation, i.e. what \texttt{\cite} would produce in \LaTeX{}.
\item \texttt{before} \quad Optional text to display before the citation.
\item \texttt{after} \quad Optional text to display after the citation.
\item \texttt{mode} \quad The “mode” of citation.
\item \texttt{abbreviate} \quad Whether to abbreviate long author lists.
\item \texttt{longnamesfirst} \quad If \texttt{abbreviate} == \texttt{TRUE}, whether to leave the first citation long.
\item \texttt{bibpunct} \quad A vector of punctuation to use in the citation, as used in \texttt{natbib}. See the Details section.
\item \texttt{previous} \quad A list of keys that have been previously cited, to be used when \texttt{abbreviate} == \texttt{TRUE} and \texttt{longnamesfirst} == \texttt{TRUE}
\end{itemize}

\textbf{Details}

Argument names are chosen based on the documentation for the \LaTeX{} \texttt{natbib} package. See that documentation for the interpretation of the \texttt{bibpunct} entries.

The entries in \texttt{bibpunct} are as follows:

1. The left delimiter.
2. The right delimiter.
3. The separator between references within a citation.
4. An indicator of the “mode”: "n" for numbers, "s" for superscripts, anything else for author-year.
5. Punctuation to go between the author and year.

6. Punctuation to go between years when authorship is suppressed.

Note that if mode is specified, it overrides the mode specification in bibpunct[4]. Partial matching is used for mode.

The defaults for citeNatbib have been chosen to match the JSS style, and by default these are used in cite. See bibstyle for how to set a different default style.

**Value**

A single element character string is returned, containing the citation.

**Author(s)**

Duncan Murdoch

**Examples**

```r
## R reference

**citEntry**

**Bibliography Entries (Older Interface)**

**Description**

Functionality for specifying bibliographic information in enhanced BibTeX style.

**Usage**

```r
citEntry(entry, textVersion, header = NULL, footer = NULL, ...)
citHeader(...)
citFooter(...)
```

**Arguments**

- `entry` a character string with a BibTeX entry type. See section **Entry Types** in `bibentry` for details.
- `textVersion` a character string with a text representation of the reference.
- `header` a character string with optional header text.
- `footer` a character string with optional footer text.
- `...` for `citEntry`, arguments of the form `tag=value` giving the fields of the entry, with `tag` and `value` the name and value of the field, respectively. See section **Entry Fields** in `bibentry` for details.

For `citHeader` and `citFooter`, character strings.

**Value**

`citEntry` produces an object of class "bibentry".
close.socket

Description

Closes the socket and frees the space in the file descriptor table. The port may not be freed immediately.

Usage

close.socket(socket, ...)

Arguments

socket A socket object
...

Value

logical indicating success or failure

Author(s)

Thomas Lumley

See Also

make.socket, read.socket

combn

Generate All Combinations of n Elements, Taken m at a Time

Description

Generate all combinations of the elements of x taken m at a time. If x is a positive integer, returns all combinations of the elements of seq(x) taken m at a time. If argument FUN is not NULL, applies a function given by the argument to each point. If simplify is FALSE, returns a list; otherwise returns an array, typically a matrix. ... are passed unchanged to the FUN function, if specified.

Usage

combn(x, m, FUN = NULL, simplify = TRUE, ...)
combn

Arguments

`x`  
vector source for combinations, or integer `n` for `x <- seq_len(n)`.

`m`  
number of elements to choose.

`FUN`  
function to be applied to each combination; default `NULL` means the identity, i.e., to return the combination (vector of length `m`).

`simplify`  
logical indicating if the result should be simplified to an `array` (typically a `matrix`); if `FALSE`, the function returns a `list`. Note that when `simplify = TRUE` as by default, the dimension of the result is simply determined from `FUN(1st combination)` (for efficiency reasons). This will badly fail if `FUN(u)` is not of constant length.

...  
optionally, further arguments to `FUN`.

Value

a `list` or `array`, see the `simplify` argument above. In the latter case, the identity `dim(combn(n, m)) == c(m, choose(n, m))` holds.

Author(s)

Scott Chasalow wrote the original in 1994 for S; R package `combinat` and documentation by Vince Carey <stvjc@channing.harvard.edu>; small changes by the R core team, notably to return an array in all cases of `simplify = TRUE`, e.g., for `combn(5, 5)`.

References

See Also

`choose` for fast computation of the number of combinations. `expand.grid` for creating a data frame from all combinations of factors or vectors.

Examples

combn(letters[1:4], 2)

`(m <- combn(10, 5, min))  # minimum value in each combination
mm <- combn(15, 6, function(x) matrix(x, 2, 3))
stopifnot(round(choose(10, 5)) == length(m),
          c(2,3, round(choose(15, 6))) == dim(mm))

## Different way of encoding points:
comb(c(1,1,1,1,2,2,2,2,3,3,4), 3, tabulate, nbins = 4)

## Compute support points and (scaled) probabilities for a
## Multivariate-Hypergeometric(n = 3, N = c(4,3,2,1)) p.f.:
# table.mat(t(cbind(c(1,1,1,1,2,2,2,2,3,3,4), 3, tabulate, nbins = 4)))

## Assuring the identity
for(n in 1:7)
  for(m in 0:n) stopifnot(is.array(cc <- combn(n, m)),
                          dim(cc) == c(m, choose(n, m)))
compareVersion

Compare Two Package Version Numbers

Description

Compare two package version numbers to see which is later.

Usage

compareVersion(a, b)

Arguments

a, b
Character strings representing package version numbers.

Details

R package version numbers are of the form x.y-z for integers x, y and z, with components after x optionally missing (in which case the version number is older than those with the components present).

Value

0 if the numbers are equal, -1 if b is later and 1 if a is later (analogous to the C function strcmp).

See Also

package_version, library, packageStatus.

Examples

compareVersion("1.0", "1.0-1")
compareVersion("7.2-0", "7.1-12")

compile

Compile Files for Use with R

Description

Compile given source files so that they can subsequently be collected into a shared object using R CMD SHLIB or an executable program using R CMD LINK.

Usage

R CMD COMPIL [options] srcfiles
Arguments

srcfiles  A list of the names of source files to be compiled. Currently, C, C++, Objective C, Objective C++ and Fortran are supported; the corresponding files should have the extensions 'c', 'cc' (or '.cpp'), 'm', 'mm' (or '.M'), 'f' and 'f90' or 'f95', respectively.

options  A list of compile-relevant settings, or for obtaining information about usage and version of the utility.

Details

\texttt{R CMD SHLIB} can both compile and link files into a shared object: since it knows what run-time libraries are needed when passed C++, Fortran and Objective C(++) sources, passing source files to \texttt{R CMD SHLIB} is more reliable.

Ratfor is not supported. If you have Ratfor source code, you need to convert it to FORTRAN. (On some Solaris systems mixing Ratfor and FORTRAN code will work.)

Objective C and Objective C++ support is optional and will work only if the corresponding compilers were available at R configure time: their main usage is on OS X.

Compilation arranges to include the paths to the R public C/C++ headers.

As this compiles code suitable for incorporation into a shared object, it generates PIC code: that might occasionally be undesirable for the main code of an executable program.

This is a \texttt{make}-based facility, so will not compile a source file if a newer corresponding '.o' file is present.

Note

Some binary distributions of R have \texttt{COMPIL}E in a separate bundle, e.g. an R-devel RPM.

This is not available on Windows.

See Also

\texttt{LINK, SHLIB, dyn.load}; the section on “Customizing compilation under Unix” in “R Administration and Installation” (see the ‘doc/manual’ subdirectory of the R source tree).

---

\texttt{contrib.url}  \textit{Find Appropriate Paths in CRAN-like Repositories}

Description

\texttt{contrib.url} adds the appropriate type-specific path within a repository to each URL in \texttt{repos}.

Usage

\texttt{contrib.url(repos, type = getOption("pkgType"))}

Arguments

repos  character vector, the base URL(s) of the repositories to use.

type  character string, indicating which type of packages: see \texttt{install.packages}.
count.fields

Description

count.fields counts the number of fields, as separated by sep, in each of the lines of file read.

Usage

count.fields(file, sep = "", quote = "\"", skip = 0, 
blank.lines.skip = TRUE, comment.char = "#")

Arguments

file a character string naming an ASCII data file, or a connection, which will be opened if necessary, and if so closed at the end of the function call.
sep the field separator character. Values on each line of the file are separated by this character. By default, arbitrary amounts of whitespace can separate fields.
quote the set of quoting characters
skip the number of lines of the data file to skip before beginning to read data.
blank.lines.skip logical: if TRUE blank lines in the input are ignored.
comment.char character: a character vector of length one containing a single character or an empty string.

Details

This used to be used by read.table and can still be useful in discovering problems in reading a file by that function.

For the handling of comments, see scan.

Consistent with scan, count.fields allows quoted strings to contain newline characters. In such a case the starting line will have the field count recorded as NA, and the ending line will include the count of all fields from the beginning of the record.

Value

A vector with the numbers of fields found.

See Also

read.table
**create.post**

**Ancillary Function for Preparing Emails and Postings**

**Description**

An ancillary function used by `bug.report` and `help.request` to prepare emails for submission to package maintainers or to R mailing lists.

**Usage**

```r
create.post(instructions = character(), description = "post", 
subject = "", 
method =getOption("mailer"), 
address = "the relevant mailing list", 
ccaddress = getOption("ccaddress", ""), 
filename = "R.post", info = character())
```

**Arguments**

- **instructions**: Character vector of instructions to put at the top of the template email.
- **description**: Character string: a description to be incorporated into messages.
- **subject**: Subject of the email. Optional except for the "mailer" method.
- **method**: Submission method, one of "none", "mailto", "gnudoit", "ess" or (Unix only) "mailx". See 'Details'.
- **address**: Recipient’s email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed).
- **ccaddress**: Optional email address for copies with the "mailx" and "mailto" methods. Use ccaddress = "" for no copy.
- **filename**: Filename to use for setting up the email (or storing it when method is "none" or sending mail fails).
- **info**: character vector of information to include in the template email below the 'please do not edit the information below' line.

**Details**

What this does depends on the method. The function first creates a template email body.

- **none**: A file editor (see `file.edit`) is opened with instructions and the template email. When this returns, the completed email is in file `file` ready to be read/pasted into an email program.
data

mailto This opens the default email program with a template email (including address, Cc: address and subject) for you to edit and send.

This works where default mailers are set up (usual on OS X and Windows, and where xdg-open is available and configured on other Unix-alikes: if that fails it tries the browser set by R_BROWSER).

This is the ‘factory-fresh’ default method as from R 2.13.0.

mailx (Unix-alikes only.) A file editor (see file.edit) is opened with instructions and the template email. When this returns, it is mailed using a Unix command line mail utility such as mailx, to the address (and optionally, the Cc: address) given.

gnudit An (X)emacs mail buffer is opened for the email to be edited and sent: this requires the gnudit program to be available. Currently subject is ignored.

ess The body of the template email is sent to stdout.

Value

Invisible NULL.

See Also

bug.report, help.request.

---

**data**

**Data Sets**

**Description**

Loads specified data sets, or list the available data sets.

**Usage**

```
data(..., list = character(), package = NULL, lib.loc = NULL, 
    verbose =getOption("verbose"), envir = .GlobalEnv)
```

**Arguments**

- `...` literal character strings or names.
- `list` a character vector.
- `package` a character vector giving the package(s) to look in for data sets, or NULL.
  By default, all packages in the search path are used, then the ‘data’ subdirectory (if present) of the current working directory.
- `lib.loc` a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.
- `verbose` a logical. If TRUE, additional diagnostics are printed.
- `envir` the environment where the data should be loaded.
Currently, four formats of data files are supported:

1. files ending `.R` or `.r` are sourced in, with the R working directory changed temporarily to the directory containing the respective file. (data ensures that the utils package is attached, in case it had been run via utils:::data.)
2. files ending `.RData` or `.rda` are loaded.
3. files ending `.tab`, `.txt` or `.TXT` are read using `read.table(..., header = TRUE)`, and hence result in a data frame.
4. files ending `.csv` or `.CSV` are read using `read.table(..., header = TRUE, sep = ";"), and also result in a data frame.

If more than one matching file name is found, the first on this list is used. (Files with extensions `.txt`, `.tab` or `.csv` can be compressed, with or without further extension `.gz`, `.bzz` or `.xz`.)

The data sets to be loaded can be specified as a set of character strings or names, or as the character vector `list`, or as both. For each given data set, the first two types (`.R` or `.r`, and `.RData` or `.rda` files) can create several variables in the load environment, which might all be named differently from the data set. The third and fourth types will always result in the creation of a single variable with the same name (without extension) as the data set.

If no data sets are specified, data lists the available data sets. It looks for a new-style data index in the `meta` or, if this is not found, an old-style `@Index` file in the `data` directory of each specified package, and uses these files to prepare a listing. If there is a `data` area but no index, available data files for loading are computed and included in the listing, and a warning is given: such packages are incomplete. The information about available data sets is returned in an object of class `packageqr`. The structure of this class is experimental. Where the datasets have a different name from the argument that should be used to retrieve them the index will have an entry like `beaverQ HbeaversI` which tells us that dataset `beaverQ` can be retrieved by the call `data(beaver)`. If `lib.loc` and package are both NULL (the default), the data sets are searched for in all the currently loaded packages then in the `data` directory (if any) of the current working directory.

If `lib.loc` = NULL but package is specified as a character vector, the specified package(s) are searched for first amongst loaded packages and then in the default library/ies (see `.libPaths`).

If `lib.loc` is specified (and not NULL), packages are searched for in the specified library/ies, even if they are already loaded from another library.

To just look in the `data` directory of the current working directory, set `package = character(0)` (and `lib.loc = NULL, the default`).

**Value**

A character vector of all data sets specified, or information about all available data sets in an object of class "packageIQR" if none were specified.

**Good practice**

data() was originally intended to allow users to load datasets from packages for use in their examples, and as such it loaded the datasets into the workspace `.GlobalEnv`. This avoided having large datasets in memory when not in use. That need has been almost entirely superseded by lazy-loading of datasets.
The ability to specify a dataset by name (without quotes) is a convenience: in programming the datasets should be specified by character strings (with quotes).

Use of data within a function without an envir argument has the almost always undesirable side-effect of putting an object in the user’s workspace (and indeed, of replacing any object of that name already there). It would almost always be better to put the object in the current evaluation environment by data(..., envir = environment()). However, two alternatives are usually preferable, both described in the ‘Writing R Extensions’ manual.

- For sets of data, set up a package to use lazy-loading of data.
- For objects which are system data, for example lookup tables used in calculations within the function, use a file ‘R/sysdata.rda’ in the package sources or create the objects by R code at package installation time.

A sometimes important distinction is that the second approach places objects in the namespace but the first does not. So if it is important that the function sees mytable as an object from the package, it is system data and the second approach should be used.

Note

One can take advantage of the search order and the fact that a '*.R' file will change directory. If raw data are stored in 'mydata.txt' then one can set up 'mydata.R' to read 'mydata.txt' and pre-process it, e.g., using transform. For instance one can convert numeric vectors to factors with the appropriate labels. Thus, the 'R' file can effectively contain a metadata specification for the plaintext formats.

See Also

help for obtaining documentation on data sets, save for creating the second ('.rda') kind of data, typically the most efficient one.

The ‘Writing R Extensions’ for considerations in preparing the ‘data’ directory of a package.

Examples

```r
require(utils)
data()  # list all available data sets
try(data(package = "rpart") )  # list the data sets in the rpart package
data(USArrests, "VADeaths")  # load the data sets 'USArrests' and 'VADeaths'
## Not run: ## Alternatively
ds <- c("USArrests", "VADeaths"); data(list = ds)
## End(Not run)
help(USArrests)  # give information on data set 'USArrests'
```

Description

A spreadsheet-like editor for entering or editing data.
Usage

```r
data.entry(..., Modes = NULL, Names = NULL)
dataentry(data, modes)
de(..., Modes = list(), Names = NULL)
```

Arguments

- `...` A list of variables: currently these should be numeric or character vectors or list containing such vectors.
- `Modes` The modes to be used for the variables.
- `Names` The names to be used for the variables.
- `data` A list of numeric and/or character vectors.
- `modes` A list of length up to that of `data` giving the modes of (some of) the variables. `list()` is allowed.

Details

The data entry editor is only available on some platforms and GUIs. Where available it provides a means to visually edit a matrix or a collection of variables (including a data frame) as described in the Notes section.

data.entry has side effects, any changes made in the spreadsheet are reflected in the variables. The functions `de`, `de.ncols`, `de.setup` and `de.restore` are designed to help achieve these side effects. If the user passes in a matrix, `X` say, then the matrix is broken into columns before `dataentry` is called. Then on return the columns are collected and glued back together and the result assigned to the variable `X`. If you don’t want this behaviour use `dataentry` directly.

The primitive function is `dataentry`. It takes a list of vectors of possibly different lengths and modes (the second argument) and opens a spreadsheet with these variables being the columns. The columns of the `dataentry` window are returned as vectors in a list when the spreadsheet is closed.

de.ncols counts the number of columns which are supplied as arguments to `data.entry`. It attempts to count columns in lists, matrices and vectors. `de.setup` sets things up so that on return the columns can be regrouped and reassigned to the correct name. This is handled by `de.restore`.

Value

`de` and `dataentry` return the edited value of their arguments. `data.entry` invisibly returns a vector of variable names but its main value is its side effect of assigning new version of those variables in the user’s workspace.

Resources

The data entry window responds to X resources of class `R_dataentry`. Resources `foreground`, `background` and `geometry` are utilized.

Note

The details of interface to the data grid may differ by platform and GUI. The following description applies to the X11-based implementation under Unix.

You can navigate around the grid using the cursor keys or by clicking with the (left) mouse button on any cell. The active cell is highlighted by thickening the surrounding rectangle. Moving to the right or down will scroll the grid as needed: there is no constraint to the rows or columns currently in use.
There are alternative ways to navigate using the keys. Return and (keypad) Enter and LineFeed all move down. Tab moves right and Shift-Tab move left. Home moves to the top left.

PageDown or Control-F moves down a page, and PageUp or Control-B up by a page. End will show the last used column and the last few rows used (in any column).

Using any other key starts an editing process on the currently selected cell: moving away from that cell enters the edited value whereas Esc cancels the edit and restores the previous value. When the editing process starts the cell is cleared. In numerical columns (the default) only letters making up a valid number (including \texttt{- .Ee}) are accepted, and entering an invalid edited value (such as blank) enters \texttt{NA} in that cell. The last entered value can be deleted using the BackSpace or Del(ete) key. Only a limited number of characters (currently 29) can be entered in a cell, and if necessary only the start or end of the string will be displayed, with the omissions indicated by > or <. (The start is shown except when editing.)

Entering a value in a cell further down a column than the last used cell extends the variable and fills the gap (if any) by N\texttt{As} (not shown on screen).

The column names can only be selected by clicking in them. This gives a popup menu to select the column type (currently Real (numeric) or Character) or to change the name. Changing the type converts the current contents of the column (and converting from Character to Real may generate N\texttt{As}.) If changing the name is selected the header cell becomes editable (and is cleared). As with all cells, the value is entered by moving away from the cell by clicking elsewhere or by any of the keys for moving down (only).

New columns are created by entering values in them (and not by just assigning a new name). The mode of the column is auto-detected from the first value entered: if this is a valid number it gives a numeric column. Unused columns are ignored, so adding data in \texttt{varU} to a three-column grid adds one extra variable, not two.

The Copy button copies the currently selected cell: paste copies the last copied value to the current cell, and right-clicking selects a cell and copies in the value. Initially the value is blank, and attempts to paste a blank value will have no effect.

Control-L will refresh the display, recalculating field widths to fit the current entries.

In the default mode the column widths are chosen to fit the contents of each column, with a default of 10 characters for empty columns. you can specify fixed column widths by setting option \texttt{de.cellwidth} to the required fixed width (in characters). (set it to zero to return to variable widths). The displayed width of any field is limited to 600 pixels (and by the window width).

### See Also
\texttt{vi, edit}: edit uses dataentry to edit data frames.

### Examples
```
# call data entry with variables x and y
## Not run: data.entry(x, y)
```

### Description
Functions to dump the evaluation environments (frames) and to examine dumped frames.
Usage

dump.frames(dumpTo = "last.dump", to.file = FALSE)
debugger(dump = last.dump)

Arguments

dumpTo a character string. The name of the object or file to dump to.
to.file logical. Should the dump be to an R object or to a file?
dump An R dump object created by dump.frames.

Details

To use post-mortem debugging, set the option error to be a call to dump.frames. By default this dumps to an R object last.dump in the workspace, but it can be set to dump to a file (a dump of the object produced by a call to save). The dumped object contain the call stack, the active environments and the last error message as returned by geterrmessage.

When dumping to file, dumpTo gives the name of the dumped object and the file name has ‘.rda’ appended.

A dump object of class "dump.frames" can be examined by calling debugger. This will give the error message and a list of environments from which to select repeatedly. When an environment is selected, it is copied and the browser called from within the copy. Note that not all the information in the original frame will be available, e.g. promises which have not yet been evaluated and the contents of any ... argument.

If dump.frames is installed as the error handler, execution will continue even in non-interactive sessions. See the examples for how to dump and then quit.

Value

Invisible NULL.

Note

Functions such as sys.parent and environment applied to closures will not work correctly inside debugger.

If the error occurred when computing the default value of a formal argument the debugger will report “recursive default argument reference” when trying to examine that environment.

Of course post-mortem debugging will not work if R is too damaged to produce and save the dump, for example if it has run out of workspace.

options for setting error options; recover is an interactive debugger working similarly to debugger but directly after the error occurs.
Examples

```r
### Not run:
options(error = quote(dump.frames("testdump", TRUE)))

f <- function() {
g <- function() stop("test dump.frames")
g()
}
f() # will generate a dump on file "testdump.rda"
options(error = NULL)

### possibly in another R session
load("testdump.rda")
debugger(testdump)
Available environments had calls:
1: f()
2: g()
3: stop("test dump.frames")

Enter an environment number, or 0 to exit
Selection: 1
Browsing in the environment with call:
f()
Called from: debugger.look(ind)
Browse[1]> ls()
[1] "g"
Browse[1]> g
function() stop("test dump.frames")
<environment: 759818>
Browse[1]>
Available environments had calls:
1: f()
2: g()
3: stop("test dump.frames")

Enter an environment number, or 0 to exit
Selection: 0

### A possible setting for non-interactive sessions
options(error = quote((dump.frames(to.file = TRUE); q())))

### End(Not run)
```

---

demo | Demonstrations of R Functionality

Description

demo is a user-friendly interface to running some demonstration R scripts. demo() gives the list of available topics.

Usage

demo(topic, package = NULL, lib.loc = NULL,
character.only = FALSE, verbose =getOption("verbose"),
echo = TRUE, ask =getOption("demo.ask"),
encoding =getOption("encoding")

Arguments

topic the topic which should be demonstrated, given as a name or literal character string, or a character string, depending on whether character.only is FALSE (default) or TRUE. If omitted, the list of available topics is displayed.

package a character vector giving the packages to look into for demos, or NULL. By default, all packages in the search path are used.

lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.

character.only logical; if TRUE, use topic as character string.

verbose a logical. If TRUE, additional diagnostics are printed.

echo a logical. If TRUE, show the R input when sourcing.

ask a logical (or "default") indicating if devAskNewPage(ask = TRUE) should be called before graphical output happens from the demo code. The value "default" (the factory-fresh default) means to ask if echo == TRUE and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the demo code. If this is evaluated to TRUE and the session is interactive, the user is asked to press RETURN to start.

encoding See source. If the package has a declared encoding, that takes preference.

Details

If no topics are given, demo lists the available demos. The corresponding information is returned in an object of class "packageIQR".

See Also

source and devAskNewPage which are called by demo.

Examples

demo() # for attached packages

## All available demos:
demo(package = .packages(all.available = TRUE))

## Display a demo, pausing between pages
demo(lm.glm, package = "stats", ask = TRUE)

## Display it without pausing
demo(lm.glm, package = "stats", ask = FALSE)

## Not run:
ch <- "scoping"
demo(ch, character = TRUE)
Description

This function can be used to download a file from the Internet.

Usage

```r
download.file(url, destfile, method, quiet = FALSE, mode = "w", cacheOK = TRUE, extra = getOption("download.file.extra"))
```

Arguments

- `url` A character string naming the URL of a resource to be downloaded.
- `destfile` A character string with the name where the downloaded file is saved. Tilde-expansion is performed.
- `method` Method to be used for downloading files. Currently download methods "internal", "wget", "curl" and "lynx" are available, and there is a value "auto": see 'Details' and 'Note'. The method can also be set through the option "download.file.method": see options().
- `quiet` If TRUE, suppress status messages (if any), and the progress bar.
- `mode` character. The mode with which to write the file. Useful values are "w", "wb" (binary), "a" (append) and "ab". Only used for the "internal" method.
- `cacheOK` logical. Is a server-side cached value acceptable? Implemented for the "internal", "wget" and "curl" methods.
- `extra` character vector of additional command-line arguments for the "wget", "curl" and "lynx" methods.

Details

The function `download.file` can be used to download a single file as described by `url` from the internet and store it in `destfile`. The `url` must start with a scheme such as ‘http://’, ‘ftp://’ or ‘file:///’.

If `method = "auto"` is chosen (the default), the internal method is chosen for ‘file://’ URLs, and for the others provided `capabilities("http/ftp")` is true (which it almost always is). Otherwise methods "wget", "curl" and "lynx" are tried in turn.

`cacheOK = FALSE` is useful for ‘http://’ URLs, and will attempt to get a copy directly from the site rather than from an intermediate cache. (Not all platforms support it.) It is used by `available.packages`.

The remaining details apply to method "internal" only.
Note that 'https://' URLs are not supported.

See `url` for how 'file:///' URLs are interpreted, especially on Windows. This function does not decode encoded URLs.

The timeout for many parts of the transfer can be set by the option `timeout` which defaults to 60 seconds.

The level of detail provided during transfer can be set by the `quiet` argument and the `internet.info` option. The details depend on the platform and scheme, but setting `internet.info` to 0 gives all available details, including all server responses. Using 2 (the default) gives only serious messages, and 3 or more suppresses all messages.

A progress bar tracks the transfer. If the file length is known, an equals sign represents 2% of the transfer completed: otherwise a dot represents 10Kb.

Code written to download binary files must use `mode = "wb"`, but the problems incurred by a text transfer will only be seen on Windows.

Method "wget" can be used with proxy firewalls which require user/password authentication if proper values are stored in the configuration file for `wget`.

**Value**

An (invisible) integer code, \(\theta\) for success and non-zero for failure. For the "wget" and "lynx" methods this is the status code returned by the external program. The "internal" method can return 1, but will in most cases throw an error.

**Setting Proxies**

This applies to the internal code only.

Proxies can be specified via environment variables. Setting "no_proxy" to "*" stops any proxy being tried. Otherwise the setting of "http_proxy" or "ftp_proxy" (or failing that, the all upper-case version) is consulted and if non-empty used as a proxy site. For FTP transfers, the username and password on the proxy can be specified by "ftp_proxy_user" and "ftp_proxy_password". The form of "http_proxy" should be "http://proxy.dom.com/" or "http://proxy.dom.com:8080/" where the port defaults to 80 and the trailing slash may be omitted. For "ftp_proxy" use the form "ftp://proxy.dom.com:3128/" where the default port is 21. These environment variables must be set before the download code is first used: they cannot be altered later by calling `Sys.setenv`.

Usernames and passwords can be set for HTTP proxy transfers via environment variable `http_proxy_user` in the form `user:password`. Alternatively, `http_proxy` can be of the form "http://user:pass@proxy.dom.com:8080/" for compatibility with `wget`. Only the HTTP/1.0 basic authentication scheme is supported.

**Note**

Methods "wget" and "lynx" are mainly for historical compatibility, but they and "curl" can be used for URLs (e.g. 'https://' URLs or those that use cookies) which the internal method does not support. They will block all other activity on the \(\mathbb{R}\) process.

For methods "wget", "curl" and "lynx" a system call is made to the tool given by method, and the respective program must be installed on your system and be in the search path for executables.

`curl` ([http://curl.haxx.se/](http://curl.haxx.se/)) is installed on OS X and commonly on Unix-alikes. Windows binaries are available at that URL.
lynx (http://lynx.browser.org/) is of historical interest.

See Also

options to set the HTTPUserAgent, timeout and internet.info options.

url for a finer-grained way to read data from URLs.

url.show, available.packages, download.packages for applications.

Contributed package RCurl provides more comprehensive facilities to download from URLs.

download.packages  Download Packages from CRAN-like Repositories

Description

These functions can be used to automatically compare the version numbers of installed packages with the newest available version on the repositories and update outdated packages on the fly.

Usage

download.packages(pkgs, destdir, available = NULL, 
  repos = getOption("repos"), 
  contriburl = contrib.url(repos, type), 
  method, type = getOption("pkgType"), ...)

Arguments

pkgs character vector of the names of packages whose latest available versions should be downloaded from the repositories.

destdir directory where downloaded packages are to be stored.

available an object as returned by available.packages listing packages available at the repositories, or NULL which makes an internal call to available.packages.

repos character vector, the base URL(s) of the repositories to use, i.e., the URL of the CRAN master such as "http://cran.r-project.org" or its Statlib mirror, "http://lib.stat.cmu.edu/R/CRAN".

contriburl URL(s) of the contrib sections of the repositories. Use this argument only if your repository mirror is incomplete, e.g., because you burned only the 'contrib' section on a CD. Overrides argument repos.

method Download method, see download.file.

type character string, indicate which type of packages: see install.packages.

... additional arguments to be passed to download.file.

Details

download.packages takes a list of package names and a destination directory, downloads the newest versions and saves them in destdir. If the list of available packages is not given as argument, it is obtained from repositories. If a repository is local, i.e. the URL starts with "file: ", then the packages are not downloaded but used directly. Both "file:" and "file:///" are allowed as prefixes to a file path. Use the latter only for URLs: see url for their interpretation. (Other forms of 'file:///' URLs are not supported.)
Value

A two-column matrix of names and destination file names of those packages successfully downloaded. If packages are not available or there is a problem with the download, suitable warnings are given.

See Also

available.packages, contrib.url.

The main use is by install.packages.

See download.file for how to handle proxies and other options to monitor file transfers.

The ‘R Installation and Administration’ manual for how to set up a repository.

---

**edit**

*Invoke a Text Editor*

Description

Invoke a text editor on an R object.

Usage

```r
## Default S3 method:
edit(name = NULL, file = "", title = NULL,
     editor = getOption("editor"), ...)
```

```r
vi(name = NULL, file = "")
emacs(name = NULL, file = "")
pico(name = NULL, file = "")
xemacs(name = NULL, file = "")
xedit(name = NULL, file = "")
```

Arguments

- name a named object that you want to edit. If name is missing then the file specified by file is opened for editing.
- file a string naming the file to write the edited version to.
- title a display name for the object being edited.
- editor a string naming the text editor you want to use. On Unix the default is set from the environment variables EDITOR or VISUAL if either is set, otherwise vi is used. On Windows it defaults to “internal”, the script editor. On the OS X GUI the argument is ignored and the document editor is always used.
- ... further arguments to be passed to or from methods.
edit invokes the text editor specified by editor with the object name to be edited. It is a generic function, currently with a default method and one for data frames and matrices.

data.entry can be used to edit data, and is used by edit to edit matrices and data frames on systems for which data.entry is available.

It is important to realize that edit does not change the object called name. Instead, a copy of name is made and it is that copy which is changed. Should you want the changes to apply to the object name you must assign the result of edit to name. (Try fix if you want to make permanent changes to an object.)

In the form edit(name), edit deparses name into a temporary file and invokes the editor editor on this file. Quitting from the editor causes file to be parsed and that value returned. Should an error occur in parsing, possibly due to incorrect syntax, no value is returned. Calling edit(), with no arguments, will result in the temporary file being reopened for further editing.

Note that deparsing is not perfect, and the object recreated after editing can differ in subtle ways from that deparsed: see dput and .deparseOpts. (The deparse options used are the same as the defaults for dump.) Editing a function will preserve its environment. See edit.data.frame for further changes that can occur when editing a data frame or matrix.

Currently only the internal editor in Windows makes use of the title option; it displays the given name in the window header.

Note

The functions vi, emacs, pico, xemacs, xedit rely on the corresponding editor being available and being on the path. This is system-dependent.

See Also

edit.data.frame, data.entry, fix.

Examples

```r
## Not run:
# use xedit on the function mean and assign the changes
mean <- edit(mean, editor = "xedit")

# use vi on mean and write the result to file mean.out
vi(mean, file = "mean.out")

## End(Not run)
```

Description

Use data editor on data frame or matrix contents.
Usage

## S3 method for class 'data.frame'
edit(name, factor.mode = c("character", "numeric"),
    edit.row.names = any(row.names(name) != 1:nrow(name)), ...)

## S3 method for class 'matrix'
edit(name, edit.row.names = !is.null(dn[[1]]), ...)

Arguments

- name: A data frame or (numeric, logical or character) matrix.
- factor.mode: How to handle factors (as integers or using character levels) in a data frame.
- edit.row.names: logical. Show the row names (if they exist) be displayed as a separate editable column? It is an error to ask for this on a matrix with NULL row names.
- ...: further arguments passed to or from other methods.

Details

At present, this only works on simple data frames containing numeric, logical or character vectors and factors, and numeric, logical or character matrices. Any other mode of matrix will give an error, and a warning is given when the matrix has a class (which will be discarded).

Data frame columns are coerced on input to character unless numeric (in the sense of `is.numeric`), logical or factor. A warning is given when classes are discarded. Special characters (tabs, non-printing ASCII, etc.) will be displayed as escape sequences.

Factors columns are represented in the spreadsheet as either numeric vectors (which are more suitable for data entry) or character vectors (better for browsing). After editing, vectors are padded with NA to have the same length and factor attributes are restored. The set of factor levels can not be changed by editing in numeric mode; invalid levels are changed to NA and a warning is issued. If new factor levels are introduced in character mode, they are added at the end of the list of levels in the order in which they encountered.

It is possible to use the data-editor’s facilities to select the mode of columns to swap between numerical and factor columns in a data frame. Changing any column in a numerical matrix to character will cause the result to be coerced to a character matrix. Changing the mode of logical columns is not supported.

For a data frame, the row names will be taken from the original object if `edit.row.names = FALSE` and the number of rows is unchanged, and from the edited output if `edit.row.names = TRUE` and there are no duplicates. (If the `row.names` column is incomplete, it is extended by entries like `row223`.) In all other cases the row names are replaced by `seq(length = nrows)`.

For a matrix, colnames will be added (of the form `col17`) if needed. The rownames will be taken from the original object if `edit.row.names = FALSE` and the number of rows is unchanged (otherwise NULL), and from the edited output if `edit.row.names = TRUE`. (If the `row.names` column is incomplete, it is extended by entries like `row223`.)

Editing a matrix or data frame will lose all attributes apart from the row and column names.

Value

The edited data frame or matrix.
Note

fix(data.frame) works for in-place editing by calling this function.
If the data editor is not available, a dump of the object is presented for editing using the default
method of edit.
At present the data editor is limited to 65535 rows.

data.entry, edit

Examples

## Not run:
edit(InsectSprays)
edit(InsectSprays, factor.mode = "numeric")

## End(Not run)

description

Run all the R code from the Examples part of R's online help topic topic with two possible
exceptions, don'trun and dontshow, see 'Details' below.

Usage

describe(topic, package = NULL, lib.loc = NULL,
character.only = FALSE, give.lines = FALSE, local = FALSE,
echo = TRUE, verbose = getOption("verbose"),
setRNG = FALSE, ask = getOption("example.ask"),
prompt.prefix = abbreviate(topic, 6),
run.dontrun = FALSE)

Arguments

topic name or literal character string: the online help topic the examples of which
should be run.
package a character vector giving the package names to look into for the topic, or NULL
(the default), when all packages on the search path are used.
lib.loc a character vector of directory names of R libraries, or NULL. The default value
of NULL corresponds to all libraries currently known. If the default is used, the
loaded packages are searched before the libraries.
character.only a logical indicating whether topic can be assumed to be a character string.
give.lines logical: if true, the *lines* of the example source code are returned as a character vector.

dontrun logical indicating that `dontrun` should be ignored.

dontshow encloses code that is invisible on help pages, but will be run both by the package checking tools, and the `example()` function. This was previously `testonly`, and that form is still accepted.

Value

The value of the last evaluated expression, unless `give.lines` is true, where a character vector is returned.

               example, character.only = TRUE, give.lines = TRUE)
sapply(lmex, length)
```

---

**file.edit**  
*Edit One or More Files*

Description

Edit one or more files in a text editor.

Usage

```r
file.edit(..., title = file, editor =getOption("editor"),
          fileEncoding = "")
```

Arguments

- `...` one or more character vectors containing the names of the files to be displayed. These will be tilde-expanded: see `path.expand`.
- `title` the title to use in the editor; defaults to the filename.
- `editor` the text editor to be used. See ‘Details’.
- `fileEncoding` the encoding to assume for the file: the default is to assume the native encoding. See the ‘Encoding’ section of the help for `file`.

Details

The behaviour of this function is very system dependent. Currently files can be opened only one at a time on Unix; on Windows, the internal editor allows multiple files to be opened, but has a limit of 50 simultaneous edit windows.

The `title` argument is used for the window caption in Windows, and is currently ignored on other platforms.
The `fileEncoding` argument was added in R 2.13.0: any error in re-encoding the files to the native encoding will cause the function to fail.

The default for `editor` is system-dependent. On Windows it defaults to "internal", the script editor, and in the OS X GUI the document editor is used whatever the value of `editor`. On Unix the default is set from the environment variables `EDITOR` or `VISUAL` if either is set, otherwise `vi` is used.

**See Also**

`files`, `file.show`, `edit`, `fix`.

**Examples**

```r
## Not run:
# open two R scripts for editing
file.edit("script1.R", "script2.R")
```

## End(Not run)

---

**file_test**

*Shell-style Tests on Files*

**Description**

Utility for shell-style file tests.

**Usage**

```r
file_test(op, x, y)
```

**Arguments**

- `op` a character string specifying the test to be performed. Unary tests (only `x` is used) are "-f" (existence and not being a directory), "-d" (existence and directory) and "-x" (executable as a file or searchable as a directory). Binary tests are "-nt" (strictly newer than, using the modification dates) and "-ot" (strictly older than): in both cases the test is false unless both files exist.

- `x, y` character vectors giving file paths.

**Details**

'Existence' here means being on the file system and accessible by the `stat` system call (or a 64-bit extension) – on a Unix-alike this requires execute permission on all of the directories in the path that leads to the file, but no permissions on the file itself.

For the meaning of "-x" on Windows see `file.access`.

**See Also**

`file.exists` which only tests for existence (test `-e` on some systems) but not for not being a directory.

`file.path`, `file.info`
Examples

```r
dir <- file.path(R.home(), "library", "stats")
file_test("-d", dir)
file_test("-nt", file.path(dir, "R"), file.path(dir, "demo"))
```

findLineNum

Find the Location of a Line of Source Code, or Set a Breakpoint There.

Description

These functions locate objects containing particular lines of source code, using the information saved when the code was parsed with `keep.source = TRUE`.

Usage

```r
findLineNum(srcfile, line, nameonly = TRUE,
            envir = parent.frame(), lastenv)
```

```r
setBreakpoint(srcfile, line, nameonly = TRUE,
              envir = parent.frame(), lastenv, verbose = TRUE,
              tracer, print = FALSE, clear = FALSE, ...)```

Arguments

- `srcfile` The name of the file containing the source code.
- `line` The line number within the file. See Details for an alternate way to specify this.
- `nameonly` If TRUE (the default), we require only a match to `basename(srcfile)`, not to the full path.
- `envir` Where do we start looking for function objects?
- `lastenv` Where do we stop? See the Details.
- `verbose` Should we print information on where breakpoints were set?
- `tracer` An optional tracer function to pass to `trace`. By default, a call to `browser` is inserted.
- `print` The print argument to pass to `trace`.
- `clear` If TRUE, call `untrace` rather than `trace`.
- `...` Additional arguments to pass to `trace`.

Details

The `findLineNum` function searches through all objects in environment `envir`, its parent, grandparent, etc., all the way back to `lastenv`.

`lastenv` defaults to the global environment if `envir` is not specified, and to the root environment `emptyenv()` if `envir` is specified. (The first default tends to be quite fast, and will usually find all user code other than S4 methods; the second one is quite slow, as it will typically search all attached system libraries.)

For convenience, `envir` may be specified indirectly: if it is not an environment, it will be replaced with `environment(envir)`.
setBreakpoint is a simple wrapper function for `trace` and `untrace`. It will set or clear breakpoints at the locations found by `findLineNum`.

The `srcfile` is normally a filename entered as a character string, but it may be a "srcfile" object, or it may include a suffix like "filename.R#nn", in which case the number `nn` will be used as a default value for `line`.

As described in the description of the `where` argument on the man page for `trace`, the R package system uses a complicated scheme that may include more than one copy of a function in a package. The user will typically see the public one on the search path, while code in the package will see a private one in the package `NAMESPACE`. If you set `envir` to the environment of a function in the package, by default `findLineNum` will find both versions, and `setBreakpoint` will set the breakpoint in both. (This can be controlled using `lastenv`; e.g. `envir = environment(foo)`, `lastenv = globalenv()` will find only the private copy, as the search is stopped before seeing the public copy.)

S version 4 methods are also somewhat tricky to find. They are stored with the generic function, which may be in the `base` or other package, so it is usually necessary to have `lastenv = emptyenv()` in order to find them. In some cases transformations are done by R when storing them and `findLineNum` may not be able to find the original code. Many special cases, e.g. methods on primitive generics, are not yet supported.

Value

`findLineNum` returns a list of objects containing location information. A `print` method is defined for them.

`setBreakpoint` has no useful return value; it is called for the side effect of calling `trace` or `untrace`.

Author(s)

Duncan Murdoch

See Also

`trace`

Examples

```r
## Not run:
# Find what function was defined in the file mysourc.R at line 100:
findLineNum("mysourc.R#100")

# Set a breakpoint in both copies of that function, assuming one is in the
# same namespace as myfunction and the other is on the search path
setBreakpoint("mysourc.R#100", envir = myfunction)

## End(Not run)
```
**Fix an Object**

**Description**

`fix` invokes `edit` on `x` and then assigns the new (edited) version of `x` in the user’s workspace.

**Usage**

`fix(x, ...)`

**Arguments**

- `x`: the name of an R object, as a name or a character string.
- `...`: arguments to pass to editor: see `edit`.

**Details**

The name supplied as `x` need not exist as an R object, in which case a function with no arguments and an empty body is supplied for editing.

Editing an R object may change it in ways other than are obvious: see the comment under `edit`. See `edit.data.frame` for changes that can occur when editing a data frame or matrix.

**See Also**

`edit`, `edit.data.frame`

**Examples**

```r
## Not run:
## Assume 'my.fun' is a user defined function :
fix(my.fun)
## now my.fun is changed
## Also, 
fix(my.data.frame) # calls up data editor
fix(my.data.frame, factor.mode="char") # use of ...
## End(Not run)
```

---

**Flush Output to A Console**

**Description**

This does nothing except on console-based versions of R. On the OS X and Windows GUIs, it ensures that the display of output in the console is current, even if output buffering is on.

**Usage**

`flush.console()`
Format Unordered and Ordered Lists

Description

Format unordered (itemize) and ordered (enumerate) lists.

Usage

```r
formatUL(x, label = "*", offset = 0,
       width = 0.9 * getopt("width"))
formatOL(x, type = "arabic", offset = 0, start = 1,
       width = 0.9 * getopt("width"))
```

Arguments

- `x` a character vector of list items.
- `label` a character string used for labelling the items.
- `offset` a non-negative integer giving the offset (indentation) of the list.
- `width` a positive integer giving the target column for wrapping lines in the output.
- `type` a character string specifying the 'type' of the labels in the ordered list. If "arabic" (default), arabic numerals are used. For "Alph" or "alph", single upper or lower case letters are employed (in this case, the number of the last item must not exceed 26. Finally, for "Roman" or "roman", the labels are given as upper or lower case roman numerals (with the number of the last item maximally 3899). `type` can be given as a unique abbreviation of the above, or as one of the HTML style tokens "1" (arabic), "A"/"a" (alphabetic), or "I"/"i" (roman), respectively.
- `start` a positive integer specifying the starting number of the first item in an ordered list.

Value

A character vector with the formatted entries.

See Also

`formatDL` for formatting description lists.

Examples

```r
## A simpler recipe.
x <- c("Mix dry ingredients thoroughly. ",
       "Pour in wet ingredients. ",
       "Mix for 10 minutes. ",
       "Bake for one hour at 300 degrees.")
## Format and output as an unordered list.
writelines(formatUL(x))
## Format and output as an ordered list.
writelines(formatOL(x))
## Ordered list using lower case roman numerals.
```
getAnywhere

getAnywhere

getAnywhere

writelines(formatOL(x, type = "i"))

writelines(formatOL(x, type = "A", offset = 5))

getAnywhere

getAnywhere

Retrieve an R Object, Including from a Namespace

Description

These functions locate all objects with name matching their argument, whether visible on the search path, registered as an S3 method or in a namespace but not exported. getAnywhere() returns the objects and argsAnywhere() returns the arguments of any objects that are functions.

Usage

getAnywhere(x)

argsAnywhere(x)

Arguments

x a character string or name.

Details

These functions look at all loaded namespaces, whether or not they are associated with a package on the search list.

They do not search literally “anywhere”: for example, local evaluation frames and namespaces that are not loaded will not be searched.

Where functions are found as registered S3 methods, an attempt is made to find which namespace registered them. This may not be correct, especially if namespaces have been unloaded.

Value

For getAnywhere() an object of class "getAnywhere". This is a list with components

name the name searched for

objs a list of objects found

where a character vector explaining where the object(s) were found

visible logical: is the object visible

dups logical: is the object identical to one earlier in the list.

In computing whether objects are identical, their environments are ignored.

Normally the structure will be hidden by the print method. There is a [ method to extract one or more of the objects found.

For argsAnywhere() one or more argument lists as returned by args.
getFromNamespace

See Also

getS3method to find the method which would be used: this might not be the one of those returned by getAnywhere since it might have come from a namespace which was unloaded or be registered under another name.

get, getFromNamespace, args

Examples

getAnywhere("format.dist")
getAnywhere("simpleLoess") # not exported from stats
argsAnywhere(format.dist)

getFromNamespace Utility functions for Developing Namespaces

Description

Utility functions to access and replace the non-exported functions in a namespace, for use in developing packages with namespaces.

They should not be used in production code (except perhaps assignInMyNamespace, but see the ‘Note’).

Usage

getFromNamespace(x, ns, pos = -1, envir = as.environment(pos))

assignInNamespace(x, value, ns, pos = -1,
    envir = as.environment(pos))

assignInMyNamespace(x, value)

fixInNamespace(x, ns, pos = -1, envir = as.environment(pos), ...)

Arguments

x an object name (given as a character string).
value an R object.
ns a namespace, or character string giving the namespace.
pos where to look for the object: see get.
envir an alternative way to specify an environment to look in.
... arguments to pass to the editor: see edit.
getFromNamespace

Details

assignInMyNamespace is intended to be called from functions within a package, and chooses the namespace as the environment of the function calling it.

The namespace can be specified in several ways. Using, for example, `ns = "stats"` is the most direct, but a loaded package can be specified via any of the methods used for `get`: `ns` can also be the environment printed as `<namespace:foo>`.

getFromNamespace is similar to (but predates) the `:::` operator: it is more flexible in how the namespace is specified.

fixInNamespace invokes `edit` on the object named `x` and assigns the revised object in place of the original object. For compatibility with `fix`, `x` can be unquoted.

Value

getFromNamespace returns the object found (or gives an error).

assignInNamespace, assignInMyNamespace and fixInNamespace are invoked for their side effect of changing the object in the namespace.

Warning

assignInNamespace should not be used in final code, and will in future throw an error if called from a package. Already certain uses are disallowed.

Note

assignInNamespace, assignInMyNamespace and fixInNamespace change the copy in the namespace, but not any copies already exported from the namespace, in particular an object of that name in the package (if already attached) and any copies already imported into other namespaces. They are really intended to be used only for objects which are not exported from the namespace. They do attempt to alter a copy registered as an S3 method if one is found.

They can only be used to change the values of objects in the namespace, not to create new objects.

See Also

get, fix, getS3method

Examples

getFromNamespace("findGeneric", "utils")
## Not run:
fixInNamespace("predict.ppr", "stats")
stats:::predict.ppr
getS3method("predict", "ppr")
## alternatively
fixInNamespace("predict.ppr", pos = 3)
fixInNamespace("predict.ppr", pos = "package:stats")
## End(Not run)
getParseData

Get detailed parse information from object.

Description

If the "keep.source" option is TRUE, R's parser will attach detailed information on the object it has parsed. These functions retrieve that information.

Usage

getParseData(x, includeText = NA)
getParseText(parseData, id)

Arguments

x an expression returned from parse, or a function or other object with source reference information
includeText logical; whether to include the text of parsed items in the result
parseData a data frame returned from getParseData
id a vector of item identifiers whose text is to be retrieved

Details

In version 3.0.0, the R parser was modified to include code written by Romain Francois in his parser package. This constructs a detailed table of information about every token and higher level construct in parsed code. This table is stored in the srcfile record associated with source references in the parsed code, and retrieved by the getParseData function.

Value

For getParseData:
If parse data is not present, NULL. Otherwise a data frame is returned, containing the following columns:

1. **line1** integer. The line number where the item starts. This is the parsed line number called "parse" in getSrcLocation, which ignores #line directives.
2. **col1** integer. The column number where the item starts. The first character is column 1. This corresponds to "column" in getSrcLocation.
3. **line2** integer. The line number where the item ends.
4. **col2** integer. The column number where the item ends.
5. **id** integer. An identifier associated with this item.
6. **parent** integer. The id of the parent of this item.
7. **token** character. The type of the token.
8. **terminal** logical. Whether the token is "terminal", i.e. a leaf in the parse tree.
9. **text** character. If includeText is TRUE, the text of all tokens; if it is NA (the default), the text of terminal tokens. If includeText == FALSE, this column is not included.
The rownames of the data frame will be equal to the id values, and the data frame will have a "srcfile" attribute containing the srcfile record which was used. The rows will be ordered by starting position within the source file, with parent items occurring before their children.

For getParseText:
A character vector of the same length as id containing the associated text items. If they are not included in parsedata, they will be retrieved from the original file.

Note
There are a number of differences in the results returned by getParseData relative to those in the original parser code:

- Fewer columns are kept.
- The internal token number is not returned.
- col1 starts counting at 1, not 0.
- The id values are not attached to the elements of the parse tree, they are only retained in the table returned by getParseData.
- #line directives are identified, but other comment markup (e.g., roxygen comments) are not.

Author(s)
Duncan Murdoch

References

parse, srcref

Examples

```r
fn <- function(x) {
  x + 1 # A comment, kept as part of the source
}

d <- getParseData(fn)
if (!is.null(d)) {
  plus <- which(d$token == "+'")
  sum <- d$parent[plus]
  print(d[as.character(sum),])
  print(getParseText(d, sum))
}
```
getS3method

Get An S3 Method

Description

Get a method for an S3 generic, possibly from a namespace or the generic’s registry.

Usage

gets3method(f, class, optional = FALSE)

Arguments

f character: name of the generic.
class character: name of the class.
optinal logical: should failure to find the generic or a method be allowed?

Details

S3 methods may be hidden in namespaces, and will not then be found by get: this function can retrieve such functions, primarily for debugging purposes.

Further, S3 methods can be registered on the generic when a namespace is loaded, and the registered method will be used if none is visible (using namespace scoping rules).

It is possible that which S3 method will be used may depend on where the generic \( f \) is called from: gets3method returns the method found if \( f \) were called from the same environment.

Value

The function found, or NULL if no function is found and optional = TRUE.

See Also

methods, get, getAnywhere

Examples

require(stats)
exists("predict.ppr") # false
gets3method("predict", "ppr")
Description

Change wildcard aka globbing patterns into the corresponding regular expressions (regexp).

Usage

glob2rx(pattern, trim.head = FALSE, trim.tail = TRUE)

Arguments

- **pattern**: character vector
- **trim.head**: logical specifying if leading "^.*" should be trimmed from the result.
- **trim.tail**: logical specifying if trailing ".*$" should be trimmed from the result.

Details

This takes a wildcard as used by most shells and returns an equivalent regular expression. ? is mapped to . (match a single character), * to .* (match any string, including an empty one), and the pattern is anchored (it must start at the beginning and end at the end). Optionally, the resulting regexp is simplified.

Note that now even _, [], and { can be used in pattern, but glob2rx() may not work correctly with arbitrary characters in pattern.

Value

A character vector of the same length as the input pattern where each wildcard is translated to the corresponding regular expression.

Author(s)

Martin Maechler, Unix/sed based version, 1991; current: 2004

See Also

- regexp about regular expression, sub, etc about substitutions using regexps.

Examples

```r
stopifnot(glob2rx("abc.*") == "abc\..",
          glob2rx("a?b.*") == "a.b\..",
          glob2rx("a?b.*", trim.tail = FALSE) == "a.b...$",
          glob2rx("*.doc") == ".*\..doc$",
          glob2rx("*.doc", trim.head = TRUE) == "\..doc$",
          glob2rx("*t*") == ".*\..t",
          glob2rx("*t??") == ".*\..t..$",
          glob2rx("*[*]") == ".*\[.."
)
**globalVariables**

Declare Variables to be Treated as Global in Checking a Package

**Description**

The names supplied are of functions or other objects that should be regarded as defined globally when the check tool is applied to this package. The call to `globalVariables` will be included in the package's source. Repeated calls in the same package accumulate the names of the global variables.

Typical examples are the fields and methods in reference classes, which appear to be global objects to `codetools`. (This case is handled automatically by `setRefClass()` and friends, using the supplied field and method names.)

**Usage**

```
globalVariables(names, package, add = TRUE)
```

**Arguments**

- `names` The character vector of object names. If omitted, the current list of global variables declared in the package will be returned, unchanged.
- `package` The relevant package, usually the character string name of the package but optionally its corresponding namespace environment.
  When the call to `globalVariables` comes in the package's source file, the argument is normally omitted, as in the example below.
- `add` Should the contents of `names` be added to the current global variables or replace it?

**Details**

The list of declared global variables is stored in a metadata object in the package's namespace, assuming the `globalVariables` call(s) occur as top-level calls in the package's source code.

The check command, as implemented in package `utils`, queries the global variables list before checking the R source code in the package for possible problems.

This was introduced in R 2.15.1 so should be used conditionally: see the example.

**Value**

The current list of declared global variables, possibly modified by this call.

**Note**

The global variables list really belongs to a restricted scope (a function or a group of method definitions, for example) rather than the package as a whole. However, implementing finer control would require changes in `check` and/or in `codetools`, so in this version the information is stored at the package level.

**Author(s)**

John Chambers
Examples

```r
## Not run:
## assume your package has some code that assigns ".obj1" and ".obj2"
## but not in a way that codetools can find.
## In the same source file (to remind you that you did it) add:
if(getRversion() >= "2.15.1") utilities::globalVariables(c(".obj1", ".obj2"))
## End(Not run)
```

---

**head**

*Return the First or Last Part of an Object*

**Description**

Returns the first or last parts of a vector, matrix, table, data frame or function. Since `head()` and `tail()` are generic functions, they may also have been extended to other classes.

**Usage**

```r
head(x, ...)
```  
```
## Default S3 method:
head(x, n = 6L, ...)
```  
```
## S3 method for class 'data.frame'
head(x, n = 6L, ...)
```  
```
## S3 method for class 'matrix'
head(x, n = 6L, ...)
```  
```
## S3 method for class 'ftable'
head(x, n = 6L, ...)
```  
```
## S3 method for class 'table'
head(x, n = 6L, ...)
```  
```
## S3 method for class 'function'
head(x, n = 6L, ...)
```  

```r
tail(x, ...)
```  
```
## Default S3 method:
tail(x, n = 6L, ...)
```  
```
## S3 method for class 'data.frame'
tail(x, n = 6L, ...)
```  
```
## S3 method for class 'matrix'
tail(x, n = 6L, addrownms = TRUE, ...)
```  
```
## S3 method for class 'ftable'
tail(x, n = 6L, addrownms = FALSE, ...)
```  
```
## S3 method for class 'table'
tail(x, n = 6L, addrownms = TRUE, ...)
```  
```
## S3 method for class 'function'
tail(x, n = 6L, ...)
```  

**Arguments**

- `x` an object
n

a single integer. If positive, size for the resulting object: number of elements for
a vector (including lists), rows for a matrix or data frame or lines for a function.
If negative, all but the n last/first number of elements of x.

addrownms

if there are no row names, create them from the row numbers.

... arguments to be passed to or from other methods.

Details

For matrices, 2-dim tables and data frames, head() (tail()) returns the first (last) n rows when
n > 0 or all but the last (first) n rows when n < 0. head.matrix() and tail.matrix() are
exported. For functions, the lines of the deparsed function are returned as character strings.
If a matrix has no row names, then tail() will add row names of the form "[n,]" to the result,
so that it looks similar to the last lines of x when printed. Setting addrownms = FALSE
suppresses this behaviour.

Value

An object (usually) like x but generally smaller. For ftable objects x, a transformed format(x).

Author(s)

Patrick Burns, improved and corrected by R-Core. Negative argument added by Vincent Goulet.

Examples

head(letters)
head(letters, n = -6L)

head(freeny.x, n = 10L)
head(freeny.y)

tail(letters)
tail(letters, n = -6L)

tail(freeny.x)
tail(freeny.y)

tail(library)

head(stats::ftable(Titanic))

Description

desc is the primary interface to the help systems.

Usage

help(topic, package = NULL, lib.loc = NULL,
    verbose = option("verbose"),
    try.all.packages = option("help.try.all.packages"),
    help_type = option("help_type"))
help

Arguments

**topic**

usually a name or character string specifying the topic for which help is sought.
A character string (enclosed in explicit single or double quotes) is always taken as naming a topic.
If the value of topic is a length-one character vector the topic is taken to be the value of the only element. Otherwise topic must be a name or a reserved word (if syntactically valid) or character string.
See ‘Details’ for what happens if this is omitted.

**package**

a name or character vector giving the packages to look into for documentation, or NULL. By default, all packages in the search path are used. To avoid a name being deparsed use e.g. (pkg_ref) (see the examples).

**lib.loc**

a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries. This is not used for HTML help (see ‘Details’).

**verbose**

logical; if TRUE, the file name is reported.

**try.all.packages**

logical; see Note.

**help_type**

character string: the type of help required. Possible values are "text", "html" and "pdf". Case is ignored, and partial matching is allowed.

Details

The following types of help are available:

- Plain text help
- HTML help pages with hyperlinks to other topics, shown in a browser by browseURL. (Where possible an existing browser window is re-used: the OS X GUI uses its own browser window.)
  If for some reason HTML help is unavailable (see startDynamicHelp), plain text help will be used instead.
- For help only, typeset as PDF – see the section on ’Offline help’.

The ‘factory-fresh’ default is text help except from the Mac OS GUI, which uses HTML help displayed in its own browser window.

The rendering of text help will use directional quotes in suitable locales (UTF-8 and single-byte Windows locales): sometimes the fonts used do not support these quotes so this can be turned off by setting **options**(useFancyQuotes = FALSE).

**topic** is not optional: if it is omitted R will give

- If a package is specified, (text or, in interactive use only, HTML) information on the package, including hints/links to suitable help topics.
- If lib.loc only is specified, a (text) list of available packages.
- Help on help itself if none of the first three arguments is specified.

Some topics need to be quoted (by backticks) or given as a character string. These include those which cannot syntactically appear on their own such as unary and binary operators, function and control-flow reserved words (including if, else for, in, repeat, while, break and next). The other reserved words can be used as if they were names, for example TRUE, NA and Inf.

If multiple help files matching **topic** are found, in interactive use a menu is presented for the user to choose one; in batch use the first on the search path is used. (For HTML help the menu will be
an HTML page, otherwise a graphical menu if possible if `getOption("menu.graphics")` is true, the default.)

Note that HTML help does not make use of `lib.loc`: it will always look first in the attached packages and then along `.libPaths()`.

### Offline help

Typeset documentation is produced by running the LaTeX version of the help page through `pdflatex`: this will produce a PDF file.

The appearance of the output can be customized through a file `Rhelp.cfg` somewhere in your LaTeX search path: this will be input as a LaTeX style file after Rd.sty. Some environment variables are consulted, notably `R_PAPERSIZE (via `getOption("papersize")`) and `R_RST4PDF` (see ‘Making manuals’ in the ‘R Installation and Administration Manual’).

If there is a function `offline_help_helper` in the workspace or further down the search path it is used to do the typesetting, otherwise the function of that name in the `utils` namespace (to which the first paragraph applies). It should accept at least two arguments, the name of the LaTeX file to be typeset and the type (which as from R 2.15.0 is ignored). It accepts a third argument, `tex inputs`, which will give the graphics path when the help document contains figures, and will otherwise not be supplied.

#### Note

Unless `lib.loc` is specified explicitly, the loaded packages are searched before those in the specified libraries. This ensures that if a library is loaded from a library not in the known library trees, then the help from the loaded library is used. If `lib.loc` is specified explicitly, the loaded packages are not searched.

If this search fails and argument `try.all.packages` is `TRUE` and neither `packages` nor `lib.loc` is specified, then all the packages in the known library trees are searched for help on topic and a list of (any) packages where help may be found is displayed (with hyperlinks for `help_type = "html"`). **NB:** searching all packages can be slow, especially the first time (caching of files by the OS can expedite subsequent searches dramatically).

### References

### See Also

? for shortcuts to help topics.

`help.search()` or `??` for finding help pages on a vague topic; `help.start()` which opens the HTML version of the R help pages; `library()` for listing available packages and the help objects they contain; `data()` for listing available data sets; `methods()`.

Use `prompt()` to get a prototype for writing help pages of your own package.

### Examples

```
help()
help(help)       # the same

help(lapply)
```
help("for")  # or ?"for", but quotes/backticks are needed

try({# requires working TeX installation:
    help(dgamma, help_type = "pdf")
    ## -> nicely formatted pdf -- including math formula -- for help(dgamma):
    system2(getOption("pdfviewer"), "dgamma.pdf", wait = FALSE)
})

help(package = "splines")  # get help even when package is not loaded

topi <- "women"
help(topi)

try(help("bs", try.all.packages = FALSE))  # reports not found (an error)
help("bs", try.all.packages = TRUE)  # reports can be found
    # in package 'splines'

## For programmatic use:
topic <- "family"; pkg_ref <- "stats"
help((topic), (pkg_ref))

## help.request  Send a Post to R-help

### Description

Prompts the user to check they have done all that is expected of them before sending a post to the R-help mailing list, provides a template for the post with session information included and optionally sends the email (on Unix systems).

### Usage

```
help.request(subject = "",
              address = "r-help@r-project.org",
              file = "R.help.request", ...)
```

### Arguments

- **subject**  subject of the email. Please do not use single quotes (') in the subject! Post separate help requests for multiple queries.
- **address**  recipient’s email address.
- **file**  filename to use (if needed) for setting up the email.
- **...**  additional named arguments such as method and ccaddress to pass to `create.post`.

### Details

This function is not intended to replace the posting guide. Please read the guide before posting to R-help or using this function (see [http://www.r-project.org/posting-guide.html](http://www.r-project.org/posting-guide.html)).

The `help.request` function:

- asks whether the user has consulted relevant resources, stopping and opening the relevant URL if a negative response is given.
help.search

- checks whether the current version of \( \mathbf{R} \) is being used and whether the add-on packages are up-to-date, giving the option of updating where necessary.
- asks whether the user has prepared appropriate (minimal, reproducible, self-contained, commented) example code ready to paste into the post.

Once this checklist has been completed a template post is prepared including current session information, and passed to `create.post`.

**Value**

Nothing useful.

**Author(s)**

Heather Turner, based on the then current code and help page of `bug.report()`.

**See Also**

The posting guide ([http://www.r-project.org/posting-guide.html](http://www.r-project.org/posting-guide.html)), also `sessionInfo()` from which you may add to the help request.

`create.post`.

---

### help.search

**Search the Help System**

**Description**

Allows for searching the help system for documentation matching a given character string in the (file) name, alias, title, concept or keyword entries (or any combination thereof), using either fuzzy matching or regular expression matching. Names and titles of the matched help entries are displayed nicely formatted.

Vignette names, titles and keywords and demo names and titles may also be searched.

**Usage**

```r
help.search(pattern, fields = c("alias", "concept", "title"),
            apropos, keyword, whatis, ignore.case = TRUE,
            package = NULL, lib.loc = NULL,
            help.db = getOption("help.db"),
            verbose = getOption("verbose"),
            rebuild = FALSE, agrep = NULL, use_UTF8 = FALSE,
            types = getOption("help.search.types"))

??pattern
field??pattern
```
Arguments

pattern a character string to be matched in the specified fields. If this is given, the arguments apropos, keyword, and whatis are ignored.

fields a character vector specifying the fields of the help database to be searched. The entries must be abbreviations of "name", "title", "alias", "concept", and "keyword", corresponding to the help page's (file) name, its title, the topics and concepts it provides documentation for, and the keywords it can be classified to. See below for how vignettes and demos are searched.

apropos a character string to be matched in the help page topics and title.

keyword a character string to be matched in the help page 'keywords'. ‘Keywords’ are really categories: the standard categories are listed in file ‘R.home(“doc”)’/KEYWORDS’ (see also the example) and some package writers have defined their own. If keyword is specified, agrep defaults to FALSE.

whatis a character string to be matched in the help page topics.

ignore.case a logical. If TRUE, case is ignored during matching; if FALSE, pattern matching is case sensitive.

package a character vector with the names of packages to search through, or NULL in which case all available packages in the library trees specified by lib.loc are searched.

lib.loc a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known.

help.db a character string giving the file path to a previously built and saved help database, or NULL.

verbose logical; if TRUE, the search process is traced. Integer values are also accepted, with TRUE being equivalent to 2, and 1 being less verbose. On Windows a progress bar is shown during rebuilding, and on Unix a heartbeat is shown for verbose = 1 and a package-by-package list for verbose >= 2.

rebuild a logical indicating whether the help database should be rebuilt. This will be done automatically if lib.loc or the search path is changed, or if package is used and a value is not found.

agrep if NULL (the default unless keyword is used) and the character string to be matched consists of alphanumeric characters, whitespace or a dash only, approximate (fuzzy) matching via agrep is used unless the string has fewer than 5 characters; otherwise, it is taken to contain a regular expression to be matched via grep. If FALSE, approximate matching is not used. Otherwise, one can give a numeric or a list specifying the maximal distance for the approximate match, see argument max.distance in the documentation for agrep.

use_UTF8 logical: should be results be given in UTF-8 encoding? Also changes the meaning of regexps in agrep to be Perl regexps.

types a character vector listing the types of documentation to search. The entries must be abbreviations of "vignette" "help" or "demo". Results will be presented in the order specified.

field a single value of fields to search.

Details

Upon installation of a package, a pre-built help.search index is serialized as ‘hsearch.rds’ in the ‘Meta’ directory (provided the package has any help pages). Vignettes are also indexed in the ‘Meta/vignette.rds’ file. These files are used to create the help search database.
The arguments `apropos` and `whatis` play a role similar to the Unix commands with the same names. Searching with `agrep = FALSE` will be several times faster than the default (once the database is built). However, as from R 2.10.0 approximate searches should be fast enough (around a second with 2000 packages installed).

If possible, the help database is saved in memory for use by subsequent calls in the session.

Note that currently the aliases in the matching help files are not displayed.

As with `?`, in `??` the pattern may be prefixed with a package name followed by `::` or `:::` to limit the search to that package.

Vignettes are searched as follows. The "name" and "alias" are both the base of the vignette filename, and the "concept" entries are taken from the `\VignetteKeywords` entries. Vignettes are not classified using the help system "keyword" classifications. Demos are handled similarly to vignettes, without the "concept" search.

**Value**

The results are returned in a list object of class "hsearch", which has a print method for nicely formatting the results of the query. This mechanism is experimental, and may change in future versions of R.

In R.app on OS X, this will show up a browser with selectable items. On exiting this browser, the help pages for the selected items will be shown in separate help windows.

The internal format of the class is undocumented and subject to change.

**See Also**

`help`, `help.start` for starting the hypertext (currently HTML) version of R’s online documentation, which offers a similar search mechanism.

`RSiteSearch` to access an on-line search of R resources.

`apropos` uses regexps and has nice examples.

**Examples**

```r
help.search("linear models")  # In case you forgot how to fit linear models
help.search("non-existent topic")

??utils::help  # All the topics matching "help" in the utils package

# Not run:
help.search("print")  # All help pages with topics or title matching 'print'
help.search(apropos = "print")  # The same
help.search(keyword = "hplot")  # All help pages documenting high-level plots.
file.show(file.path(R.home("doc"), "KEYWORDS"))  # show all keywords

# Help pages with documented topics starting with 'try'.
help.search("\btry", fields = "alias")

# End(Not run)
```
help.start

Hypertext Documentation

Description

Start the hypertext (currently HTML) version of R's online documentation.

Usage

```
help.start(update = FALSE, gui = "irrelevant",
            browser =getOption("browser"), remote = NULL)
```

Arguments

- **update** logical: should this attempt to update the package index to reflect the currently available packages. (Not attempted if remote is non-NULL.)
- **gui** just for compatibility with S-PLUS.
- **browser** the name of the program to be used as hypertext browser. It should be in the PATH, or a full path specified. Alternatively, it can be an R function which will be called with a URL as its only argument. This option is normally unset on Windows, when the file-association mechanism will be used.
- **remote** A character string giving a valid URL for the `R_HOME` directory on a remote location.

Details

Unless remote is specified this requires the HTTP server to be available (it will be started if possible: see `startDynamicHelp`).

One of the links on the index page is the HTML package index, `R.home("docs")/html/packages.html`, which can be remade by `make.packages.html()`. For local operation, the HTTP server will remake a temporary version of this list when the link is first clicked, and each time thereafter check if updating is needed (if `.libPaths` has changed or any of the directories has been changed). This can be slow, and using `update = TRUE` will ensure that the packages list is updated before launching the index page.

Argument remote can be used to point to HTML help published by another R installation: it will typically only show packages from the main library of that installation.

See Also

- `help()` for on- and off-line help in other formats.
- `browseURL` for how the help file is displayed.
- `RSiteSearch` to access an on-line search of R resources.

Examples

```
help.start()
## Not run:
## the 'remote' arg can be tested by
help.start(remote = paste0("file://", R.home()))

## End(Not run)
```
Description

Utility for installing add-on packages.

Usage

R CMD INSTALL [options] [-l lib] pkgs

Arguments

pkgs a space-separated list with the path names of the packages to be installed. See ‘Details’.

lib the path name of the R library tree to install to. Also accepted in the form ‘--library=lib’. Paths including spaces should be quoted, using the conventions for the shell in use.

options a space-separated list of options through which in particular the process for building the help files can be controlled. Use R CMD INSTALL --help for the full current list of options.

Details

This will stop at the first error, so if you want all the pkgs to be tried, call this via a shell loop.

If used as R CMD INSTALL pkgs without explicitly specifying lib, packages are installed into the library tree rooted at the first directory in the library path which would be used by R run in the current environment.

To install into the library tree lib, use R CMD INSTALL -l lib pkgs. This prepends lib to the library path for duration of the install, so required packages in the installation directory will be found (and used in preference to those in other libraries).

Both lib and the elements of pkgs may be absolute or relative path names of directories. pkgs may also contain names of package archive files: these are then extracted to a temporary directory. These are tarballs containing a single directory, optionally compressed by gzip, bzip2, xz or compress. Finally, binary package archive files (as created by R CMD INSTALL --build) can be supplied.

Tarballs are by default unpackaged by the internal untar function: if needed an external tar command can be specified by the environment variable R_INSTALL_TAR: please ensure that it can handle the type of compression used on the tarball. (This is sometimes needed for tarballs containing invalid or unsupported sections, and can be faster on very large tarballs. Setting R_INSTALL_TAR to ‘tar.exe’ has been needed to overcome permissions issues on some Windows systems.)

The package sources can be cleaned up prior to installation by ‘--preclean’ or after by ‘--clean’: cleaning is essential if the sources are to be used with more than one architecture or platform.

Some package sources contain a ‘configure’ script that can be passed arguments or variables via the option ‘--configure-args’ and ‘--configure-vars’, respectively, if necessary. The latter is useful in particular if libraries or header files needed for the package are in non-system directories. In this case, one can use the configure variables LIBS and CPPFLAGS to specify these locations (and set these via ‘--configure-vars’), see section “Configuration variables” in “R Installation and Administration” for more information. (If these are used more than once on the command line they are concatenated.) The configure mechanism can be bypassed using the option ‘--no-configure’.
install.packages

If the attempt to install the package fails, leftovers are removed. If the package was already installed, the old version is restored. This happens either if a command encounters an error or if the install is interrupted from the keyboard: after cleaning up the script terminates.

For details of the locking which is done, see the section ‘Locking’ in the help for `install.packages`.

Some platforms (notably Windows) make use of sub-architectures in which binaries for different CPUs are installed within the same library tree. For such installations, the default behaviour is to try to build packages for all installed sub-architectures unless the package has a configure script or a ‘src/Makefile’, when only the sub-architecture running R CMD INSTALL is used. To use only that sub-architecture, use ‘--no-multiarch’. To install just the compiled code for another sub-architecture, use ‘--libs-only’.

By default a package is installed with static HTML help pages if and only if R was: use options ‘--html’ and ‘--no-html’ to override this.

Packages are not by default installed keeping the source formatting (see the keep.source argument to `source`): this can be enabled by the option ‘--with-keep.source’ or by setting environment variable R_KEEP_PKG_SOURCE to yes.

Use R CMD INSTALL --help for concise usage information, including all the available options.

Note

The options do not have to precede ‘pkgs’ on the command line, although it will be more legible if they do. All the options are processed before any packages, and where options have conflicting effects the last one will win.

Some parts of the operation of INSTALL depend on the R temporary directory (see `tempdir`, usually under ‘/tmp’) having both write and execution access to the account running R. This is usually the case, but if ‘/tmp’ has been mounted as noexec, environment variable TMPDIR may need to be set to a directory from which execution is allowed.

See Also

`remove` and `library` for information on using several library trees; `update.packages` for automatic update of packages using the internet (or other R level installation of packages, such as by `install.packages`).

install.packages  Install Packages from Repositories or Local Files

Description

Download and install packages from CRAN-like repositories or from local files.
install.packages

Usage

install.packages(pkgs, lib, repos = getOption("repos"),
                 contriburl = contrib.url(repos, type),
                 method, available = NULL, destdir = NULL,
                 dependencies = NA, type = getOption("pkgType"),
                 configure.args = getOption("configure.args"),
                 configure.vars = getOption("configure.vars"),
                 clean = FALSE, Ncpus = getOption("Ncpus", 1L),
                 verbose = getOption("verbose"),
                 libs_only = FALSE, INSTALL_opts, quiet = FALSE,
                 keep_outputs = FALSE, ...)

Arguments

pkgs
character vector of the names of packages whose current versions should be
Downloaded from the repositories.
If repos = NULL, a character vector of file paths of '.tar.gz' files. These can be source archives or binary package archive files (as created by
R CMD build --binary). On a CRAN build of R for OS X these can be
'.tgz' files containing binary package archives. Tilde-expansion will be done
on the file paths.
If this is missing or a zero-length character vector, a listbox of available packages
is presented where possible in an interactive R session.

lib
character vector giving the library directories where to install the packages. Re-
cycled as needed. If missing, defaults to the first element of .libPaths()

repos
character vector, the base URL(s) of the repositories to use, e.g., the URL of a
CRAN mirror such as "http://cran.us.r-project.org".
Can be NULL to install from local files (with extension '.tar.gz' for source packages).

contriburl
URL(s) of the contrib sections of the repositories. Use this argument if your
repository mirror is incomplete, e.g., because you burned only the 'contrib'
section on a CD, or only have binary packages. Overrides argument repos. As
with repos, can also be NULL to install from local files.

method
download method, see download.file.

available
an object as returned by available.packages listing packages available
at the repositories, or NULL when the function makes an internal call to
available.packages.

destdir
directory where downloaded packages are stored. If it is NULL (the default) a
subdirectory downloaded_packages of the session temporary directory will be
used (and the files will be deleted at the end of the session).

dependencies
logical indicating to also install uninstalled packages which these pack-
ages depend on/link to/import/suggest (and so on recursively). Not
used if repos = NULL. Can also be a character vector, a subset of
c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances").
Only supported if lib is of length one (or missing), so it is unambiguous where
to install the dependent packages. If this is not the case it is ignored, with a
warning.
The default, NA, means c("Depends", "Imports", "LinkingTo").
install.packages

TRUE means to use c("Depends", "Imports", "LinkingTo", "Suggests") for pkgs and c("Depends", "Imports", "LinkingTo") for added dependencies: this installs all the packages needed to run pkgs, their examples, tests and vignettes (if the package author specified them correctly).

type

character, indicating the type of package to download and install. Possible values are "source", "mac.binary.leopard" and "win.binary": the binary types can be listed and downloaded but not installed on other platforms. The default is the appropriate binary type on Windows and on the CRAN binary OS X distribution, otherwise "source". For the platforms where binary packages are the default, an alternative is "both" which means 'try binary if available, otherwise try source'. (This will only choose the binary package if its version number is no older than the source version. In interactive use it will ask before attempting to install source packages.)

configure.args

(not used on Windows) a character vector or a named list. If a character vector with no names is supplied, the elements are concatenated into a single string (separated by a space) and used as the value for the ‘"--configure-args"’ flag in the call to R CMD INSTALL. If the character vector has names these are assumed to identify values for ‘"--configure-args"’ for individual packages. This allows one to specify settings for an entire collection of packages which will be used if any of those packages are to be installed. (These settings can therefore be re-used and act as default settings.) A named list can be used also to the same effect, and that allows multi-element character strings for each package which are concatenated to a single string to be used as the value for ‘"--configure-args"’.

configure.vars

(not used on Windows) analogous to configure.args for flag ‘"--configure-vars"’, which is used to set environment variables for the configure run.

clean

a logical value indicating whether to specify to add the ‘"--clean"’ flag to the call to R CMD INSTALL. This is sometimes used to perform additional operations at the end of the package installation in addition to removing intermediate files.

ncpus

the number of parallel processes to use for a parallel install of more than one source package. Values greater than one are supported if the make command specified by Sys.getenv("MAKE", "make") accepts argument -k -j Ncpus.

verbose

a logical indicating if some ‘progress report’ should happen.

libs_only

a logical value: should the ‘"--libs-only"’ option be used to install only additional sub-architectures? (See also INSTALL_opts.) This can also be used on Windows to install just the DLL(s) from a binary package, e.g. to add 64-bit DLLs to a 32-bit install.

INSTALL_opts

an optional character vector of additional option(s) to be passed to R CMD INSTALL for a source package install. E.g., c("--html", "--no-multiarch"). Can also be a named list of character vectors of to be used as additional options, with names the respective package names.

quiet

logical: if true, reduce the amount of output.

keep_outputs

a logical: if true, keep the outputs from installing source packages in the current working directory, with the names of the output files the package names with '.out' appended. Alternatively, a character string giving the directory where to save the outputs. Ignored when installing from local files.
 reinstall.packages

Arguments to be passed to `download.file` or to the functions for binary installs on OS X and Windows (which accept an argument "lock": see the section on 'Locking').

Details

R packages are primarily distributed as source packages, but binary packages (a packaging up of the installed package) are also supported, and the type most commonly used on Windows and from the CRAN distribution for OS X. This function can install either type where supported, either by downloading a file from a repository or from a local file. The default type is given by `getOption("pkgType")`: this defaults to "source" apart from under Windows or a CRAN binary distribution for OS X.

This is the main function to install packages. It takes a vector of names and a destination library, downloads the packages from the repositories and installs them. (If the library is omitted it defaults to the first directory in `.libPaths()`, with a message if there is more than one.) If `lib` is omitted or is of length one and is not a (group) writable directory, in interactive use the code offers to create a personal library tree (the first element of `Sys.getenv("R_LIBS_USER")`) and install there.

For source packages from a repository an attempt is made to install the packages in an order that respects their dependencies. This does assume that all the entries in `lib` are on the default library path for installs (set by `R_LIBS`).

You are advised to run `update.packages` before `install.packages` to ensure that any already installed dependencies have their latest versions.

Argument `libs_only = TRUE` is supported for source installs and for Windows binary installs.

For binary installs, the function also checks for the availability of a source package on the same repository, and reports if the source package has a later version, or is available but no binary version is. This check can be suppressed by

    options(install.packages.check.source = "no")

and should be if there is a partial repository containing only binary files.

Value

Invisible NULL.

Locking

There are various options for locking: these differ between source and binary installs.

By default for a source install, the library directory is 'locked' by creating a directory `@LOCK` within it. This has two purposes: it prevents any other process installing into that library concurrently, and is used to store any previous version of the package to restore on error. A finer-grained locking is provided by the option `--pkglock` which creates a separate lock for each package: this allows enough freedom for parallel installation. Per-package locking is the default when installing a single package, and for multiple packages when `ncpus > 1L`. Finally locking (and restoration on error) can be suppressed by `--no-lock`.

For an OS X or Windows binary install, no locking is done by default. Setting argument `lock` to `TRUE` (it defaults to the value of `getOption("install.lock", FALSE)`) will use per-directory locking as described for source installs: if the value is "pkglock" per-package locking will be used.

If package locking is used on Windows with `libs_only = TRUE` and the installation fails, the package will be restored to its previous state.
Note that it is possible for the package installation to fail so badly that the lock directory is not removed: this inhibits any further installs to the library directory (or for \texttt{--pkglock}, of the package) until the lock directory is removed manually.

**Parallel installs**

Parallel installs are attempted if \texttt{pkgs} has length greater than one and \texttt{Ncpus} \(>1\). It makes use of a parallel make, so the make specified (default make) when \texttt{R} was built must be capable of supporting \texttt{make -j n}: GNU make and \texttt{dmake} do, but FreeBSD and Solaris \texttt{make} do not: if necessary environment variable \texttt{MAKE} can be set for the current session to select a suitable make.

\texttt{install.packages} needs to be able to compute all the dependencies of \texttt{pkgs} from available, including if one element of \texttt{pkgs} depends indirectly on another. This means that if for example you are installing \texttt{CRAN} packages which depend on Bioconductor packages which in turn depend on \texttt{CRAN} packages, \texttt{available} needs to cover both \texttt{CRAN} and Bioconductor packages.

**Note**

Some binary distributions of \texttt{R} have INSTALL in a separate bundle, e.g. an \texttt{R-devel} RPM. \texttt{install.packages} will give an error if called with \texttt{type = "source"} on such a system.

Some binary distributions of \texttt{R} can be installed on a machine without the tools needed to install packages: the remedy is to do a complete install of \texttt{R} which should bring in all those tools as dependencies.

**See Also**

\texttt{update.packages}, \texttt{available.packages}, \texttt{download.packages}, \texttt{installed.packages}, \texttt{contrib.url}.

See \texttt{download.file} for how to handle proxies and other options to monitor file transfers.

\texttt{INSTALL}, \texttt{REMOVE}, \texttt{remove.packages}, \texttt{library}, \texttt{.packages}, \texttt{read.dcf}

The ‘R Installation and Administration’ manual for how to set up a repository.

**Examples**

```r
## Not run:
## A Linux example for Fedora's layout
install.packages(c("ncdf4", "RNetCDF"),
    configure.args = c(RNetCDF = "--with-netcdf-include=/usr/include/udunits2"))
```

```r
## End(Not run)
```

**installed.packages**  
*Find Installed Packages*

**Description**

Find (or retrieve) details of all packages installed in the specified libraries.

**Usage**

```r
installed.packages(lib.loc = NULL, priority = NULL,
    noCache = FALSE, fields = NULL,
    subarch = .Platform$arch)
```
installed.packages

Arguments

lib.loc character vector describing the location of R library trees to search through, or NULL for all known trees (see .libPaths).

priority character vector or NULL (default). If non-null, used to select packages; "high" is equivalent to c("base", "recommended"). To select all packages without an assigned priority use priority = "NA".

noCache Do not use cached information, nor cache it.

fields a character vector giving the fields to extract from each package’s DESCRIPTION file in addition to the default ones, or NULL (default). Unavailable fields result in NA values.

subarch character string or NULL. If non-null and non-empty, used to select packages which are installed for that sub-architecture.

Details

installed.packages scans the 'DESCRIPTION' files of each package found along lib.loc and returns a matrix of package names, library paths and version numbers.

The information found is cached (by library) for the R session and specified fields argument, and updated only if the top-level library directory has been altered, for example by installing or removing a package. If the cached information becomes confused, it can be refreshed by running installed.packages(noCache = TRUE).

Value

A matrix with one row per package, row names the package names and column names (currently) "Package", "LibPath", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "OS_type", "License" and "Built" (the R version the package was built under). Additional columns can be specified using the fields argument.

Note

This can be slow when thousands of packages are installed, so do not use this to find out if a named package is installed (use system.file or find.package) nor to find out if a package is usable (call require and check the return value) nor to find details of a small number of packages (use packageDescription). It needs to read several files per installed package, which will be slow on Windows and on some network-mounted file systems.

See Also

update.packages, install.packages, INSTALL, REMOVE.

Examples

## confine search to .Library for speed
str(ip <- installed.packages(.Library, priority = "high"))
ip[, c(1,3:5)]
plcic <- installed.packages(.Library, priority = "high", fields = "License")
## what licenses are there:
table(plcic[, "License"])

1776
Create Executable Programs

Description

Front-end for creating executable programs.

Usage

```
R CMD LINK [options] linkcmd
```

Arguments

- `linkcmd`: a list of commands to link together suitable object files (include library objects) to create the executable program.
- `options`: further options to control the linking, or for obtaining information about usage and version.

Details

The linker front-end is useful in particular when linking against the R shared or static library: see the examples.

The actual linking command is constructed by the version of `libtool` installed at `R_HOME/bin`.

```
R CMD LINK --help gives usage information.
```

Note

Some binary distributions of R have LINK in a separate bundle, e.g. an R-devel RPM.

This is not available on Windows.

See Also

`compile`.

Examples

```r
## Not run: ## examples of front-ends linked against R.
## First a C program
CC=`R CMD config CC`
R CMD LINK $CC -o foo.o 'R CMD config --ldflags'

## if Fortran code has been compiled into ForFoo.o
FLIBS=`R CMD config FLIBS`
R CMD LINK $CC -o foo.o ForFoo.o 'R CMD config --ldflags' $FLIBS

## And for a C++ front-end
CXX=`R CMD config CXX`
R CMD COMPIL foo.cc
R CMD LINK $CXX -o foo.o 'R CMD config --ldflags'

## End(Not run)
```
localeToCharset  
Select a Suitable Encoding Name from a Locale Name

Description

This function aims to find a suitable coding for the locale named, by default the current locale, and if it is a UTF-8 locale a suitable single-byte encoding.

Usage

```r
localeToCharset(locale = Sys.getlocale("LC_CTYPE"))
```

Arguments

- `locale` character string naming a locale.

Details

The operation differs by OS. Locale names are normally like `es_mx.iso88591`. If final component indicates an encoding and it is not `utf8` we just need to look up the equivalent encoding name. Otherwise, the language (here `es`) is used to choose a primary or fallback encoding.

In the C locale the answer will be "ASCII".

Value

A character vector naming an encoding and possibly a fallback single-encoding, `NA` if unknown.

Note

The encoding names are those used by `libiconv`, and ought also to work with `glibc` but maybe not with commercial Unixen.

See Also

- `Sys.getlocale`, `iconv`.

Examples

```r
localeToCharset()
```
ls.str

List Objects and their Structure

Description

ls.str and lsf.str are variations of ls applying str() to each matched name: see section Value.

Usage

```r
ls.str(pos = -1, name, envir, all.names = FALSE,
        pattern, mode = "any")
```

```r
lsf.str(pos = -1, envir, ...)
```

```r
# S3 method for class 'ls_str'
print(x, max.level = 1, give.attr = FALSE, ...,
      digits = max(1,getOption("str")$digits))
```

Arguments

- `pos` integer indicating search path position, or -1 for the current environment.
- `name` optional name indicating search path position, see ls.
- `envir` environment to use, see ls.
- `all.names` logical indicating if names which begin with a . are omitted; see ls.
- `pattern` a regular expression passed to ls. Only names matching pattern are considered.
- `max.level` maximal level of nesting which is applied for displaying nested structures, e.g., a list containing sub lists. Default 1: Display only the first nested level.
- `give.attr` logical; if TRUE (default), show attributes as sub structures.
- `mode` character specifying the mode of objects to consider. Passed to exists and get.
- `x` an object of class "ls_str".
- ... further arguments to pass. lsf.str passes them to ls.str which passes them on to ls. The (non-exported) print method print.ls_str passes them to str.
- `digits` the number of significant digits to use for printing.

Value

ls.str and lsf.str return an object of class "ls_str", basically the character vector of matching names (functions only for lsf.str), similarly to ls, with a print() method that calls str() on each object.

Author(s)

Martin Maechler

See Also

str, summary, args.
Examples

```
require(stats)

lsf.str()  #-- how do the functions look like which I am using?
ls.str(mode = "list")  #-- what are the structured objects I have defined?

## create a few objects
example(glm, echo = FALSE)
l1 <- as.list(LETTERS)
print(ls.str(), max.level = 0)# don't show details

## which base functions have "file" in their name ?
lsf.str(pos = length(search()), pattern = "file")

## demonstrating that ls.str() works inside functions
## "[browser/debug mode]"

tt <- function(x, y = 1) { aa <- 7; r <- x + y; ls.str() }
(mms <- asapply(strsplit(capture.output(tt(2))," *:"), `\[`, 1))
stopifnot(mms == c("aa","r","x","y"))
```

Description

Show the name and email address of the maintainer of a package.

Usage

```
maintainer(pkg)
```

Arguments

- **pkg**  Character string. The name of a single package.

Details

Accesses the package description to return the name and email address of the maintainer.

Questions about contributed packages should often be addressed to the package maintainer; questions about base packages should usually be addressed to the R-help or R-devel mailing lists. Bug reports should be submitted using the `bug.report` function.

Value

A character string giving the name and email address of the maintainer of the package, or `NA` if no such package is installed.

Author(s)

David Scott <d.scott@auckland.ac.nz> from code on R-help originally due to Charlie Sharpsteen <source@sharpsteen.net>; multiple corrections by R-core.
References

packageDescription, bug.report

Examples

maintainer("MASS")

Description

Re-create the HTML list of packages.

Usage

make.packages.html(lib.loc = .libPaths(), temp = FALSE,
       verbose = TRUE, docdir = R.home("doc"))

Arguments

lib.loc character vector. List of libraries to be included.
temp logical: should the package indices be created in a temporary location for use
       by the HTTP server?
verbose logical. If true, print out a message.
docdir If temp is false, directory in whose ‘html’ directory the ‘packages.html’ file is
       to be created/updated.

Details

This creates the ‘packages.html’ file, either a temporary copy for use by help.start, or the copy
in ‘R.home("doc")/html’ (for which you will need write permission).

It can be very slow, as all the package ‘DESCRIPTION’ files in all the library trees are read.

For temp = TRUE there is some caching of information, so the file will only be re-created if lib.loc
or any of the directories it lists have been changed.

Value

Invisible logical, with FALSE indicating a failure to create the file, probably due to lack of suitable
permissions.

See Also

help.start
make.socket

Create a Socket Connection

Description

With server = FALSE attempts to open a client socket to the specified port and host. With server = TRUE the R process listens on the specified port for a connection and then returns a server socket. It is a good idea to use on.exit to ensure that a socket is closed, as you only get 64 of them.

Usage

make.socket(host = "localhost", port, fail = TRUE, server = FALSE)

Arguments

host  name of remote host
port  port to connect to/listen on
fail  failure to connect is an error?
server  a server socket?

Value

An object of class "socket", a list with components:

socket  socket number. This is for internal use. On a Unix-alike it is a file descriptor.
port  port number of the connection.
host  name of remote computer.

Warning

I don’t know if the connecting host name returned when server = TRUE can be trusted. I suspect not.

Author(s)

Thomas Lumley

References

Adapted from Luke Tierney’s code for XLISP-Stat, in turn based on code from Robbins and Robbins “Practical UNIX Programming”.

Examples

## Not run:
make.packages.html()
# this can be slow for large numbers of installed packages.

## End(Not run)
memory.size

See Also

close.socket, read.socket

Examples

daytime <- function(host = "localhost"){  
a <- make.socket(host, 13)  
on.exit(close.socket(a))  
read.socket(a)  
}  
## Official time (UTC) from US Naval Observatory  
## Not run: daytime("tick.usno.navy.mil")

memory.size  
Report on Memory Allocation

Description

memory.size and memory.limit are used to manage the total memory allocation on Windows. On other platforms these are stubs which report infinity with a warning.

Usage

memory.size(max = FALSE)  
memory.limit(size = NA)

Arguments

max logical. If true the maximum amount of memory obtained from the OS is reported, otherwise the amount currently in use.

size numeric. If NA report the memory size, otherwise request a new limit, in Mb.

Details

To restrict memory usage on a Unix-alike use the facilities of the shell used to launch R, e.g. limit or ulimit.

Value

Size in bytes: always Inf.

See Also

Memory-limits for other limits.
**Menu Interaction Function**

**Description**

`menu` presents the user with a menu of choices labelled from 1 to the number of choices. To exit without choosing an item one can select ‘0’.

**Usage**

```
menu(choices, graphics = FALSE, title = NULL)
```

**Arguments**

- `choices` a character vector of choices
- `graphics` a logical indicating whether a graphics menu should be used if available.
- `title` a character string to be used as the title of the menu. `NULL` is also accepted.

**Details**

If `graphics = TRUE` and a windowing system is available (Windows, OS X or X11 via Tcl/Tk) a listbox widget is used, otherwise a text menu. It is an error to use `menu` in a non-interactive session.

Ten or fewer items will be displayed in a single column, more in multiple columns if possible within the current display width.

No title is displayed if `title` is `NULL` or `""`.

**Value**

The number corresponding to the selected item, or 0 if no choice was made.

**References**

**See Also**

`select.list`, which is used to implement the graphical menu, and allows multiple selections.

**Examples**

```r
## Not run:
switch(menu(c("List letters", "List LETTERS")) + 1,
       cat("Nothing done\n"), letters, LETTERS)

## End(Not run)
```
List Methods for S3 Generic Functions or Classes

Description
List all available methods for an S3 generic function, or all methods for a class.

Usage
methods(generic.function, class)

Arguments
generic.function
a generic function, or a character string naming a generic function.
class
a symbol or character string naming a class: only used if generic.function is not supplied.

Details
Function methods can be used to find out about the methods for a particular generic function or class. The functions listed are those which are named like methods and may not actually be methods (known exceptions are discarded in the code). Note that the listed methods may not be user-visible objects, but often help will be available for them.

If class is used, we check that a matching generic can be found for each user-visible object named. If generic.function is given, there is a warning if it appears not to be a generic function. (The check for being generic used can be fooled.)

Value
An object of class "MethodsFunction", a character vector of function names with an "info" attribute. There is a print method which marks with an asterisk any methods which are not visible: such functions can be examined by getS3method or getAnywhere.

The "info" attribute is a data frame, currently with a logical column, visible and a factor column from (indicating where the methods were found).

Note
This scheme is called S3 (S version 3). For new projects, it is recommended to use the more flexible and robust S4 scheme provided in the methods package. Functions can have both S3 and S4 methods, and function showMethods will list the S4 methods (possibly none).

The original methods function was written by Martin Maechler.

References
See Also

S3Methods, class, getS3method.
For S4, showMethods, Methods.

Examples

```r
require(stats)
methods(summary)
methods(class = "aov")
methods("[[")  # uses C-internal dispatching
methods("$")
methods("%<-%")  # replacement function
methods("**")  # binary operator
methods("Math")  # group generic
require(graphics)
methods("axis")  # looks like it has methods, but not generic
## Not run:
methods(print)  # over 100

## End(Not run)
## --> help(showMethods) for related examples
```

## mirrorAdmin

**Managing Repository Mirrors**

### Description

Functions helping to maintain CRAN, some of them may also be useful for administrators of other repository networks.

### Usage

```r
mirror2html(mirrors = NULL, file = "mirrors.html",
head = "mirrors-head.html", foot = "mirrors-foot.html")
checkCRAN(method)
```

### Arguments

- `mirrors`: A data frame, by default the CRAN list of mirrors is used.
- `file`: A connection or a character string.
- `head`: Name of optional header file.
- `foot`: Name of optional footer file.
- `method`: Download method, see `download.file`.

### Details

`mirror2html` creates the HTML file for the CRAN list of mirrors and invisibly returns the HTML text.

`checkCRAN` performs a sanity checks on all CRAN mirrors.
modifyList    

*Recursively Modify Elements of a List*

**Description**

Modifies a possibly nested list recursively by changing a subset of elements at each level to match a second list.

**Usage**

```r
modifyList(x, val, keep.null = FALSE)
```

**Arguments**

- `x` A named list, possibly empty.
- `val` A named list with components to replace corresponding components in `x`.
- `keep.null` If `TRUE`, NULL elements in `val` become NULL elements in `x`. Otherwise, the corresponding element, if present, is deleted from `x`.

**Value**

A modified version of `x`, with the modifications determined as follows (here, list elements are identified by their names). Elements in `val` which are missing from `x` are added to `x`. For elements that are common to both but are not both lists themselves, the component in `x` is replaced (or possibly deleted, depending on the value of `keep.null`) by the one in `val`. For common elements that are in both lists, `x[['name']]` is replaced by `modifyList(x[['name']], val[['name]])`.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**Examples**

```r
foo <- list(a = 1, b = list(c = "a", d = FALSE))
bar <- modifyList(foo, list(e = 2, b = list(d = TRUE)))
str(foo)
str(bar)
```

---

**news**    

*Build and Query R or Package News Information*

**Description**

Build and query the news for R or add-on packages.

**Usage**

```r
news(query, package = "R", lib.loc = NULL, format = NULL,
      reader = NULL, db = NULL)
```
Arguments

query: an expression for selecting news entries

package: a character string giving the name of an installed add-on package, or "R".

lib.loc: a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.

format: Not yet used.

reader: Not yet used.

db: a news db obtained from news().

Details

If package is "R" (default), a news db is built with the news since the 2.10.0 release of R (corresponding to R's top-level 'NEWS' file). Otherwise, if the given add-on package can be found in the given libraries, it is attempted to read its news in structured form from files 'inst/NEWS.Rd', 'NEWS' or 'inst/NEWS' (in that order).

File 'inst/NEWS.Rd' should be an Rd file given the entries as Rd itemize lists, grouped according to version using section elements with names starting with a suitable prefix (e.g., "Changes in version" followed by a space and the version number, and optionally followed by a space and a parenthesized ISO 8601 (%Y-%m-%d, see strptime) format date, and possibly further grouped according to categories using \subsection elements named as the categories.

The plain text 'NEWS' files in add-on packages use a variety of different formats; the default news reader should be capable to extract individual news entries from a majority of packages from the standard repositories, which use (slight variations of) the following format:

- Entries are grouped according to version, with version header "Changes in version" at the beginning of a line, followed by a version number, optionally followed by an ISO 8601 format date, possibly parenthesized.
- Entries may be grouped according to category, with a category header (different from a version header) starting at the beginning of a line.
- Entries are written as itemize-type lists, using one of 'o', '*', '-' or '+' as item tag. Entries must be indented, and ideally use a common indentation for the item texts.

Additional formats and readers may be supported in the future.

Package tools provides an (internal) utility function news2Rd to convert plain text 'NEWS' files to Rd. For 'NEWS' files in a format which can successfully be handled by the default reader, package maintainers can use tools::news2Rd(dir, "NEWS.Rd"), possibly with additional argument codify = TRUE, with dir a character string specifying the path to a package's root directory. Upon success, the 'NEWS.Rd' file can further be improved and then be moved to the 'inst' subdirectory of the package source directory.

The news db built is a character data frame inheriting from "news_db" with variables Version, Category, Date and Text, where the last contains the entry texts read, and the other variables may be NA if they were missing or could not be determined.

Using query, one can select news entries from the db. If missing or NULL, the complete db is returned. Otherwise, query should be an expression involving (a subset of) the variables Version, Category, Date and Text, and when evaluated within the db returning a logical vector with length the number of entries in the db. The entries for which evaluation gave TRUE are selected. When evaluating, Version and Date are coerced to numeric_version and Date objects, respectively, so that the comparison operators for these classes can be employed.
nsl

Value

An data frame inheriting from class "news_db".

Examples

## Build a db of all R news entries.
db <- news()

## Bug fixes with PR number in 2.11.0.
news(Version == "2.11.0" & grepl("^BUG", Category) & grepl("PR", Text),
    db = db)

## Which categories have been in use? % R-core maybe should standardize a bit more
## Entries with version >= 2.10.1 (including "2.10.1 patched"):
table(news(Version >= "2.10.1", db = db)$Version)

nsl

Look up the IP Address by Hostname

Description

Interface to gethostbyname.

Usage

nsl(hostname)

Arguments

hostname

the name of the host.

Details

This was included as a test of internet connectivity, to fail if the node running R is not connected. It will also return NULL if BSD networking is not supported, including the header file ‘arpa/inet.h’.

This function is not available on Windows.

Value

The IP address, as a character string, or NULL if the call fails.

Examples

## Not run: nsl("www.r-project.org")
object.size

Report the Space Allocated for an Object

Description

Provides an estimate of the memory that is being used to store an R object.

Usage

object.size(x)

## S3 method for class 'object.size'
print(x, quote = FALSE, units = "b", ...)

Arguments

x An R object.
quote logical, indicating whether or not the result should be printed with surrounding quotes.
units The units to be used in printing the size. Allowed values are "b", "Kb", "Mb", "Gb", "B", "KB", "MB", "GB", and "auto" (see ‘Details’).
... Arguments to be passed to or from other methods.

Details

Exactly which parts of the memory allocation should be attributed to which object is not clear-cut. This function merely provides a rough indication: it should be reasonably accurate for atomic vectors, but does not detect if elements of a list are shared, for example. (Sharing amongst elements of a character vector is taken into account, but not that between character vectors in a single object.)

The calculation is of the size of the object, and excludes the space needed to store its name in the symbol table.

Associated space (e.g. the environment of a function and what the pointer in an EXTPTSTRXP points to) is not included in the calculation.

Object sizes are larger on 64-bit builds than 32-bit ones, but will very likely be the same on different platforms with the same word length and pointer size.

units = "auto" in the print method chooses the largest units in which the result is one or more (before rounding). Values in kilobytes, megabytes or gigabytes are rounded to the nearest 0.1.

Value

An object of class "object.size" with a length-one double value, an estimate of the memory allocation attributable to the object in bytes.

See Also

Memory-limits for the design limitations on object size.
package.skeleton

Examples

```r
object.size(letters)
object.size(ls)
print(object.size(library), units = "auto")
### find the 10 largest objects in the base package
z <- sapply(ls("package:base"), function(x)
    object.size(get(x, envir = baseenv())))
as.matrix(rev(sort(z))[1:10])
```

Description

package.skeleton automates some of the setup for a new source package. It creates directories, saves functions, data, and R code files to appropriate places, and creates skeleton help files and a 'Read-and-delete-me' file describing further steps in packaging.

Usage

```r
package.skeleton(name = "anRpackage", list,
    environment = .GlobalEnv,
    path = ".", force = FALSE, namespace = TRUE,
    code_files = character())
```

Arguments

- **name**: character string: the package name and directory name for your package.
- **list**: character vector naming the R objects to put in the package. Usually, at most one of list, environment, or code_files will be supplied. See 'Details'.
- **environment**: an environment where objects are looked for. See 'Details'.
- **path**: path to put the package directory in.
- **force**: If FALSE will not overwrite an existing directory.
- **namespace**: a logical, no longer used, and hence deprecated.
- **code_files**: a character vector with the paths to R code files to build the package around. See 'Details'.

Details

The arguments list, environment, and code_files provide alternative ways to initialize the package. If code_files is supplied, the files so named will be sourced to form the environment, then used to generate the package skeleton. Otherwise list defaults to the objects in environment (including those whose names start with .), but can be supplied to select a subset of the objects in that environment.

Stubs of help files are generated for functions, data objects, and S4 classes and methods, using the `prompt.promptClass` and `promptMethods` functions.

The package sources are placed in subdirectory name of path. If code_files is supplied, these files are copied; otherwise, objects will be dumped into individual source files. The file names in code_files should have suffix " .R" and be in the current working directory.
The filenames created for source and documentation try to be valid for all OSes known to run R. Invalid characters are replaced by ‘_', invalid names are preceded by ‘zz’, names are converted to lower case (to avoid case collisions on case-insensitive file systems) and finally the converted names are made unique by `make.unique(sep = "\_")`. This can be done for code and help files but not data files (which are looked for by name). Also, the code and help files should have names starting with an ASCII letter or digit, and this is checked and if necessary z prepended.

Functions with names starting with a dot are placed in file ‘R/name\_internal.R’.

When you are done, delete the ‘Read-and-delete-me’ file, as it should not be distributed.

**Value**

Used for its side-effects.

**References**

Read the ‘Writing R Extensions’ manual for more details.

Once you have created a *source* package you need to install it: see the ‘R Installation and Administration’ manual, *INSTALL* and *install.packages*.

**See Also**

`prompt`, `promptClass`, and `promptMethods`.

**Examples**

```r
require(stats)

## two functions and two "data sets"

f <- function(x, y) x+y
g <- function(x, y) x-y
d <- data.frame(a = 1, b = 2)
e <- rnorm(1000)

package.skeleton(list = c("f","g","d","e"), name = "mypkg")
```

---

**packageDescription**

**Package Description**

**Description**

Parses and returns the ‘DESCRIPTION’ file of a package.

**Usage**

```r
packageDescription(pkg, lib.loc = NULL, fields = NULL, 
                  drop = TRUE, encoding = "")
packageVersion(pkg, lib.loc = NULL)
```
Arguments

pkg  a character string with the package name.

lib.loc  a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.

fields  a character vector giving the tags of fields to return (if other fields occur in the file they are ignored).

drop  If TRUE and the length of fields is 1, then a single character string with the value of the respective field is returned instead of an object of class "packageDescription".

encoding  If there is an Encoding field, to what encoding should re-encoding be attempted? If NA, no re-encoding. The other values are as used by iconv, so the default "" indicates the encoding of the current locale.

Details

A package will not be ‘found’ unless it has a ‘DESCRIPTION’ file which contains a valid Version field. Different warnings are given when no package directory is found and when there is a suitable directory but no valid ‘DESCRIPTION’ file.

An attached environment named to look like a package (e.g. package:utils) will be ignored.

packageVersion() is a convenience shortcut, allowing things like if (packageVersion("MASS") < "7.3") { do.things }.

Value

If a ‘DESCRIPTION’ file for the given package is found and can successfully be read, packageDescription returns an object of class "packageDescription", which is a named list with the values of the (given) fields as elements and the tags as names, unless drop = TRUE.

If parsing the ‘DESCRIPTION’ file was not successful, it returns a named list of NAs with the field tags as names if fields is not null, and NA otherwise.

packageVersion() returns a (length-one) object of class "package_version".

See Also

read.dcf

Examples

packageDescription("stats")
packageDescription("stats", fields = c("Package", "Version"))

packageDescription("stats", fields = "Version")
packageDescription("stats", fields = "Version", drop = FALSE)

if(packageVersion("MASS") < "7.3")
  message("you need to update 'MASS'")
**packageName**

*Find package associated with an environment.*

**Description**

Many environments are associated with a package; this function attempts to determine that package.

**Usage**

```r
className(env = parent.frame())
```

**Arguments**

- `env` The environment whose name we seek.

**Details**

Environment `env` would be associated with a package if `topenv(env)` is the namespace environment for that package. Thus when `env` is the environment associated with functions inside a package, or local functions defined within them, `packageName` will normally return the package name.

Not all environments are associated with a package: for example, the global environment, or the evaluation frames of functions defined there. `packageName` will return `NULL` in these cases.

**Value**

A length one character vector containing the name of the package, or `NULL` if there is no name.

**See Also**

- `getPackageName` is a more elaborate function that can construct a name if none is found.

**Examples**

```r
packageName()
packageName(environment(mean))
```

---

**packageStatus**

*Package Management Tools*

**Description**

Summarize information about installed packages and packages available at various repositories, and automatically upgrade outdated packages.
**Usage**

```r
downloads <- packageStatus(lib.loc = NULL, repositories = NULL, method = getOption("pkgType"))
```

**Arguments**

- `lib.loc` a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known.
- `repositories` a character vector of URLs describing the location of R package repositories on the Internet or on the local machine.
- `method` Download method, see `download.file`.
- `type` type of package distribution: see `install.packages`.
- `object` an object of class "packageStatus" as returned by `packageStatus`.
- `ask` if TRUE, the user is prompted which packages should be upgraded and which not.
- `...` currently not used.

**Details**

The URLs in `repositories` should be full paths to the appropriate contrib sections of the repositories. The default is `contrib.url(getOption("repos"))`.

There are print and summary methods for the "packageStatus" objects: the print method gives a brief tabular summary and the summary method prints the results.

The update method updates the "packageStatus" object. The upgrade method is similar to `update.packages`: it offers to install the current versions of those packages which are not currently up-to-date.

**Value**

An object of class "packageStatus". This is a list with two components

- `inst` a data frame with columns as the `matrix` returned by `installed.packages` plus "Status", a factor with levels c("ok", "upgrade"). Only the newest version of each package is reported, in the first repository in which it appears.
- `avail` a data frame with columns as the `matrix` returned by `available.packages` plus "Status", a factor with levels c("installed", "not installed", "unavailable").

For the summary method the result is also of class "summary.packageStatus" with additional components.
Libs a list with one element for each library
Repos a list with one element for each repository

with the elements being lists of character vectors of package name for each status.

See Also

installed.packages, available.packages

Examples

## Not run:
x <- packageStatus()
print(x)
summary(x)
upgrade(x)
x <- update(x)
print(x)

## End(Not run)

page

Invoke a Pager on an R Object

Description

Displays a representation of the object named by x in a pager via file.show.

Usage

page(x, method = c("dput", "print"), ...)

Arguments

x An R object, or a character string naming an object.
method The default method is to dump the object via dput. An alternative is to use
print and capture the output to be shown in the pager.
... additional arguments for dput, print or file.show (such as title).

Details

If x is a length-one character vector, it is used as the name of an object to look up in the environment
from which page is called. All other objects are displayed directly.

A default value of title is passed to file.show if one is not supplied in ....

See Also

file.show, edit, fix.

To go to a new page when graphing, see frame.
Examples

```r
## Not run: ## four ways to look at the code of 'page'
person(page) # as an object
page("page") # a character string
v <- "page"; page(v) # a length-one character vector
page(utilities::page) # a call

## End(Not run)
```

## person Persons

**Description**

A class and utility methods for holding information about persons like name and email address.

**Usage**

```r
person(given = NULL, family = NULL, middle = NULL,
       email = NULL, role = NULL, comment = NULL,
       first = NULL, last = NULL)

## Default S3 method:
as.person(x)

## S3 method for class 'person'
format(x,
       include = c("given", "family", "email", "role", "comment"),
       braces = list(given = "", family = "", email = c("<", ">"),
                     role = c("[", "]"), comment = c("("", ")")),
       collapse = list(given = " ", family = " ", email = " ",
                      role = " ", comment = " ",
                      ...
                      )
)
```

**Arguments**

- `given`: a character vector with the `given` names, or a list thereof.
- `family`: a character string with the `family` name, or a list thereof.
- `middle`: a character string with the collapsed middle name(s). Deprecated, see `Details`.
- `email`: a character string giving the email address, or a list thereof.
- `role`: a character string specifying the role of the person (see `Details`), or a list thereof.
- `comment`: a character string providing a comment, or a list thereof.
- `first`: a character string giving the first name. Deprecated, see `Details`.
- `last`: a character string giving the last name. Deprecated, see `Details`.
- `x`: a character string for the `as.person` default method; an object of class "person" otherwise.
- `include`: a character vector giving the fields to be included when formatting.
- `braces`: a list of characters (see `Details`).
- `collapse`: a list of characters (see `Details`).
- ... currently not used.
Details

Objects of class "person" can hold information about an arbitrary positive number of persons. These can be obtained by one call to `person()` with list arguments, or by first creating objects representing single persons and combining these via `c()`.

The `format()` method collapses information about persons into character vectors (one string for each person): the fields include are selected, each collapsed to a string using the respective element of `collapse` and subsequently “embraced” using the respective element of braces, and finally collapsed into one string separated by white space. If braces and/or `collapse` do not specify characters for all fields, the defaults shown in the usage are imputed. The `print()` method calls the `format()` method and prints the result, the `toBibTeX()` method creates a suitable BibTeX representation.

Person objects can be subscripted by fields (using `[]`) or by position (using `[[]`). `as.person()` is a generic function. Its default method tries to reverse the default person formatting, and can also handle formatted person entries collapsed by comma or "and" (with appropriate white space).

Personal names are rather tricky, e.g., http://en.wikipedia.org/wiki/Personal_name.

The current implementation (starting from R 2.12.0) of the "person" class uses the notions of `given` (including middle names) and `family` names, as specified by `given` and `family` respectively. Earlier versions used a scheme based on first, middle and last names, as appropriate for most of Western culture where the given name precedes the family name, but not universal, as some other cultures place it after the family name, or use no family name. To smooth the transition to the new scheme, arguments `first`, `middle` and `last` are still supported, but their use is deprecated and they must not be given in combination with the corresponding new style arguments.

The new scheme also adds the possibility of specifying roles based on a subset of the MARC Value List for Relators and Roles (http://www.loc.gov/standards/sourcelist/relator-role.html). When giving the roles of persons in the context of authoring R packages, the following usage is suggested.

"aut" (Author) Use for full authors who have made substantial contributions to the package and should show up in the package citation.

"com" (Compiler) Use for persons who collected code (potentially in other languages) but did not make further substantial contributions to the package.

"ctb" (Contributor) Use for authors who have made smaller contributions (such as code patches etc.) but should not show up in the package citation.

"cph" (Copyright holder) Use for all copyright holders.

"cre" (Creator) Use for the package maintainer.

"ths" (Thesis advisor) If the package is part of a thesis, use for the thesis advisor.

"trl" (Translator) If the R code is a translation from another language (typically S), use for the translator to R.

In the old scheme, person objects were used for single persons, and a separate "personList" class with corresponding creator `personList()` for collections of these. The new scheme employ a single class for information about an arbitrary positive number of persons, eliminating the need for the `personList` mechanism.

Value

`person()` and `as.person()` return objects of class "person".

citation

Examples

## Create a person object directly ...
p1 <- person("Karl", "Pearson", email = "pearson@stats.heaven")

## ... or convert a string.
p2 <- as.person("Ronald Aylmer Fisher")

## Combining and subsetting.
p <- c(p1, p2)
p[1]
p[-1]

## Extracting fields.
p$family
p$email
p[1]$email

## Specifying package authors, example from "boot":
## AC is the first author [aut] who wrote the S original.
## BR is the second author [aut], who translated the code to R [trl],
## and maintains the package [cre].
b <- c(person("Angelo", "Canty", role = "aut", comment =
    "S original, http://statwww.epfl.ch/davison/BMA/library.html"),
    person(c("Brian", "D."), "Ripley", role = c("aut", "trl", "cre"),
    comment = "R port", email = "ripley@stats.ox.ac.uk")
    )

b

## Formatting.
format(b)
format(b, include = c("family", "given", "role"),
    braces = list(family = c("", ","), role = c("(Role(s): ", ")")
    )

## Conversion to BibTeX author field.
paste(format(b, include = c("given", "family")), collapse = " and ")
toBibtex(b)
process.events

Arguments

pkgdirs a list of names of directories with sources of R add-on packages. For check these can also be the filenames of compressed tar archives with extension '.tar.gz', '.tgz', '.tar.bz2' or '.tar.xz'.

options further options to control the processing, or for obtaining information about usage and version of the utility.

Details

R CMD check checks R add-on packages from their sources, performing a wide variety of diagnostic checks.

R CMD build builds R source tarballs. The name(s) of the packages are taken from the 'DESCRIPTION' files and not from the directory names. This works entirely on a copy of the supplied source directories.

Use R CMD foo --help to obtain usage information on utility foo.

The defaults for some of the options to R CMD build can be set by environment variables _R_BUILD_RESAVE_DATA_ and _R_BUILD_COMPACT_VIGNETTES_: see ‘Writing R Extensions’. Many of the checks in R CMD check can be turned off or on by environment variables: see Chapter 6 of the ‘R Internals’ manual.

By default R CMD build uses the “internal” option to tar to prepare the tarball. An external tar program can be specified by the R_BUILD_TAR environment variable. This may be substantially faster for very large packages, and can be needed for packages with long path names (over 100 bytes) or very large files (over 8GB): however, the resulting tarball may not be portable.

R CMD check by default unpacks tarballs by the internal untar function: if needed an external tar command can be specified by the environment variable R_INSTALL_TAR: please ensure that it can handle the type of compression used on the tarball. (This is sometimes needed for tarballs containing invalid or unsupported sections, and can be faster on very large tarballs. Setting R_INSTALL_TAR to 'tar.exe' has been needed to overcome permissions issues on some Windows systems.)

The sections on “Checking and building packages” and “Processing Rd format” in “Writing R Extensions” (see the ‘doc/manual’ subdirectory of the R source tree).

process.events  Trigger event handling

Description

R front ends like the Windows GUI handle key presses and mouse clicks through “events” generated by the OS. These are processed automatically by R at intervals during computations, but in some cases it may be desirable to trigger immediate event handling. The process.events function does that.

Usage

process.events()
Details

This is a simple wrapper for the C API function `r_processEvents`. As such, it is possible that it will not return if the user has signalled to interrupt the calculation.

Value

NULL is returned invisibly.

Author(s)

Duncan Murdoch

prompt  Produce Prototype of an R Documentation File

Description

Facilitate the constructing of files documenting R objects.

Usage

```r
prompt(object, filename = NULL, name = NULL, ...) # Default S3 method:
prompt(object, filename = NULL, name = NULL,
       force.function = FALSE, ...)

# S3 method for class 'data.frame'
prompt(object, filename = NULL, name = NULL, ...)
```

Arguments

- `object`  an R object, typically a function for the default method. Can be `missing` when name is specified.
- `filename`  usually, a `connection` or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is `name` followed by "\.Rd". Can also be `NA` (see below).
- `name`  a character string specifying the name of the object.
- `force.function`  a logical. If `TRUE`, treat `object` as function in any case.
- `...`  further arguments passed to or from other methods.
Details

Unless filename is NA, a documentation shell for object is written to the file specified by filename, and a message about this is given. For function objects, this shell contains the proper function and argument names. R documentation files thus created still need to be edited and moved into the 'man' subdirectory of the package containing the object to be documented.

If filename is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n"), where x is the list-style representation.

When prompt is used in for loops or scripts, the explicit name specification will be useful.

Value

If filename is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

Warning

The default filename may not be a valid filename under limited file systems (e.g. those on Windows). Currently, calling prompt on a non-function object assumes that the object is in fact a data set and hence documents it as such. This may change in future versions of R. Use promptData to create documentation skeletons for data sets.

Note

The documentation file produced by prompt.data.frame does not have the same format as many of the data frame documentation files in the base package. We are trying to settle on a preferred format for the documentation.

Author(s)

Douglas Bates for prompt.data.frame

For creation of many help pages (for a package), see package.skeleton.

To prompt the user for input, see readline.

Examples

```r
require(graphics)
prompt(plot.default)
prompt(interactive, force.function = TRUE)
unlink("plot.default.Rd")
unlink("interactive.Rd")
```
promptData

Generate Outline Documentation for a Data Set

Description
Generate a shell of documentation for a data set.

Usage
promptData(object, filename = NULL, name = NULL)

Arguments
object an \texttt{R} object to be documented as a data set.
filename usually, a \texttt{connection} or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is name followed by \`.Rd\'. Can also be \texttt{NA} (see below).
name a character string specifying the name of the object.

Details
Unless \texttt{filename} is \texttt{NA}, a documentation shell for \texttt{object} is written to the file specified by \texttt{filename}, and a message about this is given.
If \texttt{filename} is \texttt{NA}, a list-style representation of the documentation shell is created and returned.
Writing the shell to a file amounts to \texttt{cat(unlist(x), file = filename, sep = "\n"), where \texttt{x} is the list-style representation.
Currently, only data frames are handled explicitly by the code.

Value
If \texttt{filename} is \texttt{NA}, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

prompt
Examples

```r
promptData(sunspots)
unlink("sunspots.Rd")
```

---

**promptPackage**

*Generate a Shell for Documentation of a Package*

**Description**

Generates a shell of documentation for an installed or source package.

**Usage**

```r
promptPackage(package, lib.loc = NULL, filename = NULL,
               name = NULL, final = FALSE)
```

**Arguments**

- `package` a character string with the name of an *installed* or *source* package to be documented.
- `lib.loc` a character vector describing the location of R library trees to search through, or `NULL`. The default value of `NULL` corresponds to all libraries currently known. For a source package this should specify the parent directory of the package’s sources.
- `filename` usually, a *connection* or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is `name` followed by "Rd". Can also be `NA` (see below).
- `name` a character string specifying the name of the help topic, typically of the form `<pkg>-package`.
- `final` a logical value indicating whether to attempt to create a usable version of the help topic, rather than just a shell.

**Details**

Unless `filename` is `NA`, a documentation shell for `package` is written to the file specified by `filename`, and a message about this is given.

If `filename` is `NA`, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n"), where x is the list-style representation.

If `final` is `TRUE`, the generated documentation will not include the place-holder slots for manual editing, it will be usable as-is. In most cases a manually edited file is preferable (but `final = TRUE` is certainly less work).

**Value**

If `filename` is `NA`, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.
See Also

`prompt`

Examples

```r
filename <- tempfile()
promptPackage("utils", filename = filename)
file.show(filename)
unlink(filename)
```

Description

These functions provide access to documentation. Documentation on a topic with name `name` (typically, an R object or a data set) can be displayed by either `help("name")` or `?name`.

Usage

```r
?topic
type?topic
```

Arguments

`topic`

Usually, a `name` or character string specifying the topic for which help is sought. Alternatively, a function call to ask for documentation on a corresponding S4 method: see the section on S4 method documentation. The calls `pkg:::topic` and `pkg:::topic` are treated specially, and look for help on `topic` in package `pkg`.

`type`

dohe special type of documentation to use for this topic; for example, if the type is `class`, documentation is provided for the class with name `topic`. See the Section ‘S4 Method Documentation’ for the uses of `type` to get help on formal methods, including `methods?function` and `method?call`.

Details

This is a shortcut to `help` and uses its default type of help.

Some topics need to be quoted (by `backticks`) or given as a character string. There include those which cannot syntactically appear on their own such as unary and binary operators, `function` and control-flow `reserved` words (including `if`, `else` for, `in`, `repeat`, `while`, `break` and `next`. The other `reserved` words can be used as if they were names, for example `TRUE, NA and Inf`. 
S4 Method Documentation

Authors of formal ('S4') methods can provide documentation on specific methods, as well as overall documentation on the methods of a particular function. The "?" operator allows access to this documentation in three ways.

The expression `methods?f` will look for the overall documentation methods for the function `f`. Currently, this means the documentation file containing the alias `f-methods`.

There are two different ways to look for documentation on a particular method. The first is to supply the `topic` argument in the form of a function call, omitting the `type` argument. The effect is to look for documentation on the method that would be used if this function call were actually evaluated. See the examples below. If the function is not a generic (no S4 methods are defined for it), the help reverts to documentation on the function name.

The "?" operator can also be called with `doc_type` supplied as `method`; in this case also, the `topic` argument is a function call, but the arguments are now interpreted as specifying the class of the argument, not the actual expression that will appear in a real call to the function. See the examples below.

The first approach will be tedious if the actual call involves complicated expressions, and may be slow if the arguments take a long time to evaluate. The second approach avoids these issues, but you do have to know what the classes of the actual arguments will be when they are evaluated.

Both approaches make use of any inherited methods; the signature of the method to be looked up is found by using `selectMethod` (see the documentation for `getMethod`).

`help`  
`??` for finding help pages on a vague topic.

Examples

```r
?lapply

?"for"  # but quotes/backticks are needed
?`+`

?women  # information about data set "women"

## Not run:
require(methods)
## define a S4 generic function and some methods
combo <- function(x, y) c(x, y)
setGeneric("combo")
setMethod("combo", c("numeric", "numeric"), function(x, y) x+y)

## assume we have written some documentation
## for combo, and its methods ....

?combo  # produces the function documentation
```
methods?combo # looks for the overall methods documentation
method?combo("numeric", "numeric") # documentation for the method above
?combo(1:10, rnorm(10)) # ... the same method, selected according to
# the arguments (one integer, the other numeric)
?combo(1:10, letters) # documentation for the default method
## End(Not run)

A Completion Generator for R

Description

This page documents a mechanism to generate relevant completions from a partially completed command line. It is not intended to be useful by itself, but rather in conjunction with other mechanisms that use it as a backend. The functions listed in the usage section provide a simple control and query mechanism. The actual interface consists of a few unexported functions described further down.

Usage

rc.settings(ops, ns, args, func, ipck, S3, data, help,
    argdb, quotes, files)
rc.status()
rc.getOption(name)
rc.options(...)
.DollarNames(x, pattern)

## Default S3 method:
.DollarNames(x, pattern = "")
## S3 method for class 'list'
.DollarNames(x, pattern = "")
## S3 method for class 'environment'
.DollarNames(x, pattern = "")

Arguments

ops, ns, args, func, ipck, S3, data, help, argdb, quotes, files
    logical, turning some optional completion features on and off.
ops: Activates completion after the $ and @ operators.
ns: Controls namespace related completions.
args: Enables completion of function arguments.
func: Enables detection of functions. If enabled, a customizable extension ("f" by default) is appended to function names. The process of determining whether a potential completion is a function requires evaluation, including
for lazy loaded symbols. This is undesirable for large objects, because of potentially wasteful use of memory in addition to the time overhead associated with loading. For this reason, this feature is disabled by default.

S3: When \texttt{args} = \texttt{TRUE}, activates completion on arguments of all S3 methods (otherwise just the generic, which usually has very few arguments).

\texttt{ipck}: Enables completion of installed package names inside \texttt{library} and \texttt{require}.

\texttt{data}: Enables completion of data sets (including those already visible) inside \texttt{data}.

\texttt{help}: Enables completion of help requests starting with a question mark, by looking inside help index files.

\texttt{argdb}: When \texttt{args} = \texttt{TRUE}, completion is attempted on function arguments. Generally, the list of valid arguments is determined by dynamic calls to \texttt{args}. While this gives results that are technically correct, the use of the \ldots argument often hides some useful arguments. To give more flexibility in this regard, an optional table of valid arguments names for specific functions is retained internally. Setting \texttt{argdb} = \texttt{TRUE} enables preferential lookup in this internal data base for functions with an entry in it. Of course, this is useful only when the data base contains information about the function of interest. Some functions are already included, and more can be added by the user through the unexported function \texttt{addFunctionInfo} (see below).

\texttt{quotes}: Enables completion in R code when inside quotes. This normally leads to filename completion, but can be otherwise depending on context (for example, when the open quote is preceded by \texttt{?}, help completion is invoked. Setting this to \texttt{FALSE} relegates completion to the underlying completion front-end, which may do its own processing (for example, \texttt{readline} on Unix-alikes will do filename completion).

\texttt{files}: Deprecated. Use \texttt{quotes} instead.

All settings are turned on by default except \texttt{ipck} and \texttt{func}. Turn more off if your CPU cycles are valuable; you will still retain basic completion on names of objects in the search list. See below for additional details.

name, \ldots user-settable options. Currently valid names are

\texttt{function.suffix}: default "("  
\texttt{funarg.suffix}: default " = "  
\texttt{package.suffix} default "::"

Usage is similar to that of \texttt{options}.

\texttt{x} An R object for which valid names after "$" are computed and returned.

\texttt{pattern} A regular expression. Only matching names are returned.

\textbf{Details}

There are several types of completion, some of which can be disabled using \texttt{rc.settings}. The most basic level, which can not be turned off once the completion functionality is activated, provides completion on names visible on the search path, along with a few special keywords (e.g. \texttt{TRUE}). This type of completion is not attempted if the partial ‘word’ (a.k.a. token) being completed is empty (since there would be too many completions). The more advanced types of completion are described below.
Completion after extractors $ and @: When the $ps setting is turned on, completion after $ and @ is attempted. This requires the prefix to be evaluated, which is attempted unless it involves an explicit function call (implicit function calls involving the use of [, $, etc do not inhibit evaluation).

Valid completions after the $ extractor are determined by the generic function .DollarNames. Some basic methods are provided, and more can be written for custom classes.

Completion inside namespaces: When the ns setting is turned on, completion inside namespaces is attempted when a token is preceded by the :: or ::: operators. Additionally, the basic completion mechanism is extended to include attached namespaces, or more precisely, f@opkg:: becomes a valid completion of foo if the return value of search() includes the string “package: fopkg”.

The completion of package namespaces applies only to attached packages, i.e. if MASS is not attached (whether or not it is loaded), MASS will not complete to MASS:::. However, attempted completion inside an apparent namespace will attempt to load the namespace if it is not already loaded, e.g. trying to complete on MASS:::f will load MASS (but not necessarily attach it) even if it is not already loaded.

Completion for help items: When the help setting is turned on, completion on help topics is attempted when a token is preceded by _. Prefixes (such as class, method) are supported, as well as quoted help topics containing special characters.

Completion of function arguments: When the args setting is turned on, completion on function arguments is attempted whenever deemed appropriate. The mechanism used will currently fail if the relevant function (at the point where completion is requested) was entered on a previous prompt (which implies in particular that the current line is being typed in response to a continuation prompt, usually +). Note that separation by newlines is fine.

The list of possible argument completions that is generated can be misleading. There is no problem for non-generic functions (except that ... is listed as a completion; this is intentional as it signals the fact that the function can accept further arguments). However, for generic functions, it is practically impossible to give a reliable argument list without evaluating arguments (and not even then, in some cases), which is risky (in addition to being difficult to code, which is the real reason it hasn’t even been tried), especially when that argument is itself an inline function call. Our compromise is to consider arguments of all currently available methods of that generic. This has two drawbacks. First, not all listed completions may be appropriate in the call currently being constructed. Second, for generics with many methods (like print and plot), many matches will need to be considered, which may take a noticeable amount of time. Despite these drawbacks, we believe this behaviour to be more useful than the only other practical alternative, which is to list arguments of the generic only.

Only S3 methods are currently supported in this fashion, and that can be turned off using the sS setting.

Since arguments can be unnamed in R function calls, other types of completion are also appropriate whenever argument completion is. Since there are usually many many more visible objects than formal arguments of any particular function, possible argument completions are often buried in a bunch of other possibilities. However, recall that basic completion is suppressed for blank tokens. This can be useful to list possible arguments of a function. For example, trying to complete seq([TAB] and seq(from = 1, [TAB]) will both list only the arguments of seq (or any of its methods), whereas trying to complete seq(length[TAB] will list both the length.out argument and the length() function as possible completions. Note that no attempt is made to remove arguments already supplied, as that would incur a further speed penalty.

Special functions: For a few special functions (library, data, etc), the first argument is treated specially, in the sense that normal completion is suppressed, and some function specific completions are enabled if so requested by the settings. The ipck setting, which controls whether
library and require will complete on installed packages, is disabled by default because the first call to installed.packages is potentially time consuming (e.g. when packages are installed on a remote network file server). Note, however, that the results of a call to installed.packages is cached, so subsequent calls are usually fast, so turning this option on is not particularly onerous even in such situations.

Value

If rc.settings is called without any arguments, it returns the current settings as a named logical vector. Otherwise, it returns NULL invisibly.

rc.status returns, as a list, the contents of an internal (unexported) environment that is used to record the results of the last completion attempt. This can be useful for debugging. For such use, one must resist the temptation to use completion when typing the call to rc.status itself, as that then becomes the last attempt by the time the call is executed.

The items of primary interest in the returned list are:

- comps: The possible completions generated by the last call to .completeToken, as a character vector.
- token: The token that was (or, is to be) completed, as set by the last call to .assignToken (possibly inside a call to .guessTokenFromLine).
- linebuffer: The full line, as set by the last call to .assignLinebuffer.
- start: The start position of the token in the line buffer, as set by the last call to .assignStart.
- end: The end position of the token in the line buffer, as set by the last call to .assignEnd.
- fileName: Logical, indicating whether the cursor is currently inside quotes.
- fgue: The name of the function the cursor is currently inside.
- isFirstArg: Logical. If cursor is inside a function, is it the first argument?

In addition, the components settings and options give the current values of settings and options respectively.

rc.getOption and rc.options behave much like getopt and options respectively.

Unexported API

There are several unexported functions in the package. Of these, a few are special because they provide the API through which other mechanisms can make use of the facilities provided by this package (they are unexported because they are not meant to be called directly by users). The usage of these functions are:

```
.assignToken(text)
.assignLinebuffer(line)
.assignStart(start)
.assignEnd(end)

.completeToken()
.retrieveCompletions()
.getFileComp()

.guessTokenFromLine()
```
.win32consoleCompletion(linebuffer, cursorPosition, 
  check.repeat = TRUE, 
  minlength = -1)

.addFunctionInfo(...)

The first four functions set up a completion attempt by specifying the token to be completed (text),
and indicating where (start and end, which should be integers) the token is placed within the
complete line typed so far (line).

Potential completions of the token are generated by .completeToken, and the completions can be
retrieved as an R character vector using .retrieveCompletions.

If the cursor is inside quotes, completion may be suppressed. The function .getFileComp can be
used after a call to .completeToken to determine if this is the case (returns TRUE), and alternative
completions generated as deemed useful. In most cases, filename completion is a reasonable fallback.

The .guessTokenFromLine function is provided for use with backends that do not already break a
line into tokens. It requires the linebuffer and endpoint (cursor position) to be already set, and itself
sets the token and the start position. It returns the token as a character string.

The .win32consoleCompletion is similar in spirit, but is more geared towards the Windows GUI
(or rather, any front-end that has no completion facilities of its own). It requires the linebuffer
and cursor position as arguments, and returns a list with three components, addition, possible
and comps. If there is an unambiguous extension at the current position, addition contains the
additional text that should be inserted at the cursor. If there is more than one possibility, these are
available either as a character vector of preformatted strings in possible, or as a single string in
comps. possible consists of lines formatted using the current width option, so that printing them
on the console one line at a time will be a reasonable way to list them. comps is a space separated
(collapsed) list of the same completions, in case the front-end wishes to display it in some other
fashion.

The minlength argument can be used to suppress completion when the token is too short (which can
be useful if the front-end is set up to try completion on every keypress). If check.repeat is TRUE,
it is detected if the same completion is being requested more than once in a row, and ambiguous
completions are returned only in that case. This is an attempt to emulate GNU Readline behaviour,
where a single TAB completes up to any unambiguous part, and multiple possibilities are reported
only on two consecutive TABs.

As the various front-end interfaces evolve, the details of these functions are likely to change as well.
The function .addFunctionInfo can be used to add information about the permitted argument
names for specific functions. Multiple named arguments are allowed in calls to it, where the tags
are names of functions and values are character vectors representing valid arguments. When the
argdb setting is TRUE, these are used as a source of valid argument names for the relevant functions.

Note

If you are uncomfortable with unsolicited evaluation of pieces of code, you should set ops = FALSE.
Otherwise, trying to complete foo@ba will evaluate foo, trying to complete foo[i, 1:10]@ba will
evaluate foo[i, 1:10], etc. This should not be too bad, as explicit function calls (involving
parentheses) are not evaluated in this manner. However, this will affect promises and lazy loaded
symbols.

Author(s)

Deepayan Sarkar, <deepayan.sarkar@r-project.org>
Description

Reads a file in Data Interchange Format (DIF) and creates a data frame from it. DIF is a format for data matrices such as single spreadsheets.

Usage

read.DIF(file, header = FALSE,
        dec = ".", row.names, col.names,
        as.is = !stringsAsFactors,
        na.strings = "NA", colClasses = NA, nrow = -1,
        skip = 0, check.names = TRUE,
        blank.lines.skip = TRUE,
        stringsAsFactors = default.stringsAsFactors(),
        transpose = FALSE)

Arguments

file        the name of the file which the data are to be read from, or a connection, or a complete URL.
            The name "clipboard" may also be used on Windows, in which case read.DIF("clipboard") will look for a DIF format entry in the Windows clipboard.
header      a logical value indicating whether the spreadsheet contains the names of the variables as its first line. If missing, the value is determined from the file format: header is set to TRUE if and only if the first row contains only character values and the top left cell is empty.
dec         the character used in the file for decimal points.
row.names   a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names. If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if row.names is missing, the rows are numbered. Using row.names = NULL forces row numbering.
col.names   a vector of optional names for the variables. The default is to use "V" followed by the column number.
as.is       the default behavior of read.DIF is to convert character variables to factors. The variable as.is controls the conversion of columns not otherwise specified by colClasses. Its value is either a vector of logicals (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors.
            Note: In releases prior to R 2.12.1, cells marked as being of character type were converted to logical, numeric or complex using type.convert as in read.table.
Note: to suppress all conversions including those of numeric columns, set `colClasses = "character".

Note that `as.is` is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.

**Value**

A data frame (data.frame) containing a representation of the data in the file. Empty input is an error unless `col.names` is specified, when a 0-row data frame is returned: similarly giving just a header line if `header = TRUE` results in a 0-row data frame.

**Note**

The columns referred to in `as.is` and `colClasses` include the column of row names (if any).

Less memory will be used if `colClasses` is specified as one of the six atomic vector classes.

**Author(s)**

R Core; transpose option by Christoph Buser, ETH Zurich
References

The DIF format specification can be found by searching on http://www.wotsit.org/; the optional header fields are ignored. See also http://en.wikipedia.org/wiki/Data_Exchange_Format.

The term is likely to lead to confusion: Windows will have a ‘Windows Data Interchange Format (DIF) data format’ as part of its WinFX system, which may or may not be compatible.

See Also

The R Data Import/Export manual.

scan, type.convert, read.fwf for reading fixed width formatted input; read.table; data.frame.

Examples

```r
## read.DIF() needs transpose = TRUE for file exported from Excel
dir <- system.file("misc", package = "utils")
dd <- read.DIF(file.path(dir, "exDIF.dif"), header = TRUE, transpose = TRUE)
dc <- read.csv(file.path(dir, "exDIF.csv"), header = TRUE)
stopifnot(identical(dd, dc), dim(dd) == c(4,2))
```

**Description**

Read fixed-format data files using Fortran-style format specifications.

**Usage**

```r
read.fortran(file, format, ..., as.is = TRUE, colClasses = NA)
```

**Arguments**

- `file` File or connection to read from
- `format` Character vector or list of vectors. See ‘Details’ below.
- `...` Other arguments for `read.fwf`
- `as.is` Keep characters as characters?
- `colClasses` Variable classes to override defaults. See `read.table` for details.

**Details**

The format for a field is of one of the following forms: `rf1.d`, `rd1.d`, `rx1`, `ra1`, `ri1`, where `l` is the number of columns, `d` is the number of decimal places, and `r` is the number of repeats. `F` and `D` are numeric formats, `A` is character, `I` is integer, and `X` indicates columns to be skipped. The repeat code `r` and decimal place code `d` are always optional. The length code `l` is required except for `X` formats when `r` is present.

For a single-line record, `format` should be a character vector. For a multiline record it should be a list with a character vector for each line.

Skipped (X) columns are not passed to `read.fwf`, so `colClasses`, `col.names`, and similar arguments passed to `read.fwf` should not reference these columns.
Value

A data frame

Note

read.fortran does not use actual Fortran input routines, so the formats are at best rough approximations to the Fortran ones. In particular, specifying \( d > 0 \) in the F or D format will shift the decimal \( d \) places to the left, even if it is explicitly specified in the input file.

See Also

read.fwf, read.table, read.csv

Examples

```r
ff <- tempfile()
cat(file = ff, "123456", "987654", sep = "\n")
read.fortran(ff, c("F2.1","F2.0","I2"))
read.fortran(ff, c("2F1.0","2X","2A1"))
unlink(ff)
cat(file = ff, "123456AB", "987654CD", sep = "\n")
read.fortran(ff, list(c("2F3.1","A2"), c("3I2","2X")))
unlink(ff)
# Note that the first number is read differently than Fortran would
# read it:
cat(file = ff, "12.3456", "1234567", sep = "\n")
read.fortran(ff, "F7.4")
unlink(ff)
```

---

**read.fwf**  
*Read Fixed Width Format Files*

Description

Read a table of fixed width formatted data into a data.frame.

Usage

```r
read.fwf(file, widths, header = FALSE, sep = "\t",
          skip = 0, row.names, col.names, n = -1,
          buffersize = 2000, ...)
```

Arguments

- **file**: the name of the file which the data are to be read from. Alternatively, `file` can be a connection, which will be opened if necessary, and if so closed at the end of the function call.
- **widths**: integer vector, giving the widths of the fixed-width fields (of one line), or list of integer vectors giving widths for multiline records.
- **header**: a logical value indicating whether the file contains the names of the variables as its first line. If present, the names must be delimited by `sep`. 
sep character; the separator used internally; should be a character that does not occur in the file (except in the header).
skip number of initial lines to skip; see read.table.
row.names see read.table.
col.names see read.table.
n the maximum number of records (lines) to be read, defaulting to no limit.
buffersize Maximum number of lines to read at one time
... further arguments to be passed to read.table. Useful further arguments include as.is, na.strings, colClasses and strip.white.

Details

Multiline records are concatenated to a single line before processing. Fields that are of zero-width or are wholly beyond the end of the line in file are replaced by NA.

Negative-width fields are used to indicate columns to be skipped, e.g., -5 to skip 5 columns. These fields are not seen by read.table and so should not be included in a col.names or colClasses argument (nor in the header line, if present).

Reducing the buffersize argument may reduce memory use when reading large files with long lines. Increasing buffersize may result in faster processing when enough memory is available.

Value

A data.frame as produced by read.table which is called internally.

Author(s)

Brian Ripley for R version: original Perl by Kurt Hornik.

scan and read.table.

Examples

ff <- tempfile()
cat(file = ff, "123456", "987654", sep = "\n")
read.fwf(ff, widths = c(1,2,3))  #> 1  23 456 \ 9 87 654
read.fwf(ff, widths = c(1,-2,3))  #> 1  456 \ 654
unlink(ff)
cat(file = ff, "123", "987654", sep = "\n")
read.fwf(ff, widths = c(1,0, 2,3))  #> 1 NA 23 NA \ 9 NA 87 654
unlink(ff)
cat(file = ff, "123456", "987654", sep = "\n")
read.fwf(ff, widths = list(c(1,0, 2,3), c(2,2,2)))  #> 1 NA 23 456 98 76 54
unlink(ff)
Description

read.socket reads a string from the specified socket, write.socket writes to the specified socket. There is very little error checking done by either.

Usage

```
read.socket(socket, maxlen = 256L, loop = FALSE)
write.socket(socket, string)
```

Arguments

- `socket`: a socket object.
- `maxlen`: maximum length (in bytes) of string to read.
- `loop`: wait for ever if there is nothing to read?
- `string`: string to write to socket.

Value

- `read.socket` returns the string read as a length-one character vector.
- `write.socket` returns the number of bytes written.

`close.socket`, `make.socket`

Examples

```r
finger <- function(user, host = "localhost", port = 79, print = TRUE) {
  if (!is.character(user))
    stop("user name must be a string")
  user <- paste(user,\"\r\n")
  socket <- make.socket(host, port)
  on.exit(close.socket(socket))
  write.socket(socket, user)
  output <- character(0)
  repeat{
    ss <- read.socket(socket)
    if (ss == "") break
    output <- paste(output, ss)
  }
  close.socket(socket)
  if (print) cat(output)
  invisible(output)
}
read.table

Description

Reads a file in table format and creates a data frame from it, with cases corresponding to lines and variables to fields in the file.

Usage

read.table(file, header = FALSE, sep = " ", quote = "\\"",
  dec = ".", row.names, col.names,
  as.is = !stringsAsFactors,
  na.strings = "NA", colClasses = NA, nrow = -1,
  skip = 0, check.names = TRUE, fill = !blank.lines.skip,
  strip.white = FALSE, blank.lines.skip = TRUE,
  comment.char = ",",
  allowEscapes = FALSE, flush = FALSE,
  stringsAsFactors = default.stringsAsFactors(),
  fileEncoding = "", encoding = "unknown", text)

read.csv(file, header = TRUE, sep = ",", quote = "\\"",
  dec = ".", fill = TRUE, comment.char = "", ...)

read.csv2(file, header = TRUE, sep = ";", quote = "\\"",
  dec = ",", fill = TRUE, comment.char = "", ...)

read.delim(file, header = TRUE, sep = "\t", quote = "\\"",
  dec = ".", fill = TRUE, comment.char = "", ...)

read.delim2(file, header = TRUE, sep = "\t", quote = "\\"",
  dec = ",", fill = TRUE, comment.char = "", ...)

Arguments

file

the name of the file which the data are to be read from. Each row of the table appears as one line of the file. If it does not contain an absolute path, the file name is relative to the current working directory, getwd(). Tilde-expansion is performed where supported. This can be a compressed file (see file).

Alternatively, file can be a readable text-mode connection (which will be opened for reading if necessary, and if so closed (and hence destroyed) at the end of the function call). (If stdin() is used, the prompts for lines may be somewhat confusing. Terminate input with a blank line or an EOF signal, Ctrl-D on Unix and Ctrl-Z on Windows. Any pushback on stdin() will be cleared before return.)

file can also be a complete URL. (For the supported URL schemes, see the ‘URLs’ section of the help for url.)
header: a logical value indicating whether the file contains the names of the variables as its first line. If missing, the value is determined from the file format: header is set to TRUE if and only if the first row contains one fewer field than the number of columns.

sep: the field separator character. Values on each line of the file are separated by this character. If sep = "" (the default for read.table) the separator is 'white space', that is one or more spaces, tabs, newlines or carriage returns.

quote: the set of quoting characters. To disable quoting altogether, use quote = "". See scan for the behaviour on quotes embedded in quotes. Quoting is only considered for columns read as character, which is all of them unless colClasses is specified.

dec: the character used in the file for decimal points.

row.names: a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names.

If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if row.names is missing, the rows are numbered.

Using row.names = NULL forces row numbering. Missing or NULL row.names generate row names that are considered to be ‘automatic’ (and not preserved by as.matrix).

col.names: a vector of optional names for the variables. The default is to use "V" followed by the column number.

as.is: the default behavior of read.table is to convert character variables (which are not converted to logical, numeric or complex) to factors. The variable as.is controls the conversion of columns not otherwise specified by colClasses. Its value is either a vector of logicals (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors.

Note: to suppress all conversions including those of numeric columns, set colClasses = "character".

Note that as.is is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.

na.strings: a character vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields.

colClasses: character. A vector of classes to be assumed for the columns. Recycled as necessary, or if the character vector is named, unspecified values are taken to be NA.

Possible values are NA (the default, when type.convert is used), "NULL" (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or "factor", "Date" or "POSIXct". Otherwise there needs to be an as method (from package methods) for conversion from "character" to the specified formal class.

Note that colClasses is specified per column (not per variable) and so includes the column of row names (if any).

nrows: integer: the maximum number of rows to read in. Negative and other invalid values are ignored.

skip: integer: the number of lines of the data file to skip before beginning to read data.
check.names logical. If TRUE then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by make.names) so that they are, and also to ensure that there are no duplicates.

fill logical. If TRUE then in case the rows have unequal length, blank fields are implicitly added. See ‘Details’.

strip.white logical. Used only when sep has been specified, and allows the stripping of leading and trailing white space from unquoted character fields (numeric fields are always stripped). See scan for further details (including the exact meaning of ‘white space’), remembering that the columns may include the row names.

blank.lines.skip logical: if TRUE blank lines in the input are ignored.

comment.char character: a character vector of length one containing a single character or an empty string. Use ‘’ to turn off the interpretation of comments altogether.

allowEscapes logical. Should C-style escapes such as ‘\n’ be processed or read verbatim (the default)? Note that if not within quotes these could be interpreted as a delimiter (but not as a comment character). For more details see scan.

flush logical: if TRUE, scan will flush to the end of the line after reading the last of the fields requested. This allows putting comments after the last field.

stringsAsFactors logical: should character vectors be converted to factors? Note that this is overridden by as.is and colClasses, both of which allow finer control.

fileEncoding character string: if non-empty declares the encoding used on a file (not a connection) so the character data can be re-encoded. See the ‘Encoding’ section of the help for file, the ‘R Data Import/Export Manual’ and ‘Note’.

encoding encoding to be assumed for input strings. It is used to mark character strings as known to be in Latin-1 or UTF-8 (see encoding): it is not used to re-encode the input, but allows R to handle encoded strings in their native encoding (if one of those two). See ‘Value’.

text character string: if file is not supplied and this is, then data are read from the value of text via a text connection. Notice that a literal string can be used to include (small) data sets within R code.

Details

This function is the principal means of reading tabular data into R.

Unless colClasses is specified, all columns are read as character columns and then converted using type.convert to logical, integer, numeric, complex or (depending on as.is) factor as appropriate. Quotes are (by default) interpreted in all fields, so a column of values like "42" will result in an integer column.

A field or line is ‘blank’ if it contains nothing (except whitespace if no separator is specified) before a comment character or the end of the field or line.

If row.names is not specified and the header line has one less entry than the number of columns, the first column is taken to be the row names. This allows data frames to be read in from the format in which they are printed. If row.names is specified and does not refer to the first column, that column is discarded from such files.

The number of data columns is determined by looking at the first five lines of input (or the whole file if it has less than five lines), or from the length of col.names if it is specified and is longer.
This could conceivably be wrong if fill or blank.lines.skip are true, so specify col.names if necessary (as in the 'Examples').

`read.csv` and `read.csv2` are identical to `read.table` except for the defaults. They are intended for reading 'comma separated value' files (`.csv`) or (`read.csv2`) the variant used in countries that use a comma as decimal point and a semicolon as field separator. Similarly, `read.delim` and `read.delim2` are for reading delimited files, defaulting to the TAB character for the delimiter. Notice that header = TRUE and fill = TRUE in these variants, and that the comment character is disabled.

The rest of the line after a comment character is skipped; quotes are not processed in comments. Complete comment lines are allowed provided blank.lines.skip = TRUE; however, comment lines prior to the header must have the comment character in the first non-blank column.

Quoted fields with embedded newlines are supported except after a comment character.

**Value**

A data frame (data.frame) containing a representation of the data in the file.

Empty input is an error unless col.names is specified, when a 0-row data frame is returned: similarly giving just a header line if header = TRUE results in a 0-row data frame. Note that in either case the columns will be logical unless colClasses was supplied.

Character strings in the result (including factor levels) will have a declared encoding if encoding is "latin1" or "UTF-8".

**Memory usage**

These functions can use a surprising amount of memory when reading large files. There is extensive discussion in the ‘R Data Import/Export’ manual, supplementing the notes here.

Less memory will be used if colClasses is specified as one of the six atomic vector classes. This can be particularly so when reading a column that takes many distinct numeric values, as storing each distinct value as a character string can take up to 14 times as much memory as storing it as an integer.

Using nrows, even as a mild over-estimate, will help memory usage.

Using comment.char = "" will be appreciably faster than the `read.table` default.

`read.table` is not the right tool for reading large matrices, especially those with many columns: it is designed to read data frames which may have columns of very different classes. Use `scan` instead for matrices.

**Note**

The columns referred to in as.is and colClasses include the column of row names (if any).

Because this function uses `pushBack` it can only handle character strings which can be represented in the current locale. So although fileEncoding can be used to specify the encoding of the input file (or a connection can be specified which re-encodes), the implied re-encoding must be possible. This is not a problem in UTF-8 locales, but it can be on Windows — `readLines` or `scan` can be used to avoid this limitation since they have special provisions to convert input to UTF-8.

**References**

**recover**

**Browsing after an Error**

**Description**

This function allows the user to browse directly on any of the currently active function calls, and is suitable as an error option. The expression `options(error = recover)` will make this the error option.

**Usage**

`recover()`

**Details**

When called, `recover` prints the list of current calls, and prompts the user to select one of them. The standard R `browser` is then invoked from the corresponding environment; the user can type ordinary R language expressions to be evaluated in that environment.

When finished browsing in this call, type `c` to return to `recover` from the browser. Type another frame number to browse some more, or type `0` to exit `recover`.

**See Also**

The 'R Data Import/Export' manual.

`scan`, `type.convert`, `read.fwf` for reading fixed width formatted input; `write.table`; `data.frame`.

`count.fields` can be useful to determine problems with reading files which result in reports of incorrect record lengths (see the 'Examples' below).

**Examples**

```r
## using count.fields to handle unknown maximum number of fields
## when fill = TRUE
test1 <- c(1:5, "6,7", "8,9,10")
tf <- tempfile()
writeLines(test1, tf)

read.csv(tf, fill = TRUE) # 1 column
ncol <- max(count.fields(tf, sep = ","))
read.csv(tf, fill = TRUE, header = FALSE,
         col.names = paste0("V", seq_len(ncol)))
unlink(tf)

## "Inline" data set, using text=
## Notice that leading and trailing empty lines are auto-trimmed

read.table(header = TRUE, text = "
a b
1 2
3 4
")
```

---

**recover**

---

**Browsing after an Error**

**Description**

This function allows the user to browse directly on any of the currently active function calls, and is suitable as an error option. The expression `options(error = recover)` will make this the error option.

**Usage**

`recover()`

**Details**

When called, `recover` prints the list of current calls, and prompts the user to select one of them. The standard R `browser` is then invoked from the corresponding environment; the user can type ordinary R language expressions to be evaluated in that environment.

When finished browsing in this call, type `c` to return to `recover` from the browser. Type another frame number to browse some more, or type `0` to exit `recover`.
The use of `recover` largely supersedes `dump.frames` as an error option, unless you really want to wait to look at the error. If `recover` is called in non-interactive mode, it behaves like `dump.frames`. For computations involving large amounts of data, `recover` has the advantage that it does not need to copy out all the environments in order to browse in them. If you do decide to quit interactive debugging, call `dump.frames` directly while browsing in any frame (see the examples).

**Value**

Nothing useful is returned. However, you *can* invoke `recover` directly from a function, rather than through the error option shown in the examples. In this case, execution continues after you type `0` to exit `recover`.

**Compatibility Note**

The R `recover` function can be used in the same way as the S function of the same name; therefore, the error option shown is a compatible way to specify the error action. However, the actual functions are essentially unrelated and interact quite differently with the user. The navigating commands up and down do not exist in the R version; instead, exit the browser and select another frame.

**References**

See the compatibility note above, however.

**See Also**

`browser` for details about the interactive computations; `options` for setting the error option; `dump.frames` to save the current environments for later debugging.

**Examples**

```r
## Not run:

options(error = recover) # setting the error option

## Example of interaction

> myfit <- lm(y ~ x, data = xy, weights = w)

## End(Not run)

---

relist

**Allow Re-Listing an unlist()ed Object**

**Description**

relist() is an S3 generic function with a few methods in order to allow easy inversion of unlist() when that is used with an object obj of (S3) class "relistable".

**Usage**

relist(flesh, skeleton)

## Default S3 method:
relist(flesh, skeleton = attr(flesh, "skeleton"))

## S3 method for class 'factor'
relist(flesh, skeleton = attr(flesh, "skeleton"))

## S3 method for class 'list'
relist(flesh, skeleton = attr(flesh, "skeleton"))

## S3 method for class 'matrix'
relist(flesh, skeleton = attr(flesh, "skeleton"))

as.relistable(x)
is.relistable(x)

## S3 method for class 'relistable'
unlist(x, recursive = TRUE, use.names = TRUE)

**Arguments**

- **flesh**: a vector to be relisted
- **skeleton**: a list, the structure of which determines the structure of the result
- **x**: an R object, typically a list (or vector).
- **recursive**: logical. Should unlisting be applied to list components of x?
- **use.names**: logical. Should names be preserved?

**Details**

Some functions need many parameters, which are most easily represented in complex structures, e.g., nested lists. Unfortunately, many mathematical functions in R, including optim and nlm can only operate on functions whose domain is a vector. R has unlist() to convert nested list objects into a vector representation. relist(), its methods and the functionality mentioned here provide the inverse operation to convert vectors back to the convenient structural representation. This allows structured functions (such as optim()) to have simple mathematical interfaces.
For example, a likelihood function for a multivariate normal model needs a variance-covariance matrix and a mean vector. It would be most convenient to represent it as a list containing a vector and a matrix. A typical parameter might look like

```r
list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0))).
```

However, `optim` cannot operate on functions that take lists as input; it only likes numeric vectors. The solution is conversion. Given a function `mvdnorm(x, mean, vcov, log = FALSE)` which computes the required probability density, then

```r
ipar <- list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0)))
initial.param <- as.relistable(ipar)

ll <- function(param.vector)
{
  param <- relist(param.vector, skeleton = ipar)
  -sum(mvdnorm(x, mean = param$mean, vcov = param$vcov,
              log = TRUE))
}

optim(unlist(initial.param), ll)
```

relist takes two parameters: skeleton and flesh. Skeleton is a sample object that has the right shape but the wrong content. Flesh is a vector with the right content but the wrong shape. Invoking

```r
relist(flesh, skeleton)
```

will put the content of flesh on the skeleton. You don’t need to specify skeleton explicitly if the skeleton is stored as an attribute inside flesh. In particular, if flesh was created from some object `obj` with `unlist(as.relistable(obj))` then the skeleton attribute is automatically set. (Note that this does not apply to the example here, as `optim` is creating a new vector to pass to `ll` and not its `par` argument.)

As long as skeleton has the right shape, it should be a precise inverse of `unlist`. These equalities hold:

```r
relist(unlist(x), x) == x
unlist(relist(y, skeleton)) == y
x <- as.relistable(x)
relist(unlist(x)) == x
```

**Value**

an object of (S3) class "relistable" (and "list").

**Author(s)**

R Core, based on a code proposal by Andrew Clausen.

**See Also**

`unlist`
Examples

```r
ipar <- list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0))
initial.param <- as.relistable(ipar)
ul <- unlist(initial.param)
relist(ul)
stopifnot(identical(relist(ul), initial.param))
```

Description

Utility for removing add-on packages.

Usage

```r
R CMD REMOVE [options] [-l lib] pkgs
```

Arguments

- `pkgs` a space-separated list with the names of the packages to be removed.
- `lib` the path name of the \texttt{R} library tree to remove from. May be absolute or relative. Also accepted in the form `\texttt{--library=lib}`.
- `options` further options for help or version.

Details

If used as \texttt{R CMD REMOVE pkgs} without explicitly specifying \texttt{lib}, packages are removed from the library tree rooted at the first directory in the library path which would be used by \texttt{R} run in the current environment.

To remove from the library tree \texttt{lib} instead of the default one, use \texttt{R CMD REMOVE \texttt{--lib=lib}} \texttt{pkgs}.

Use \texttt{R CMD REMOVE \texttt{--help}} for more usage information.

Note

Some binary distributions of \texttt{R} have \texttt{REMOVE} in a separate bundle, e.g. an \texttt{R-devel} RPM.

See Also

\texttt{INSTALL, remove.packages}
remove.packages

Remove Installed Packages

Description

Removes installed packages/bundles and updates index information as necessary.

Usage

remove.packages(pkgs, lib)

Arguments

pkgs a character vector with the names of the packages to be removed.
lib a character vector giving the library directories to remove the packages from. If missing, defaults to the first element in .libPaths().

See Also

REMOVED for a command line version; install.packages for installing packages.

removeSource

Remove Stored Source from a Function.

Description

When options("keep.source") is TRUE, a copy of the original source code to a function is stored with it. This function removes that copy.

Usage

removeSource(fn)

Arguments

fn A single function from which to remove the source.

Details

This removes both the "source" attribute (from R version 2.13.x or earlier) and the "srcRef" and related attributes.

Value

A copy of the function with the source removed.

See Also

srcRef for a description of source reference records, deparse for a description of how functions are deparsed.
Examples

```r
fn <- function(x) {
  x + 1  # A comment, kept as part of the source
}
fn
fn <- removeSource(fn)
fn
```

R Home Directory

**Description**

Returns the location of the R home directory, which is the root of the installed R tree.

**Usage**

```r
R RHOME
```

Roman Numerals

**Description**

Manipulate integers as roman numerals.

**Usage**

```r
as.roman(x)
```

**Arguments**

- `x` a numeric vector, or a character vector of arabic or roman numerals.

**Details**

`as.roman` creates objects of class "roman" which are internally represented as integers, and have suitable methods for printing, formatting, subsetting, and coercion to character.

Only numbers between 1 and 3899 have a unique representation as roman numbers.

**References**

Examples

```r
## First five roman 'numbers'.
(y <- as.roman(1:5))
## Middle one.
y[3]
## Current year as a roman number.
(y <- as.roman(format(Sys.Date(), "%y")));
## 10 years ago ...
y - 10
```

**Rprof**  
*Enable Profiling of R's Execution*

**Description**
Enable or disable profiling of the execution of R expressions.

**Usage**

```r
Rprof(filename = "Rprof.out", append = FALSE, interval = 0.02,  
memory.profiling = FALSE, gc.profiling = FALSE,  
line.profiling = FALSE, numfiles = 100L, bufsize = 10000L)
```

**Arguments**

- `filename` The file to be used for recording the profiling results. Set to NULL or "" to disable profiling.
- `append` logical: should the file be over-written or appended to?
- `interval` real: time interval between samples.
- `memory.profiling` logical: write memory use information to the file?
- `gc.profiling` logical: record whether GC is running?
- `line.profiling` logical: write line locations to the file?
- `numfiles`, `bufsize` integers: line profiling memory allocation

**Details**
Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling works by writing out the call stack every `interval` seconds, to the file specified. Either the `summaryRprof` function or the wrapper script R CMD Rprof can be used to process the output file to produce a summary of the usage; use R CMD Rprof --help for usage information.

How time is measured varies by platform: on a Unix-alike it is the CPU time of the R process, so for example excludes time when R is waiting for input or for processes run by system to return.

Note that the timing interval cannot usefully be too small: once the timer goes off, the information is not recorded until the next timing click (probably in the range 1–10msecs).

Functions will only be recorded in the profile log if they put a context on the call stack (see `sys.calls`). Some primitive functions do not do so: specifically those which are of type "special" (see the 'R Internals' manual for more details).
Individual statements will be recorded in the profile log if `line.profiling` is TRUE, and if the code being executed was parsed with source references. See `parse` for a discussion of source references. By default the statement locations are not shown in `summaryRprof`, but see that help page for options to enable the display.

**Note**

Profiling is not available on all platforms. By default, support for profiling is compiled in if possible – configure R with `--disable-R-profiling` to change this.

As R profiling uses the same mechanisms as C profiling, the two cannot be used together, so do not use `Rprof` in an executable built for C-level profiling.

**Note**

The profiler interrupts R asynchronously, and it cannot allocate memory to store results as it runs. This affects line profiling, which needs to store an unknown number of file pathnames. The `numfiles` and `bufsize` arguments control the size of pre-allocated buffers to hold these results: the former counts the maximum number of paths, the latter counts the numbers of bytes in them. If the profiler runs out of space it will skip recording the line information for new files, and issue a warning when `Rprof(NULL)` is called to finish profiling.

**See Also**

The chapter on “Tidying and profiling R code” in “Writing R Extensions” (see the ‘doc/manual’ subdirectory of the R source tree).

`summaryRprof` to analyse the output file.

`tracemem, Rprofmem` for other ways to track memory use.

**Examples**

```r
## Not run: Rprof()
## some code to be profiled
Rprof(NULL)
## some code NOT to be profiled
Rprof(append = TRUE)
## some code to be profiled
Rprof(NULL)
...
## Now post-process the output as described in Details
## End(Not run)
```

---

### Rprofmem

**Enable Profiling of R’s Memory Use**

**Description**

Enable or disable reporting of memory allocation in R.

**Usage**

```r
Rprofmem(filename = "Rprofmem.out", append = FALSE, threshold = 0)
```
Rprofmem

Arguments

filename  The file to be used for recording the memory allocations. Set to NULL or "" to disable reporting.
append    logical: should the file be over-written or appended to?
threshold numeric: allocations on R’s “large vector” heap larger than this number of bytes will be reported.

Details

Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling writes the call stack to the specified file every time malloc is called to allocate a large vector object or to allocate a page of memory for small objects. The size of a page of memory and the size above which malloc is used for vectors are compile-time constants, by default 2000 and 128 bytes respectively.

The profiler tracks allocations, some of which will be to previously used memory and will not increase the total memory use of R.

Value

None

Note

The memory profiler slows down R even when not in use, and so is a compile-time option. The memory profiler can be used at the same time as other R and C profilers.

See Also

The R sampling profiler, Rprof also collects memory information.
tracemem traces duplications of specific objects.

The ”Writing R Extensions” manual section on ”Tidying and profiling R code”

Examples

## Not run:
## not supported unless R is compiled to support it.
Rprofmem("Rprofmem.out", threshold = 1000)
exmaple(glm)
Rprofmem(NULL)
noquote(readlines("Rprofmem.out", n = 5))

## End(Not run)
Rscript  
*Scripting Front-End for R*

**Description**

This is an alternative front end for use in ‘#!’ scripts and other scripting applications.

**Usage**

```
Rscript [options] [-e expression] file [args]
```

**Arguments**

- **options**: A list of options beginning with ‘--’. These can be any of the options of the standard R front-end, and also those described in the details.
- **expression**: a R expression.
- **file**: The name of a file containing R commands. ‘-‘ indicates ‘stdin’.
- **args**: Arguments to be passed to the script in file.

**Details**

Rscript --help gives details of usage, and Rscript --version gives the version of Rscript.

Other invocations invoke the R front-end with selected options. This front-end is convenient for writing ‘#!’ scripts since it is an executable and takes file directly as an argument. Options ‘--slave --no-restore’ are always supplied: these imply ‘--no-save’. (The standard Windows command line has no concept of ‘#!’ scripts, but Cygwin shells do.)

Either one or more ‘-e’ options or file should be supplied. When using ‘-e’ options be aware of the quoting rules in the shell used: see the examples.

Additional options accepted (before file or args) are

- ‘--verbose’ gives details of what Rscript is doing. Also passed on to R.
- ‘--default-packages=list’ where list is a comma-separated list of package names or NULL.
   Sets the environment variable R_DEFAULT_PACKAGES which determines the packages loaded on startup. The default for Rscript omits methods as it takes about 60% of the startup time.

Spaces are allowed in expression and file (but will need to be protected from the shell in use, if any, for example by enclosing the argument in quotes).

Normally the version of R is determined at installation, but this can be overridden by setting the environment variable R_HOME.

stdin() refers to the input file, and file("stdin") to the stdin file stream of the process.

**Note**

Rscript is only supported on systems with the execv system call.
Examples

```r
## Not run:
Rscript -e 'date() -e 'format(Sys.time(), "%a %b %d %X %Y")'
```

```r
# example #! script for a Unix-alike

#!/path/to/Rscript --vanilla --default-packages=utils
args <- commandArgs(TRUE)
res <- try(install.packages(args))
if(inherits(res, "try-error")) q(status=1) else q()
```

## End(Not run)

---

### Description

Utility function to find and display R documentation.

### Usage

```r
RShowDoc(what, type = c("pdf", "html", "txt"), package)
```

### Arguments

- **what**: a character string: see ‘Details’.
- **type**: an optional character string giving the preferred format.
- **package**: an optional character string specifying the name of a package within which to look for documentation.

### Details

what can specify one of several different sources of documentation, including the R manuals (R-admin, R-data, R-exts, R-intro, R-ints, R-lang), NEWS, COPYING (the GPL licence), any of the licenses in ‘share/licenses’, FAQ (also available as R-FAQ), and the files in ‘R_HOME/doc’.

Only on Windows, the R for Windows FAQ is specified by rw-FAQ.

If package is supplied, documentation is looked for in the ‘doc’ and top-level directories of an installed package of that name.

If what is missing a brief usage message is printed.

The documentation types are tried in turn starting with the first specified in type (or "pdf" if none is specified).

### Value

A invisible character string given the path to the file found.
RSiteSearch

Search for Key Words or Phrases in Documentation

Description

Search for key words or phrases in help pages, vignettes or task views, using the search engine at http://search.r-project.org and view them in a web browser.

Usage

RSiteSearch(string, restrict = c("functions", "vignettes", "views"), format = c("normal", "short"), sortby = c("score", "date:late", "date:early", "subject", "subject:descending", "from", "from:descending", "size", "size:descending"), matchesPerPage = 20)

Arguments

string A character string specifying word(s) or a phrase to search. If the words are to be searched as one entity, enclose all words in braces (see the first example).
restrict a character vector, typically of length greater than one. Possible areas to search in: functions for help pages, views for task views and vignettes for package vignettes.
format normal or short (no excerpts); can be abbreviated.
sortby character string (can be abbreviated) indicating how to sort the search results: (score, date:late for sorting by date with latest results first, date:early for earliest first, subject for subject in alphabetical order, subject:descending for reverse alphabetical order, from or from:descending for sender (when applicable), size or size:descending for size.)
matchesPerPage How many items to show per page.

Details

This function is designed to work with the search site at http://search.r-project.org, and depends on that site continuing to be made available (thanks to Jonathan Baron and the School of Arts and Sciences of the University of Pennsylvania).

Unique partial matches will work for all arguments. Each new browser window will stay open unless you close it.
rtags

An Etags-like Tagging Utility for R

Description

rtags provides etags-like indexing capabilities for R code, using R’s own parser.

Usage

rtags(path = ".", pattern = "\\.[RrSs]$", recursive = FALSE,
src = list.files(path = path, pattern = pattern,
full.names = TRUE,
recursive = recursive),
keep.re = NULL,
ofile = "", append = FALSE,
verbose = getOption("verbose"))

Arguments

path, pattern, recursive
Arguments passed on to list.files to determine the files to be tagged. By default, these are all files with extension .R, .r, .S, and .s in the current directory. These arguments are ignored if src is specified.

src
A vector of file names to be indexed.

keep.re
A regular expression further restricting src (the files to be indexed). For example, specifying keep.re = "/R/[\^/]*/\\.R$" will only retain files with extension .R inside a directory named R.

Value

(Invisibly) the complete URL passed to the browser, including the query string.

Author(s)

Andy Liaw and Jonathan Baron

See Also

help.search, help.start for local searches.
browseURL for how the help file is displayed.

Examples

# need Internet connection
RSiteSearch("(logistic regression)") # matches exact phrase
Sys.sleep(5) # allow browser to open, take a quick look
## search in vignettes and store the query-string:
fullquery <- RSiteSearch("lattice", restrict = "vignettes")
fullquery # a string of ~ 110 characters
Passed on to `cat` as the `file` argument; typically the output file where the tags will be written ("TAGS" by convention). By default, the output is written to the R console (unless redirected).

Logical, indicating whether the output should overwrite an existing file, or append to it.

Logical. If `TRUE`, file names are echoed to the R console as they are processed.

**Details**

Many text editors allow definitions of functions and other language objects to be quickly and easily located in source files through a tagging utility. This functionality requires the relevant source files to be preprocessed, producing an index (or tag) file containing the names and their corresponding locations. There are multiple tag file formats, the most popular being the vi-style `ctags` format and the adn emacs-style `etags` format. Tag files in these formats are usually generated by the `ctags` and `etags` utilities respectively. Unfortunately, these programs do not recognize R code syntax. They do allow tagging of arbitrary language files through regular expressions, but this too is insufficient.

The `rtags` function is intended to be a tagging utility for R code. It parses R code files (using R’s parser) and produces tags in Emacs’ `etags` format. Support for vi-style tags is currently absent, but should not be difficult to add.

`list.files.cat`

**Examples**

```r
## Not run:
rtags("/path/to/src/repository",
       pattern = "[.]\*[.][Rr][Ss]*$",
       keep.re = "/R/",
       verbose = TRUE,
       ofile = "TAGS",
       append = FALSE,
       recursive = TRUE)

## End(Not run)
```
Description

A driver for Stangle that extracts R code chunks.

Usage

Rtangle()
RtangleSetup(file, syntax, output = NULL, annotate = TRUE,
             split = FALSE, quiet = FALSE, ...)

Arguments

file       Name of Sweave source file. See the description of the corresponding argument of Sweave.
syntax    An object of class SweaveSyntax.
output     Name of output file used unless split = TRUE: see ‘Details’.
annotate  By default, code chunks are separated by comment lines specifying the names and numbers of the code chunks. If FALSE the decorating comments are omitted.
split      Split output into a file for each code chunk?
quiet      If TRUE all progress messages are suppressed.
...        Additional named arguments setting defaults for further options.

Details

Unless split = TRUE, the default name of the output file is basename(file) with an extension corresponding to the Sweave syntax (e.g. 'Rnw', 'Stex') replaced by 'R'. File names "stdout" and "stderr" are interpreted as the output and message connection respectively.

If splitting is selected (including by the options in the file), each chunk is written to a separate file with extension the name of the 'engine' (default '.R').

The annotation is of one of the forms

```
# code chunk number 3: viewport

# code chunk number 18: grid.Rnw:647-648

# code chunk number 19: trellisdata (eval = FALSE)
```

using either the chunk label or the file name and line numbers.

Note that this driver does not simple extract the code chunks verbatim because code chunks can re-use earlier chunks.
Supported Options

Rtangle supports the following options for code chunks (the values in parentheses show the default values):

- **engine**: character string ("R"). Only chunks with engine equal to "R" or "S" are processed.
- **keep.source**: logical (TRUE). If keep.source == TRUE the original source is copied to the file. Otherwise, deparsed source is output.
- **eval**: logical (TRUE). If FALSE, the code chunk is copied across but commented out.
- **prefix**: Used if split = TRUE. See prefix.string.
- **prefix.string**: a character string, default is the name of the source file (without extension). Used if split = TRUE as the prefix for the filename if the chunk has no label, or if it has a label and prefix = TRUE. Note that this is used as part of filenames, so needs to be portable.
- **show.line.nos**: logical (FALSE). Should the output be annotated with comments showing the line number of the first code line of the chunk?

Author(s)

Friedrich Leisch and R-core.

**Sweave**, **RweaveLatex**

---

**RweaveLatex** **R/LaTeX Driver for Sweave**

**Description**

A driver for **Sweave** that translates R code chunks in LaTeX files.

**Usage**

RweaveLatex()

RweaveLatexSetup(file, syntax, output = NULL, quiet = FALSE,
  debug = FALSE, stylepath, ...)

**Arguments**

- **file**: Name of Sweave source file. See the description of the corresponding argument of **Sweave**.
- **syntax**: An object of class **SweaveSyntax**.
- **output**: Name of output file. The default is to remove extension ".nw", ".Rnw" or ".Snw" and to add extension ".tex". Any directory paths in file are also removed such that the output is created in the current working directory.
- **quiet**: If TRUE all progress messages are suppressed.
- **debug**: If TRUE, input and output of all code chunks is copied to the console.
- **stylepath**: See ‘Details’.
- **...**: named values for the options listed in ‘Supported Options’. 
Details

The LaTeX file generated needs to contain the line `\usepackage{Sweave}`, and if this is not present in the Sweave source file (possibly in a comment), it is inserted by the `rweavelatex` driver. If `stylepath = TRUE`, a hard-coded path to the file `Sweave.sty` in the R installation is set in place of `Sweave`. The hard-coded path makes the LaTeX file less portable, but avoids the problem of installing the current version of `Sweave.sty` to some place in your TeX input path. However, TeX may not be able to process the hard-coded path if it contains spaces (as it often will under Windows) or TeX special characters.

The default for `stylepath` is now taken from the environment variable `SWEAVE_STYLEPATH_DEFAULT`, or is `FALSE` if that is unset or empty. If set, it should be exactly `TRUE` or `FALSE`: any other values are taken as `FALSE`.

The simplest way for frequent Sweave users to ensure that `Sweave.sty` is in the TeX input path is to add `\R_HOME/share/texmf` as a ‘texmf tree’ (‘root directory’ in the parlance of the ‘MiKTeX settings’ utility).

By default, `Sweave.sty` sets the width of all included graphics to: `\setkeys{Gin}{width=0.8\textwidth}`.

This setting affects the width size option passed to the `\includegraphics{}` directive for each plot file and in turn impacts the scaling of your plot files as they will appear in your final document. Thus, for example, you may set `width=3` in your figure chunk and the generated graphics files will be set to 3 inches in width. However, the width of your graphic in your final document will be set to `0.8\textwidth` and the height dimension will be scaled accordingly. Fonts and symbols will be similarly scaled in the final document.

You can adjust the default value by including the `\setkeys{Gin}{width=...}` directive in your `.Rnw` file after the `\begin{document}` directive and changing the width option value as you prefer, using standard LaTeX measurement values.

If you wish to override this default behavior entirely, you can add a `\usepackage[nogin]{Sweave}` directive in your preamble. In this case, no size/scaling options will be passed to the `\includegraphics{}` directive and the height and width options will determine both the runtime generated graphic file sizes and the size of the graphics in your final document.

`Sweave.sty` also supports the `[noae]` option, which suppresses the use of the ‘ae’ package, the use of which may interfere with certain encoding and typeface selections. If you have problems in the rendering of certain character sets, try this option.

The use of fancy quotes (see `sQuote`) can cause problems when setting R output. Either set `options(useFancyQuotes = FALSE)` or arrange that LaTeX is aware of the encoding used (by a `\usepackage[utf8]{inputenc}` declaration: Windows users of Sweave from Rgui.exe will need to replace ‘utf8’ by ‘cp1252’ or similar) and ensure that typewriter fonts containing directional quotes are used.

Some LaTeX graphics drivers do not include ‘.png’ or ‘.jpg’ in the list of known extensions. To enable them, add something like `\DeclareGraphicsExtensions{.png,.pdf,.jpg}` to the preamble of your document or check the behavior of your graphics driver. When both pdf and png are `TRUE` both files will be produced by Sweave, and their order in the ‘DeclareGraphicsExtensions’ list determines which will be used by pdflatex.

Supported Options

`Rweavelatex` supports the following options for code chunks (the values in parentheses show the default values). Character string values should be quoted when passed from `Sweave` through ... but not when use in the header of a code chunk.
engine: character string ("R"). Only chunks with engine equal to "R" or "S" are processed.
echo: logical (TRUE). Include R code in the output file?
keep.source: logical (TRUE). When echoing, if keep.source == TRUE the original source is copied to the file. Otherwise, deparsed source is echoed.
eval: logical (TRUE). If FALSE, the code chunk is not evaluated, and hence no text nor graphical output produced.
results: character string ("verbatim"). If "verbatim", the output of R commands is included in the verbatim-like ‘soutput’ environment. If "tex", the output is taken to be already proper LaTeX markup and included as is. If "hide" then all output is completely suppressed (but the code executed during the weave).
print: logical (FALSE). If TRUE, this forces auto-printing of all expressions.
term: logical (TRUE). If TRUE, visibility of values emulates an interactive R session: values of assignments are not printed, values of single objects are printed. If FALSE, output comes only from explicit print or similar statements.
split: logical (FALSE). If TRUE, text output is written to separate files for each code chunk.
strip.white: character string ("true"). If "true", blank lines at the beginning and end of output are removed. If "all", then all blank lines are removed from the output. If "false" then blank lines are retained.
A ‘blank line’ is one that is empty or includes only whitespace (spaces and tabs).
Note that blank lines in a code chunk will usually produce a prompt string rather than a blank line on output.
prefix: logical (TRUE). If TRUE generated filenames of figures and output all have the common prefix given by the prefix.string option: otherwise only unlabelled chunks use the prefix.
prefix.string: a character string, default is the name of the source file (without extension). Note that this is used as part of filenames, so needs to be portable.
include: logical (TRUE), indicating whether input statements for text output (if split = TRUE) and ‘\includegraphics’ statements for figures should be auto-generated. Use include = FALSE if the output should appear in a different place than the code chunk (by placing the input line manually).
fig: logical (FALSE), indicating whether the code chunk produces graphical output. Note that only one figure per code chunk can be processed this way. The labels for figure chunks are used as part of the file names, so should preferably be alphanumeric.
eps: logical (FALSE), indicating whether EPS figures should be generated. Ignored if fig = FALSE.
pdf: logical (TRUE), indicating whether PDF figures should be generated. Ignored if fig = FALSE.
pdf.version, pdf.encoding, pdf.compress: passed to pdf to set the version, encoding and compression (or not). Defaults taken from pdf.options().
png: logical (FALSE), indicating whether PNG figures should be generated. Ignored if fig = FALSE. Only available in R >= 2.13.0.
jpeg: logical (FALSE), indicating whether JPEG figures should be generated. Ignored if fig = FALSE. Only available in R >= 2.13.0.
grdevice: character (NULL): see section ‘Custom Graphics Devices’. Ignored if fig = FALSE. Only available in R >= 2.13.0.
width: numeric (6), width of figures in inches. See ‘Details’.
height: numeric (6), height of figures in inches. See ‘Details’.
resolution: numeric (300), resolution in pixels per inch: used for PNG and JPEG graphics. Note that the default is a fairly high value, appropriate for high-quality plots. Something like 100 is a better choice for package vignettes.
concordance: logical (FALSE). Write a concordance file to link the input line numbers to the output line numbers. This is an experimental feature; see the source code for the output format, which is subject to change in future releases.

figs.only: logical (FALSE). By default each figure chunk is run once, then re-run for each selected type of graphics. That will open a default graphics device for the first figure chunk and use that device for the first evaluation of all subsequent chunks. If this option is true, the figure chunk is run only for each selected type of graphics, for which a new graphics device is opened and then closed.

In addition, users can specify further options, either in the header of an individual code section or in a `\SweaveOpts{}` line in the document. Prior to R 2.14.0 unknown options were taken as logical: now their type is set at first use.

Custom Graphics Devices

If option grdevice is supplied for a code chunk with both fig and eval true, the following call is made

```r
get(options$grdevice, envir = .GlobalEnv)(name =, width =,
    height =, options =)
```

which should open a graphics device. The chunk's code is then evaluated and dev.off is called. Normally a function of the name given will have been defined earlier in the Sweave document, e.g.

```r
<<results=hide>>=
my.Swd <- function(name, width, height, ...)
    grDevices::png(filename = paste(name, "png", sep = "."),
        width = width, height = height, res = 100,
        units = "in", type = "quartz", bg = "transparent")
@
```

Currently only one custom device can be used for each chunk, but different devices can be used for different chunks.

A replacement for dev.off can be provided as a function with suffix .off, e.g. my.Swd.off().

Hook Functions

Before each code chunk is evaluated, zero or more hook functions can be executed. If getOption("SweaveHooks") is set, it is taken to be a named list of hook functions. For each logical option of a code chunk (echo, print, ...) a hook can be specified, which is executed if and only if the respective option is TRUE. Hooks must be named elements of the list returned by getOption("SweaveHooks") and be functions taking no arguments. E.g., if option "SweaveHooks" is defined as list(fig = foo), and foo is a function, then it would be executed before the code in each figure chunk. This is especially useful to set defaults for the graphical parameters in a series of figure chunks.

Note that the user is free to define new Sweave logical options and associate arbitrary hooks with them. E.g., one could define a hook function for a new option called clean that removes all objects in the workspace. Then all code chunks specified with clean = TRUE would start operating on an empty workspace.

Friedrich Leisch and R-core
savehistory

Load or Save or Display the Commands History

Description

Load or save or display the commands history.

Usage

loadhistory(file = "\.Rhistory")
savehistory(file = "\.Rhistory")

history(max.show = 25, reverse = FALSE, pattern, ...)

timestamp(stamp = date(),
        prefix = "####-", suffix = "------", quiet = FALSE)

Arguments

file
max.show
reverse
pattern
... stamp
prefix
suffix
quiet

The name of the file in which to save the history, or from which to load it. The path is relative to the current working directory.
The maximum number of lines to show. \texttt{Inf} will give all of the currently available history.
logical. If true, the lines are shown in reverse order. Note: this is not useful when there are continuation lines.
A character string to be matched against the lines of the history. When supplied, only \texttt{unique} matching lines are shown.
Arguments to be passed to \texttt{grep} when doing the matching.
A value or vector of values to be written into the history.
A prefix to apply to each line.
A suffix to apply to each line.
If \texttt{TRUE}, suppress printing timestamp to the console.

Details

There are several history mechanisms available for the different \texttt{R} consoles, which work in similar but not identical ways. There are separate versions of this help file for Unix and Windows.
The functions described here work on Unix-alikes under the \texttt{readline} command-line interface but may not otherwise (for example, in batch use or in an embedded application). Note that \texttt{R} can be built without \texttt{readline}.
\texttt{R.app}, the console on OS X, has a separate and largely incompatible history mechanism, which by default uses a file \texttt{`.Rapp.history`} and saves up to 250 entries. These functions are not currently implemented there.

See Also

`Sweave User Manual`, a vignette in the \texttt{utils} package.
\texttt{Sweave}, \texttt{Rtangle}
The readline history mechanism is controlled by two environment variables: `R_HISTSIZE` controls the number of lines that are saved (default 512), and `R_HISTFILE` (default `.Rhistory`) sets the filename used for the loading/saving of history if requested at the beginning/end of a session (but not the default for `loadhistory/savehistory`). There is no limit on the number of lines of history retained during a session, so setting `R_HISTSIZE` to a large value has no penalty unless a large file is actually generated.

These environment variables are read at the time of saving, so can be altered within a session by the use of `Sys.setenv`.

Note that readline history library saves files with permission `660`, that is with read/write permission for the user and not even read permission for any other account.

The `timestamp` function writes a timestamp (or other message) into the history and echos it to the console. On platforms that do not support a history mechanism only the console message is printed.

**Note**

If you want to save the history at the end of (almost) every interactive session (even those in which you do not save the workspace), you can put a call to `savehistory()` in `.Last`. See the examples.

**Examples**

```r
## Not run:
## Save the history in the home directory: note that it is not
## (by default) read from there but from the current directory
.Last <- function()
   if(interactive()) try(savehistory("~/.Rhistory"))

## End(Not run)
```

---

**select.list**

*Select Items from a List*

**Description**

Select item(s) from a character vector.

**Usage**

```r
select.list(choices, preselect = NULL, multiple = FALSE,
           title = NULL, graphics = getOption("menu.graphics"))
```

**Arguments**

- `choices`: a character vector of items.
- `preselect`: a character vector, or NULL. If non-null and if the string(s) appear in the list, the item(s) are selected initially.
- `multiple`: logical: can more than one item be selected?
- `title`: optional character string for window title, or NULL for no title.
- `graphics`: logical: should a graphical widget be used?
Details

The normal default is graphics = TRUE. Under the OS X GUI this brings up a modal dialog box with a (scrollable) list of items, which can be selected by the mouse. On other Unix-like platforms it will use a Tcl/Tk listbox widget if possible.

If graphics is FALSE or no graphical widget is available it displays a text list from which the user can choose by number(s). The multiple = FALSE case uses menu. Preselection is only supported for multiple = TRUE, where it is indicated by a "*" preceding the item.

It is an error to use select.list in a non-interactive session.

Value

A character vector of selected items. If multiple is false and no item was selected (or Cancel was used), "" is returned. If multiple is true and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

See Also

menu, tk_select.list for a graphical version using Tcl/Tk.

Examples

## Not run:
select.list(sort(.packages(all.available = TRUE)))

## End(Not run)

---

**sessionInfo**

*Collect Information About the Current R Session*

**Description**

Print version information about R and attached or loaded packages.

**Usage**

sessionInfo(package = NULL)

## S3 method for class 'sessionInfo'
print(x, locale = TRUE, ...)

## S3 method for class 'sessionInfo'
toLatex(object, locale = TRUE, ...)

**Arguments**

package a character vector naming installed packages, or NULL (the default) meaning all attached packages.

x an object of class "sessionInfo".

object an object of class "sessionInfo".

locale show locale information?

... currently not used.
Value

An object of class "sessionInfo", which has a print method. This is a list with components

- **R.version**: a list, the result of calling `R.Version()`.
- **platform**: a character string describing the platform. For recent versions where sub-architectures are in use this is of the form 'platform/sub-arch (nn-bit)'.
- **locale**: a character string, the result of calling `Sys.getlocale()`.
- **basePkgs**: a character vector of base packages which are attached.
- **otherPkgs**: (not always present): a character vector of other attached packages.
- **loadedOnly**: (not always present): a named list of the results of calling `packageDescription` on packages whose namespaces are loaded but are not attached.

Note

The information on 'loaded' packages and namespaces is the current version installed at the location the package was loaded from: it can be wrong if another process has been changing packages during the session.

See Also

- `R.version`

Examples

```r
sessionInfo()
toLatex(sessionInfo(), locale = FALSE)
```

---

**setRepositories**  
*Select Package Repositories*

Description

Interact with the user to choose the package repositories to be used.

Usage

```r
setRepositories(graphics =getOption("menu.graphics"),  
    ind = NULL, addURLs = character())
```

Arguments

- **graphics**: Logical. If true, use a graphical list: on Windows or OS X GUI use a list box, and on a Unix-alike if `tcltk` and an X server are available, use Tk widget. Otherwise use a text menu.
- **ind**: NULL or a vector of integer indices, which have the same effect as if they were entered at the prompt for `graphics = FALSE`.
- **addURLs**: A character vector of additional URLs: it is often helpful to use a named vector.
Details

The default list of known repositories is stored in the file `
R_HOME/etc/repositories`. That file can be edited for a site, or a user can have a personal copy in `
HOME/.R/repositories` which will take precedence.

A Bioconductor mirror can be selected by setting `options("BioC_mirror")`: the default value is `"http://www.bioconductor.org"`.

The items that are preselected are those that are currently in `options("repos")` plus those marked as default in the list of known repositories.

The list of repositories offered depends on the setting of option "pkgType" as some repositories only offer a subset of types (e.g. only source packages or not OS X binary packages). Further, for binary packages some repositories (notably R-Forge) only offer packages for the current or recent versions of R.

Repository `CRAN` is treated specially: the value is taken from the current setting of `getOption("repos")` if this has an element "CRAN": this ensures mirror selection is sticky.

This function requires the R session to be interactive unless `ind` is supplied.

Value

This function is invoked mainly for its side effect of updating `options("repos")`. It returns (invisibly) the previous `repos` options setting (as a list with component repos) or `NULL` if no changes were applied.

Note

This does not set the list of repositories at startup: to do so set `options(repos =)` in a start up file (see help topic Startup).

See Also

chooseCRANmirror, install.packages.

Examples

```r
## Not run:
setRepositories(addURLs =
  c(CRANxtras = "http://www.stats.ox.ac.uk/pub/RWin"))
## End(Not run)
```

SHLIB Build Shared Object/DLL for Dynamic Loading

Description

Compile the given source files and then link all specified object files into a shared object aka DLL which can be loaded into R using `dyn.load` or `library.dynam`.

Usage

```r
R CMD SHLIB [options] [-o dllname] files
```
Arguments

files

A list specifying the object files to be included in the shared object/DLL. You can also include the name of source files (for which the object files are automagically made from their sources) and library linking commands.

dllname

The full name of the shared object/DLL to be built, including the extension (typically `.so` on Unix systems, and `.dll` on Windows). If not given, the basename of the object/DLL is taken from the basename of the first file.

options

Further options to control the processing. Use `R CMD SHLIB --help` for a current list.

Details

R CMD SHLIB is the mechanism used by INSTALL to compile source code in packages. It will generate suitable compilation commands for C, C++, Objective C(++) and Fortran sources: Fortran 90/95 sources can also be used but it may not be possible to mix these with other languages (on most platforms it is possible to mix with C, but mixing with C++ rarely works).

Please consult section ‘Creating shared objects’ in the manual ‘Writing R Extensions’ for how to customize it (for example to add cpp flags and to add libraries to the link step) and for details of some of its quirks.

Items in `files` with extensions `.c`, `.cpp`, `.cc`, `.C`, `.f`, `.f90`, `.f95`, `.m` (ObjC), `.M` and `.mm` (ObjC++) are regarded as source files, and those with extension `.o` as object files. All other items are passed to the linker.

Objective C(++) support is optional when R was configured: their main usage is on OS X.

Note that the appropriate run-time libraries will be used when linking if C++, Fortran or Objective C(++) sources are supplied, but not for compiled object files from these languages.

Option `--n` (also known as `--dry-run`) will show the commands that would be run without actually executing them.

Note

Some binary distributions of R have SHLIB in a separate bundle, e.g., an R-devel RPM.

See Also

`compile`, `dyn.load`, `library.dynam`.

The ‘R Installation and Administration’ and ‘Writing R Extensions’ manuals, including the section on “Customizing compilation” in the former.

Examples

```r
## Not run:
# To link against a library not on the system library paths:
R CMD SHLIB -o mylib.so a.f b.f -L/opt/acml3.5.0/gnu64/lib -lacml
## End(Not run)
```
**sourceutils**  
*Source Reference Utilities*

**Description**
These functions extract information from source references.

**Usage**

```r
getSrcFilename(x, full.names = FALSE, unique = TRUE)  
getSrcDirectory(x, unique = TRUE)  
getSrcRef(x)  
getSrcLocation(x, which = c("line", "column", "byte", "parse"),  
               first = TRUE)
```

**Arguments**

- `x` An object (typically a function) containing source references.
- `full.names` Whether to include the full path in the filename result.
- `unique` Whether to list only unique filenames/directories.
- `which` Which part of a source reference to extract.
- `first` Whether to show the first (or last) location of the object.

**Details**

Each statement of a function will have its own source reference if the "keep.source" option is `TRUE`. These functions retrieve all of them.

The components are as follows:

- **line** The line number where the object starts or ends.
- **column** The column number where the object starts or ends.
- **byte** As for "column", but counting bytes, which may differ in case of multibyte characters.
- **parse** As for "line", but this ignores #line directives.

**Value**

getSrcFilename and getSrcDirectory return character vectors holding the filename/directory.
getSrcRef returns a list of "srcRef" objects or NULL if there are none.
getSrcLocation returns an integer vector of the requested type of locations.

**See Also**

`srcRef`, `getParseData`
Examples

```r
fn <- function(x) {
  x + 1  # A comment, kept as part of the source
}

# Show the temporary file directory
# where the example was saved
getSrcDirectory(fn)
getSrcLocation(fn, "line")
```

---

**stack**  
*Stack or Unstack Vectors from a Data Frame or List*

**Description**

Stacking vectors concatenates multiple vectors into a single vector along with a factor indicating where each observation originated. Unstacking reverses this operation.

**Usage**

```r
stack(x, ...)
## Default S3 method:
stack(x, ...)
## S3 method for class 'data.frame'
stack(x, select, ...)

unstack(x, ...)
## Default S3 method:
unstack(x, form, ...)
## S3 method for class 'data.frame'
unstack(x, form, ...)
```

**Arguments**

- `x`  
  a list or data frame to be stacked or unstacked.

- `select`  
  an expression, indicating which variable(s) to select from a data frame.

- `form`  
  a two-sided formula whose left side evaluates to the vector to be unstacked and whose right side evaluates to the indicator of the groups to create. Defaults to `formula(x)` in the data frame method for `unstack`.

- `...`  
  further arguments passed to or from other methods.

**Details**

The `stack` function is used to transform data available as separate columns in a data frame or list into a single column that can be used in an analysis of variance model or other linear model. The `unstack` function reverses this operation.

Note that `stack` applies to vectors (as determined by `is.vector`): non-vector columns (e.g., factors) will be ignored (with a warning as from R 2.15.0). Where vectors of different types are selected they are concatenated by `unlist` whose help page explains how the type of the result is chosen.

These functions are generic: the supplied methods handle data frames and objects coercible to lists by `as.list`. 
unstack produces a list of columns according to the formula \( \text{form} \). If all the columns have the same length, the resulting list is coerced to a data frame.

stack produces a data frame with two columns:

- **values**: the result of concatenating the selected vectors in \( x \).
- **ind**: a factor indicating from which vector in \( x \) the observation originated.

Douglas Bates

See Also

`lm, reshape`

Examples

```r
require(stats)
formula(PlantGrowth)  # check the default formula
pg <- unstack(PlantGrowth)  # unstack according to this formula
pg
stack(pg)  # now put it back together
stack(pg, select = -ctrl)  # omitting one vector
```

---

**Description**

Compactly display the internal structure of an R object, a diagnostic function and an alternative to `summary` (and to some extent, `dput`). Ideally, only one line for each 'basic' structure is displayed. It is especially well suited to compactly display the (abbreviated) contents of (possibly nested) lists. The idea is to give reasonable output for any R object. It calls `args` for (non-primitive) function objects.

`strOptions()` is a convenience function for setting `options(str = .)`, see the examples.

**Usage**

```r
str(object, ...)
```

### S3 method for class 'data.frame'

```r
str(object, ...)
```

### Default S3 method:

```r
str(object, max.level = NA,
    vec.len = str0$vec.len, digits.d = str0$digits.d,
    nchar.max = 128, give.attr = TRUE,
    give.head = TRUE, give.length = give.head,
    width =getOption("width"), nest.lev = 0,
    indent.str = paste(rep.int(" ", max(0, nest.lev + 1)),
```
collapse = ". . ",
comp.str = "+ ", no.list = FALSE, envir = baseenv(),
strict.width = strO$strict.width,
formatNum = strO$formatNum, list.len = 99, ...)

strOptions(strict.width = "no", digits.d = 3, vec.len = 4,
formatNum = function(x, ...)
  format(x, trim = TRUE, drop.trailing = TRUE, ...))

Arguments

object any R object about which you want to have some information.
max.level maximal level of nesting which is applied for displaying nested structures, e.g.,
a list containing sub lists. Default NA: Display all nesting levels.
vec.len numeric (>= 0) indicating how many ‘first few’ elements are displayed of each
vector. The number is multiplied by different factors (from .5 to 3) depending
on the kind of vector. Defaults to the vec.len component of option "str" (see
options) which defaults to 4.
digits.d number of digits for numerical components (as for print). Defaults to the
digits.d component of option "str" which defaults to 3.
nchar.max maximal number of characters to show for character strings. Longer strings
are truncated, see longch example below.
give.attr logical; if TRUE (default), show attributes as sub structures.
give.length logical; if TRUE (default), indicate length (as [1: ... ]).
give.head logical; if TRUE (default), give (possibly abbreviated) mode/class and length (as
<type>[1: ... ]).
width the page width to be used. The default is the currently active
options("width"); note that this has only a weak effect, unless strict.width
is not "no".
nest.lev current nesting level in the recursive calls to str.
indent.str the indentation string to use.
comp.str string to be used for separating list components.
no.list logical; if true, no ‘list of . . . ’ nor the class are printed.
envir the environment to be used for promise (see delayedAssign) objects only.
strict.width string indicating if the width argument’s specification should be fol-
lowed strictly, one of the values c("no", "cut", "wrap"). De-
defaults to the strict.width component of option "str" (see options)
which defaults to "no" for back compatibility reasons; "wrap" uses
strwrap(*, width = width) whereas "cut" cuts directly to width. Note
that a small vec.length may be better than setting strict.width = "wrap".
formatNum a function such as format for formatting numeric vectors. It defaults to the
formatNum component of option "str", see “Usage” of strOptions() above,
which is almost back compatible to R <= 2.7.x, however, using formatC may
be slightly better.
list.len numeric; maximum number of list elements to display within a level.
... potential further arguments (required for Method/Generic reasons).
Value

str does not return anything, for efficiency reasons. The obvious side effect is output to the terminal.

    sum(dpois(y, lambda=ymax/(1+x/xh), log=TRUE))
fit <- mle(l1)
str(fit)

### `summaryRprof`

#### Summarise Output of R Sampling Profiler

**Description**

Summarise the output of the `Rprof` function to show the amount of time used by different R functions.

**Usage**

```r
summaryRprof(filename = "Rprof.out", chunksize = 5000,
memory = c("none", "both", "tseries", "stats"),
lines = c("hide", "show", "both"),
index = 2, diff = TRUE, exclude = NULL,
basenames = 1)
```

**Arguments**

- `filename` Name of a file produced by `Rprof()`.
- `chunksize` Number of lines to read at a time.
- `memory` Summaries for memory information. See ‘Memory profiling’ below.
- `lines` Summaries for line information. See ‘Line profiling’ below.
- `index` How to summarize the stack trace for memory information. See ‘Details’ below.
- `diff` If TRUE memory summaries use change in memory rather than current memory.
- `exclude` Functions to exclude when summarizing the stack trace for memory summaries.
- `basenames` Number of components of the path to filenames to display.

**Details**

This function provides the analysis code for Rprof files used by R CMD Rprof.

As the profiling output file could be larger than available memory, it is read in blocks of chunksize lines. Increasing chunksize will make the function run faster if sufficient memory is available.
Value

If `memory = "none"` and `lines = "hide"`, a list with components

- `by.self` A data frame of timings sorted by ‘self’ time.
- `by.total` A data frame of timings sorted by ‘total’ time.
- `sample.interval` The sampling interval.
- `sampling.time` Total time of profiling run.

The first two components have columns ‘self.time’, ‘self.pct’, ‘total.time’ and ‘total.pct’, the times in seconds and percentages of the total time spent executing code in that function and code in that function or called from that function, respectively.

If `lines = "show"`, an additional component is added to the list:

- `by.line` A data frame of timings sorted by source location.

If `memory = "both"` the same list but with memory consumption in Mb in addition to the timings.

If `memory = "tseries"` a data frame giving memory statistics over time.

If `memory = "stats"` a `by` object giving memory statistics by function.

Prior to R 2.15.3 an error was thrown if no events were recorded: now zero-row data frames are returned.

Memory profiling

Options other than `memory = "none"` apply only to files produced by `Rprof(memory.profiling = TRUE)`.

When called with `memory.profiling = TRUE`, the profiler writes information on three aspects of memory use: vector memory in small blocks on the R heap, vector memory in large blocks (from `malloc`), memory in nodes on the R heap. It also records the number of calls to the internal function `duplicate` in the time interval. `duplicate` is called by C code when arguments need to be copied. Note that the profiler does not track which function actually allocated the memory.

With `memory = "both"` the change in total memory (truncated at zero) is reported in addition to timing data.

With `memory = "tseries"` or `memory = "stats"` the index argument specifies how to summarize the stack trace. A positive number specifies that many calls from the bottom of the stack; a negative number specifies the number of calls from the top of the stack. With `memory = "tseries"` the index is used to construct labels and may be a vector to give multiple sets of labels. With `memory = "stats"` the index must be a single number and specifies how to aggregate the data to the maximum and average of the memory statistics. With both `memory = "tseries"` and `memory = "stats"` the argument `diff = TRUE` asks for summaries of the increase in memory use over the sampling interval and `diff = FALSE` asks for the memory use at the end of the interval.

Line profiling

If the code being run has source reference information retained (via `keep.source = TRUE` in `source` or `KeepSource = TRUE` in a package ‘DESCRIPTION’ file or some other way), then information about the origin of lines is recorded during profiling. By default this is not displayed, but the `lines` parameter can enable the display.

If `lines = "show"`, line locations will be used in preference to the usual function name information, and the results will be displayed ordered by location in addition to the other orderings.

If `lines = "both"`, line locations will be mixed with function names in a combined display.
Sweave

Automatic Generation of Reports

Description

Sweave provides a flexible framework for mixing text and R/S code for automatic report generation. The basic idea is to replace the code with its output, such that the final document only contains the text and the output of the statistical analysis: however, the source code can also be included.

Usage

```r
Sweave(file, driver = RweaveLatex(),
       syntax =getOption("SweaveSyntax"), encoding = ",", ...)

Stangle(file, driver = Rtangle(),
        syntax =getOption("SweaveSyntax"), encoding = ",", ...)
```

Arguments

- **file**: Path to Sweave source file. Note that this can be supplied without the extension, but the function will only proceed if there is exactly one Sweave file in the directory whose basename matches file.
- **driver**: The actual workhorse, see ‘Details’.
- **syntax**: NULL or an object of class SweaveSyntax or a character string with its name. See the section ‘Syntax Definition’.
- **encoding**: The default encoding to assume for file.
- **...**: Further arguments passed to the driver’s setup function: see section ‘Drivers’, RweaveLatex and Rtangle.

See Also

The chapter on “Tidying and profiling R code” in “Writing R Extensions” (see the ‘doc/manual’ subdirectory of the R source tree).

Rprof

`tracemem` traces copying of an object via the C function `duplicate`. `Rprofmem` is a non-sampling memory-use profiler.

http://developer.r-project.org/memory-profiling.html

Examples

```r
## Not run:
## Rprof() is not available on all platforms
Rprof(tmp <- tempfile())
example(glm)
Rprof()
summaryRprof(tmp)
unlink(tmp)

## End(Not run)
```
Details

Automatic generation of reports by mixing word processing markup (like latex) and S code. The S code gets replaced by its output (text or graphs) in the final markup file. This allows a report to be re-generated if the input data change and documents the code to reproduce the analysis in the same file that also produces the report.

Sweave combines the documentation and code chunks together (or their output) into a single document. Stangle extracts only the code from the Sweave file creating an S source file that can be run using source. (Code inside \$expr{} statements is ignored by Stangle.)

Stangle is just a wrapper to Sweave specifying a different default driver. Alternative drivers can be used: the CRAN package cacheSweave and the Bioconductor package weaver both provide drivers based on the default driver RweaveLatex which incorporate ideas of caching the results of computations on code chunks.

Environment variable SWEAVE_OPTIONS can be used to override the initial options set by the driver: it should be a comma-separated set of key=value items, as would be used in a ‘\SweaveOpts’ statement in a document.

Non-ASCII source files must contain a line of the form

\usepackage[foo]{inputenc}

(where ‘foo’ is typically ‘latin1’, ‘latin2’, ‘utf8’ or ‘cp1252’ or ‘cp1250’) or they will give an error. Re-encoding can be turned off completely with argument encoding = "bytes".

Syntax Definition

Sweave allows a flexible syntax framework for marking documentation and text chunks. The default is a noweb-style syntax, as alternative a latex-style syntax can be used. (See the user manual for further details.)

If syntax = NULL (the default) then the available syntax objects are consulted in turn, and selected if their extension component matches (as a regexp) the file name. Objects SweaveSyntaxNoWeb (with extension = "[.][rsRS]nw$") and SweaveSyntaxLatex (with extension = "[.][rsRS]tex$") are supplied, but users or packages can supply others with names matching the pattern SweaveSyntax.*.

Author(s)

Friedrich Leisch and R-core.

SweaveSyntConv Convert Sweave Syntax

Description

This function converts the syntax of files in Sweave format to another Sweave syntax definition.

Usage

SweaveSyntConv(file, syntax, output = NULL)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file</td>
<td>Name of Sweave source file.</td>
</tr>
<tr>
<td>syntax</td>
<td>An object of class SweaveSyntax or a character string with its name giving the target syntax to which the file is converted.</td>
</tr>
<tr>
<td>output</td>
<td>Name of output file, default is to remove the extension from the input file and to add the default extension of the target syntax. Any directory names in file are also removed such that the output is created in the current working directory.</td>
</tr>
</tbody>
</table>

## and run it through Sweave
Sweave("Sweave-test-1.Stex")

tar

Create a Tar Archive

Description

Create a tar archive.

Usage

tar(tarfile, files = NULL,
    compression = c("none", "gzip", "bzip2", "xz"),
    compression_level = 6, tar = Sys.getenv("tar"),
    extra_flags = "")

Arguments

tarfile The pathname of the tar file: tilde expansion (see path.expand) will be performed. Alternatively, a connection that can be used for binary writes.
files A character vector of filepaths to be archived: the default is to archive all files under the current directory.
compression character string giving the type of compression to be used (default none). Can be abbreviated.
compression_level integer: the level of compression. Only used for the internal method.
tar character string: the path to the command to be used. If the command itself contains spaces it needs to be quoted (e.g. by shQuote) – but argument tar can also contain flags separated from the command by spaces.
extra_flags any extra flags for an external tar.

Details

This is either a wrapper for a tar command or uses an internal implementation in \texttt{R}. The latter is used if tarfile is a connection or if the argument tar is "internal" or "" (the 'factory-fresh' default). Note that whereas Unix-alike versions of \texttt{R} set the environment variable TAR, its value is not the default for this function.

Argument extra_flags is passed to an external tar and so is platform-dependent. Possibly useful values include ‘-h’ (follow symbolic links, also ‘-L’ on some platforms), ‘--acls’, ‘--exclude-backups’, ‘--exclude-vcs’ (and similar) and on Windows ‘--force-local’ (so drives can be included in filepaths: however, this is the default for the Rtools tar). For GNU
tar, `--format=ustar` forces a more portable format (the current default in version 1.26 is `--format=gnu`, but the manual says the intention is to change to `--format=pax` which GNU incorrectly calls ‘POSIX’ – it was never part of the POSIX standard for tar). For libarchive tar, `--format=ustar` is more portable than the default.

Value

The return code from `system` or 0 for the internal version, invisibly.

Portability

The ‘tar’ format no longer has an agreed standard! ‘Unix Standard Tar’ was part of POSIX 1003.1:1998 but has been removed in favour of pax, and in any case many common implementations diverged from the former standard. Most R platforms use a version of GNU tar (including Rtools on Windows, but the behaviour seems to be changed with each version), Mac OS >= 10.6 and FreeBSD use `bsdtar` from the ‘libarchive’ project, and commercial Unixes will have their own versions.

Known problems arise from

- The handling of file paths of more than 100 bytes. These were unsupported in early versions of tar, and supported in one way by POSIX tar and in another by GNU tar and yet another by the POSIX pax command which recent tar programs often support. The internal implementation warns on paths of more than 100 bytes, uses the ‘ustar’ way from the 1998 POSIX standard which supports up to 256 bytes (depending on the path: in particular the final component is limited to 100 bytes) if possible, or the GNU way (which is widely supported). Most formats do not record the encoding of file paths.
- (File) links. tar was developed on an OS that used hard links, and physical files that were referred to more than once in the list of files to be included were included only once, the remaining instances being added as links. Later a means to include symbolic links was added. The internal implementation supports symbolic links (on OSes that support them), only. Of course, the question arises as to how links should be unpacked on OSes that do not support them: for regular files, at least, file copies can be used.

Names of links in the ‘ustar’ format are restricted to 100 bytes. There is an GNU extension for arbitrarily long link names, but `bsdtar` does not read. The internal method uses the GNU extension, with a warning.
- Header fields, in particular the padding to be used when fields are not full or not used. POSIX did define the correct behaviour but commonly used implementations did (and still do) not comply.
- File sizes. The ‘ustar’ format is restricted to 8GB per (uncompressed) file.

For portability, avoid file paths of more than 100 bytes and all links (especially hard links and symbolic links to directories).

The internal implementation writes only the blocks of 512 bytes required (including trailing blocks of nuls), unlike GNU tar which by default pads with ‘nul’ to a multiple of 20 blocks (10KB). Implementations which pad differ on whether the block padding should occur before or after compression (or both): padding was designed for improved performance on physical tape drives.

See Also

toLatex  \hspace{0.3cm} Converting R Objects to BibTeX or LaTeX

Description

These methods convert R objects to character vectors with BibTeX or LaTeX markup.

Usage

```r
toBibtex(object, ...)  
toLatex(object, ...)  
## S3 method for class 'Bibtex'  
print(x, prefix = "", ...)  
## S3 method for class 'Latex'  
print(x, prefix = "", ...)  
```

Arguments

- `object` object of a class for which a `toBibtex` or `toLatex` method exists.
- `x` object of class "Bibtex" or "Latex".
- `prefix` a character string which is printed at the beginning of each line, mostly used to insert whitespace for indentation.
- `...` in the print methods, passed to `writeLines`.

Details

Objects of class "Bibtex" or "Latex" are simply character vectors where each element holds one line of the corresponding BibTeX or LaTeX file.

`citEntry` and `sessionInfo` for examples

---

txtProgressBar  \hspace{0.3cm} Text Progress Bar

Description

Text progress bar in the R console.
Usage

txtProgressBar(min = 0, max = 1, initial = 0, char = "=", width = NA, title, label, style = 1, file = "")

def getTxtProgressBar(pb)
def setTxtProgressBar(pb, value, title = NULL, label = NULL)

Arguments

min, max (finite) numeric values for the extremes of the progress bar. Must have min < max.

initial, value initial or new value for the progress bar. See ‘Details’ for what happens with invalid values.

char the character (or character string) to form the progress bar.

width the width of the progress bar, as a multiple of the width of char. If NA, the default, the number of characters is that which fits into getOption("width").

style the 'style' of the bar – see ‘Details’.

file an open connection object or "" which indicates the console: stderr() might be useful here.

pb, con an object of class "txtProgressBar".

title, label ignored, for compatibility with other progress bars.

for consistency with the generic.

Details

txtProgressBar will display a progress bar on the R console (or a connection) via a text representation.

setTxtProgressBar will update the value. Missing (NA) and out-of-range values of value will be (silently) ignored. (Such values of initial cause the progress bar not to be displayed until a valid value is set.)

The progress bar should be closed when finished with: this outputs the final newline character.

style = 1 and style = 2 just shows a line of char. They differ in that style = 2 redraws the line each time, which is useful if other code might be writing to the R console. style = 3 marks the end of the range by | and gives a percentage to the right of the bar.

Value

For txtProgressBar an object of class "txtProgressBar".

For getTxtProgressBar and setTxtProgressBar, a length-one numeric vector giving the previous value (invisibly for setTxtProgressBar).

Note

Using style 2 or 3 or reducing the value with style = 1 uses ‘\r’ to return to the left margin – the interpretation of carriage return is up to the terminal or console in which R is running, and this is liable to produce ugly output on a connection other than a terminal, including when stdout() is redirected to a file.
See Also
tkProgressBar.

Windows versions of R also have winProgressBar.

Examples

```r
# slow
testit <- function(x = sort(runif(20)), ...)
{
  pb <- txtProgressBar(...)
  for(i in c(0, x, 1)) {
    Sys.sleep(0.5); setTxtProgressBar(pb, i)
    Sys.sleep(1)
    close(pb)
  }
  testit()
testit(runif(10))
testit(style = 2)
```

---

**type.convert**

Type Conversion on Character Variables

Description

Convert a character vector to logical, integer, numeric, complex or factor as appropriate.

Usage

```r
type.convert(x, na.strings = "NA", as.is = FALSE, dec = ".")
```

Arguments

- `x` a character vector.
- `na.strings` a vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric or complex vectors.
- `as.is` logical. See ‘Details’.
- `dec` the character to be assumed for decimal points.

Details

This is principally a helper function for `read.table`. Given a character vector, it attempts to convert it to logical, integer, numeric or complex, and failing that converts it to factor unless `as.is` = TRUE. The first type that can accept all the non-missing values is chosen (numeric and complex return values will represented approximately, of course).

Vectors which are entirely missing values are converted to logical, since NA is primarily logical.

Vectors containing just F, T, FALSE, TRUE and values from `na.strings` are converted to logical.

Vectors containing optional whitespace followed by decimal constants representable as R integers or values from `na.strings` are converted to integer. Other vectors containing optional whitespace followed by other decimal or hexadecimal constants (see `NumericConstants`), or NaN, Inf or infinity (ignoring case) or values from `na.strings` are converted to numeric.

Since this is a helper function, the caller should always pass an appropriate value of `as.is`. 
untar

Value

A vector of the selected class, or a factor.

See Also

read.table

untar

Extract or List Tar Archives

Description

Extract files from or list a tar archive.

Usage

untar(tarfile, files = NULL, list = FALSE, exdir = ".",
compressed = NA, extras = NULL, verbose = FALSE,
restore_times = TRUE, tar = Sys.getenv("TAR"))

Arguments

tarfile
A character string: the path to the command to be used. If the command itself contains spaces it needs to be quoted – but tar can also contain flags separated from the command by spaces.

files
A character vector of recorded filepaths to be extracted: the default is to extract all files.

list
If TRUE, list the files (the equivalent of tar -tf). Otherwise extract the files (the equivalent of tar -xf).

exdir
The directory to extract files to (the equivalent of tar -C). It will be created if necessary.

compressed
logical or character. Values "gzip", "bzip2" and "xz" select that form of compression (and may be abbreviated to the first letter). TRUE indicates gzip compression, FALSE no known compression (but an external tar command may detect compression automagically), and NA (the default) that the type is inferred from the file header.

extras
NULL or a character string: further command-line flags such as ‘-p’ to be passed to an external tar program.

verbose
logical: if true echo the command used.

restore_times
logical. If true (default) restore file modification times. If false, the equivalent of the ‘-m’ flag. Times in tarballs are supposed to be in UTC, but tarballs are submitted to CRAN with times in the future or far past: this argument allows such times to be discarded.

tar
character string: the path to the command to be used. If the command itself contains spaces it needs to be quoted – but tar can also contain flags separated from the command by spaces.
Details

This is either a wrapper for a `tar` command or for an internal implementation written in R. The latter is used if `tarfile` is a connection or if the argument `tar` is "internal" or "" (except on Windows, when `tar.exe` is tried first).

What options are supported will depend on the `tar` used. Modern GNU flavours of `tar` will support compressed archives, and since 1.15 are able to detect the type of compression automatically: version 1.20 added support for lzma and version 1.22 for xz compression using LZMA2. Mac OS 10.6 and later (and FreeBSD and some other OSes) have a `tar` also known as `bsdtar` from the ‘libarchive’ project used by Mac OS 10.6 and later which can also detect gzip and bzip2 compression automatically. For other flavours of `tar`, environment variable `R_GZICMD` gives the command to decompress gzip and compress files, and `R_BZIPCMD` for bzip2 files.

Arguments compressed, extras and verbose are only used when an external `tar` is used.

The internal implementation restores symbolic links as links on a Unix-alike, and as file copies on Windows (which works only for existing files, not for directories), and hard links as links. If the linking operation fails (as it may on a FAT file system), a file copy is tried. Since it uses `gzfile` to read a file it can handle files compressed by any of the methods that function can handle: at least compress, gzip, bzip2 and xz compression, and some types of lzma compression. It does not guard against restoring absolute file paths, as some `tar` implementations do. It will create the parent directories for directories or files in the archive if necessary. It handles the standard (USTAR/POSIX), GNU and pax ways of handling file paths of more than 100 bytes, and the GNU way of handling link targets of more than 100 bytes.

You may see warnings from the internal implementation such as

```
unsupported entry type 'x'
```

This often indicates an invalid archive: entry types "A-Z" are allowed as extensions, but other types are reserved. The only thing you can do with such an archive is to find a `tar` program that handles it, and look carefully at the resulting files. There may also be the warning

```
using pax extended headers
```

This is indicates that additional information may have been discarded, such as ACLs, encodings ..., and long path and link names are only used as from R 2.15.3.

The standards only support ASCII filenames (indeed, only alphanumeric plus period, underscore and hyphen). `untar` makes no attempt to map filenames to those acceptable on the current system, and treats the filenames in the archive as applicable without any re-encoding in the current locale.

Value

If `list = TRUE`, a character vector of (relative or absolute) paths of files contained in the tar archive.

Otherwise the return code from `system`, invisibly.

See Also

`tar`, `unzip`. 
unzip

Extract or List Zip Archives

Description

Extract files from or list a zip archive.

Usage

```r
unzip(zipfile, files = NULL, list = FALSE, overwrite = TRUE,
      junkpaths = FALSE, exdir = ".", unzip = "internal",
      setTimes = FALSE)
```

Arguments

- **zipfile**: The pathname of the zip file: tilde expansion (see `path.expand`) will be performed.
- **files**: A character vector of recorded filepaths to be extracted: the default is to extract all files.
- **list**: If `TRUE`, list the files and extract none. The equivalent of `unzip -l`.
- **overwrite**: If `TRUE`, overwrite existing files, otherwise ignore such files. The equivalent of `unzip -o`.
- **junkpaths**: If `TRUE`, use only the basename of the stored filepath when extracting. The equivalent of `unzip -j`.
- **exdir**: The directory to extract files to (the equivalent of `unzip -d`). It will be created if necessary.
- **unzip**: The method to be used. An alternative is to use `getOption("unzip")`, which on a Unix-alike may be set to the path to a `unzip` program.
- **setTimes**: logical. For the internal method only, should the file time be set based on the times in the zip file? (NB: this applies to files, not to directories).

Value

If `list = TRUE`, a data frame with columns `Name` (character), `Length` (the size of the uncompressed file, numeric) and `Date` (of class "POSIXct"). Otherwise for the "internal" method, a character vector of the filepaths extracted to, invisibly.

Note

The default internal method is a minimal implementation, principally designed for Windows’ users to be able to unpack Windows binary packages without external software. It does not (for example) support Unicode filenames as introduced in `zip 3.0`: for that use `unzip = "unzip"` with `unzip 6.00` or later. (As from `R 2.14.0` it does have support for files of more than 4GB and `bzip2` compression.)

If `unzip` specifies a program, the format of the dates listed with `list = TRUE` is unknown (on Windows it can even depend on the current locale) and the return values could be `NA` or expressed in the wrong timezone or misinterpreted (the latter being far less likely as from `unzip 6.00`).

File times in zip files are stored in the style of MS-DOS, as local times to an accuracy of 2 seconds. This is not very useful when transferring zip files between machines (even across continents), so we chose not to restore them by default.
Source

The internal C code uses zlib and is in particular based on the contributed ‘minizip’ application in the zlib sources (from http://zlib.net) by Gilles Vollant.

update.packages

Compare Installed Packages with CRAN-like Repositories

Description

old.packages indicates packages which have a (suitable) later version on the repositories whereas update.packages offers to download and install such packages.
new.packages looks for (suitable) packages on the repositories that are not already installed, and optionally offers them for installation.

Usage

update.packages(lib.loc = NULL, repos = getOption("repos"),
                 contriburl = contrib.url(repos, type),
                 method, instlib = NULL,
                 ask = TRUE, available = NULL,
                 oldPkgs = NULL, ..., checkBuilt = FALSE,
                 type = getOption("pkgType"))

old.packages(lib.loc = NULL, repos = getOption("repos"),
               contriburl = contrib.url(repos, type),
               instPkgs = installed.packages(lib.loc = lib.loc),
               method, available = NULL, checkBuilt = FALSE,
               type = getOption("pkgType"))

new.packages(lib.loc = NULL, repos = getOption("repos"),
              contriburl = contrib.url(repos, type),
              instPkgs = installed.packages(lib.loc = lib.loc),
              method, available = NULL, ask = FALSE, ..., 
              type = getOption("pkgType"))

Arguments

lib.loc character vector describing the location of R library trees to search through (and update packages therein), or NULL for all known trees (see .libPaths).
repos character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as "http://cran.us.r-project.org".
contriburl URL(s) of the contrib sections of the repositories. Use this argument if your repository is incomplete. Overrides argument repos.
method Download method, see download.file.
update.packages

instlib
character string giving the library directory where to install the packages.

ask
logical indicating whether to ask user before packages are actually downloaded and installed, or the character string "graphics", which brings up a widget to allow the user to (de-)select from the list of packages which could be updated or added. The latter value only works on systems with a GUI version of select.list, and is otherwise equivalent to ask = TRUE.

available
an object as returned by available.packages listing packages available at the repositories, or NULL which makes an internal call to available.packages.

checkBuilt
If TRUE, a package built under an earlier major.minor version of R (e.g. 2.14) is considered to be 'old'.

oldPkgs
if specified as non-NULL, update.packages() only considers these packages for updating. This may be a character vector of package names or a matrix as returned by old.packages().

instPkgs
by default all installed packages, installed.packages(lib.loc = lib.loc). A subset can be specified; currently this must be in the same (character matrix) format as returned by installed.packages().

... Arguments such as destdir and dependencies to be passed to install.packages.

type
character, indicating the type of package to download and install. See install.packages.

Details

old.packages compares the information from available.packages with that from instPkgs (computed by installed.packages by default) and reports installed packages that have newer versions on the repositories or, if checkBuilt = TRUE, that were built under an earlier minor version of R (for example built under 2.14.x when running R 2.15.0). (For binary package types here is no check that the version on the repository was built under the current minor version of R, but it is advertised as being suitable for this version.)

new.packages does the same comparison but reports uninstalled packages that are available at the repositories. If ask ! = FALSE it asks which packages should be installed in the first element of lib.loc.

The main function of the set is update.packages. First a list of all packages found in lib.loc is created and compared with those available at the repositories. If ask = TRUE (the default) packages with a newer version are reported and for each one the user can specify if it should be updated. If so the packages are downloaded from the repositories and installed in the respective library path (or instlib if specified).

For how the list of suitable available packages is determined see available.packages. available = NULL make a call to available.packages(contriburl = contriburl, method = method) and hence by default filters on R version, OS type and removes duplicates.

Value

update.packages returns NULL invisibly.

For old.packages, NULL or a matrix with one row per package, row names the package names and column names "Package", "LibPath", "Installed" (the version), "Built" (the version built under), "ReposVer" and "Repository".

For new.packages a character vector of package names, after any selected via ask have been installed.
Warning

Take care when using dependencies (passed to `install.packages`) with `update.packages`, for it is unclear where new dependencies should be installed. The current implementation will only allow it if all the packages to be updated are in a single library, when that library will be used.

---

**url.show**

*Display a text URL*

**Description**

Extension of `file.show` to display text files from a remote server.

**Usage**

```r
url.show(url, title = url, file = tempfile(), delete.file = TRUE, method, ...)
```

**Arguments**

- `url` The URL to read from.
- `title` Title for the browser.
- `file` File to copy to.
- `delete.file` Delete the file afterwards?
- `method` File transfer method: see `download.file`
- `...` Arguments to pass to `file.show`.

**Note**

Since this is for text files, it will convert to CRLF line endings on Windows.

**See Also**

`url`, `file.show`, `download.file`

**Examples**

```r
## Not run: url.show("http://lib.stat.cmu.edu/datasets/csb/ch3a.txt")
```
URLencode

Encode or Decode a (partial) URL

Description

Functions to encode or decode characters in URLs.

Usage

URLencode(URL, reserved = FALSE)
URLdecode(URL)

Arguments

URL A character string.
reserved should reserved characters be encoded? See ‘Details’.

Details

Characters in a URL other than the English alphanumeric characters and ‘$ – _ . + ! * ’ ( ) , ’ should be encoded as % plus a two-digit hexadecimal representation, and any single-byte character can be so encoded. (Multi-byte characters are encoded as byte-by-byte.)

In addition, ‘; / ? : @ = ’ are reserved characters, and should be encoded unless used in their reserved sense, which is scheme specific. The default in URLencode is to leave them alone, which is appropriate for ‘file://’ URLs, but probably not for ‘http://’ ones.

Value

A character string.

References

Examples

(y <- URLencode("a url with spaces and / and @"))
URLdecode(y)
(y <- URLencode("a url with spaces and / and @", reserved = TRUE))
URLdecode(y)
URLdecode("ab%20cd")
Deprecated Functions in Package `utils`

Description

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

See Also

`deprecated`, `defunct`

---

Invoke a Data Viewer

Description

Invoke a spreadsheet-style data viewer on a matrix-like R object.

Usage

`View(x, title)`

Arguments

- `x`: an R object which can be coerced to a data frame with non-zero numbers of rows and columns.
- `title`: title for viewer window. Defaults to name of `x` prefixed by `Data:`.

Details

Object `x` is coerced (if possible) to a data frame, and all non-numeric columns are then coerced to character. The object is then viewed in a spreadsheet-like data viewer, a read-only version of `data.entry`.

If there are row names on the data frame that are not `1:nrow`, they are displayed in a separate first column called `row.names`.

Objects with zero columns or zero rows are not accepted.

The array of cells can be navigated by the cursor keys and Home, End, Page Up and Page Down (where supported by X11) as well as Enter and Tab.

Value

Invisible NULL. The functions puts up a window and returns immediately: the window can be closed via its controls or menus.

See Also

`edit.data.frame`, `data.entry`
Description

View a specified package vignette, or list the available ones.

Usage

vignette(topic, package = NULL, lib.loc = NULL, all = TRUE)

## S3 method for class 'vignette'
print(x, ...)

## S3 method for class 'vignette'
edit(name, ...)

Arguments

topic a character string giving the (base) name of the vignette to view. If omitted, all vignettes from all installed packages are listed.

package a character vector with the names of packages to search through, or NULL in which 'all' packages (as defined by argument all) are searched.

lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.

all logical; if TRUE search all available packages in the library trees specified by lib.loc, and if FALSE, search only attached packages.

x, name Object of class vignette.

... Ignored by the print method, passed on to `file.edit` by the edit method.

Details

Function vignette returns an object of the same class, the print method opens a viewer for it. Currently, only PDF versions of vignettes can be viewed. The program specified by the `pdfviewer` option is used for this. If several vignettes have PDF versions with base name identical to topic, the first one found is used.

If no topics are given, all available vignettes are listed. The corresponding information is returned in an object of class "packageIQR".

The edit method extracts the R code from the vignette to a temporary file and opens the file in an editor (see `edit`). This makes it very easy to execute the commands line by line, modify them in any way you want to help you test variants, etc.. An alternative way of extracting the R code from the vignette is to run `Stangle` on the source code of the vignette, see the examples below.

See Also

`browseVignettes` for an HTML-based vignette browser.
Examples

```r
## List vignettes from all *attached* packages
vignette(all = FALSE)

## List vignettes from all *installed* packages (can take a long time!):
vignette(all = TRUE)

## Not run:
## Open the grid intro vignette
vignette("grid")

## The same
v1 <- vignette("grid")
print(v1)

## Now let us have a closer look at the code
edit(v1)

## An alternative way of extracting the code,
## R file is written to current working directory
Stangle(v1$file)

## A package can have more than one vignette (package grid has several):
vignette(package = "grid")
vignette("rotated")

## The same, but without searching for it:
vignette("rotated", package = "grid")

## End(Not run)
```

write.table | Data Output

Description

write.table prints its required argument `x` (after converting it to a data frame if it is not one nor a matrix) to a file or connection.

Usage

```r
write.table(x, file = "", append = FALSE, quote = TRUE, sep = " ", eol = "\n", na = "NA", dec = ".", row.names = TRUE, col.names = TRUE, qmethod = c("escape", "double"), fileEncoding = ")
write.csv(...)
write.csv2(...)
```

Arguments

- **x**
  - the object to be written, preferably a matrix or data frame. If not, it is attempted to coerce `x` to a data frame.
write.table

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file</td>
<td>either a character string naming a file or a connection open for writing. &quot;&quot; indicates output to the console.</td>
</tr>
<tr>
<td>append</td>
<td>logical. Only relevant if file is a character string. If TRUE, the output is appended to the file. If FALSE, any existing file of the name is destroyed.</td>
</tr>
<tr>
<td>quote</td>
<td>a logical value (TRUE or FALSE) or a numeric vector. If TRUE, any character or factor columns will be surrounded by double quotes. If a numeric vector, its elements are taken as the indices of columns to quote. In both cases, row and column names are quoted if they are written. If FALSE, nothing is quoted.</td>
</tr>
<tr>
<td>sep</td>
<td>the field separator string. Values within each row of x are separated by this string.</td>
</tr>
<tr>
<td>eol</td>
<td>the character(s) to print at the end of each line (row). For example, eol = &quot;\r\n&quot; will produce Windows’ line endings on a Unix-alike OS, and eol = &quot;\r&quot; will produce files as expected by Excel:mach 2004.</td>
</tr>
<tr>
<td>na</td>
<td>the string to use for missing values in the data.</td>
</tr>
<tr>
<td>dec</td>
<td>the string to use for decimal points in numeric or complex columns: must be a single character.</td>
</tr>
<tr>
<td>row.names</td>
<td>either a logical value indicating whether the row names of x are to be written along with x, or a character vector of row names to be written.</td>
</tr>
<tr>
<td>col.names</td>
<td>either a logical value indicating whether the column names of x are to be written along with x, or a character vector of column names to be written. See the section on ‘CSV files’ for the meaning of col.names = NA.</td>
</tr>
<tr>
<td>qmethod</td>
<td>a character string specifying how to deal with embedded double quote characters when quoting strings. Must be one of &quot;escape&quot; (default for write.table), in which case the quote character is escaped in C style by a backslash, or &quot;double&quot; (default for write.csv and write.csv2), in which case it is doubled. You can specify just the initial letter.</td>
</tr>
<tr>
<td>fileEncoding</td>
<td>character string: if non-empty declares the encoding to be used on a file (not a connection) so the character data can be re-encoded as they are written. See file.</td>
</tr>
</tbody>
</table>

Details

If the table has no columns the rownames will be written only if row.names = TRUE, and vice versa.

Real and complex numbers are written to the maximal possible precision.

If a data frame has matrix-like columns these will be converted to multiple columns in the result (via as.matrix) and so a character col.names or a numeric quote should refer to the columns in the result, not the input. Such matrix-like columns are unquoted by default.

Any columns in a data frame which are lists or have a class (e.g. dates) will be converted by the appropriate as.character method: such columns are unquoted by default. On the other hand, any class information for a matrix is discarded and non-atomic (e.g. list) matrices are coerced to character.

Only columns which have been converted to character will be quoted if specified by quote.

The dec argument only applies to columns that are not subject to conversion to character because they have a class or are part of a matrix-like column (or matrix), in particular to columns protected by I(). Use options("OutDec") to control such conversions.
In almost all cases the conversion of numeric quantities is governed by the option "scipen" (see options), but with the internal equivalent of digits = 15. For finer control, use format to make a character matrix/data frame, and call write.table on that.

These functions check for a user interrupt every 1000 lines of output.

If file is a non-open connection, an attempt is made to open it and then close it after use.

To write a Unix-style file on Windows, use a binary connection e.g. file = file("filename", "wb").

CSV files

By default there is no column name for a column of row names. If col.names = NA and row.names = TRUE a blank column name is added, which is the convention used for CSV files to be read by spreadsheets. Note that such CSV files can be read in R by

\[ \text{read.csv(file = "<filename>", row.names = 1)} \]

write.csv and write.csv2 provide convenience wrappers for writing CSV files. They set sep and dec (see below), qmethod = "double", and col.names to NA if row.names = TRUE (the default) and to TRUE otherwise.

write.csv uses "," for the decimal point and a comma for the separator.

write.csv2 uses a comma for the decimal point and a semicolon for the separator, the Excel convention for CSV files in some Western European locales.

These wrappers are deliberately inflexible: they are designed to ensure that the correct conventions are used to write a valid file. Attempts to change append, col.names, sep, dec or qmethod are ignored, with a warning.

CSV files do not record an encoding, and this causes problems if they are not ASCII for many other applications. Windows Excel 2007/10 will open files (e.g. by the file association mechanism) correctly if they are ASCII or UTF-16 (use fileEncoding = "UTF-16LE") or perhaps in the current Windows codepage (e.g. "CP1252"), but the ‘Text Import Wizard’ (from the ‘Data’ tab) allows far more choice of encodings. Excel:mac 2004/8 can import only Macintosh (which seems to mean MacRoman), Windows (perhaps Latin-1) and ‘PC-8’ files. OpenOffice 3.x asks for the character set when opening the file.

There is an IETF RFC4180 (http://tools.ietf.org/html/rfc4180) for CSV files, which mandates comma as the separator and CRLF line endings. write.csv writes compliant files on Windows: use \eol\ = "\r\n" on other platforms.

Note

write.table can be slow for data frames with large numbers (hundreds or more) of columns: this is inevitable as each column could be of a different class and so must be handled separately. If they are all of the same class, consider using a matrix instead.

See Also

The ‘R Data Import/Export’ manual.

\[ \text{read.table, write, write.matrix} \text{ in package MASS}. \]
Examples

```r
## Not run:
## To write a CSV file for input to Excel one might use
x <- data.frame(a = I("a \" quote"), b = pi)
write.table(x, file = "foo.csv", sep = ",", col.names = NA,
            qmethod = "double")
## and to read this file back into R one needs
read.table("foo.csv", header = TRUE, sep = ",", row.names = 1)
## NB: you do need to specify a separator if qmethod = "double".

## Alternatively
write.csv(x, file = "foo.csv")
read.csv("foo.csv", row.names = 1)
## or without row names
write.csv(x, file = "foo.csv", row.names = FALSE)
read.csv("foo.csv")

## To write a file in MacRoman for simple use in Mac Excel 2004/8
write.csv(x, file = "Foo.csv", fileEncoding = "macroman")
## or for Windows Excel 2007/10
write.csv(x, file = "Foo.csv", fileEncoding = "UTF-16LE")

## End(Not run)
```

zip

Create Zip archives

Description

A wrapper for an external zip command to create zip archives.

Usage

```r
zip(zipfile, files, flags = "-r9X", extras = "",
    zip = Sys.getenv("R_ZIPCMD", "zip"))
```

Arguments

- `zipfile` The pathname of the zip file: tilde expansion (see `path.expand`) will be performed.
- `files` A character vector of recorded filepaths to be included.
- `flags` A character string of flags to be passed to the command: see ‘Details’.
- `extras` An optional character vector: see ‘Details’.
- `zip` A character string specifying the external command to be used.

Details

On a Unix-alike, the default for zip will by default use the value of R_ZIPCMD, which is set in ‘etc/Renviron’ if an unzip command was found during configuration. On Windows, the default relies on a zip program (for example that from Rtools) being in the path.
The default for flags is that appropriate for zipping up a directory tree in a portable way: see the system-specific help for the `zip` command for other possibilities.

Argument `extras` can be used to specify `-x` or `-i` followed by a list of filepaths to exclude or include.

**Value**

The status value returned by the external command, invisibly.

**See Also**

`unzip`, `unz`.

The KernSmooth package

bkde

Compute a Binned Kernel Density Estimate

Description

Returns x and y coordinates of the binned kernel density estimate of the probability density of the data.

Usage

bkde(x, kernel = "normal", canonical = FALSE, bandwidth, gridsize = 401L, range.x, truncate = TRUE)

Arguments

x numeric vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.

bandwidth the kernel bandwidth smoothing parameter. Larger values of bandwidth make smoother estimates, smaller values of bandwidth make less smooth estimates. The default is a bandwidth computed from the variance of x, specifically the 'oversmoothed bandwidth selector' of Wand and Jones (1995, page 61).

kernel character string which determines the smoothing kernel. kernel can be: "normal" - the Gaussian density function (the default). "box" - a rectangular box. "epanech" - the centred beta(2,2) density. "biweight" - the centred beta(3,3) density. "triweight" - the centred beta(4,4) density. This can be abbreviated to any unique abbreviation.

canonical logical flag: if TRUE, canonically scaled kernels are used.

gridsize the number of equally spaced points at which to estimate the density.

range.x vector containing the minimum and maximum values of x at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel.

truncate logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.
Details

This is the binned approximation to the ordinary kernel density estimate. Linear binning is used to obtain the bin counts. For each \( x \) value in the sample, the kernel is centered on that \( x \) and the heights of the kernel at each datapoint are summed. This sum, after a normalization, is the corresponding \( y \) value in the output.

Value

- A list containing the following components:
  - \( x \): vector of sorted \( x \) values at which the estimate was computed.
  - \( y \): vector of density estimates at the corresponding \( x \).

Background

Density estimation is a smoothing operation. Inevitably there is a trade-off between bias in the estimate and the estimate’s variability: large bandwidths will produce smooth estimates that may hide local features of the density; small bandwidths may introduce spurious bumps into the estimate.

density, dpik, hist, ksmooth.

Examples

data(geyser, package="MASS")
x <- geyser$duration
est <- bkde2D(x, bandwidth=0.25)
plot(est, type="l")
Arguments

x a two-column numeric matrix containing the observations from the distribution whose density is to be estimated. Missing values are not allowed.

bandwidth numeric vector of length 2, containing the bandwidth to be used in each coordinate direction.

gridsize vector containing the number of equally spaced points in each direction over which the density is to be estimated.

range.x a list containing two vectors, where each vector contains the minimum and maximum values of x at which to compute the estimate for each direction. The default minimum in each direction is minimum data value minus 1.5 times the bandwidth for that direction. The default maximum is the maximum data value plus 1.5 times the bandwidth for that direction.

truncate logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Value

a list containing the following components:

x1 vector of values of the grid points in the first coordinate direction at which the estimate was computed.

x2 vector of values of the grid points in the second coordinate direction at which the estimate was computed.

fhat matrix of density estimates over the mesh induced by x1 and x2.

Details

This is the binned approximation to the 2D kernel density estimate. Linear binning is used to obtain the bin counts and the Fast Fourier Transform is used to perform the discrete convolutions. For each x1,x2 pair the bivariate Gaussian kernel is centered on that location and the heights of the kernel, scaled by the bandwidths, at each datapoint are summed. This sum, after a normalization, is the corresponding fhat value in the output.

persp(est$fhat)
Compute a Binned Kernel Functional Estimate

**Description**

Returns an estimate of a binned approximation to the kernel estimate of the specified density functional. The kernel is the standard normal density.

**Usage**

\[ \text{bkfe}(x, \text{drv}, \text{bandwidth}, \text{gridsize} = 401L, \text{range}.x, \text{binned} = \text{FALSE}, \text{truncate} = \text{TRUE}) \]

**Arguments**

- \( x \) numeric vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.
- \( \text{drv} \) order of derivative in the density functional. Must be a non-negative even integer.
- \( \text{bandwidth} \) the kernel bandwidth smoothing parameter. Must be supplied.
- \( \text{gridsize} \) the number of equally-spaced points over which binning is performed.
- \( \text{range}.x \) vector containing the minimum and maximum values of \( x \) at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel.
- \( \text{binned} \) logical flag: if \( \text{TRUE} \), then \( x \) and \( y \) are taken to be grid counts rather than raw data.
- \( \text{truncate} \) logical flag: if \( \text{TRUE} \), data with \( x \) values outside the range specified by \( \text{range}.x \) are ignored.

**Details**

The density functional of order \( \text{drv} \) is the integral of the product of the density and its \( \text{drv} \)th derivative. The kernel estimates of such quantities are computed using a binned implementation, and the kernel is the standard normal density.

**Value**

the (scalar) estimated functional.

**Background**

Estimates of this type were proposed by Sheather and Jones (1991).

**References**

Examples

data(geyser, package="MASS")
x <- geyser$duration
est <- bkfe(x, drv=4, bandwidth=0.3)

Description

Uses direct plug-in methodology to select the bin width of a histogram.

Usage

dpih(x, scalest = "minim", level = 2L, gridsize = 401L, range.x = range(x), truncate = TRUE)

Arguments

x numeric vector containing the sample on which the histogram is to be constructed.
scalest estimate of scale.
level number of levels of functional estimation used in the plug-in rule.
gridsize number of grid points used in the binned approximations to functional estimates.
range.x range over which functional estimates are obtained. The default is the minimum and maximum data values.
truncate if truncate is TRUE then observations outside of the interval specified by range.x are omitted. Otherwise, they are used to weight the extreme grid points.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bin width and bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

Value

the selected bin width.

Background

This method for selecting the bin width of a histogram is described in Wand (1995). It is an extension of the normal scale rule of Scott (1979) and uses plug-in ideas from bandwidth selection for kernel density estimation (e.g. Sheather and Jones, 1991).

**dpik**  
*Select a Bandwidth for Kernel Density Estimation*

Description

Use direct plug-in methodology to select the bandwidth of a kernel density estimate.

Usage

dpak(x, scalest = "minim", level = 2L, kernel = "normal",  
canonical = FALSE, gridsize = 401L, range.x = range(x),  
truncate = TRUE)

Arguments

- `x` numeric vector containing the sample on which the kernel density estimate is to be constructed.
- `scalest` estimate of scale.
  - "stdev" - standard deviation is used.
  - "iqr" - inter-quartile range divided by 1.349 is used.
  - "minim" - minimum of "stdev" and "iqr" is used.
- `level` number of levels of functional estimation used in the plug-in rule.
- `kernel` character string which determines the smoothing kernel. kernel can be:  
  - "normal" - the Gaussian density function (the default).  
  - "box" - a rectangular box.  
  - "epanech" - the centred beta(2,2) density.  
  - "biweight" - the centred beta(3,3) density.  
  - "triweight" - the centred beta(4,4) density. This can be abbreviated to any unique abbreviation.
- `canonical` logical flag: if TRUE, canonically scaled kernels are used
- `gridsize` the number of equally-spaced points over which binning is performed to obtain kernel functional approximation.
range.x vector containing the minimum and maximum values of x at which to compute the estimate. The default is the minimum and maximum data values.

truncate logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

Value

the selected bandwidth.

Background

This method for selecting the bandwidth of a kernel density estimate was proposed by Sheather and Jones (1991) and is described in Section 3.6 of Wand and Jones (1995).

bkde, density, ksmooth

Examples

data(geyser, package="MASS")
x <- geyser$duration
h <- dpill(x)
est <- bkde(x, bandwidth=h)
plot(est,type="l")

```r

dpillar

Select a Bandwidth for Local Linear Regression

Description

Use direct plug-in methodology to select the bandwidth of a local linear Gaussian kernel regression estimate, as described by Ruppert, Sheather and Wand (1995).

Usage

dpillar(x, y, blockmax = 5, divisor = 20, trim = 0.01, proptrun = 0.05,
gridsize = 401L, range.x, truncate = TRUE)
```
Arguments

x numeric vector of x data. Missing values are not accepted.
y numeric vector of y data. This must be same length as x, and missing values are not accepted.
blockmax the maximum number of blocks of the data for construction of an initial parametric estimate.
divisor the value that the sample size is divided by to determine a lower limit on the number of blocks of the data for construction of an initial parametric estimate.
trim the proportion of the sample trimmed from each end in the x direction before application of the plug-in methodology.
proptrun the proportion of the range of x at each end truncated in the functional estimates.
gridsize number of equally-spaced grid points over which the function is to be estimated.
range.x vector containing the minimum and maximum values of x at which to compute the estimate. For density estimation the default is the minimum and maximum data values with 5% of the range added to each end. For regression estimation the default is the minimum and maximum data values.
truncate logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The kernel is the standard normal density. Least squares quartic fits over blocks of data are used to obtain an initial estimate. Mallow’s $C_p$ is used to select the number of blocks.

Value

the selected bandwidth.

Warning

If there are severe irregularities (i.e. outliers, sparse regions) in the x values then the local polynomial smooths required for the bandwidth selection algorithm may become degenerate and the function will crash. Outliers in the y direction may lead to deterioration of the quality of the selected bandwidth.

ksmooth, locpoly.
Estimate Functions Using Local Polynomials

Description
Estimates a probability density function, regression function or their derivatives using local polynomials. A fast binned implementation over an equally-spaced grid is used.

Usage
locpoly(x, y, drv = 0L, degree, kernel = "normal", bandwidth, gridsize = 401L, bwdisc = 25, range.x, binned = FALSE, truncate = TRUE)

Arguments
x numeric vector of x data. Missing values are not accepted.
bandwidth the kernel bandwidth smoothing parameter. It may be a single number or an array having length gridsize, representing a bandwidth that varies according to the location of estimation.
y vector of y data. This must be same length as x, and missing values are not accepted.
drv order of derivative to be estimated.
degree degree of local polynomial used. Its value must be greater than or equal to the value of drv. The default value is of degree is drv + 1.
kernel "normal" - the Gaussian density function. Currently ignored.
gridsize number of equally-spaced grid points over which the function is to be estimated.
bwdisc number of logarithmically-equally-spaced bandwidths on which bandwidth is discretised, to speed up computation.
range.x vector containing the minimum and maximum values of x at which to compute the estimate.
binned logical flag: if TRUE, then x and y are taken to be grid counts rather than raw data.
truncate logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Examples
data(geyser, package = "MASS")
x <- geyser$duration
y <- geyser$waiting
plot(x, y)
h <- dpill(x, y)
fit <- locpoly(x, y, bandwidth = h)
lines(fit)
Value

if y is specified, a local polynomial regression estimate of E[Y|X] (or its derivative) is computed. If y is missing, a local polynomial estimate of the density of x (or its derivative) is computed.

a list containing the following components:

x vector of sorted x values at which the estimate was computed.
y vector of smoothed estimates for either the density or the regression at the corresponding x.

Details

Local polynomial fitting with a kernel weight is used to estimate either a density, regression function or their derivatives. In the case of density estimation, the data are binned and the local fitting procedure is applied to the bin counts. In either case, binned approximations over an equally-spaced grid is used for fast computation. The bandwidth may be either scalar or a vector of length gridsize.

*Accidental Deaths in the US 1973-1978*

**Description**

A regular time series giving the monthly totals of accidental deaths in the USA.

**Usage**

`accdeaths`

**Details**

The values for first six months of 1979 (p. 326) were 7798 7406 8363 8460 9217 9316.

1889
addterm

Try All One-Term Additions to a Model

Description

Try fitting all models that differ from the current model by adding a single term from those supplied, maintaining marginality.

This function is generic; there exist methods for classes lm and glm and the default method will work for many other classes.

Usage

addterm(object, ...)  

## Default S3 method:
addterm(object, scope, scale = 0, test = c("none", "Chisq"),  
        k = 2, sorted = FALSE, trace = FALSE, ...)

## S3 method for class 'lm'
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),  
        k = 2, sorted = FALSE, ...)

## S3 method for class 'glm'
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),  
        k = 2, sorted = FALSE, trace = FALSE, ...)

Arguments

object   An object fitted by some model-fitting function.
scope    a formula specifying a maximal model which should include the current one. All additional terms in the maximal model with all marginal terms in the original model are tried.
scale    used in the definition of the AIC statistic for selecting the models, currently only for lm, aov and glm models. Specifying scale asserts that the residual standard error or dispersion is known.
test     should the results include a test statistic relative to the original model? The F test is only appropriate for lm and aov models, and perhaps for some over-dispersed glm models. The Chisq test can be an exact test (lm models with known scale) or a likelihood-ratio test depending on the method.
k        the multiple of the number of degrees of freedom used for the penalty. Only k=2 gives the genuine AIC: k = log(n) is sometimes referred to as BIC or SBC.
sorted   should the results be sorted on the value of AIC?
trace     if TRUE additional information may be given on the fits as they are tried.
...    arguments passed to or from other methods.
Details

The definition of AIC is only up to an additive constant: when appropriate (in models with specified scale) the constant is taken to be that used in Mallows’ Cp statistic and the results are labelled accordingly.

Value

A table of class "anova" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

house.glm0 <- glm(Freq ~ Infl*Type*Cont + Sat, family=poisson, data=housing)
addterm(house.glm0, . ~ + Sat:(Infl+Type+Cont), test="Chisq")

house.glm1 <- update(house.glm0, . ~ . + Sat:(Infl+Type+Cont))
addterm(house.glm1, . ~ . + Sat:(Infl+Type+Cont)^2, test = "Chisq")

Aids2

Australian AIDS Survival Data

Description

Data on patients diagnosed with AIDS in Australia before 1 July 1991.

Usage

Aids2

Format

This data frame contains 2843 rows and the following columns:

state  Grouped state of origin: "NSW" "includes ACT and "other" is WA, SA, NT and TAS.
sex Sex of patient.
diag (Julian) date of diagnosis.
dead (Julian) date of death or end of observation.
status "A" (alive) or "D" (dead) at end of observation.
t.categ Reported transmission category.
age Age (years) at diagnosis.
Note

This data set has been slightly jittered as a condition of its release, to ensure patient confidentiality.

Anorexia Data on Weight Change

Description

The anorexia data frame has 72 rows and 3 columns. Weight change data for young female anorexia patients.

Usage

anorexia

Format

This data frame contains the following columns:

- **treat**: Factor of three levels: "Cont" (control), "CBT" (Cognitive Behavioural treatment) and "FT" (family treatment).
- **prewt**: Weight of patient before study period, in lbs.
- **postwt**: Weight of patient after study period, in lbs.

Source

(Note that the original source mistakenly says that weights are in kg.)

References

anova.negbin

Likelihood Ratio Tests for Negative Binomial GLMs

Description

Method function to perform sequential likelihood ratio tests for Negative Binomial generalized linear models.

Usage

```r
## S3 method for class 'negbin'
anova(object, ..., test = "Chisq")
```
Arguments

object: Fitted model object of class "negbin", inheriting from classes "glm" and "lm", specifying a Negative Binomial fitted GLM. Typically the output of \texttt{glm.nb}().

...: Zero or more additional fitted model objects of class "negbin". They should form a nested sequence of models, but need not be specified in any particular order.

test: Argument to match the test argument of \texttt{anova.glm}. Ignored (with a warning if changed) if a sequence of two or more Negative Binomial fitted model objects is specified, but possibly used if only one object is specified.

Details

This function is a method for the generic function \texttt{anova}() for class "negbin". It can be invoked by calling \texttt{anova(x)} for an object \(x\) of the appropriate class, or directly by calling \texttt{anova.negbin(x)} regardless of the class of the object.

Note

If only one fitted model object is specified, a sequential analysis of deviance table is given for the fitted model. The \(\theta\) parameter is kept fixed. If more than one fitted model object is specified they must all be of class "negbin" and likelihood ratio tests are done of each model within the next. In this case \(\theta\) is assumed to have been re-estimated for each model.

Examples

\begin{verbatim}
m1 <- glm.nb(Days ~ Eth*Age*Lrn*Sex, quine, link = log) m2 <- update(m1, . ~ . - Eth:Age:Lrn:Sex) anova(m2, m1) anova(m2)
\end{verbatim}

---

area

\textbf{Adaptive Numerical Integration}

Description

Integrate a function of one variable over a finite range using a recursive adaptive method. This function is mainly for demonstration purposes.

Usage

\begin{verbatim}
area(f, a, b, ..., fa = f(a, ...), fb = f(b, ...),
    limit = 10, eps = 1e-05)
\end{verbatim}
**Arguments**

- **f**: The integrand as an S function object. The variable of integration must be the first argument.
- **a**: Lower limit of integration.
- **b**: Upper limit of integration.
- **...**: Additional arguments needed by the integrand.
- **fa**: Function value at the lower limit.
- **fb**: Function value at the upper limit.
- **limit**: Limit on the depth to which recursion is allowed to go.
- **eps**: Error tolerance to control the process.

**Details**

The method divides the interval in two and compares the values given by Simpson’s rule and the trapezium rule. If these are within eps of each other the Simpson’s rule result is given, otherwise the process is applied separately to each half of the interval and the results added together.

**Value**

The integral from a to b of f(x).

**References**

**Examples**

area(sin, 0, pi) # integrate the sin function from 0 to pi.

**Description**

Tests of the presence of the bacteria *H. influenzae* in children with otitis media in the Northern Territory of Australia.

**Usage**

bacteria
bacteria

Format

This data frame has 220 rows and the following columns:

- y presence or absence: a factor with levels n and y.
- ap active/placebo: a factor with levels a and p.
- hilo hi/low compliance: a factor with levels hi and lo.
- week numeric: week of test.
- ID subject ID: a factor.
- trt a factor with levels placebo, drug and drug+, a re-coding of ap and hilo.

Details

Dr A. Leach tested the effects of a drug on 50 children with a history of otitis media in the Northern Territory of Australia. The children were randomized to the drug or the a placebo, and also to receive active encouragement to comply with taking the drug.

The presence of H. influenzae was checked at weeks 0, 2, 4, 6 and 11: 30 of the checks were missing and are not included in this data frame.

```
bandwidth.nrd

Bandwidth for density() via Normal Reference Distribution

Description

A well-supported rule-of-thumb for choosing the bandwidth of a Gaussian kernel density estimator.

Usage

bandwidth.nrd(x)

Arguments

x A data vector.

Value

A bandwidth on a scale suitable for the width argument of density.

References

Examples

# The function is currently defined as
function(x)
{
  r <- quantile(x, c(0.25, 0.75))
  h <- (r[2] - r[1])/1.34
  4 * 1.06 * min(sqrt(var(x)), h) * length(x)^(-1/5)
}

bcv

Biased Cross-Validation for Bandwidth Selection

Description

Uses biased cross-validation to select the bandwidth of a Gaussian kernel density estimator.

Usage

bcv(x, nb = 1000, lower, upper)

Arguments

x a numeric vector
nb number of bins to use.
lower, upper Range over which to minimize. The default is almost always satisfactory.
Value

a bandwidth

Belgian-phones  Belgium Phone Calls 1950-1973

Description

A list object with the annual numbers of telephone calls, in Belgium. The components are:

year  last two digits of the year.
calls  number of telephone calls made (in millions of calls).
**Usage**

phones

**Source**

<table>
<thead>
<tr>
<th>biopsy</th>
<th>Biopsy Data on Breast Cancer Patients</th>
</tr>
</thead>
</table>

**Description**

This breast cancer database was obtained from the University of Wisconsin Hospitals, Madison from Dr. William H. Wolberg. He assessed biopsies of breast tumours for 699 patients up to 15 July 1992; each of nine attributes has been scored on a scale of 1 to 10, and the outcome is also known. There are 699 rows and 11 columns.

**Usage**

biopsy

**Format**

This data frame contains the following columns:

- **ID**: sample code number (not unique).
- **vQ**: clump thickness.
- **vR**: uniformity of cell size.
- **vS**: uniformity of cell shape.
- **vT**: marginal adhesion.
- **vU**: single epithelial cell size.
- **vV**: bare nuclei (16 values are missing).
- **vW**: bland chromatin.
- **vX**: normal nucleoli.
- **vY**: mitoses.
- **class**: "benign" or "malignant".

**birthwt**

**Risk Factors Associated with Low Infant Birth Weight**

### Description

The *birthwt* data frame has 189 rows and 10 columns. The data were collected at Baystate Medical Center, Springfield, Mass during 1986.

### Usage

*birthwt*

### Format

This data frame contains the following columns:

- `low` indicator of birth weight less than 2.5 kg.
- `age` mother’s age in years.
- `lwt` mother’s weight in pounds at last menstrual period.
- `race` mother’s race (1 = white, 2 = black, 3 = other).
- `smoke` smoking status during pregnancy.
- `ptl` number of previous premature labours.
- `ht` history of hypertension.
- `ui` presence of uterine irritability.
- `ftv` number of physician visits during the first trimester.
- `bwt` birth weight in grams.
### Boston

**Source**

**References**

**Examples**

```r
bwt <- with(birthwt, {
  race <- factor(race, labels = c("white", "black", "other"))
  ptd <- factor(ptd > 0)
  ftv <- factor(ftv)
  levels(ftv)[c(1:2)] <- "2+
  data.frame(low = factor(low), age, lwt, race, smoke = (smoke > 0),
               ptd, ht = (ht > 0), ui = (ui > 0), ftv)
})
options(contrasts = c("contr.treatment", "contr.poly"))
glm(low ~ ., binomial, bwt)
```

---

**Description**
The Boston data frame has 506 rows and 14 columns.

**Usage**

*Boston*

**Format**
This data frame contains the following columns:

- **crim**: per capita crime rate by town.
- **zn**: proportion of residential land zoned for lots over 25,000 sq.ft.
- **indus**: proportion of non-retail business acres per town.
- **chas**: Charles River dummy variable (= 1 if tract bounds river; 0 otherwise).
- **nox**: nitrogen oxides concentration (parts per 10 million).
- **rm**: average number of rooms per dwelling.
- **age**: proportion of owner-occupied units built prior to 1940.
- **dis**: weighted mean of distances to five Boston employment centres.
- **rad**: index of accessibility to radial highways.
- **tax**: full-value property-tax rate per \$10,000.
- **ptratio**: pupil-teacher ratio by town.
- **black**: 1000(Blk − 0.63)^2 where Blk is the proportion of blacks by town.
- **lstat**: lower status of the population (percent).
- **medv**: median value of owner-occupied homes in \$1000s.
Source

---

**boxcox**

*Box-Cox Transformations for Linear Models*

**Description**

Computes and optionally plots profile log-likelihoods for the parameter of the Box-Cox power transformation.

**Usage**

```r
boxcox(object, ...)```

## Default S3 method:

```r
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,
       interp, eps = 1/50, xlab = expression(lambda),
       ylab = "log-Likelihood", ...)```

## S3 method for class ‘formula’

```r
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,
       interp, eps = 1/50, xlab = expression(lambda),
       ylab = "log-Likelihood", ...)```

## S3 method for class ‘lm’

```r
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,
       interp, eps = 1/50, xlab = expression(lambda),
       ylab = "log-Likelihood", ...)```

**Arguments**

- `object`: a formula or fitted model object. Currently only `lm` and `aov` objects are handled.
- `lambda`: vector of values of lambda – default (−2, 2) in steps of 0.1.
- `plotit`: logical which controls whether the result should be plotted.
- `interp`: logical which controls whether spline interpolation is used. Default to TRUE if plotting with lambda of length less than 100.
- `eps`: Tolerance for lambda = 0; defaults to 0.02.
- `xlab`: defaults to "lambda".
- `ylab`: defaults to "log-Likelihood".
- `...`: additional parameters to be used in the model fitting.

**Value**

A list of the lambda vector and the computed profile log-likelihood vector, invisibly if the result is plotted.
Side Effects

If plotit = TRUE plots log-likelihood vs lambda and indicates a 95% confidence interval about the maximum observed value of lambda. If interp = TRUE, spline interpolation is used to give a smoother plot.

References

Examples

```r
boxcox(Volume ~ log(Height) + log(Girth), data = trees,
       lambda = seq(-0.25, 0.25, length = 10))

boxcox(Days+1 ~ Eth*Sex*Age*Lrn, data = quine,
       lambda = seq(-0.05, 0.45, len = 20))
```

---

**cabbages**

*Data from a cabbage field trial*

Description

The cabbages data set has 60 observations and 4 variables

Usage

cabbages

Format

This data frame contains the following columns:

- **Cult** Factor giving the cultivar of the cabbage, two levels: c30 and c52.
- **Date** Factor specifying one of three planting dates: d16, d20 or d21.
- **HeadWt** Weight of the cabbage head, presumably in kg.
- **VitC** Ascorbic acid content, in undefined units.

Source

Cars93  

Data from 93 Cars on Sale in the USA in 1993

Description

The Cars93 data frame has 93 rows and 27 columns.

Usage

Cars93
Cars93

Format

This data frame contains the following columns:

- **Manufacturer**: Manufacturer.
- **Model**: Model.
- **Type**: Type: a factor with levels "Small", "Sporty", "Compact", "Midsize", "Large" and "Van".
- **Min.Price**: Minimum Price (in $\$$1,000): price for a basic version.
- **Price**: Midrange Price (in $\$$1,000): average of Min.Price and Max.Price.
- **Max.Price**: Maximum Price (in $\$$1,000): price for "a premium version".
- **MPG.city**: City MPG (miles per US gallon by EPA rating).
- **MPG.highway**: Highway MPG.
- **AirBags**: Air Bags standard. Factor: none, driver only, or driver & passenger.
- **DriveTrain**: Drive train type: rear wheel, front wheel or 4WD; (factor).
- **Cylinders**: Number of cylinders (missing for Mazda RX-7, which has a rotary engine).
- **EngineSize**: Engine size (litres).
- **Horsepower**: Horsepower (maximum).
- **RPM**: RPM (revs per minute at maximum horsepower).
- **Rev.per.mile**: Engine revolutions per mile (in highest gear).
- **Man.trans.avail**: Is a manual transmission version available? (yes or no, Factor).
- **Fuel.tank.capacity**: Fuel tank capacity (US gallons).
- **Passengers**: Passenger capacity (persons).
- **Length**: Length (inches).
- **Wheelbase**: Wheelbase (inches).
- **Width**: Width (inches).
- **Turn.circle**: U-turn space (feet).
- **Rear.seat.room**: Rear seat room (inches) (missing for 2-seater vehicles).
- **Luggage.room**: Luggage capacity (cubic feet) (missing for vans).
- **Weight**: Weight (pounds).
- **Origin**: Of non-USA or USA company origins? (factor).
- **Make**: Combination of Manufacturer and Model (character).

Details

Cars were selected at random from among 1993 passenger car models that were listed in both the *Consumer Reports* issue and the *PACE Buying Guide*. Pickup trucks and Sport/Utility vehicles were eliminated due to incomplete information in the *Consumer Reports* source. Duplicate models (e.g., Dodge Shadow and Plymouth Sundance) were listed at most once. Further description can be found in Lock (1993).

cement  

Heat Evolved by Setting Cements

Description

Experiment on the heat evolved in the setting of each of 13 cements.

Usage
cement

Format

x1, x2, x3, x4 Proportions (%) of active ingredients.

y  heat evolved in cals/gm.

Details

Thirteen samples of Portland cement were set. For each sample, the percentages of the four main chemical ingredients was accurately measured. While the cement was setting the amount of heat evolved was also measured.
Source

\texttt{con2tr} Convert Lists to Data Frames for use by lattice

Description
Convert lists to data frames for use by lattice.

Usage
\texttt{con2tr(obj)}

Arguments
\texttt{obj} A list of components \texttt{x}, \texttt{y} and \texttt{z} as passed to contour.

Details
\texttt{con2tr} repeats the \texttt{x} and \texttt{y} components suitably to match the vector \texttt{z}. 
Value

A data frame suitable for passing to lattice (formerly trellis) functions.

References

---

**confint**

Confidence Intervals for Model Parameters

Description

Computes confidence intervals for one or more parameters in a fitted model. Package MASS adds methods for glm and nls fits.

Usage

```r
## S3 method for class 'glm'
confint(object, parm, level = 0.95, trace = FALSE, ...)

## S3 method for class 'nls'
confint(object, parm, level = 0.95, ...)
```

Arguments

- object: a fitted model object. Methods currently exist for the classes "glm", "nls" and for profile objects from these classes.
- parm: a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.
- level: the confidence level required.
- trace: logical. Should profiling be traced?
- ...: additional argument(s) for methods.

Details

`confint` is a generic function in package stats.

These confint methods call the appropriate profile method, then find the confidence intervals by interpolation in the profile traces. If the profile object is already available it should be used as the main argument rather than the fitted model object itself.

Value

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1 - level)/2 and 1 - (1 - level)/2 in % (by default 2.5% and 97.5%).

References

contr.sdif

Successive Differences Contrast Coding

Description

A coding for factors based on successive differences.

Usage

contr.sdif(n, contrasts = TRUE, sparse = FALSE)

Arguments

n
The number of levels required.

contrasts
Logical: Should there be n - 1 columns orthogonal to the mean (the default) or n columns spanning the space?
sparse logical. If true and the result would be sparse (only true for contrasts = FALSE), return a sparse matrix.

Details

The contrast coefficients are chosen so that the coded coefficients in a one-way layout are the differences between the means of the second and first levels, the third and second levels, and so on. This makes most sense for ordered factors, but does not assume that the levels are equally spaced.

Value

If contrasts is TRUE, a matrix with n rows and n - 1 columns, and the n by n identity matrix if contrasts is FALSE.

References

corresp

Simple Correspondence Analysis

Description
Find the principal canonical correlation and corresponding row- and column-scores from a correspondence analysis of a two-way contingency table.

Usage
corresp(x, ...)
corresp(x, nf = 1, ...)
corresp(x, y, ...)
corresp(x, ...)ncorresp(x, ...)ncorresp(y, ...)
corresp(formula, data, ...)

Arguments
x, formula The function is generic, accepting various forms of the principal argument for specifying a two-way frequency table. Currently accepted forms are matrices, data frames (coerced to frequency tables), objects of class "xtabs" and formulas of the form ~ F1 + F2, where F1 and F2 are factors.
nf The number of factors to be computed. Note that although 1 is the most usual, one school of thought takes the first two singular vectors for a sort of biplot.
y a second factor for a cross-classification.
data a data frame against which to preferentially resolve variables in the formula.
... If the principal argument is a formula, a data frame may be specified as well from which variables in the formula are preferentially satisfied.
Details

See Venables & Ripley (2002). The plot method produces a graphical representation of the table if nf=1, with the areas of circles representing the numbers of points. If nf is two or more the biplot method is called, which plots the second and third columns of the matrices $A = D^{\times(-1/2)} U L$ and $B = D^{\times(1/2)} V L$ where the singular value decomposition is $U L V$. Thus the x-axis is the canonical correlation times the row and column scores. Although this is called a biplot, it does not have any useful inner product relationship between the row and column scores. Think of this as an equally-scaled plot with two unrelated sets of labels. The origin is marked on the plot with a cross. (For other versions of this plot see the book.)

Value

An list object of class "correspondence" for which print, plot and biplot methods are supplied. The main components are the canonical correlation(s) and the row and column scores.

References

See Also

svd, princomp.

Examples

```r
(ct <- corresp(~ Age + Eth, data = quine))
## Not run: plot(ct)

corresp(caith)
biplot(corresp(caith, nf = 2))
```

Description

Compute a multivariate location and scale estimate with a high breakdown point – this can be thought of as estimating the mean and covariance of the good part of the data. cov.mve and cov.mcd are compatibility wrappers.

Usage

```r
cov.robx(cov, cor = FALSE, quantile.used = floor((n + p + 1)/2),
         method = c("mve", "mcd", "classical"),
         nsamp = "best", seed)
cov.mve(...)
cov.mcd(...)
```
cov.rob

Arguments

x
a matrix or data frame.

cor
should the returned result include a correlation matrix?

quantile.used
the minimum number of the data points regarded as good points.

method
the method to be used – minimum volume ellipsoid, minimum covariance determinant or classical product-moment. Using cov.mve or cov.mcd forces mve or mcd respectively.

nsamp
the number of samples or "best" or "exact" or "sample". If "sample" the number chosen is \( \min(5p, 3000) \), taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples: if "exact" exhaustive enumeration will be attempted however many samples are needed.

seed
the seed to be used for random sampling: see RNGkind. The current value of .Random.seed will be preserved if it is set.

... arguments to cov.rob other than method.

Details

For method "mve", an approximate search is made of a subset of size quantile.used with an enclosing ellipsoid of smallest volume; in method "mcd" it is the volume of the Gaussian confidence ellipsoid, equivalently the determinant of the classical covariance matrix, that is minimized. The mean of the subset provides a first estimate of the location, and the rescaled covariance matrix a first estimate of scatter. The Mahalanobis distances of all the points from the location estimate for this covariance matrix are calculated, and those points within the 97.5% point under Gaussian assumptions are declared to be good. The final estimates are the mean and rescaled covariance of the good points.

The rescaling is by the appropriate percentile under Gaussian data; in addition the first covariance matrix has an ad hoc finite-sample correction given by Marazzi.

For method "mve" the search is made over ellipsoids determined by the covariance matrix of \( p \) of the data points. For method "mcd" an additional improvement step suggested by Rousseeuw and van Driessen (1999) is used, in which once a subset of size quantile.used is selected, an ellipsoid based on its covariance is tested (as this will have no larger a determinant, and may be smaller).

Value

A list with components

center
the final estimate of location.

cov
the final estimate of scatter.

cor
(only is cor = TRUE) the estimate of the correlation matrix.

sing
message giving number of singular samples out of total

crit
the value of the criterion on log scale. For MCD this is the determinant, and for MVE it is proportional to the volume.

best
the subset used. For MVE the best sample, for MCD the best set of size quantile.used.

n.obs
total number of observations.
References

lqs

Examples

```r
set.seed(123)
cov.rob(stackloss)
cov.rob(stack.x, method = "mcd", nsamp = "exact")
```

cov.trob

Covariance Estimation for Multivariate t Distribution

Description

Estimates a covariance or correlation matrix assuming the data came from a multivariate t distribution: this provides some degree of robustness to outlier without giving a high breakdown point.

Usage

```r
cov.trob(x, wt = rep(1, n), cor = FALSE, center = TRUE, nu = 5,
          maxit = 25, tol = 0.01)
```

Arguments

- **x**: data matrix. Missing values (NAs) are not allowed.
- **wt**: A vector of weights for each case: these are treated as if the case i actually occurred wt[i] times.
- **cor**: Flag to choose between returning the correlation (cor = TRUE) or covariance (cor = FALSE) matrix.
- **center**: a logical value or a numeric vector providing the location about which the covariance is to be taken. If center = FALSE, no centering is done; if center = TRUE the MLE of the location vector is used.
- **nu**: ‘degrees of freedom’ for the multivariate t distribution. Must exceed 2 (so that the covariance matrix is finite).
- **maxit**: Maximum number of iterations in fitting.
- **tol**: Convergence tolerance for fitting.
Value

A list with the following components

- `cov` the fitted covariance matrix.
- `center` the estimated or specified location vector.
- `wt` the specified weights: only returned if the `wt` argument was given.
- `n.obs` the number of cases used in the fitting.
- `cor` the fitted correlation matrix: only returned if `cor = TRUE`.
- `call` The matched call.
- `iter` The number of iterations used.

denumeraten

*Transform an Allowable Formula for `loglm` into one for `terms`*

**Description**

`loglm` allows dimension numbers to be used in place of names in the formula. `denumerate` modifies such a formula into one that `terms` can process.

**Usage**

denumerate(x)

**Arguments**

- `x` A formula conforming to the conventions of `loglm`, that is, it may allow dimension numbers to stand in for names when specifying a log-linear model.

**Details**

The model fitting function `loglm` fits log-linear models to frequency data using iterative proportional scaling. To specify the model the user must nominate the margins in the data that remain fixed under the log-linear model. It is convenient to allow the user to use dimension numbers, 1, 2, 3, ... for the first, second, third, ..., margins in a similar way to variable names. As the model formula has to be parsed by `terms`, which treats 1 in a special way and requires parseable variable names, these formulae have to be modified by giving genuine names for these margin, or dimension numbers. `denumerate` replaces these numbers with names of a special form, namely `n` is replaced by `.vn`. This allows `terms` to parse the formula in the usual way.
Value

A linear model formula like that presented, except that where dimension numbers, say \( n \), have been used to specify fixed margins these are replaced by names of the form \( N\cdot vn \) which may be processed by terms.

renumerate

Examples

denumerate(-(1+2+3)^3 + a/b)
## Not run: ~(.v1 + .v2 + .v3)^3 + a/b

dose.p

Predict Doses for Binomial Assay model

Description

Calibrate binomial assays, generalizing the calculation of LD50.

Usage

dose.p(obj, cf = 1:2, p = 0.5)

Arguments

obj A fitted model object of class inheriting from "glm".

\( cf \) The terms in the coefficient vector giving the intercept and coefficient of (log-)

\( p \) Probabilities at which to predict the dose needed.

Value

An object of class "glm.dose" giving the prediction (attribute "p" and standard error (attribute "SE") at each response probability.

References

Examples

ldose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg0 <- glm(SF ~ sex + ldose - 1, family = binomial)
dose.p(budworm.lg0, cf = c(1,3), p = 1:3/4)
dose.p(update(budworm.lg0, family = binomial(link=probit)),
   cf = c(1,3), p = 1:3/4)
dropterm

Drivers

Description

A regular time series giving the monthly totals of car drivers in Great Britain killed or seriously
injured Jan 1969 to Dec 1984. Compulsory wearing of seat belts was introduced on 31 Jan 1983

Usage

dropterm

Source

University Press, pp. 519–523.

References

Springer.

dropterm

Try All One-Term Deletions from a Model

Description

Try fitting all models that differ from the current model by dropping a single term, maintaining
marginality.

This function is generic; there exist methods for classes lm and glm and the default method will
work for many other classes.

Usage

dropterm (object, ...)  
## Default S3 method:
dropterm(object, scope, scale = 0, test = c("none", "Chisq"),
   k = 2, sorted = FALSE, trace = FALSE, ...)

## S3 method for class 'lm'
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
   k = 2, sorted = FALSE, ...)

## S3 method for class 'glm'
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
   k = 2, sorted = FALSE, trace = FALSE, ...)
Arguments

- **object**: A object fitted by some model-fitting function.
- **scope**: a formula giving terms which might be dropped. By default, the model formula. Only terms that can be dropped and maintain marginality are actually tried.
- **scale**: used in the definition of the AIC statistic for selecting the models, currently only for lm, aov and glm models. Specifying scale asserts that the residual standard error or dispersion is known.
- **test**: should the results include a test statistic relative to the original model? The F test is only appropriate for lm and aov models, and perhaps for some over-dispersed glm models. The Chisq test can be an exact test (lm models with known scale) or a likelihood-ratio test depending on the method.
- **k**: the multiple of the number of degrees of freedom used for the penalty. Only \( k = 2 \) gives the genuine AIC: \( k = \log(n) \) is sometimes referred to as BIC or SBC.
- **sorted**: should the results be sorted on the value of AIC?
- **trace**: if TRUE additional information may be given on the fits as they are tried.
- **...**: arguments passed to or from other methods.

Details

The definition of AIC is only up to an additive constant: when appropriate (lm models with specified scale) the constant is taken to be that used in Mallows’ Cp statistic and the results are labelled accordingly.

Value

A table of class "anova" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

Foraging Ecology of Bald Eagles

Description

Knight and Skagen collected during a field study on the foraging behaviour of wintering Bald Eagles in Washington State, USA data concerning 160 attempts by one (pirating) Bald Eagle to steal a chum salmon from another (feeding) Bald Eagle.

Usage
eagles

Format

The eagles data frame has 8 rows and 5 columns.

y Number of successful attempts.
n Total number of attempts.
P Size of pirating eagle (L = large, S = small).
A Age of pirating eagle (I = immature, A = adult).
V Size of victim eagle (L = large, S = small).

Source

Seizure Counts for Epileptics

**Description**

Thall and Vail (1990) give a data set on two-week seizure counts for 59 epileptics. The number of seizures was recorded for a baseline period of 8 weeks, and then patients were randomly assigned to a treatment group or a control group. Counts were then recorded for four successive two-week periods. The subject’s age is the only covariate.

**Usage**

epil

**Format**

This data frame has 236 rows and the following 9 columns:

- **y**: the count for the 2-week period.
- **trt**: treatment, “placebo” or “progabide”.
- **base**: the counts in the baseline 8-week period.
- **age**: subject’s age, in years.
- **V4**: 0/1 indicator variable of period 4.
- **subject**: subject number, 1 to 59.
- **period**: period, 1 to 4.
- **lbase**: log-counts for the baseline period, centred to have zero mean.
- **lage**: log-ages, centred to have zero mean.

**Source**

**References**

**Examples**

```r
summary(glm(y ~ 1base+trt + lage + V4, family = poisson, data = epil), cor = FALSE)
epil2 <- epil[epil$period == 1, ]
epil2["period"] <- rep(0, 59); epil2["y"] <- epil2["base"]
epil2["time"] <- 1; epil2["time"] <- 4
epil2 <- rbind(epil, epil2)
epil2$pred <- unclass(epil2$trt) * (epil2$period > 0)
epil2$subject <- factor(epil2$subject)
epil3 <- aggregate(epil2, list(epil2$subject, epil2$period > 0),
                   function(x) if(is.numeric(x)) sum(x) else x[1])
```
Plots with Geometrically Equal Scales

Description

Version of a scatterplot with scales chosen to be equal on both axes, that is 1cm represents the same units on each

Usage

eqscplot(x, y, ratio = 1, tol = 0.04, uin, ...)

Arguments

- `x` vector of x values, or a 2-column matrix, or a list with components `x` and `y`
- `y` vector of y values
- `ratio` desired ratio of units on the axes. Units on the y axis are drawn at `ratio` times the size of units on the x axis. Ignored if `uin` is specified and of length 2.
- `tol` proportion of white space at the margins of plot
- `uin` desired values for the units-per-inch parameter. If of length 1, the desired units per inch on the x axis.
- `...` further arguments for `plot` and graphical parameters. Note that `par(xaxs="i", yaxs="i")` is enforced, and `xlim` and `ylim` will be adjusted accordingly.

Details

Limits for the x and y axes are chosen so that they include the data. One of the sets of limits is then stretched from the midpoint to make the units in the ratio given by `ratio`. Finally both are stretched by `1 + tol` to move points away from the axes, and the points plotted.

Value

invisibly, the values of `uin` used for the plot.

Side Effects

performs the plot.
farms

Note

Arguments ratio and uin were suggested by Bill Dunlap.

---

**Description**

The *farms* data frame has 20 rows and 4 columns. The rows are farms on the Dutch island of Terschelling and the columns are factors describing the management of grassland.

**Usage**

*farms*

**Format**

This data frame contains the following columns:

- **Mois**: Five levels of soil moisture – level 3 does not occur at these 20 farms.
- **Manag**: Grassland management type (SF = standard, BF = biological, HF = hobby farming, NM = nature conservation).
- **Use**: Grassland use (U1 = hay production, U2 = intermediate, U3 = grazing).
- **Manure**: Manure usage – classes C0 to C4.

**Source**

Quoted as from:

**References**

**Examples**

```r
farms.mca <- mca(farms, abbrev = TRUE)  # Use levels as names
eqscplot(farms.mca$cs, type = "n")

text(farms.mca$cs, labels = dimnames(farms.mca$cs)[[1]], cex = 0.7)
```
**fg1**

*Measurements of Forensic Glass Fragments*

**Description**

The `fg1` data frame has 214 rows and 10 columns. It was collected by B. German on fragments of glass collected in forensic work.

**Usage**

`fg1`

**Format**

This data frame contains the following columns:

- `ri` refractive index; more precisely the refractive index is 1.518xxxx.
- The next 8 measurements are percentages by weight of oxides.
  - `Na` sodium.
  - `Mg` manganese.
  - `Al` aluminium.
  - `Si` silicon.
  - `K` potassium.
  - `Ca` calcium.
  - `Ba` barium.
  - `Fe` iron.
- `type` The fragments were originally classed into seven types, one of which was absent in this dataset. The categories which occur are window float glass (`Winf`: 70), window non-float glass (`WinfF`: 76), vehicle window glass (`Veh`: 17), containers (`Con`: 13), tableware (`Tab`: 9) and vehicle headlamps (`Head`: 29).

**References**

**fitdistr**

*Maximum-likelihood Fitting of Univariate Distributions*

**Description**

Maximum-likelihood fitting of univariate distributions, allowing parameters to be held fixed if desired.

**Usage**

`fitdistr(x, densfun, start, ...)`
Arguments

- **x**: A numeric vector of length at least one containing only finite values.
- **densfun**: Either a character string or a function returning a density evaluated at its first argument. Distributions "beta", "cauchy", "chi-squared", "exponential", "f", "gamma", "geometric", "log-normal", "lognormal", "logistic", "negative binomial", "normal", "Poisson", "t" and "weibull" are recognised, case being ignored.
- **start**: A named list giving the parameters to be optimized with initial values. This can be omitted for some of the named distributions and must be for others (see Details).
- **...**: Additional parameters, either for densfun or for optim. In particular, it can be used to specify bounds via lower or upper or both. If arguments of densfun (or the density function corresponding to a character-string specification) are included they will be held fixed.

Details

For the Normal, log-Normal, geometric, exponential and Poisson distributions the closed-form MLEs (and exact standard errors) are used, and start should not be supplied.

For all other distributions, direct optimization of the log-likelihood is performed using optim. The estimated standard errors are taken from the observed information matrix, calculated by a numerical approximation. For one-dimensional problems the Nelder-Mead method is used and for multi-dimensional problems the BFGS method, unless arguments named lower or upper are supplied (when L-BFGS-B is used) or method is supplied explicitly.

For the "t" named distribution the density is taken to be the location-scale family with location m and scale s.

For the following named distributions, reasonable starting values will be computed if start is omitted or only partially specified: "cauchy", "gamma", "logistic", "negative binomial" (parametrized by mu and size), "t" and "weibull". Note that these starting values may not be good enough if the fit is poor: in particular they are not resistant to outliers unless the fitted distribution is long-tailed.

There are print, coef, vcov and logLik methods for class "fitdistr".

Value

An object of class "fitdistr", a list with four components,

- **estimate**: the parameter estimates,
- **sd**: the estimated standard errors,
- **vcov**: the estimated variance-covariance matrix, and
- **loglik**: the log-likelihood.

Note

Numerical optimization cannot work miracles: please note the comments in optim on scaling data. If the fitted parameters are far away from one, consider re-fitting specifying the control parameter parscale.

## fractions

**Rational Approximation**

### Description

Find rational approximations to the components of a real numeric object using a standard continued fraction method.

### Usage

```r
fractions(x, cycles = 10, max.denominator = 2000, ...)
```

### Arguments

- `x`: Any object of mode numeric. Missing values are now allowed.
- `cycles`: The maximum number of steps to be used in the continued fraction approximation process.
- `max.denominator`: An early termination criterion. If any partial denominator exceeds `max.denominator` the continued fraction stops at that point.
- `...`: arguments passed to or from other methods.

### Details

Each component is first expanded in a continued fraction of the form

\[
x = \text{floor}(x) + \frac{1}{p_1 + \frac{1}{p_2 + \ldots}}
\]

where \( p_1, p_2, \ldots \) are positive integers, terminating either at `cycles` terms or when a \( p_j > \text{max.denominator} \). The continued fraction is then re-arranged to retrieve the numerator and denominator as integers.

The numerators and denominators are then combined into a character vector that becomes the "fracs" attribute and used in printed representations.

Arithmetic operations on "fractions" objects have full floating point accuracy, but the character representation printed out may not.

### Value

An object of class "fractions". A structure with `.Data` component the same as the input numeric `x`, but with the rational approximations held as a character vector attribute, "fracs". Arithmetic operations on "fractions" objects are possible.

### References

GAGurine            Level of GAG in Urine of Children

Description

Data were collected on the concentration of a chemical GAG in the urine of 314 children aged from zero to seventeen years. The aim of the study was to produce a chart to help a paediatrician to assess if a child’s GAG concentration is ‘normal’.

Usage

GAGurine

Format

This data frame contains the following columns:

Age  age of child in years.
GAG  concentration of GAG (the units have been lost).

Source

Mrs Susan Prosser, Paediatrics Department, University of Oxford, via Department of Statistics Consulting Service.

References

galaxies            Velocities for 82 Galaxies

Description

A numeric vector of velocities in km/sec of 82 galaxies from 6 well-separated conic sections of an unfilled survey of the Corona Borealis region. Multimodality in such surveys is evidence for voids and superclusters in the far universe.

Usage

galaxies
Note

There is an 83rd measurement of 5607 km/sec in the Postman et al. paper which is omitted in Roeder (1990) and from the dataset here.

There is also a typo: this dataset has 78th observation 26690 which should be 26960.

Source

References

Examples

gal <- galaxies/1000
c(width.SJ(gal, method = "dpi"), width.SJ(gal))
plot(x = c(0, 40), y = c(0, 0.3), type = "n", bty = "l",
     xlab = "velocity of galaxy (1000km/s)", ylab = "density")
rug(gal)
lines(density(gal, width = 3.25, n = 200), lty = 1)
lines(density(gal, width = 2.56, n = 200), lty = 3)

gamma.dispersion  Calculate the MLE of the Gamma Dispersion Parameter in a GLM Fit

Description

A front end to gamma.shape for convenience. Finds the reciprocal of the estimate of the shape parameter only.

Usage

gamma.dispersion(object, ...)

Arguments

object  Fitted model object giving the gamma fit.
...
  Additional arguments passed on to gamma.shape.

Value

The MLE of the dispersion parameter of the gamma distribution.

References

gamma.shape

Estimate the Shape Parameter of the Gamma Distribution in a GLM Fit

Description

Find the maximum likelihood estimate of the shape parameter of the gamma distribution after fitting a Gamma generalized linear model.

Usage

```r
## S3 method for class 'glm'
gamma.shape(object, it.lim = 10,
            eps.max = .Machine$double.eps^0.25, verbose = FALSE, ...)
```

Arguments

- `object`: Fitted model object from a Gamma family or quasi family with variance \( \mu^2 \).
- `it.lim`: Upper limit on the number of iterations.
- `eps.max`: Maximum discrepancy between approximations for the iteration process to continue.
- `verbose`: If TRUE, causes successive iterations to be printed out. The initial estimate is taken from the deviance.
- `...`: Further arguments passed to or from other methods.

Details

A glm fit for a Gamma family correctly calculates the maximum likelihood estimate of the mean parameters but provides only a crude estimate of the dispersion parameter. This function takes the results of the glm fit and solves the maximum likelihood equation for the reciprocal of the dispersion parameter, which is usually called the shape (or exponent) parameter.

Value

List of two components

- `alpha`: the maximum likelihood estimate
- `SE`: the approximate standard error, the square-root of the reciprocal of the observed information.

References

Line Transect of Soil in Gilgai Territory

Description

This dataset was collected on a line transect survey in gilgai territory in New South Wales, Australia. Gilgais are natural gentle depressions in otherwise flat land, and sometimes seem to be regularly distributed. The data collection was stimulated by the question: are these patterns reflected in soil properties? At each of 365 sampling locations on a linear grid of 4 meters spacing, samples were taken at depths 0-10 cm, 30-40 cm and 80-90 cm below the surface. pH, electrical conductivity and chloride content were measured on a 1:5 soil:water extract from each sample.

Usage

gilgais
Format

This data frame contains the following columns:

- \( \text{phPP} \) pH at depth 0–10 cm.
- \( \text{phSP} \) pH at depth 30–40 cm.
- \( \text{phXP} \) pH at depth 80–90 cm.
- \( \text{ePP} \) electrical conductivity in mS/cm (0–10 cm).
- \( \text{eSP} \) electrical conductivity in mS/cm (30–40 cm).
- \( \text{eXP} \) electrical conductivity in mS/cm (80–90 cm).
- \( \text{cPP} \) chloride content in ppm (0–10 cm).
- \( \text{cSP} \) chloride content in ppm (30–40 cm).
- \( \text{cXP} \) chloride content in ppm (80–90 cm).

### ginv

**Generalized Inverse of a Matrix**

**Description**

Calculates the Moore-Penrose generalized inverse of a matrix \( X \).

**Usage**

\[
ginv(X, \text{tol} = \text{sqrt(.Machine$double.eps))}
\]

**Arguments**

- \( X \) Matrix for which the Moore-Penrose inverse is required.
- \( \text{tol} \) A relative tolerance to detect zero singular values.

**Value**

A MP generalized inverse matrix for \( X \).

**References**

glm.convert

function(X, tol = sqrt(.Machine$double.eps))
{
  ## Generalized Inverse of a Matrix
dnx <- dimnames(X)
  if(is.null(dnx)) dnx <- vector("list", 2)
s <- svd(X)
nz <- s$d > tol * s$d[1]
  structure(
    if(any(nz)) sv$v[, nz] %*% t(t(s$u[, nz])/s$d[nz]) else X,
    dimnames = dnx[2:1])
}

## End(Not run)

glm.convert  Change a Negative Binomial fit to a GLM fit

Description

This function modifies an output object from glm.nb() to one that looks like the output from glm() with a negative binomial family. This allows it to be updated keeping the theta parameter fixed.

Usage

glm.convert(object)

Arguments

object  An object of class "negbin", typically the output from glm.nb().

Details

Convenience function needed to effect some low level changes to the structure of the fitted model object.

Value

An object of class "glm" with negative binomial family. The theta parameter is then fixed at its present estimate.

See Also

glm.nb, negative.binomial, glm
**Examples**

```r
quine.nb1 <- glm.nb(Days ~ Sex/(Age + Eth*Lrn), data = quine)
quine.nbA <- glm.convert(quine.nb1)
quine.nbB <- update(quine.nb1, . ~ . + Sex:Age:Lrn)
anova(quine.nbA, quine.nbB)
```

---

**glm.nb**

*Fit a Negative Binomial Generalized Linear Model*

**Description**

A modification of the system function `glm()` to include estimation of the additional parameter, theta, for a Negative Binomial generalized linear model.

**Usage**

```r
glm.nb(formula, data, weights, subset, na.action, 
start = NULL, etastart, mustart, 
control = glm.control(...), method = "glm.fit", 
model = TRUE, x = FALSE, y = TRUE, contrasts = NULL, ..., 
init.theta, link = log)
```

**Arguments**

- `formula`, `data`, `weights`, `subset`, `na.action`, `start`, `etastart`, `mustart`, `control`, `method`, `model`, `x`, arguments for the `glm()` function. Note that these exclude `family` and `offset` (but `offset()` can be used).
- `init.theta` Optional initial value for the theta parameter. If omitted a moment estimator after an initial fit using a Poisson GLM is used.
- `link` The link function. Currently must be one of `log`, `sqrt` or `identity`.

**Details**

An alternating iteration process is used. For given theta the GLM is fitted using the same process as used by `glm()`. For fixed means the theta parameter is estimated using score and information iterations. The two are alternated until convergence of both. (The number of alternations and the number of iterations when estimating theta are controlled by the `maxit` parameter of `glm.control`.)

Setting `trace > 0` traces the alternating iteration process. Setting `trace > 1` traces the `glm` fit, and setting `trace > 2` traces the estimation of theta.

**Value**

A fitted model object of class `negbin` inheriting from `glm` and `lm`. The object is like the output of `glm` but contains three additional components, namely `theta` for the ML estimate of theta, `SE.theta` for its approximate standard error (using observed rather than expected information), and `twologlik` for twice the log-likelihood function.

**References**

See Also

`glm`, `negative.binomial`, `anova.negbin`, `summary.negbin`, `theta.md`

There is a `simulate` method.

Examples

```r
quine.nb1 <- glm.nb(Days ~ Sex/(Age + Eth*Lrn), data = quine)
quine.nb2 <- update(quine.nb1, . ~ . + Sex:Age:Lrn)
quine.nb3 <- update(quine.nb2, Days ~ .^4)
anova(quine.nb1, quine.nb2, quine.nb3)
```

---

**Description**

Fit a GLMM model with multivariate normal random effects, using Penalized Quasi-Likelihood.

**Usage**

```r
glmmPQL(fixed, random, family, data, correlation, weights, 
control, niter = 10, verbose = TRUE, ...)
```

**Arguments**

- `fixed`: a two-sided linear formula giving fixed-effects part of the model.
- `random`: a formula or list of formulae describing the random effects.
- `family`: a GLM family.
- `data`: an optional data frame used as the first place to find variables in the formulae, weights and if present in ..., subset.
- `correlation`: an optional correlation structure.
- `weights`: optional case weights as in glm.
- `control`: an optional argument to be passed to `lme`.
- `niter`: maximum number of iterations.
- `verbose`: logical: print out record of iterations?
- `...`: Further arguments for `lme`.

**Details**

`glmmPQL` works by repeated calls to `lme`, so package `nlme` will be loaded at first use if necessary.

**Value**

A object of class "lme": see `lmeObject`. 
hills

References

See Also

lme

Examples

```r
library(nlme) # will be loaded automatically if omitted
summary(glmmPQL(y ~ trt + I(week > 2), random = ~ 1 | ID,
    family = binomial, data = bacteria))
```

The components are:

- **dist**: distance in miles (on the map).

hist.scott

Plot a Histogram with Automatic Bin Width Selection

Description

Plot a histogram with automatic bin width selection, using the Scott or Freedman–Diaconis formulae.

Usage

```r
hist.scott(x, prob = TRUE, xlab = deparse(substitute(x)), ...)
hist.FD(x, prob = TRUE, xlab = deparse(substitute(x)), ...)
```

Arguments

- `x` A data vector
- `prob` Should the plot have unit area, so be a density estimate?
- `xlab, ...` Further arguments to `hist`.

Value

For the `nclass.*` functions, the suggested number of classes.

Side Effects

Plot a histogram.

housing

Frequency Table from a Copenhagen Housing Conditions Survey

Description

The housing data frame has 72 rows and 5 variables.

Usage

```r
housing
```
Format

Sat  Satisfaction of householders with their present housing circumstances, (High, Medium or Low, ordered factor).

Inf1  Perceived degree of influence householders have on the management of the property (High, Medium, Low).

Type  Type of rental accommodation, (Tower, Atrium, Apartment, Terrace).

Cont  Contact residents are afforded with other residents, (Low, High).

Freq  Frequencies: the numbers of residents in each class.

huber

Huber M-estimator of Location with MAD Scale

Description
Finds the Huber M-estimator of location with MAD scale.

Usage
huber(y, k = 1.5, tol = 1e-06)

Arguments

y     vector of data values
k     Winsorizes at k standard deviations
tol   convergence tolerance

Value
list of location and scale parameters

mu     location estimate
s      MAD scale estimate

---

`hubers`  
*Huber Proposal 2 Robust Estimator of Location and/or Scale*

Description

Finds the Huber M-estimator for location with scale specified, scale with location specified, or both if neither is specified.

Usage

`hubers(y, k = 1.5, mu, s, initmu = median(y), tol = 1e-06)`

Arguments

- `y`: vector y of data values
- `k`: Winsorizes at k standard deviations
- `mu`: specified location
- `s`: specified scale
- `initmu`: initial value of `mu`
- `tol`: convergence tolerance

Value

- list of location and scale estimates
- `mu`: location estimate
- `s`: scale estimate

hubers(chem)
hubers(chem, mu=3.68)

Description

The `immer` data frame has 30 rows and 4 columns. Five varieties of barley were grown in six locations in each of 1931 and 1932.

Usage

immer

Format

This data frame contains the following columns:

- **Loc** The location.
- **Var** The variety of barley ("manchuria", "svansota", "velvet", "trebi" and "peatland").
- **Y1** Yield in 1931.
- **Y2** Yield in 1932.

Source

Examples

immer.aov <- aov(cbind(Y1,Y2) ~ Loc + Var, data = immer)
summary(immer.aov)

immer.aov <- aov((Y1+Y2)/2 ~ Var + Loc, data = immer)
summary(immer.aov)
model.tables(immer.aov, type = "means", se = TRUE, cterms = "Var")
Insurance

Numbers of Car Insurance claims

Description

The data given in data frame Insurance consist of the numbers of policyholders of an insurance company who were exposed to risk, and the numbers of car insurance claims made by those policyholders in the third quarter of 1973.

Usage

Insurance

Format

This data frame contains the following columns:

- **District**: factor: district of residence of policyholder (1 to 4): 4 is major cities.
- **Group**: an ordered factor: group of car with levels <1 litre, 1–1.5 litre, 1.5–2 litre, >2 litre.
- **Age**: an ordered factor: the age of the insured in 4 groups labelled <25, 25–29, 30–35, >35.
- **Holders**: numbers of policyholders.
- **Claims**: numbers of claims

Source

References

Examples

```r
## main-effects fit as Poisson GLM with offset
glm(Claims ~ District + Group + Age + offset(log(Holders)),
    data = Insurance, family = poisson)

# same via loglm
loglm(Claims ~ District + Group + Age + offset(log(Holders)),
      data = Insurance)
```
isoMDS

Kruskal’s Non-metric Multidimensional Scaling

Description
One form of non-metric multidimensional scaling

Usage
isoMDS(d, y = cmdscale(d, k), k = 2, maxit = 50, trace = TRUE,
tol = 1e-3, p = 2)

Shepard(d, x, p = 2)

Arguments
d           distance structure of the form returned by dist, or a full, symmetric matrix.
            Data are assumed to be dissimilarities or relative distances, but must be positive
            except for self-distance. Both missing and infinite values are allowed.
y           An initial configuration. If none is supplied, cmdscale is used to provide the
            classical solution, unless there are missing or infinite dissimilarities.
k           The desired dimension for the solution, passed to cmdscale.
maxit       The maximum number of iterations.
trace       Logical for tracing optimization. Default TRUE.
tol         convergence tolerance.
p           Power for Minkowski distance in the configuration space.
x           A final configuration.

Details
This chooses a k-dimensional (default k = 2) configuration to minimize the stress, the square root of
the ratio of the sum of squared differences between the input distances and those of the configuration
to the sum of configuration distances squared. However, the input distances are allowed a monotonic
transformation.

An iterative algorithm is used, which will usually converge in around 10 iterations. As this is
necessarily an O(n^2) calculation, it is slow for large datasets. Further, since for the default p = 2
the configuration is only determined up to rotations and reflections (by convention the centroid is at
the origin), the result can vary considerably from machine to machine.

Value
Two components:
points       A k-column vector of the fitted configuration.
stress       The final stress achieved (in percent).

Side Effects
If trace is true, the initial stress and the current stress are printed out every 5 iterations.
Two-Dimensional Kernel Density Estimation

Two-dimensional kernel density estimation with an axis-aligned bivariate normal kernel, evaluated on a square grid.

Usage

kde2d(x, y, h, n = 25, lims = c(range(x), range(y)))

Arguments

x  x coordinate of data
y  y coordinate of data
h  vector of bandwidths for x and y directions. Defaults to normal reference bandwidth (see bandwidth.nrd). A scalar value will be taken to apply to both directions.
n  Number of grid points in each direction. Can be scalar or a length-2 integer vector.
lims  The limits of the rectangle covered by the grid as c(x1, xu, y1, yu).

Value

A list of three components.

x, y  The x and y coordinates of the grid points, vectors of length n.
References

Examples

```r
attach(geyser)
plot(duration, waiting, xlim = c(0.5, 6), ylim = c(40, 100))
f1 <- kde2d(duration, waiting, n = 50, lims = c(0.5, 6, 40, 100))
image(f1, zlim = c(0, 0.05))
f2 <- kde2d(duration, waiting, n = 50, lims = c(0.5, 6, 40, 100),
          h = c(width.SJ(duration), width.SJ(waiting)))

     ylim = c(1, 6), xlab = "previous duration", ylab = "duration")
f1 <- kde2d(duration[-272], duration[-1],
            h = rep(1.5, 2), n = 50, lims = c(0.5, 6, 0.5, 6))
contour(f1, xlab = "previous duration",
       ylab = "duration", levels = c(0.05, 0.1, 0.2, 0.4))
f1 <- kde2d(duration[-272], duration[-1],
            h = rep(0.6, 2), n = 50, lims = c(0.5, 6, 0.5, 6))
contour(f1, xlab = "previous duration",
       ylab = "duration", levels = c(0.05, 0.1, 0.2, 0.4))
f1 <- kde2d(duration[-272], duration[-1],
            h = rep(0.4, 2), n = 50, lims = c(0.5, 6, 0.5, 6))
contour(f1, xlab = "previous duration",
       ylab = "duration", levels = c(0.05, 0.1, 0.2, 0.4))
detach("geyser")
```

---

**lda**

Linear Discriminant Analysis

Description

Linear discriminant analysis.

Usage

```r
lda(x, ...)
```

## S3 method for class 'formula'

```r
lda(formula, data, ..., subset, na.action)
```

## Default S3 method:

```r
lda(x, grouping, prior = proportions, tol = 1.0e-4,
    method, CV = FALSE, nu, ...)
```

## S3 method for class 'data.frame'

```r
lda(x, ...)
```

## S3 method for class 'matrix'

```r
lda(x, grouping, ..., subset, na.action)
```
Arguments

**formula**
A formula of the form `groups ~ x1 + x2 + ...`. That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.

**data**
Data frame from which variables specified in `formula` are preferentially to be taken.

**x**
(required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.

**grouping**
(required if no formula principal argument is given.) a factor specifying the class for each observation.

**prior**
the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If present, the probabilities should be specified in the order of the factor levels.

**tol**
A tolerance to decide if a matrix is singular; it will reject variables and linear combinations of unit-variance variables whose variance is less than `tol*2`.

**subset**
An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)

**na.action**
A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is `na.omit`, which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)

**method**
"moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use `cov.mve`, or "t" for robust estimates based on a *t* distribution.

**CV**
If true, returns results (classes and posterior probabilities) for leave-one-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.

**nu**
degrees of freedom for `method` = "t".

... arguments passed to or from other methods.

Details

The function tries hard to detect if the within-class covariance matrix is singular. If any variable has within-group variance less than `tol*2` it will stop and report the variable as constant. This could result from poor scaling of the problem, but is more likely to result from constant variables.

Specifying the prior will affect the classification unless over-ridden in `predict.lda`. Unlike in most statistical packages, it will also affect the rotation of the linear discriminants within their space, as a weighted between-groups covariance matrix is used. Thus the first few linear discriminants emphasize the differences between groups with the weights given by the prior, which may differ from their prevalence in the dataset.

If one or more groups is missing in the supplied data, they are dropped with a warning, but the classifications produced are with respect to the original set of levels.

Value

If `CV` = TRUE the return value is a list with components `class`, the MAP classification (a factor), and posterior, posterior probabilities for the classes.

Otherwise it is an object of class "lda" containing the following components:

**prior**
the prior probabilities used.
ldahist

1953

means
the group means.

scaling
a matrix which transforms observations to discriminant functions, normalized so that within groups covariance matrix is spherical.

svd
the singular values, which give the ratio of the between- and within-group standard deviations on the linear discriminant variables. Their squares are the canonical F-statistics.

N
The number of observations used.

call
The (matched) function call.

Note
This function may be called giving either a formula and optional data frame, or a matrix and grouping factor as the first two arguments. All other arguments are optional, but subset= and na.action=, if required, must be fully named.

If a formula is given as the principal argument the object may be modified using update() in the usual way.

ldahist

Histograms or Density Plots of Multiple Groups

Description
Plot histograms or density plots of data on a single Fisher linear discriminant.
Usage

 Idahoist(data, g, nbins = 25, h, x0 = - h/1000, breaks,
    xlim = range(breaks), ymax = 0, width,
    type = c("histogram", "density", "both"),
    sep = (type != "density"),
    col = 5, xlab = deparse(substitute(data)), bty = "n", ...)

Arguments

data vector of data. Missing values (NAs) are allowed and omitted.
g factor or vector giving groups, of the same length as data.
nbins Suggested number of bins to cover the whole range of the data.
h The bin width (takes precedence over nbins).
x0 Shift for the bins - the breaks are at x0 + h * (... -1, 0, 1, ...)
breaks The set of breakpoints to be used. (Usually omitted, takes precedence over h and nbins).
xlim The limits for the x-axis.
ymax The upper limit for the y-axis.
width Bandwidth for density estimates. If missing, the Sheather-Jones selector is used for each group separately.
type Type of plot.
sep Whether there is a separate plot for each group, or one combined plot.
col The colour number for the bar fill.
xlab label for the plot x-axis. By default, this will be the name of data.
bty The box type for the plot - defaults to none.
... additional arguments to polygon.

Side Effects

Histogram and/or density plots are plotted on the current device.

leuk

Survival Times and White Blood Counts for Leukaemia Patients

Description
A data frame of data from 33 leukaemia patients.

Usage
leuk

Format
A data frame with columns:

- wbc white blood count.
- ag a test result, "present" or "absent".
- time survival time in weeks.

Details
Survival times are given for 33 patients who died from acute myelogenous leukaemia. Also measured was the patient’s white blood cell count at the time of diagnosis. The patients were also factored into 2 groups according to the presence or absence of a morphologic characteristic of white blood cells. Patients termed AG positive were identified by the presence of Auer rods and/or significant granulation of the leukaemic cells in the bone marrow at the time of diagnosis.

References

Examples
library(survival)
plot(survfit(Surv(time) ~ ag, data = leuk), lty = 2:3, col = 2:3)

# now Cox models
leuk.cox <- coxph(Surv(time) ~ ag + log(wbc), leuk)
summary(leuk.cox)
Description

Fit linear models by Generalized Least Squares

Usage

```r
lm.gls(formula, data, W, subset, na.action, inverse = FALSE, 
       method = "qr", model = FALSE, x = FALSE, y = FALSE, 
       contrasts = NULL, ...)
```

Arguments

- `formula`: a formula expression as for regression models, of the form `response ~ predictors`. See the documentation of `formula` for other details.
- `data`: an optional data frame in which to interpret the variables occurring in `formula`.
- `W`: a weight matrix.
- `subset`: expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
- `na.action`: a function to filter missing data.
- `inverse`: logical: if true `W` specifies the inverse of the weight matrix: this is appropriate if a variance matrix is used.
- `method`: method to be used by `lm.fit`.
- `model`: should the model frame be returned?
- `x`: should the design matrix be returned?
- `y`: should the response be returned?
- `contrasts`: a list of contrasts to be used for some or all of
- `...`: additional arguments to `lm.fit`.

Details

The problem is transformed to uncorrelated form and passed to `lm.fit`.

Value

An object of class "lm.gls", which is similar to an "lm" object. There is no "weights" component, and only a few "lm" methods will work correctly. As from version 7.1-22 the residuals and fitted values refer to the untransformed problem.

See Also

gls, lm, lm.ridge
lm.ridge

Ridge Regression

Description

Fit a linear model by ridge regression.

Usage

```r
lm.ridge(formula, data, subset, na.action, lambda = 0, model = FALSE,
          x = FALSE, y = FALSE, contrasts = NULL, ...)
```

Arguments

- `formula`: a formula expression as for regression models, of the form `response ~ predictors`. See the documentation of `formula` for other details. `offset` terms are allowed.
- `data`: an optional data frame in which to interpret the variables occurring in `formula`.
- `subset`: expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
- `na.action`: a function to filter missing data.
- `lambda`: A scalar or vector of ridge constants.
- `model`: should the model frame be returned? Not implemented.
- `x`: should the design matrix be returned? Not implemented.
- `y`: should the response be returned? Not implemented.
- `contrasts`: a list of contrasts to be used for some or all of factor terms in the formula. See the `contrasts.arg` of `model.matrix.default`.
- `...`: additional arguments to `lm.fit`.

Details

If an intercept is present in the model, its coefficient is not penalized. (If you want to penalize an intercept, put in your own constant term and remove the intercept.)

Value

A list with components

- `coef`: matrix of coefficients, one row for each value of `lambda`. Note that these are not on the original scale and are for use by the `coef` method.
- `scales`: scalings used on the X matrix.
- `Inter`: was intercept included?
- `lambda`: vector of lambda values
- `ym`: mean of y
- `xm`: column means of x matrix
- `GCV`: vector of GCV values
- `kHKB`: HKB estimate of the ridge constant.
- `kLW`: L-W estimate of the ridge constant.

loglm

Description
This function provides a front-end to the standard function, loglin, to allow log-linear models to be specified and fitted in a manner similar to that of other fitting functions, such as glm.

Usage
loglm(formula, data, subset, na.action, ...)

Arguments
formula
A linear model formula specifying the log-linear model.
If the left-hand side is empty, the data argument is required and must be a (complete) array of frequencies. In this case the variables on the right-hand side may be the names of the dimnames attribute of the frequency array, or may be the positive integers: 1, 2, 3, ..., used as alternative names for the 1st, 2nd, 3rd, ..., dimension (classifying factor). If the left-hand side is not empty it specifies a vector of frequencies. In this case the data argument, if present, must be a data frame from which the left-hand side vector and the classifying factors on the right-hand side are (preferentially) obtained. The usual abbreviation of a . to stand for ‘all other variables in the data frame’ is allowed. Any non-factors on the right-hand side of the formula are coerced to factor.
data
Numeric array or data frame. In the first case it specifies the array of frequencies; in the second it provides the data frame from which the variables occurring in the formula are preferentially obtained in the usual way. This argument may be the result of a call to xtabs.
subset
Specifies a subset of the rows in the data frame to be used. The default is to take all rows.
na.action
Specifies a method for handling missing observations. The default is to fail if missing values are present.
...
May supply other arguments to the function loglm.
Details

If the left-hand side of the formula is empty the data argument supplies the frequency array and the right-hand side of the formula is used to construct the list of fixed faces as required by loglin. Structural zeros may be specified by giving a start argument with those entries set to zero, as described in the help information for loglin.

If the left-hand side is not empty, all variables on the right-hand side are regarded as classifying factors and an array of frequencies is constructed. If some cells in the complete array are not specified they are treated as structural zeros. The right-hand side of the formula is again used to construct the list of faces on which the observed and fitted totals must agree, as required by loglin. Hence terms such as a:b, a*b and a/b are all equivalent.

Value

An object of class "loglm" conveying the results of the fitted log-linear model. Methods exist for the generic functions print, summary, deviance, fitted, coef, resid, anova and update, which perform the expected tasks. Only log-likelihood ratio tests are allowed using anova.

The deviance is simply an alternative name for the log-likelihood ratio statistic for testing the current model within a saturated model, in accordance with standard usage in generalized linear models.

Warning

If structural zeros are present, the calculation of degrees of freedom may not be correct. loglin itself takes no action to allow for structural zeros. loglm deducts one degree of freedom for each structural zero, but cannot make allowance for gains in error degrees of freedom due to loss of dimension in the model space. (This would require checking the rank of the model matrix, but since iterative proportional scaling methods are developed largely to avoid constructing the model matrix explicitly, the computation is at least difficult.)

When structural zeros (or zero fitted values) are present the estimated coefficients will not be available due to infinite estimates. The deviances will normally continue to be correct, though.

**logtrans**

*Estimate log Transformation Parameter*

**Description**

Find and optionally plot the marginal (profile) likelihood for alpha for a transformation model of the form \( \log(y + \alpha) \sim x_1 + x_2 + \ldots \).

**Usage**

```r
logtrans(object, ...)
```

## Default S3 method:

```r
logtrans(object, ..., alpha = seq(0.5, 6, by = 0.25) - min(y),
         plotit = TRUE, interp =, xlab = "alpha",
         ylab = "log Likelihood")
```

## S3 method for class 'formula'

```r
logtrans(object, data, ...)
```

## S3 method for class 'lm'

```r
logtrans(object, ...)
```

**Arguments**

- **object** Fitted linear model object, or formula defining the untransformed model that is \( y \sim x_1 + x_2 + \ldots \). The function is generic.
- **...** If object is a formula, this argument may specify a data frame as for `lm`. 
**lqs**

Set of values for the transformation parameter, alpha.

Should plotting be done?

Should the marginal log-likelihood be interpolated with a spline approximation? (Default is TRUE if plotting is to be done and the number of real points is less than 100.)

as for plot.

as for plot.

optional data argument for `lm` fit.

**Value**

List with components x (for alpha) and y (for the marginal log-likelihood values).

**Side Effects**

A plot of the marginal log-likelihood is produced, if requested, together with an approximate mle and 95% confidence interval.

**References**

**See Also**

`boxcox`

**Examples**

```r
logtrans(Days ~ Age*Sex*Eth*Lrn, data = quine,
         alpha = seq(0.75, 6.5, len=20))
```

---

**lqs**

Resistant Regression

**Description**

Fit a regression to the good points in the dataset, thereby achieving a regression estimator with a high breakdown point. `lmsreg` and `ltsreg` are compatibility wrappers.

**Usage**

```r
lqs(x, ...)
```

```
## S3 method for class 'formula'
lqs(formula, data, ...,
    method = c("lts", "lqs", "lms", "S", "model.frame"),
    subset, na.action, model = TRUE,
    x.ret = FALSE, y.ret = FALSE, contrasts = NULL)
```

```
## Default S3 method:
lqs(x, y, intercept = TRUE, method = c("lts", "lqs", "lms", "S"),
    ...)
```
quantile, control = lqs.control(...), k0 = 1.548, seed, ...)

lmsreg(...)
ltsreg(...)

**Arguments**

- **formula**: a formula of the form \( y \sim x_1 + x_2 + \ldots \)
- **data**: data frame from which variables specified in `formula` are preferentially to be taken.
- **subset**: an index vector specifying the cases to be used in fitting. (NOTE: If given, this argument must be named exactly.)
- **na.action**: function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. Alternatives include `na.omit` and `na.exclude`, which lead to omission of cases with missing values on any required variable. (NOTE: If given, this argument must be named exactly.)
- **model, x.ret, y.ret**: logical. If TRUE the model frame, the model matrix and the response are returned, respectively.
- **contrasts**: an optional list. See the `contrasts.arg` of `model.matrix.default`.
- **x**: a matrix or data frame containing the explanatory variables.
- **y**: the response: a vector of length the number of rows of `x`.
- **intercept**: should the model include an intercept?
- **method**: the method to be used. `model.frame` returns the model frame: for the others see the Details section. Using `lmsreg` or `ltsreg` forces "lms" and "lts" respectively.
- **quantile**: the quantile to be used: see Details. This is over-ridden if `method = "lms"`.
- **control**: additional control items: see Details.
- **k0**: the cutoff/tuning constant used for \( \chi() \) and \( \psi() \) functions when `method = "S"`, currently corresponding to Tukey’s ‘biweight’.
- **seed**: the seed to be used for random sampling: see `.Random.seed`. The current value of `.Random.seed` will be preserved if it is set.
- **...**: arguments to be passed to `lqs.default` or `lqs.control`, see control above and Details.

**Details**

Suppose there are \( n \) data points and \( p \) regressors, including any intercept.

The first three methods minimize some function of the sorted squared residuals. For methods "lqs" and "lms" is the quantile squared residual, and for "lts" it is the sum of the quantile smallest squared residuals. "lqs" and "lms" differ in the defaults for quantile, which are \( \text{floor}((n+p+1)/2) \) and \( \text{floor}((n+1)/2) \) respectively. For "lts" the default is \( \text{floor}(n/2) + \text{floor}((p+1)/2) \).

The "S" estimation method solves for the scale \( s \) such that the average of a function \( \chi() \) of the residuals divided by \( s \) is equal to a given constant.

The `control` argument is a list with components

- **psamp**: the size of each sample. Defaults to \( p \).
nsamp: the number of samples or "best" (the default) or "exact" or "sample". If "sample" the number chosen is min(5*p, 3000), taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples; if "exact" exhaustive enumeration will be attempted however many samples are needed.

adjust: should the intercept be optimized for each sample? Defaults to TRUE.

Value
An object of class "lqs". This is a list with components

- crit: the value of the criterion for the best solution found, in the case of method == "S" before IWLS refinement.
- sing: character. A message about the number of samples which resulted in singular fits.
- coefficients: of the fitted linear model
- bestone: the indices of those points fitted by the best sample found (prior to adjustment of the intercept, if requested).
- fitted.values: the fitted values.
- residuals: the residuals.
- scale: estimate(s) of the scale of the error. The first is based on the fit criterion. The second (not present for method == "S") is based on the variance of those residuals whose absolute value is less than 2.5 times the initial estimate.

Note
There seems no reason other than historical to use the lms and lqs options. LMS estimation is of low efficiency (converging at rate \( n^{-1/3} \)) whereas LTS has the same asymptotic efficiency as an M estimator with trimming at the quartiles (Marazzi, 1993, p.201). LQS and LTS have the same maximal breakdown value of \( \text{floor}(\text{quantile} \times (n-p) / 2) \) attained if \( \text{quantile} \geq \text{quantile} \times (n-p+1) / 2 \). The only drawback mentioned of LTS is greater computation, as a sort was thought to be required (Marazzi, 1993, p.201) but this is not true as a partial sort can be used (and is used in this implementation).

Adjusting the intercept for each trial fit does need the residuals to be sorted, and may be significant extra computation if \( n \) is large and \( p \) small.

Opinions differ over the choice of psamp. Rousseeuw and Hubert (1997) only consider \( p \); Marazzi (1993) recommends \( p+1 \) and suggests that more samples are better than adjustment for a given computational limit.

The computations are exact for a model with just an intercept and adjustment, and for LQS for a model with an intercept plus one regressor and exhaustive search with adjustment. For all other cases the minimization is only known to be approximate.

**Brain and Body Weights for 62 Species of Land Mammals**

Description

A data frame with average brain and body weights for 62 species of land mammals.

Usage

mammals

Format

- **body**: body weight in kg.
- **brain**: brain weight in g.
- **name**: Common name of species. (Rock hyrax-a = *Heterohyrax brucci*, Rock hyrax-b = *Procavia habessinica*.)

Source

References

Description

Computes a multiple correspondence analysis of a set of factors.

Usage

mca(df, nf = 2, abbrev = FALSE)

Arguments

- **df**: A data frame containing only factors
- **nf**: The number of dimensions for the MCA. Rarely 3 might be useful.
- **abbrev**: Should the vertex names be abbreviated? By default these are of the form ‘factor.level’ but if abbrev = TRUE they are just ‘level’ which will suffice if the factors have distinct levels.

Value

An object of class "mca", with components

- **rs**: The coordinates of the rows, in nf dimensions.
- **cs**: The coordinates of the column vertices, one for each level of each factor.
- **fs**: Weights for each row, used to interpolate additional factors in predict.mca.
- **p**: The number of factors
- **d**: The singular values for the nf dimensions.
- **call**: The matched call.

### Survival from Malignant Melanoma

**Description**

The *Melanoma* data frame has data on 205 patients in Denmark with malignant melanoma.

**Usage**

```r
Melanoma
```

**Format**

- `time` survival time in days, possibly censored.
- `status` 1 died from melanoma, 2 alive, 3 dead from other causes.
- `sex` 1 = male, 0 = female.
- `age` age in years.
- `year` of operation.
- `thickness` tumour thickness in mm.
- `ulcer` 1 = presence, 0 = absence.
Source

Description

Proportions of female children at various ages during adolescence who have reached menarche.

Usage

menarche

Format

This data frame contains the following columns:

- **Age**: Average age of the group. (The groups are reasonably age homogeneous.)
- **Total**: Total number of children in the group.
- **Menarche**: Number who have reached menarche.

Source

The data are also given in

Examples

```r
mprob <- glm(chind(Menarche, Total ~ Menarche) ~ Age,
             binomial(link = probit), data = menarche)
```
Michelson’s Speed of Light Data

Description

Measurements of the speed of light in air, made between 5th June and 2nd July, 1879. The data consists of five experiments, each consisting of 20 consecutive runs. The response is the speed of light in km/s, less 299000. The currently accepted value, on this scale of measurement, is 734.5.

Usage

michelson

Format

The data frame contains the following components:

Expt  The experiment number, from 1 to 5.
Run   The run number within each experiment.
Speed Speed-of-light measurement.

Minnesota High School Graduates of 1938

Description

The Minnesota high school graduates of 1938 were classified according to four factors, described below. The minn38 data frame has 168 rows and 5 columns.

Usage

minn38

Format

This data frame contains the following columns:

hs  high school rank: "L", "M" and "U" for lower, middle and upper third.
phs post high school status: Enrolled in college, ("C"), enrolled in non-collegiate school, ("N"), employed full-time, ("E") and other, ("O").
f01 father’s occupational level, (seven levels, "F1", "F2", ..., "F7").
sex sex: factor with levels"F" or "M".
f  frequency.

References

Examples

```r
library(survival)
p <- survfit(Surv(time, cens) ~ factor(temp), motors), conf.int = FALSE)
# fit Weibull model
motor.wei <- survreg(Surv(time, cens) ~ temp, motors)
summary(motor.wei)
# and predict at 130C
unlist(predict(motor.wei, data.frame(temp=130), se.fit = TRUE))

motor.cox <- coxph(Surv(time, cens) ~ temp, motors)
summary(motor.cox)
# predict at temperature 200
```
Effect of Calcium Chloride on Muscle Contraction in Rat Hearts

Description

The purpose of this experiment was to assess the influence of calcium in solution on the contraction of heart muscle in rats. The left auricle of 21 rat hearts was isolated and on several occasions a constant-length strip of tissue was electrically stimulated and dipped into various concentrations of calcium chloride solution, after which the shortening of the strip was accurately measured as the response.

Usage

`musc`e

Format

This data frame contains the following columns:

- `strip` which heart muscle strip was used?
- `concentration` concentration of calcium chloride solution, in multiples of 2.2 mM.
- `length` the change in length (shortening) of the strip, (allegedly) in mm.

Source

References

Examples

```r
A <- model.matrix(~ Strip - 1, data=musc)
rats.nls1 <- nls(log(Length) ~ cbind(A, rho^Conc),
   data = musc, start = c(rho=0.1), algorithm="plinear")
(B <- coef(rats.nls1))

st <- list(alpha = B[2:22], beta = B[23], rho = B[1])
(rats.nls2 <- nls(log(Length) ~ alpha[strip] + beta*rho^Conc,
   data = musc, start = st))

Muscle <- with(musc, {
   Muscle <- expand.grid(Conc = sort(unique(Conc)), Strip = levels(Strip))
   Muscle$Yhat <- predict(rats.nls2, Muscle)
   Muscle <- cbind(Muscle, logLength = rep(as.numeric(NA), 126))
})
```

```r
plot(survfit(motor.cox, newdata = data.frame(temp=200),
   conf.type = "log-log"))
summary( survfit(motor.cox, newdata = data.frame(temp=130)) )
```
Simulate from a Multivariate Normal Distribution

Description

Produces one or more samples from the specified multivariate normal distribution.

Usage

`mvrnorm(n = 1, mu, Sigma, tol = 1e-6, empirical = FALSE, EISPACK = FALSE)`

Arguments

- `n` the number of samples required.
- `mu` a vector giving the means of the variables.
- `Sigma` a positive-definite symmetric matrix specifying the covariance matrix of the variables.
- `tol` tolerance (relative to largest variance) for numerical lack of positive-definiteness in `Sigma`.
- `empirical` logical. If true, `mu` and `Sigma` specify the empirical not population mean and covariance matrix.
- `EISPACK` logical. Set to true to reproduce results from MASS versions prior to 3.1-21.

Details

The matrix decomposition is done via `eigen`; although a Choleski decomposition might be faster, the eigendecomposition is stabler.

Value

If `n = 1` a vector of the same length as `mu`, otherwise an `n` by `length(mu)` matrix with one sample in each row.

Side Effects

Causes creation of the dataset `.Random.seed` if it does not already exist, otherwise its value is updated.
negative.binomial

Family function for Negative Binomial GLMs

Description

Specifies the information required to fit a Negative Binomial generalized linear model, with known
theta parameter, using glm().

Usage

negative.binomial(theta = stop("'theta' must be specified"), link = "log")

Arguments

theta:
The known value of the additional parameter, theta.
link:
The link function, as a character string, name or one-element character vector
specifying one of log, sqrt or identity, or an object of class "link-glm".

Value

An object of class "family", a list of functions and expressions needed by glm() to fit a Negative
Binomial generalized linear model.

References

Springer.

newcomb

Newcomb’s Measurements of the Passage Time of Light

Description

A numeric vector giving the ‘Third Series’ of measurements of the passage time of light recorded by Newcomb in 1882. The given values divided by 1000 plus 24 give the time in millionths of a second for light to traverse a known distance. The ‘true’ value is now considered to be 33.02.

Usage

newcomb

Source

nlschools

Eighth-Grade Pupils in the Netherlands

Description

Snijders and Bosker (1999) use as a running example a study of 2287 eighth-grade pupils (aged about 11) in 132 classes in 131 schools in the Netherlands. Only the variables used in our examples are supplied.

Usage

nlschools

Format

This data frame contains 2287 rows and the following columns:

lang  language test score.
IQ   verbal IQ.
class class ID.
GS   class size: number of eighth-grade pupils recorded in the class (there may be others: see COMB, and some may have been omitted with missing values).
SES  social-economic status of pupil’s family.
COMB were the pupils taught in a multi-grade class (0/1)? Classes which contained pupils from grades 7 and 8 are coded 1, but only eighth-graders were tested.

Source

References

Examples

```r
nl1 <- within(nlschools, {
  IQave <- tapply(IQ, class, mean)[as.character(class)]
  IQ <- IQ - IQave
})
  cen <- c("IQ", "IQave", "SES")
  nl1[cen] <- scale(nl1[cen], center = TRUE, scale = FALSE)
  nl.1me <- nlme::lme(lang ~ IQ*COMB + IQave + SES,
                         random = ~ IQ | class, data = nl1)
summary(nl.1me)
```

npk

Classical N, P, K Factorial Experiment

Description

A classical N, P, K (nitrogen, phosphate, potassium) factorial experiment on the growth of peas conducted on 6 blocks. Each half of a fractional factorial design confounding the NPK interaction was used on 3 of the plots.

Usage

npk

Format

The npk data frame has 24 rows and 5 columns:

- block which block (label 1 to 6).
- N indicator (0/1) for the application of nitrogen.
- P indicator (0/1) for the application of phosphate.
- K indicator (0/1) for the application of potassium.
- yield Yield of peas, in pounds/plot (the plots were (1/70) acre).

Note

This dataset is also contained in R 3.0.2 and later.

Null Spaces of Matrices

Description

Given a matrix, \( M \), find a matrix \( N \) giving a basis for the null space. That is \( t(N) \%\% M \) is the zero and \( N \) has the maximum number of linearly independent columns.

Usage

\[ \text{Null}(M) \]

Arguments

- \( M \): Input matrix. A vector is coerced to a 1-column matrix.

Value

The matrix \( N \) with the basis for the null space, or an empty vector if the matrix \( M \) is square and of maximal rank.

References

See Also

\( qr, qr.Q \).

Examples

```r
# The function is currently defined as
function(M)
{
  tmp <- qr(M)
  set <- if(tmp$rank == 0) 1:ncol(M) else - (1:tmp$rank)
  qr.Q(tmp, complete = TRUE)[, set, drop = FALSE]
}
```

Data from an Oats Field Trial

Description

The yield of oats from a split-plot field trial using three varieties and four levels of manurial treatment. The experiment was laid out in 6 blocks of 3 main plots, each split into 4 sub-plots. The varieties were applied to the main plots and the manurial treatments to the sub-plots.

Usage

\( oats \)
Tests of Auditory Perception in Children with OME

**Description**

Experiments were performed on children on their ability to differentiate a signal in broad-band noise. The noise was played from a pair of speakers and a signal was added to just one channel; the subject had to turn his/her head to the channel with the added signal. The signal was either coherent (the amplitude of the noise was increased for a period) or incoherent (independent noise was added for the same period to form the same increase in power).

The threshold used in the original analysis was the stimulus loudness needs to get 75% correct responses. Some of the children had suffered from otitis media with effusion (OME).

**Usage**

OME
The OME data frame has 1129 rows and 7 columns:

- **ID**: Subject ID (1 to 99, with some IDs missing). A few subjects were measured at different ages.
- **OME low** or **high** or **N/A** (at ages other than 30 and 60 months).
- **Age**: Age of the subject (months).
- **Loud**: Loudness of stimulus, in decibels.
- **Noise**: Whether the signal in the stimulus was "coherent" or "incoherent".
- **Correct**: Number of correct responses from Trials trials.
- **Trials**: Number of trials performed.

The experiment was to study otitis media with effusion (OME), a very common childhood condition where the middle ear space, which is normally air-filled, becomes congested by a fluid. There is a concomitant fluctuating, conductive hearing loss which can result in various language, cognitive and social deficits. The term ‘binaural hearing’ is used to describe the listening conditions in which the brain is processing information from both ears at the same time. The brain computes differences in the intensity and/or timing of signals arriving at each ear which contributes to sound localisation and also to our ability to hear in background noise.

Some years ago, it was found that children of 7–8 years with a history of significant OME had significantly worse binaural hearing than children without such a history, despite having equivalent sensitivity. The question remained as to whether it was the timing, the duration, or the degree of severity of the otitis media episodes during critical periods, which affected later binaural hearing. In an attempt to begin to answer this question, 95 children were monitored for the presence of effusion every month since birth. On the basis of OME experience in their first two years, the test population was split into one group of high OME prevalence and one of low prevalence.

The Painter's Data of de Piles

Description

The subjective assessment, on a 0 to 20 integer scale, of 54 classical painters. The painters were assessed on four characteristics: composition, drawing, colour and expression. The data is due to the Eighteenth century art critic, de Piles.

Usage

painters

Format

The row names of the data frame are the painters. The components are:

- Composition  Composition score.
- Drawing  Drawing score.
- Colour  Colour score.
- Expression  Expression score.
- School  The school to which a painter belongs, as indicated by a factor level code as follows: "A": Renaissance; "B": Mannerist; "C": Seicento; "D": Venetian; "E": Lombard; "F": Sixteenth Century; "G": Seventeenth Century; "H": French.

Source

**pairs.lda**

*Produce Pairwise Scatterplots from an 'lda' Fit*

**Description**

Pairwise scatterplot of the data on the linear discriminants.

**Usage**

```r
## S3 method for class 'lda'
pairs(x, labels = colnames(x), panel = panel.lda,
      dimen, abbrev = FALSE, ..., cex=0.7, type = c("std", "trellis"))
```

**Arguments**

- `x`: Object of class "lda".
- `labels`: vector of character strings for labelling the variables.
- `panel`: panel function to plot the data in each panel.
- `dimen`: The number of linear discriminants to be used for the plot; if this exceeds the number determined by x the smaller value is used.
- `abbrev`: whether the group labels are abbreviated on the plots. If abbrev > 0 this gives minlength in the call to abbreviate.
- `...`: additional arguments for `pairs.default`.
- `cex`: graphics parameter cex for labels on plots.
- `type`: type of plot. The default is in the style of `pairs.default`; the style "trellis" uses the Trellis function `splom`.

**Details**

This function is a method for the generic function `pairs()` for class "lda". It can be invoked by calling `pairs(x)` for an object `x` of the appropriate class, or directly by calling `pairs.lda(x)` regardless of the class of the object.

**References**

**See Also**

`pairs`
Description

Parallel coordinates plot

Usage

```r
parcoord(x, col = 1, lty = 1, var.label = FALSE, ...)
```

Arguments

- **x**: a matrix or data frame whose columns represent variables. Missing values are allowed.
- **col**: A vector of colours, recycled as necessary for each observation.
- **lty**: A vector of line types, recycled as necessary for each observation.
- **var.label**: If TRUE, each variable’s axis is labelled with maximum and minimum values.
- **...**: Further graphics parameters which are passed to `matplot`.

Side Effects

A parallel coordinates plot is drawn.

Author(s)

B. D. Ripley. Enhancements based on ideas and code by Fabian Scheipl.

References

Examples

```r
parcoord(state.x77[, c(7, 4, 6, 2, 5, 3)])

ir <- rbind(iris3[,1], iris3[,2], iris3[,3])
parcoord(log(ir)[, c(3, 4, 2, 1)], col = 1 + (0:149)/150)
```
Description

The yield of a petroleum refining process with four covariates. The crude oil appears to come from only 10 distinct samples.

These data were originally used by Prater (1956) to build an estimation equation for the yield of the refining process of crude oil to gasoline.

Usage

petrol

Format

The variables are as follows

No  crude oil sample identification label. (Factor.)
SG  specific gravity, degrees API. (Constant within sample.)
VP  vapour pressure in pounds per square inch. (Constant within sample.)
V10  volatility of crude; ASTM 10% point. (Constant within sample.)
EP  desired volatility of gasoline. (The end point. Varies within sample.)
Y   yield as a percentage of crude.

Source

Diabetes in Pima Indian Women

Description
A population of women who were at least 21 years old, of Pima Indian heritage and living near Phoenix, Arizona, was tested for diabetes according to World Health Organization criteria. The data were collected by the US National Institute of Diabetes and Digestive and Kidney Diseases. We used the 532 complete records after dropping the (mainly missing) data on serum insulin.

Usage
Pima.tr
Pima.tr2
Pima.te

Format
These data frames contains the following columns:

npreg number of pregnancies.
glu plasma glucose concentration in an oral glucose tolerance test.
bp diastolic blood pressure (mm Hg).
skin triceps skin fold thickness (mm).
bmi body mass index (weight in kg/(height in m)^2).
ped diabetes pedigree function.
age age in years.
type Yes or No, for diabetic according to WHO criteria.

Details
The training set Pima.tr contains a randomly selected set of 200 subjects, and Pima.te contains the remaining 332 subjects. Pima.tr2 contains Pima.tr plus 100 subjects with missing values in the explanatory variables.

Source

plot.lda  

Plot Method for Class "lda"

Description

Plots a set of data on one, two or more linear discriminants.

Usage

## S3 method for class 'lda'
plot(x, panel = panel.lda, ..., cex = 0.7, dimen, 
      abbrev = FALSE, xlab = "LD1", ylab = "LD2")

Arguments

x            An object of class "lda".
panel        the panel function used to plot the data.
...          additional arguments to pairs, ldahist or eqscplot.
cex          graphics parameter cex for labels on plots.
dimen        The number of linear discriminants to be used for the plot; if this exceeds the 
              number determined by x the smaller value is used.
abbrev       whether the group labels are abbreviated on the plots. If abbrev > 0 this gives 
              minlength in the call to abbreviate.
xlab         label for the x axis
ylab         label for the y axis

Details

This function is a method for the generic function plot() for class "lda". It can be invoked 
by calling plot(x) for an object x of the appropriate class, or directly by calling plot.lda(x) 
regardless of the class of the object.

The behaviour is determined by the value of dimen. For dimen > 2, a pairs plot is used. For 
dimen = 2, an equiscaled scatter plot is drawn. For dimen = 1, a set of histograms or density plots 
are drawn. Use argument type to match "histogram" or "density" or "both".

plot.mca  

Plot Method for Objects of Class 'mca'

Description

Plot a multiple correspondence analysis.

Usage

```r
## S3 method for class 'mca'
plot(x, rows = TRUE, col, cex = par("cex"), ...)
```

Arguments

- `x`: An object of class "mca".
- `rows`: Should the coordinates for the rows be plotted, or just the vertices for the levels?
- `col, cex`: The colours and cex to be used for the row points and level vertices respectively.
- `...`: Additional parameters to plot.

References

`mca, predict.mca`

Examples

```r
plot(mca(farms, abbrev = TRUE))
```

plot.profile  

Plotting Functions for 'profile' Objects

Description

`plot` and `pairs` methods for objects of class "profile".

Usage

```r
## S3 method for class 'profile'
plot(x, ...)
## S3 method for class 'profile'
pairs(x, colours = 2:3, ...)
```

Arguments

- `x`: an object inheriting from class "profile".
- `colours`: Colours to be used for the mean curves conditional on x and y respectively.
- `...`: arguments passed to or from other methods.
Details

This is the main plot method for objects created by \texttt{profile.glm}. It can also be called on objects created by \texttt{profile.nls}, but they have a specific method, \texttt{plot.profile.nls}.

The \texttt{pairs} method shows, for each pair of parameters $x$ and $y$, two curves intersecting at the maximum likelihood estimate, which give the loci of the points at which the tangents to the contours of the bivariate profile likelihood become vertical and horizontal, respectively. In the case of an exactly bivariate normal profile likelihood, these two curves would be straight lines giving the conditional means of $y|x$ and $x|y$, and the contours would be exactly elliptical.

Author(s)

Originally, D. M. Bates and W. N. Venables. (For S in 1996.)

See Also

\texttt{profile.glm}, \texttt{profile.nls}.

Examples

```r
## see ?profile.glm for an example using glm fits.

## a version of example(profile.nls) from R >= 2.8.0
fm1 <- nls(demand ~ SSasympOrig(Time, A, lrc), data = BOD)
pr1 <- profile(fm1, alpha = 0.1)
MASS:::plot.profile(pr1)
pairs(pr1) # a little odd since the parameters are highly correlated

## an example from ?nls
x <- -(1:100)/10
y <- 100 + 10 * exp(x / 2) + rnorm(x)/10
nlmod <- nls(y ~ Const + A * exp(B * x), start=list(Const=100, A=10, B=1))
pairs(profile(nlmod))
```

\texttt{polr}

\textit{Ordered Logistic or Probit Regression}

Description

Fits a logistic or probit regression model to an ordered factor response. The default logistic case is \textit{proportional odds logistic regression}, after which the function is named.

Usage

\texttt{polr(formula, data, weights, start, ..., subset, na.action,}
\texttt{ contrasts = NULL, Hess = FALSE, model = TRUE,}
\texttt{ method = c("logistic", "probit", "cloglog", "cauchit")}

Arguments

formula a formula expression as for regression models, of the form
response ~ predictors. The response should be a factor (preferably
an ordered factor), which will be interpreted as an ordinal response, with levels
ordered as in the factor. The model must have an intercept: attempts to remove
one will lead to a warning and be ignored. An offset may be used. See the
documentation of formula for other details.
data an optional data frame in which to interpret the variables occurring in formula.
weights optional case weights in fitting. Default to 1.
start initial values for the parameters. This is in the format c(coefficients, zeta):
see the Values section.
... additional arguments to be passed to optim, most often a control argument.
subset expression saying which subset of the rows of the data should be used in the fit.
All observations are included by default.
na.action a function to filter missing data.
contrasts a list of contrasts to be used for some or all of the factors appearing as variables
in the model formula.
Hess logical for whether the Hessian (the observed information matrix) should be
returned. Use this if you intend to call summary or vcov on the fit.
model logical for whether the model matrix should be returned.
method logistic or probit or complementary log-log or cauchit (corresponding to a
Cauchy latent variable).

Details

This model is what Agresti (2002) calls a *cumulative link* model. The basic interpretation is as a
*coarsened* version of a latent variable \( Y_i \) which has a logistic or normal or extreme-value or Cauchy
distribution with scale parameter one and a linear model for the mean. The ordered factor which is
observed is which bin \( Y_i \) falls into with breakpoints

\[
\zeta_0 = -\infty < \zeta_1 < \cdots < \zeta_K = \infty
\]

This leads to the model

\[
\text{logit} P(Y \leq k|x) = \zeta_k - \eta
\]

with \text{logit} replaced by \text{probit} for a normal latent variable, and \( \eta \) being the linear predictor, a linear
function of the explanatory variables (with no intercept). Note that it is quite common for other
software to use the opposite sign for \( \eta \) (and hence the coefficients beta).

In the logistic case, the left-hand side of the last display is the log odds of category \( k \) or less, and
since these are log odds which differ only by a constant for different \( k \), the odds are proportional.
Hence the term *proportional odds logistic regression*.

In the complementary log-log case, we have a *proportional hazards* model for grouped survival
times.

There are methods for the standard model-fitting functions, including predict, summary, vcov,
anova, model.frame and an extractAIC method for use with stepAIC (and step. There are also
profile and confint methods.
Value

A object of class "polr". This has components

- **coefficients**: the coefficients of the linear predictor, which has no intercept.
- **zeta**: the intercepts for the class boundaries.
- **deviance**: the residual deviance.
- **fitted.values**: a matrix, with a column for each level of the response.
- **lev**: the names of the response levels.
- **terms**: the terms structure describing the model.
- **df.residual**: the number of residual degrees of freedoms, calculated using the weights.
- **edf**: the (effective) number of degrees of freedom used by the model.
- **n, nobs**: the (effective) number of observations, calculated using the weights. (nobs is for use by `stepAIC`.
- **call**: the matched call.
- **method**: the matched method used.
- **convergence**: the convergence code returned by `optim`.
- **niter**: the number of function and gradient evaluations used by `optim`.
- **lp**: the linear predictor (including any offset).
- **Hessian**: (if Hess is true). Note that this is a numerical approximation derived from the optimization proces.
- **model**: (if model is true).

Note

The `vcov` method uses the approximate Hessian: for reliable results the model matrix should be sensibly scaled with all columns having range the order of one.

Examples

```r
options(contrasts = c("contr.treatment", "contr.poly"))
house.plr <- polr(Sat ~ Infl + Type + Cont, weights = Freq, data = housing)
house.plr
summary(house.plr, digits = 3)
## slightly worse fit from
summary(update(house.plr, method = "probit", Hess = TRUE), digits = 3)
## although it is not really appropriate, can fit
summary(update(house.plr, method = "cloglog", Hess = TRUE), digits = 3)

predict(house.plr, housing, type = "p")
addterm(house.plr, ~.^2, test = "Chisq")
```
predict.glmmPQL

Predict Method for glmmPQL Fits

Description
Obtains predictions from a fitted generalized linear model with random effects.

Usage
```r
## S3 method for class 'glmmPQL'
predict(object, newdata = NULL, type = c("link", "response"),
    level = NULL, na.action = na.pass, ...)
```

Arguments
- `object`: a fitted object of class inheriting from "glmmPQL".
- `newdata`: optionally, a data frame in which to look for variables with which to predict.
- `type`: the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and type = "response" gives the predicted probabilities.
- `level`: an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping.
- `na.action`: function determining what should be done with missing values in newdata. The default is to predict NA.
- `...`: further arguments passed to or from other methods.

Value
If level is a single integer, a vector otherwise a data frame.

See Also
glmmPQL, predict.lme.

Examples
```r
fit <- glmmPQL(y ~ trt + I(week > 2), random = ~1 | ID,
    family = binomial, data = bacteria)
predict(fit, bacteria, level = 0, type="response")
predict(fit, bacteria, level = 1, type="response")
```
**predict.lda**

Classify multivariate observations in conjunction with `lda`, and also project data onto the linear discriminants.

**Usage**

```r
## S3 method for class 'lda'
predict(object, newdata, prior = object$prior, dimen, 
         method = c("plug-in", "predictive", "debiased"), ...)
```

**Arguments**

- `object` object of class "lda"
- `newdata` data frame of cases to be classified or, if `object` has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If `newdata` is missing, an attempt will be made to retrieve the data used to fit the `lda` object.
- `prior` The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to `lda`.
- `dimen` the dimension of the space to be used. If this is less than `min(n, pg-1)`, only the first `dimen` discriminant components are used (except for `method="predictive"`), and only those dimensions are returned in `x`.
- `method` This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior.
- `...` arguments based from or to other methods

**Details**

This function is a method for the generic function `predict()` for class "lda". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.lda(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the linear discriminants cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

This version centres the linear discriminants so that the weighted mean (weighted by `prior`) of the group centroids is at the origin.

**Value**

A list with components

- `class` The MAP classification (a factor)
- `posterior` posterior probabilities for the classes
- `x` the scores of test cases on up to `dimen` discriminant variables

train <- rbind(iris3[tr,1], iris3[tr,2], iris3[tr,3])
test <- rbind(iris3[-tr,1], iris3[-tr,2], iris3[-tr,3])
c1 <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
z <- lda(train, c1)
predict(z, test)$class
```

```
predict.lqs  Predict from an lqs Fit
```

Description

Predict from an resistant regression fitted by `lqs`.

Usage

```r
## S3 method for class 'lqs'
predict(object, newdata, na.action = na.pass, ...)
```

Arguments

- `object`: object inheriting from class "lqs"
- `newdata`: matrix or data frame of cases to be predicted or, if `object` has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If `newdata` is missing, an attempt will be made to retrieve the data used to fit the `lqs` object.
- `na.action`: function determining what should be done with missing values in `newdata`. The default is to predict NA.
- `...`: arguments to be passed from or to other methods.

Details

This function is a method for the generic function `predict()` for class `lqs`. It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.lqs(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning NA if the linear fit cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.
Value
A vector of predictions.

fm <- lqs(stack.loss ~ ., data = stackloss, method = "S", nsamp = "exact")
predict(fm, stackloss)
```

predict.mca

**Predict Method for Class 'mca'**

Description
Used to compute coordinates for additional rows or additional factors in a multiple correspondence analysis.

Usage
```r
## S3 method for class 'mca'
predict(object, newdata, type = c("row", "factor"), ...)
```

Arguments
- `object`: An object of class "mca", usually the result of a call to mca.
- `newdata`: A data frame containing either additional rows of the factors used to fit object or additional factors for the cases used in the original fit.
- `type`: Are predictions required for further rows or for new factors?
- `...`: Additional arguments from predict: unused.

Value
- If `type = "row"`, the coordinates for the additional rows.
- If `type = "factor"`, the coordinates of the column vertices for the levels of the new factors.

References

mca, plot.mca
**predict.qda**  
*Classify from Quadratic Discriminant Analysis*

**Description**

Classify multivariate observations in conjunction with qda

**Usage**

```r
## S3 method for class 'qda'
predict(object, newdata, prior = object$prior,
        method = c("plug-in", "predictive", "debiased", "loocv"), ...)
```

**Arguments**

- `object`: object of class "qda"
- `newdata`: data frame of cases to be classified or, if object has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If newdata is missing, an attempt will be made to retrieve the data used to fit the qda object.
- `prior`: The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to qda.
- `method`: This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior. With "loocv" the leave-one-out cross-validation fits to the original dataset are computed and returned.

... arguments based from or to other methods

**Details**

This function is a method for the generic function `predict()` for class "qda". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.qda(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the quadratic discriminants cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

**Value**

a list with components

- `class`: The MAP classification (a factor)
- `posterior`: posterior probabilities for the classes

**References**

profile.glm

Method for Profiling glm Objects

Description

Investigates the profile log-likelihood function for a fitted model of class "glm".

Usage

```r
## S3 method for class 'glm'
profile(fitted, which = 1:p, alpha = 0.01, maxsteps = 10,
        del = zmax/5, trace = FALSE, ...)
```

Arguments

- `fitted`: the original fitted model object.
- `which`: the original model parameters which should be profiled. This can be a numeric or character vector. By default, all parameters are profiled.
- `alpha`: highest significance level allowed for the profile t-statistics.
- `maxsteps`: maximum number of points to be used for profiling each parameter.
- `del`: suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.
- `trace`: logical: should the progress of profiling be reported?
- `...`: further arguments passed to or from other methods.

Details

The profile t-statistic is defined as the square root of change in sum-of-squares divided by residual standard error with an appropriate sign.

Value

A list of classes "profile.glm" and "profile" with an element for each parameter being profiled. The elements are data-frames with two variables

- `par.vals`: a matrix of parameter values for each fitted model.
- `tau`: the profile t-statistics.

Examples

```r
tr <- sample(1:50, 25)
train <- rbind(iris3[tr,,1], iris3[tr,,2], iris3[tr,,3])
test <- rbind(iris3[-tr,,1], iris3[-tr,,2], iris3[-tr,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
zq <- qda(train, cl)
predict(zq, test)$class
```
Author(s)

Originally, D. M. Bates and W. N. Venables. (For S in 1996.)

See Also

`glm`, `profile`, `plot.profile`

Examples

```r
options(contrasts = c("contr.treatment", "contr.poly"))
dose <- rep(0.5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 8, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg <- glm(SF ~ sex+dose, family = binomial)
pr1 <- profile(budworm.lg)
plot(pr1)
pairs(pr1)
```

## qda

### Quadratic Discriminant Analysis

**Description**

Quadratic discriminant analysis.

**Usage**

```r
qda(x, ...)
```

## S3 method for class 'formula'

```r
qda(formula, data, ..., subset, na.action)
```

## Default S3 method:

```r
qda(x, grouping, prior = proportions,
    method, CV = FALSE, nu, ...)
```

## S3 method for class 'data.frame'

```r
qda(x, ...)
```

## S3 method for class 'matrix'

```r
qda(x, grouping, ..., subset, na.action)
```

**Arguments**

- `formula`: A formula of the form `~ x1 + x2 + ...`. That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.
- `data`: Data frame from which variables specified in `formula` are preferentially to be taken.
- `x` (required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.
qda

grouping (required if no formula principal argument is given.) a factor specifying the class for each observation.

prior the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If specified, the probabilities should be specified in the order of the factor levels.

subset An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)

na.action A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is na.omit, which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)

method "moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use cov.mve, or "t" for robust estimates based on a t distribution.

CV If true, returns results (classes and posterior probabilities) for leave-out-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.

nu degrees of freedom for method = "t".

... arguments passed to or from other methods.

Details

Uses a QR decomposition which will give an error message if the within-group variance is singular for any group.

Value

an object of class "qda" containing the following components:

prior the prior probabilities used.
means the group means.
scaling for each group i, scaling[,]i] is an array which transforms observations so that within-groups covariance matrix is spherical.
ldet a vector of half log determinants of the dispersion matrix.
lev the levels of the grouping factor.
terms (if formula is a formula) an object of mode expression and class term summarizing the formula.
call the (matched) function call.

unless CV=TRUE, when the return value is a list with components:

class The MAP classification (a factor)
posterior posterior probabilities for the classes

predict.qda.lda

Examples

```r
tr <- sample(1:50, 25)
train <- rbind(iris3[tr,1], iris3[tr,2], iris3[tr,3])
test <- rbind(iris3[-tr,1], iris3[-tr,2], iris3[-tr,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
z <- qda(train, cl)
predict(z, test)$class
```

Description

The *quine* data frame has 146 rows and 5 columns. Children from Walgett, New South Wales, Australia, were classified by Culture, Age, Sex and Learner status and the number of days absent from school in a particular school year was recorded.

Usage

quine

Format

This data frame contains the following columns:

- *Eth*: ethnic background: Aboriginal or Not, ("A" or "N").
- *Sex*: sex: factor with levels ("M" or "F").
- *Age*: age group: Primary ("F0"), or forms "F1", "F2" or "F3".
- *Lrn*: learner status: factor with levels Average or Slow learner, ("AL" or "SL").
- *Days*: days absent from school in the year.

**Blood Pressure in Rabbits**

**Description**

Five rabbits were studied on two occasions, after treatment with saline (control) and after treatment with the $5-HT_3$ antagonist MDL 72222. After each treatment ascending doses of phenylbiguanide were injected intravenously at 10 minute intervals and the responses of mean blood pressure measured. The goal was to test whether the cardiogenic chemoreflex elicited by phenylbiguanide depends on the activation of $5-HT_3$ receptors.

**Usage**

Rabbit

**Format**

This data frame contains 60 rows and the following variables:

- `bpchange`: change in blood pressure relative to the start of the experiment.
- `dose`: dose of Phenylbiguanide in micrograms.
- `run`: label of run ("C1" to "C5", then "M1" to "M5").
- `treatment`: placebo or the $5-HT_3$ antagonist MDL 72222.
- `animal`: label of animal used ("R1" to "R5").

**Source**

[The numerical data are not in the paper but were supplied by Professor Ludbrook]

---

**Rational Approximation**

**Description**

Find rational approximations to the components of a real numeric object using a standard continued fraction method.

**Usage**

`rational(x, cycles = 10, max.denominator = 2000, ...)`
Arguments

- **x**: Any object of mode numeric. Missing values are now allowed.
- **cycles**: The maximum number of steps to be used in the continued fraction approximation process.
- **max.denominator**: An early termination criterion. If any partial denominator exceeds `max.denominator` the continued fraction stops at that point.
- **...**: arguments passed to or from other methods.

Details

Each component is first expanded in a continued fraction of the form

\[ x = \frac{1}{p_1 + \frac{1}{p_2 + \ldots}} \]

where \( p_1, p_2, \ldots \) are positive integers, terminating either at \( \text{cycles} \) terms or when a \( p_j > \text{max.denominator} \). The continued fraction is then re-arranged to retrieve the numerator and denominator as integers and the ratio returned as the value.

Value

A numeric object with the same attributes as \( x \) but with entries rational approximations to the values. This effectively rounds relative to the size of the object and replaces very small entries by zero.

See Also

- `fractions`

Examples

```r
X <- matrix(runif(25), 5, 5)
zapsmall(solve(X, X/5)) # print near-zeroes as zero
rational(solve(X, X/5))
```

---

**renumerate**

Convert a Formula Transformed by 'denumerate'

Description

denumerate converts a formula written using the conventions of `loglm` into one that terms is able to process. renumerate converts it back again to a form like the original.

Usage

`renumerate(x)`

Arguments

- **x**: A formula, normally as modified by denumerate.
Details

This is an inverse function to \texttt{denumerate}. It is only needed since \texttt{terms} returns an expanded form of the original formula where the non-marginal terms are exposed. This expanded form is mapped back into a form corresponding to the one that the user originally supplied.

Value

A formula where all variables with names of the form \texttt{.vn}, where \texttt{n} is an integer, converted to numbers, \texttt{n}, as allowed by the formula conventions of \texttt{loglm}.

See Also

\texttt{denumerate}

Examples

\begin{verbatim}
denumerate(~(1+2+3)^3 + a/b)
## ~ (.v1 + .v2 + .v3)^3 + a/b
renumerate(.Last.value)
## ~ (1 + 2 + 3)^3 + a/b
\end{verbatim}

---

\texttt{rlm}

\textit{Robust Fitting of Linear Models}

Description

Fit a linear model by robust regression using an M estimator.

Usage

\begin{verbatim}
rlm(x, ...

## S3 method for class 'formula'
rlm(formula, data, weights, ..., subset, na.action,
    method = c("M", "MM", "model.frame"),
    wt.method = c("inv.var", "case"),
    model = TRUE, x.ret = TRUE, y.ret = FALSE, contrasts = NULL)

## Default S3 method:
rlm(x, y, weights, ..., w = rep(1, nrow(x)),
    init = "ls", psi = psi.huber,
    scale.est = c("MAD", "Huber", "proposal 2"), k2 = 1.345,
    method = c("M", "MM"), wt.method = c("inv.var", "case"),
    maxit = 20, acc = 1e-4, test.vec = "resid", lqs.control = NULL)
\end{verbatim}

\begin{verbatim}
psi.huber(u, k = 1.345, deriv = 0)
psi.hampel(u, a = 2, b = 4, c = 8, deriv = 0)
psi.bisquare(u, c = 4.685, deriv = 0)
\end{verbatim}
Arguments

- **formula**: a formula of the form $y \sim x_1 + x_2 + \ldots$
- **data**: data frame from which variables specified in formula are preferentially to be taken.
- **weights**: a vector of prior weights for each case.
- **subset**: An index vector specifying the cases to be used in fitting.
- **na.action**: A function to specify the action to be taken if NAs are found. The ‘factory-fresh’ default action in R is `na.omit`, and can be changed by `options(na.action=)`. 
- **x**: a matrix or data frame containing the explanatory variables.
- **y**: the response: a vector of length the number of rows of x.
- **method**: currently either M-estimation or MM-estimation or (for the formula method only) find the model frame. MM-estimation is M-estimation with Tukey’s biweight initialized by a specific S-estimator. See the ‘Details’ section.
- **wt.method**: are the weights case weights (giving the relative importance of case, so a weight of 2 means there are two of these) or the inverse of the variances, so a weight of two means this error is half as variable?
- **model**: should the model frame be returned in the object?
- **x.ret**: should the model matrix be returned in the object?
- **y.ret**: should the response be returned in the object?
- **contrasts**: optional contrast specifications: see `lm`.
- **w**: (optional) initial down-weighting for each case.
- **init**: (optional) initial values for the coefficients OR a method to find initial values OR the result of a fit with a coef component. Known methods are "ls" (the default) for an initial least-squares fit using weights w=weights, and "lts" for an unweighted least-trimmed squares fit with 200 samples.
- **psi**: the psi function is specified by this argument. It must give (possibly by name) a function g(x, \ldots, deriv) that for deriv=0 returns psi(x)/x and for deriv=1 returns psi'(x). Tuning constants will be passed in via ....
- **scale.est**: method of scale estimation: re-scaled MAD of the residuals (default) or Huber’s proposal 2 (which can be selected by either "Huber" or "proposal 2").
- **k2**: tuning constant used for Huber proposal 2 scale estimation.
- **maxit**: the limit on the number of IWLS iterations.
- **acc**: the accuracy for the stopping criterion.
- **test.vec**: the stopping criterion is based on changes in this vector.
- **\ldots**: additional arguments to be passed to `r1m.default` or to the psi function.
- **lqs.control**: An optional list of control values for `lqs`.
- **u**: numeric vector of evaluation points.
- **k, a, b, c**: tuning constants.
- **deriv**: 0 or 1: compute values of the psi function or of its first derivative.
Details

Fitting is done by iterated re-weighted least squares (IWLS). Psi functions are supplied for the Huber, Hampel and Tukey bisquare proposals as psi.huber, psi.hampel and psi.bisquare. Huber’s corresponds to a convex optimization problem and gives a unique solution (up to collinearity). The other two will have multiple local minima, and a good starting point is desirable.

Selecting method = "MM" selects a specific set of options which ensures that the estimator has a high breakdown point. The initial set of coefficients and the final scale are selected by an S-estimator with k0 = 1.548; this gives (for n \gg p) breakdown point 0.5. The final estimator is an M-estimator with Tukey’s biweight and fixed scale that will inherit this breakdown point provided c > k0; this is true for the default value of c that corresponds to 95% relative efficiency at the normal. Case weights are not supported for method = "MM".

Value

An object of class "rlm" inheriting from "lm". Note that the df.residual component is deliberately set to NA to avoid inappropriate estimation of the residual scale from the residual mean square by "lm" methods.

The additional components not in an lm object are

- s: the robust scale estimate used
- w: the weights used in the IWLS process
- psi: the psi function with parameters substituted
- conv: the convergence criteria at each iteration
- converged: did the IWLS converge?
- wresid: a working residual, weighted for "inv.var" weights only.

Relative Curvature Measures for Non-Linear Regression

Description
Calculates the root mean square parameter effects and intrinsic relative curvatures, \( \theta \) and \( \iota \), for a fitted nonlinear regression, as defined in Bates & Watts, section 7.3, p. 253ff.

Usage
```r
rms.curv(obj)
```

Arguments
- `obj` Fitted model object of class "nls". The model must be fitted using the default algorithm.

Details
The method of section 7.3.1 of Bates & Watts is implemented. The function `deriv3` should be used to generate a model function with first derivative (gradient) matrix and second derivative (Hessian) array attributes. This function should then be used to fit the nonlinear regression model.

A print method, `print.rms.curv`, prints the `pc` and `ic` components only, suitably annotated.

If either `pc` or `ic` exceeds some threshold (0.3 has been suggested) the curvature is unacceptably high for the planar assumption.

Value
A list of class `rms.curv` with components `pc` and `ic` for parameter effects and intrinsic relative curvatures multiplied by \( \sqrt{F} \), `ct` and `ci` for \( \theta \) and \( \iota \) (unmultiplied), and `C` the C-array as used in section 7.3.1 of Bates & Watts.

References

See Also
- `deriv3`

Examples
```r
# The treated sample from the Puromycin data
mmcurve <- deriv3(~ Vm * conc/(K + conc), c("Vm", "K"),
    function(Vm, K, conc) NULL)
Treated <- Puromycin[Puromycin$state == "treated", ]
(Purfit1 <- nls(rate ~ mmcurve(Vm, K, conc), data = Treated, start = list(Vm=200, K=0.1)))
rms.curv(Purfit1)
```

### Parameter effects: \( \theta \) x \( \sqrt{F} \) = 0.2121

### Intrinsic: \( \iota \) x \( \sqrt{F} \) = 0.092
**rnegbin**

**Simulate Negative Binomial Variates**

**Description**

Function to generate random outcomes from a Negative Binomial distribution, with mean \( \mu \) and variance \( \mu + \mu^2/\theta \).

**Usage**

```r
rnegbin(n, mu = n, theta = stop("'theta' must be specified"))
```

**Arguments**

- `n` If a scalar, the number of sample values required. If a vector, `length(n)` is the number required and `n` is used as the mean vector if `mu` is not specified.
- `mu` The vector of means. Short vectors are recycled.
- `theta` Vector of values of the theta parameter. Short vectors are recycled.

**Details**

The function uses the representation of the Negative Binomial distribution as a continuous mixture of Poisson distributions with Gamma distributed means. Unlike `rbinom`, the index can be arbitrary.

**Value**

Vector of random Negative Binomial variate values.

**Side Effects**

Changes `.Random.seed` in the usual way.

**Examples**

```r
# Negative Binomials with means fitted(fm) and theta = 4.5
fm <- glm.nb(Days ~ ., data = quine)
dummy <- rnegbin(fitted(fm), theta = 4.5)
```

tens  tensile strength in kg/sq m.

**Source**

**References**

**sammon**

*Sammon’s Non-Linear Mapping*

**Description**

One form of non-metric multidimensional scaling.

**Usage**

```r
sammon(d, y = cmdscale(d, k), k = 2, niter = 100, trace = TRUE,
       magic = 0.2, tol = 1e-4)
```
Arguments

- **d**: distance structure of the form returned by `dist`, or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. This can contain missing values.
- **y**: An initial configuration. If none is supplied, `cmdscale` is used to provide the classical solution. (If there are missing values in **d**, an initial configuration must be provided.) This must not have duplicates.
- **k**: The dimension of the configuration.
- **niter**: The maximum number of iterations.
- **trace**: Logical for tracing optimization. Default `TRUE`.
- **magic**: initial value of the step size constant in diagonal Newton method.
- **tol**: Tolerance for stopping, in units of stress.

Details

This chooses a two-dimensional configuration to minimize the stress, the sum of squared differences between the input distances and those of the configuration, weighted by the distances, the whole sum being divided by the sum of input distances to make the stress scale-free.

An iterative algorithm is used, which will usually converge in around 50 iterations. As this is necessarily an \(O(n^2)\) calculation, it is slow for large datasets. Further, since the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine. In this release the algorithm has been modified by adding a step-length search (`magic`) to ensure that it always goes downhill.

Value

Two components:

- **points**: A two-column vector of the fitted configuration.
- **stress**: The final stress achieved.

Side Effects

If trace is true, the initial stress and the current stress are printed out every 10 iterations.

```

Snail Mortality Data

Description

Groups of 20 snails were held for periods of 1, 2, 3 or 4 weeks in carefully controlled conditions of temperature and relative humidity. There were two species of snail, A and B, and the experiment was designed as a 4 by 3 by 4 by 2 completely randomized design. At the end of the exposure time the snails were tested to see if they had survived; the process itself is fatal for the animals. The object of the exercise was to model the probability of survival in terms of the stimulus variables, and in particular to test for differences between species.

The data are unusual in that in most cases fatalities during the experiment were fairly small.

Usage

```r
snails
```
Format

The data frame contains the following components:

Species  snail species A (1) or B (2).
Exposure  exposure in weeks.
Rel.Hum  relative humidity (4 levels).
Temp  temperature, in degrees Celsius (3 levels).
Deaths  number of deaths.
N  number of snails exposed.

stepAIC

Choose a model by AIC in a Stepwise Algorithm

Description

Performs stepwise model selection by AIC.

Usage

stepAIC(object, scope, scale = 0, direction = c("both", "backward", "forward"), trace = 1, keep = NULL, steps = 1000, use.start = FALSE, k = 2, ...)

Arguments

object an object representing a model of an appropriate class. This is used as the initial model in the stepwise search.
scope defines the range of models examined in the stepwise search. This should be either a single formula, or a list containing components upper and lower, both formulae. See the details for how to specify the formulae and how they are used.
scale used in the definition of the AIC statistic for selecting the models, currently only for \( \text{lm} \) and \( \text{aov} \) models (see extractAIC for details).
direction the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the scope argument is missing the default for direction is "backward".
trace if positive, information is printed during the running of stepAIC. Larger values may give more information on the fitting process.
keep a filter function whose input is a fitted model object and the associated AIC statistic, and whose output is arbitrary. Typically keep will select a subset of the components of the object and return them. The default is not to keep anything.
steps the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.
use.start if true the updated fits are done starting at the linear predictor for the currently selected model. This may speed up the iterative calculations for \( \text{glm} \) (and other fits), but it can also slow them down. Not used in R.
k the multiple of the number of degrees of freedom used for the penalty. Only \( k = 2 \) gives the genuine AIC: \( k = \log(n) \) is sometimes referred to as BIC or SBC.

... any additional arguments to extractAIC. (None are currently used.)
Details

The set of models searched is determined by the scope argument. The right-hand-side of its lower component is always included in the model, and right-hand-side of the model is included in the upper component. If scope is a single formula, it specifies the upper component, and the lower model is empty. If scope is missing, the initial model is used as the upper model.

Models specified by scope can be templates to update object as used by `update.formula`.

There is a potential problem in using `glm` fits with a variable scale, as in that case the deviance is not simply related to the maximized log-likelihood. The `glm` method for `extractAIC` makes the appropriate adjustment for a gaussian family, but may need to be amended for other cases. (The binomial and poisson families have fixed scale by default and do not correspond to a particular maximum-likelihood problem for variable scale.)

Where a conventional deviance exists (e.g. for `lm`, `aov` and `glm` fits) this is quoted in the analysis of variance table: it is the unscaled deviance.

Value

the stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the `keep` argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding `lm`, `aov` and `survreg` fits, for example).

Note

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and an `na.action` other than `na.fail` is used (as is the default in R). We suggest you remove the missing values first.

```
The Stormer Viscometer Data

Description

The Stormer viscometer measures the viscosity of a fluid by measuring the time taken for an inner cylinder in the mechanism to perform a fixed number of revolutions in response to an actuating weight. The viscometer is calibrated by measuring the time taken with varying weights while the mechanism is suspended in fluids of accurately known viscosity. The data comes from such a calibration, and theoretical considerations suggest a nonlinear relationship between time, weight and viscosity, of the form

\[
\text{time} = \frac{B_1 \times \text{viscosity}}{(\text{weight} - B_2)} + \varepsilon
\]

where \(B_1\) and \(B_2\) are unknown parameters to be estimated, and \(\varepsilon\) is error.

Usage

stormer

Format

The data frame contains the following components:

- \text{viscosity}\hspace{1em}\text{viscosity of fluid.}
- \text{wt}\hspace{1em}\text{actuating weight.}
- \text{time}\hspace{1em}\text{time taken.}

summary.loglm

Summary Method Function for Objects of Class 'loglm'

Description

Returns a summary list for log-linear models fitted by iterative proportional scaling using loglm.

Usage

## S3 method for class 'loglm'
summary(object, fitted = FALSE, ...)

Arguments

object a fitted loglm model object.
fitted if TRUE return observed and expected frequencies in the result. Using fitted = TRUE may necessitate re-fitting the object.
... arguments to be passed to or from other methods.
Details

This function is a method for the generic function `summary()` for class "loglm". It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.loglm(x)` regardless of the class of the object.

Value

A list is returned for use by `print.summary.loglm`. This has components

- `formula` - the formula used to produce `object`
- `tests` - the table of test statistics (likelihood ratio, Pearson) for the fit.
- `oe` - if `fitted = TRUE`, an array of the observed and expected frequencies, otherwise `NULL`.

References

See Also

`loglm`, `summary`

---

**summary.negbin**

Summary Method Function for Objects of Class 'negbin'

Description

Identical to `summary.glm`, but with three lines of additional output: the ML estimate of theta, its standard error, and twice the log-likelihood function.

Usage

```r
## S3 method for class 'negbin'
summary(object, dispersion = 1, correlation = FALSE, ...)
```

Arguments

- `object` - fitted model object of class `negbin` inheriting from `glm` and `lm`. Typically the output of `glm.nb`.
- `dispersion` - as for `summary.glm`, with a default of 1.
- `correlation` - as for `summary.glm`.
- `...` - arguments passed to or from other methods.

Details

`summary.glm` is used to produce the majority of the output and supply the result. This function is a method for the generic function `summary()` for class "negbin". It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.negbin(x)` regardless of the class of the object.
Value
As for summary.glm; the additional lines of output are not included in the resultant object.

Side Effects
A summary table is produced as for summary.glm, with the additional information described above.

summary(glm.nb(Days ~ Eth*Age*Lrn*Sex, quine, link = log))

summary.rlm  Summary Method for Robust Linear Models

Description
summary method for objects of class "rlm"

Usage
## S3 method for class 'rlm'
summary(object, method = c("XTX", "XTWX"), correlation = FALSE, ...)

Arguments
object  the fitted model. This is assumed to be the result of some fit that produces an object inheriting from the class rlm, in the sense that the components returned by the rlm function will be available.

method  Should the weighted (by the IWLS weights) or unweighted cross-products matrix be used?

correlation  logical. Should correlations be computed (and printed)?

...  arguments passed to or from other methods.

Details
This function is a method for the generic function summary() for class "rlm". It can be invoked by calling summary(x) for an object x of the appropriate class, or directly by calling summary.rlm(x) regardless of the class of the object.
Value

If printing takes place, only a null value is returned. Otherwise, a list is returned with the following components. Printing always takes place if this function is invoked automatically as a method for the summary function.

correlation The computed correlation coefficient matrix for the coefficients in the model.
cov.unscaled The unscaled covariance matrix; i.e., a matrix such that multiplying it by an estimate of the error variance produces an estimated covariance matrix for the coefficients.
sigma The scale estimate.
stddev A scale estimate used for the standard errors.
tr The number of degrees of freedom for the model and for residuals.
coefficients A matrix with three columns, containing the coefficients, their standard errors and the corresponding t statistic.
terms The terms object used in fitting this model.

## End(Not run)
Description

This data frame contains the responses of 237 Statistics I students at the University of Adelaide to a number of questions.

Usage

survey

Format

The components of the data frame are:

- **Sex**: The sex of the student. (Factor with levels "Male" and "Female".)
- **Wt. Hnd**: span (distance from tip of thumb to tip of little finger of spread hand) of writing hand, in centimetres.
- **NW. Hnd**: span of non-writing hand.
- **W. Hnd**: writing hand of student. (Factor, with levels "Left" and "Right".)
- **Fold**: “Fold your arms! Which is on top?” (Factor, with levels "R on L", "L on R", "Neither").
- **Pulse**: pulse rate of student (beats per minute).
- **Clap**: ‘Clap your hands! Which hand is on top?’ (Factor, with levels "Right", "Left", "Neither").
- **Exer**: how often the student exercises. (Factor, with levels "Freq" (frequently), "Some", "None").
- **Smoke**: how much the student smokes. (Factor, levels "Heavy", "Regul" (regularly), "Occas" (occasionally), "Never").
- **Height**: height of the student in centimetres.
- **M. I**: whether the student expressed height in imperial (feet/inches) or metric (centimetres/metres) units. (Factor, levels "Metric", "Imperial").
- **Age**: age of the student in years.

References

**Description**

The `synth.tr` data frame has 250 rows and 3 columns. The `synth.te` data frame has 100 rows and 3 columns. It is intended that `synth.tr` be used from training and `synth.te` for testing.

**Usage**

```r
synth.tr
synth.te
```

**Format**

These data frames contain the following columns:

- `xs` x-coordinate
- `ys` y-coordinate
- `yc` class, coded as 0 or 1.

**Source**

---

**Description**

Given the estimated mean vector, estimate `theta` of the Negative Binomial Distribution.

**Usage**

```r
theta.md(y, mu, dfr, weights, limit = 20, eps = .Machine$double.eps^0.25)
theta.ml(y, mu, n, weights, limit = 10, eps = .Machine$double.eps^0.25, trace = FALSE)
theta.mm(y, mu, dfr, weights, limit = 10, eps = .Machine$double.eps^0.25)
```
Arguments

- **y**: Vector of observed values from the Negative Binomial.
- **mu**: Estimated mean vector.
- **n**: Number of data points (defaults to the sum of weights).
- **dfr**: Residual degrees of freedom (assuming theta known). For a weighted fit this is the sum of the weights minus the number of fitted parameters.
- **weights**: Case weights. If missing, taken as 1.
- **limit**: Limit on the number of iterations.
- **eps**: Tolerance to determine convergence.
- **trace**: logical: should iteration progress be printed?

Details

theta.md estimates by equating the deviance to the residual degrees of freedom, an analogue of a moment estimator.

theta.ml uses maximum likelihood.

theta.mm calculates the moment estimator of theta by equating the Pearson chi-square $\sum(y - \mu)^2 / (\mu + \mu^2/\theta)$ to the residual degrees of freedom.

Value

The required estimate of theta, as a scalar. For theta.ml, the standard error is given as attribute "SE".

Examples

```r
quine.nb <- glm.nb(Days ~ .^2, data = quine)
theta.md(quine$Days, fitted(quine.nb), dfr = df.residual(quine.nb))
theta.ml(quine$Days, fitted(quine.nb))
theta.mm(quine$Days, fitted(quine.nb), dfr = df.residual(quine.nb))
```

```r
### weighted example
yeast <- data.frame(cbind(numbers = 0:5, fr = c(213, 128, 37, 18, 3, 1)))
fit <- glm.nb(numbers ~ 1, weights = fr, data = yeast)
summary(fit)
mu <- fitted(fit)
theta.md(yeast$numbers, mu, dfr = 399, weights = yeast$fr)
theta.ml(yeast$numbers, mu, limit = 15, weights = yeast$fr)
theta.mm(yeast$numbers, mu, dfr = 399, weights = yeast$fr)
```
### topo

*Spatial Topographic Data*

**Description**

The `topo` data frame has 52 rows and 3 columns, of topographic heights within a 310 feet square.

**Usage**

`topo`

**Format**

This data frame contains the following columns:

- **x**: x coordinates (units of 50 feet)
- **y**: y coordinates (units of 50 feet)
- **z**: heights (feet)

**Source**

Davis, J.C. (1973) *Statistics and Data Analysis in Geology*. Wiley.

**References**

### Traffic

*Effect of Swedish Speed Limits on Accidents*

**Description**

An experiment was performed in Sweden in 1961–2 to assess the effect of a speed limit on the motorway accident rate. The experiment was conducted on 92 days in each year, matched so that day \( j \) in 1962 was comparable to day \( j \) in 1961. On some days the speed limit was in effect and enforced, while on other days there was no speed limit and cars tended to be driven faster. The speed limit days tended to be in contiguous blocks.

**Usage**

`Traffic`

**Format**

This data frame contains the following columns:

- **year**: 1961 or 1962.
- **day**: of year.
- **limit**: was there a speed limit?
- **y**: traffic accident count for that day.
truehist

Source

References

truehist

*Plot a Histogram*

Description

Creates a histogram on the current graphics device.

Usage

```
truehist(data, nbins = "Scott", h, x0 = -h/1000, breaks, prob = TRUE, xlab = range(breaks),
        ymax = max(est), col = "cyan",
        xlab = deparse(substitute(data)), bty = "n", ...)
```

Arguments

- **data**: numeric vector of data for histogram. Missing values (NAs) are allowed and omitted.
- **nbins**: The suggested number of bins. Either a positive integer, or a character string naming a rule: "Scott" or "Freedman–Diaconis" or "FD". (Case is ignored.)
- **h**: The bin width, a strictly positive number (takes precedence over `nbins`).
- **x0**: Shift for the bins - the breaks are at `x0 + h` (..., -1, 0, 1, ...)
- **breaks**: The set of breakpoints to be used. (Usually omitted, takes precedence over `h` and `nbins`).
- **prob**: If true (the default) plot a true histogram. The vertical axis has a relative frequency density scale, so the product of the dimensions of any panel gives the relative frequency. Hence the total area under the histogram is 1 and it is directly comparable with most other estimates of the probability density function. If false plot the counts in the bins.
- **xlim**: The limits for the x-axis.
- **ymax**: The upper limit for the y-axis.
- **col**: The colour for the bar fill: the default is colour 5 in the default R palette.
- **xlab**: label for the plot x-axis. By default, this will be the name of `data`.
- **bty**: The box type for the plot - defaults to none.
- **...**: additional arguments to `rect` or `plot`. 
Details

This plots a true histogram, a density estimate of total area 1. If `breaks` is specified, those breakpoints are used. Otherwise if `h` is specified, a regular grid of bins is used with width `h`. If neither `breaks` nor `h` is specified, `nbins` is used to select a suitable `h`.

Side Effects

A histogram is plotted on the current device.

**ucv**

Unbiased Cross-Validation for Bandwidth Selection

Description

Uses unbiased cross-validation to select the bandwidth of a Gaussian kernel density estimator.

Usage

```r
ucv(x, nb = 1000, lower, upper)
```

Arguments

- `x`: a numeric vector
- `nb`: number of bins to use.
- `lower`, `upper`: Range over which to minimize. The default is almost always satisfactory.

Value

a bandwidth.

UScereal

Nutritional and Marketing Information on US Cereals

Description

The UScereal data frame has 65 rows and 11 columns. The data come from the 1993 ASA Statistical Graphics Exposition, and are taken from the mandatory F&DA food label. The data have been normalized here to a portion of one American cup.

Usage

UScereal

Format

This data frame contains the following columns:

- mfr  Manufacturer, represented by its first initial:  G=General Mills,  K=Kelloggs,  N=Nabisco,  P=Post,  Q=Quaker Oats,  R=Ralston Purina.
- calories  number of calories in one portion.
- protein  grams of protein in one portion.
- fat  grams of fat in one portion.
- sodium  milligrams of sodium in one portion.
- fibre  grams of dietary fibre in one portion.
- carbo  grams of complex carbohydrates in one portion.
- sugars  grams of sugars in one portion.
- shelf  display shelf (1, 2, or 3, counting from the floor).
- potassium  grams of potassium.
- vitamins  vitamins and minerals (none, enriched, or 100%).

Source

The original data are available at http://lib.stat.cmu.edu/datasets/1993.expo/.

References

Criminologists are interested in the effect of punishment regimes on crime rates. This has been studied using aggregate data on 47 states of the USA for 1960 given in this data frame. The variables seem to have been re-scaled to convenient numbers.

This data frame contains the following columns:

- So: indicator variable for a Southern state.
- Ed: mean years of schooling.
- Po1: police expenditure in 1960.
- Po2: police expenditure in 1959.
- LF: labour force participation rate.
- M.F: number of males per 1000 females.
- Pop: state population.
- NW: number of non-whites per 1000 people.
- U1: unemployment rate of urban males 14–24.
- U2: unemployment rate of urban males 35–39.
- GDP: gross domestic product per head.
- Ineq: income inequality.
- Prb: probability of imprisonment.
- Time: average time served in state prisons.
- y: rate of crimes in a particular category per head of population.

Description

Veteran’s Administration lung cancer trial from Kalbfleisch & Prentice.

Usage

VA

Format

A data frame with columns:
- stime  survival or follow-up time in days.
- status  dead or censored.
- treat  treatment: standard or test.
- age  patient’s age in years.
- Karn  Karnofsky score of patient’s performance on a scale of 0 to 100.
- diag.time  times since diagnosis in months at entry to trial.
- cell  one of four cell types.
- prior  prior therapy?

Examples

plot(corresp(waders, nf=2))
### Description

Mr Derek Whiteside of the UK Building Research Station recorded the weekly gas consumption and average external temperature at his own house in south-east England for two heating seasons, one of 26 weeks before, and one of 30 weeks after cavity-wall insulation was installed. The object of the exercise was to assess the effect of the insulation on gas consumption.

### Usage

```r
whiteside
```

### Format

The `whiteside` data frame has 56 rows and 3 columns:

- **Insul**: A factor, before or after insulation.
- **Temp**: Purportedly the average outside temperature in degrees Celsius. (These values is far too low for any 56-week period in the 1960s in South-East England. It might be the weekly average of daily minima.)
- **Gas**: The weekly gas consumption in 1000s of cubic feet.

### Source

A data set collected in the 1960s by Mr Derek Whiteside of the UK Building Research Station. Reported by

### Examples

```r
require(lattice)
xypplot(Gas ~ Temp | Insul, whiteside, panel =
  function(x, y, ...) {
    panel.xypplot(x, y, ...)
    panel.lmline(x, y, ...)
  }, xlab = "Average external temperature (deg. C)",
ylab = "Gas consumption (1000 cubic feet)", aspect = "xy",
  strip = function(...) strip.default(..., style = 1))

gasB <- lm(Gas ~ Temp, whiteside, subset = Insul=="Before")
gasA <- update(gasB, subset = Insul=="After")
summary(gasB)
summary(gasA)
gasBA <- lm(Gas ~ Insul.Temp - 1, whiteside)
summary(gasBA)
```
Bandwidth Selection by Pilot Estimation of Derivatives

Description

Uses the method of Sheather & Jones (1991) to select the bandwidth of a Gaussian kernel density estimator.

Usage

width.SJ(x, nb = 1000, lower, upper, method = c("ste", "dpi"))

Arguments

- **x**: a numeric vector
- **nb**: number of bins to use.
- **upper, lower**: range over which to search for solution if method = "ste".
- **method**: Either "ste" ("solve-the-equation") or "dpi" ("direct plug-in").

Value

- a bandwidth.

References

See Also

Examples

width.SJ(geyser$duration, method = "dpi")

width.SJ(geyser$duration)

width.SJ(galaxies, method = "dpi")

width.SJ(galaxies)
write.matrix

Write a Matrix or Data Frame

Description

Writes a matrix or data frame to a file or the console, using column labels and a layout respecting columns.

Usage

write.matrix(x, file = "", sep = " ", blocksize)

Arguments

- x: matrix or data frame.
- file: name of output file. The default (""') is the console.
- sep: The separator between columns.
- blocksize: If supplied and positive, the output is written in blocks of blocksize rows. Choose as large as possible consistent with the amount of memory available.

Details

If x is a matrix, supplying blocksize is more memory-efficient and enables larger matrices to be written, but each block of rows might be formatted slightly differently.

If x is a data frame, the conversion to a matrix may negate the memory saving.

Side Effects

A formatted file is produced, with column headings (if x has them) and columns of data.

wtloss

Weight Loss Data from an Obese Patient

Description

The data frame gives the weight, in kilograms, of an obese patient at 52 time points over an 8 month period of a weight rehabilitation programme.

Usage

wtloss
Format

This data frame contains the following columns:

- Days: time in days since the start of the programme.
- Weight: weight in kilograms of the patient.

Source

Dr T. Davies, Adelaide.

References

Examples

```r
wtloss.fm <- nls(Weight ~ b0 + b1*2^(-Days/th),
                 data = wtloss, start = list(b0=90, b1=95, th=120))
wttloss.fm
plot(wtloss)
with(wtloss, lines(Days, fitted(wtloss.fm)))
```
Chapter 17

The Matrix package

abIndex-class

Class “abIndex” of Abstract Index Vectors

Description

The "abIndex" class, short for "Abstract Index Vector", is used for dealing with large index vectors more efficiently, than using integer (or numeric) vectors of the kind 2:1000000 or c(0:1e5, 1000:1e6).

Note that the current implementation details are subject to change, and if you consider working with these classes, please contact the package maintainers (packageDescription("Matrix")$Maintainer).

Objects from the Class

Objects can be created by calls of the form new("abIndex", ...), but more easily and typically either by as(x, "abIndex") where x is an integer (valued) vector, or directly by abIseq() and combination c(...) of such.

Slots

kind: a character string, one of("int32", "double", "rleDiff"), denoting the internal structure of the abIndex object.

x: Object of class "numLike"; is used (i.e., not of length 0) only iff the object is not compressed, i.e., currently exactly when kind != "rleDiff".

rle0: object of class "rleDiff", used for compression via rle.

Methods

as.numeric, as.integer, as.vector signature(x = "abIndex"): ...

[ signature(x = "abIndex", i = "index", j = "ANY", drop = "ANY"): ...

coerce signature(from = "numeric", to = "abIndex"): ...

coerce signature(from = "abIndex", to = "numeric"): ...

coerce signature(from = "abIndex", to = "integer"): ...

length signature(x = "abIndex"): ...
abIseq

Operations signature(e1 = "numeric", e2 = "abIndex"): These and the following arithmetic and logic operations are **not yet implemented**: see **Ops** for a list of these (S4) group methods.

Ops signature(e1 = "abIndex", e2 = "abIndex"): ...

Ops signature(e1 = "abIndex", e2 = "numeric"): ...

Summary signature(x = "abindex"): ...

show ("abIndex"): simple show method, building on show(<rleDiff>).

is.na ("abIndex"): works analogously to regular vectors.

is.finite, is.infinite ("abIndex"): ditto.

**Note**

This is currently experimental and not yet used for our own code. Please contact us (packageDescription("Matrix")#Maintainer), if you plan to make use of this class.

Partly builds on ideas and code from Jens Oehlschlaegel, as implemented (around 2008, in the GPL'ed part of) package **ff**.

**See Also**

rle (base) which is used here: numeric

**Examples**

```r
showClass("abIndex")
ii <- c(-3:40, 20:70)
str(ai <- as(ii, "abIndex"))# note
ai # -> show() method

stopifnot(identical(x3:20,
    as(abIseq(-3,20), "vector")))
```

**abIseq**

*Sequence Generation of "abIndex", Abstract Index Vectors*

**Description**

Generation of abstract index vectors, i.e., objects of class "abIndex".

abIseq() is designed to work entirely like seq, but producing "abIndex" vectors.

abIseq1() is its basic building block, where abIseq1(n,m) corresponds to n:m.

C(x, ...) will return an "abIndex" vector, when x is one.

**Usage**

abIseq1(from = 1, to = 1)
abIseq (from = 1, to = 1, by = ((to - from)/(length.out - 1)),
    length.out = NULL, along.with = NULL)

## S3 method for class 'abIndex'
c(...)

Arguments

from, to the starting and (maximal) end value of the sequence.
by number: increment of the sequence.
length.out desired length of the sequence. A non-negative number, which for seq and
seq.int will be rounded up if fractional.
along.with take the length from the length of this argument.
... in general an arbitrary number of R objects; here, when the first is an "abIndex"
vector, these arguments will be concatenated to a new "abIndex" object.

Value

An abstract index vector, i.e., object of class "abIndex".

See Also

the class abIndex documentation; rep2abI() for another constructor; rle (base).

Examples

stopifnot(identical(-3:20,
               as(abIseq(-3,20), "vector")))

try( ## (arithmetic) not yet implemented
    abIseq(1, 50, by = 3)
    )

"Matrix" Methods for Functions all() and any()

Description

The basic R functions all and any now have methods for Matrix objects and should behave as for
matrix ones.

Methods

all signature(x = "Matrix", ..., na.rm = FALSE):...
any signature(x = "Matrix", ..., na.rm = FALSE):...
all signature(x = "ldenseMatrix", ..., na.rm = FALSE):...
all signature(x = "lsparseMatrix", ..., na.rm = FALSE):...

Examples

M <- Matrix(1:12 +0, 3,4)
all(M >= 1) # TRUE
any(M < 0 ) # FALSE
MN <- M; MN[2,3] <- NA; MN
all(MN >= 0) # NA
any(MN < 0 ) # NA
any(MN < 0, na.rm = TRUE) # -> FALSE
all.equal-methods  Matrix Package Methods for Function all.equal()

Description
Methods for function `all.equal()` (from \texttt{R} package \texttt{base}) are defined for all \texttt{Matrix} classes.

Methods

\begin{verbatim}
  target = "Matrix", current = "Matrix" \\
  target = "ANY", current = "Matrix" \\
  target = "Matrix", current = "ANY" these three methods are simply using \texttt{all.equal.numeric} directly and work via \texttt{as.vector()}.
\end{verbatim}

Examples

\begin{verbatim}
(A <- spMatrix(3,3, i= c(1:3,3:1), j= c(3:1,1:2), x = 1:5))
ex <- expand(lu. <- lu(A))
stopifnot( all.equal(as(A@lu @p + 1L, lu.@eq + 1L, "CsparseMatrix"),
                   lu.@L %*% lu.@U),
               with(ex, all.equal(as(P %*% A %*% Q, "CsparseMatrix"),
                                  L %*% U)),
               with(ex, all.equal(as(A, "CsparseMatrix"),
                                  t(P) %*% L %*% U %*% t(Q))))
\end{verbatim}

atomicVector-class  Virtual Class "atomicVector" of Atomic Vectors

Description

The class "atomicVector" is a virtual class containing all atomic vector classes of base \texttt{R}, as also implicitly defined via \texttt{is.atomic}.

Objects from the Class

A virtual Class: No objects may be created from it.

Methods

In the \texttt{Matrix} package, the "atomicVector" is used in signatures where typically "old-style" "matrix" objects can be used and can be substituted by simple vectors.

Extends

The atomic classes "logical", "integer", "double", "numeric", "complex", "raw" and "character" are extended directly. Note that "numeric" already contains "integer" and "double", but we want all of them to be direct subclasses of "atomicVector".

Author(s)

Martin Maechler
See Also

is.atomic, integer, numeric, complex, etc.

Examples

showClass("atomicVector")

---

**Description**

Returns a new matrix formed by extracting the lower triangle (tril) or the upper triangle (triu) or a general band relative to the diagonal (band), and setting other elements to zero. The general forms of these functions include integer arguments to specify how many diagonal bands above or below the main diagonal are not set to zero.

**Usage**

```r
band(x, k1, k2, ...)
tril(x, k = 0, ...)  
triu(x, k = 0, ...)
```

**Arguments**

- `x` a matrix-like object
- `k, k1, k2` integers specifying the diagonal bands that will not be set to zero. These are given relative to the main diagonal, which is `k = 0`. A negative value of `k` indicates a diagonal below the main diagonal and a positive value indicates a diagonal above the main diagonal.
- `...` Optional arguments used by specific methods. (None used at present.)

**Value**

An object of an appropriate matrix class. The class of the value of `tril` or `triu` inherits from `triangularMatrix` when appropriate. Note that the result is of class `sparseMatrix` only if `x` is.

**Methods**

- `x = "CsparseMatrix"` method for compressed, sparse, column-oriented matrices.
- `x = "TsparseMatrix"` method for sparse matrices in triplet format.
- `x = "RsparseMatrix"` method for compressed, sparse, row-oriented matrices.
- `x = "ddenseMatrix"` method for dense numeric matrices, including packed numeric matrices.

**See Also**

`bandSparse` for the *construction* of a banded sparse matrix directly from its non-zero diagonals.
Examples

```r
## A random sparse matrix :
set.seed(7)
m <- matrix(0, 5, 5)
m[sample(length(m), size = 14)] <- rep(1:9, length=14)
(mm <- as(m, "CsparseMatrix"))

tril(mm)          # lower triangle
tril(mm, -1)      # strict lower triangle
triu(mm, 1)       # strict upper triangle
band(mm, -1, 2)  # general band

(m5 <- Matrix(rnorm(25), nc = 5))
tril(m5)          # lower triangle
tril(m5, -1)      # strict lower triangle
triu(m5, 1)       # strict upper triangle
band(m5, -1, 2)  # general band

(m65 <- Matrix(rnorm(30), nc = 5))  # not square
triu(m65)         # result in not dtrMatrix unless square
(sm5 <- crossprod(m65))  # symmetric
  band(sm5, -1, 1) # symmetric band preserves symmetry property
as(band(sm5, -1, 1), "sparseMatrix") # often preferable
```

### bandSparse

Construct Sparse Banded Matrix from (Sup-/Super-) Diagonals

**Description**

Construct a sparse banded matrix by specifying its non-zero sup- and super-diagonals.

**Usage**

```r
bandSparse(n, m = n, k, diagonals, symmetric = FALSE, giveCsparse = TRUE)
```

**Arguments**

- `n, m`: the matrix dimension \((n, m) = (\text{row}, \text{col})\).
- `k`: integer vector of “diagonal numbers”, with identical meaning as in `band(*, k)`.
- `diagonals`: optional list of sub-/super- diagonals; if missing, the result will be a pattern matrix, i.e., inheriting from class `nMatrix`.
  - Diagonals can also be \(n' \times d\) matrix, where \(d = \text{length}(k)\) and \(n' \geq \text{min}(n, m)\). In that case, the sub-/super- diagonals are taken from the columns of diagonals, where only the first several rows will be used (typically) for off-diagonals.
- `symmetric`: logical; if true the result will be symmetric (inheriting from class `symmetricMatrix`) and only the upper or lower triangle must be specified (via `k` and `diagonals`).
- `giveCsparse`: logical indicating if the result should be a `CsparseMatrix` or a `TsparseMatrix`.
  - The default, TRUE is very often more efficient subsequently, but not always.
Value

A sparse matrix (of \texttt{class CsparseMatrix}) of dimension $n \times m$ with diagonal “bands” as specified.

See Also

\texttt{band}, for extraction of matrix bands; \texttt{bdiag}, \texttt{diag}, \texttt{sparseMatrix}, \texttt{Matrix}.

Examples

diags <- list(1:30, 10*(1:20), 100*(1:20))
s1 <- bandSparse(13, k = -c(0:2, 6), diag = c(diags, diags[2]), symm=TRUE)
s1
s2 <- bandSparse(13, k = c(0:2, 6), diag = c(diags, diags[2]), symm=TRUE)
stopifnot(identical(s1, t(s2)), is(s1,"CsparseMatrix"))

## a pattern Matrix of *full* (sub-)diagonals:
bk <- c(0:4, 7,9)
(s3 <- bandSparse(30, k = bk, symm = TRUE))

## If you want a pattern matrix, but with "sparse"-diagonals,
## you currently need to go via logical sparse:
llis <- lapply(list(rpois(20, 2), rpois(20,1), rpois(20,3)) [c(1:3,2:3,3:2)],
  as.logical)
(s4 <- bandSparse(20, k = bk, symm = TRUE, diag = llis))
(s4. <- as(drop0(s4), "nspareMatrix"))
n <- 1e4
bk <- c(0:5, 7,11)
bMat <- matrix(1:8, n, 8, byrow=TRUE)
blis <- as.data.frame(bMat)
B <- bandSparse(n, k = bk, diag = blis)
Bs <- bandSparse(n, k = bk, diag = blis, symmetric=TRUE)
B [1:15, 1:30]
Bs[1:15, 1:30]

## can use a list *or* a matrix for specifying the diagonals:
stopifnot(identical(B, bandSparse(n, k = bk, diag = bMat)),
  identical(Bs, bandSparse(n, k = bk, diag = bMat, symmetric=TRUE)))

\begin{tabular}{ll}
\textbf{bdiag} & \textit{Construct a Block Diagonal Matrix} \\
\end{tabular}

Description

Build a block diagonal matrix given several building block matrices.

Usage

\texttt{bdiag(...)}

.bdiag(1st)

Arguments

\begin{itemize}
\item \texttt{...} \hspace{1cm} individual matrices or a \texttt{list} of matrices.
\item \texttt{1st} \hspace{1cm} non-empty \texttt{list} of matrices.
\end{itemize}
Details

For non-trivial argument list, bdiag() calls .bdiag(). The latter maybe useful to programmers.

Value

A *sparse* matrix obtained by combining the arguments into a block diagonal matrix.

The value of bdiag() inheris from class CsparseMatrix, whereas .bdiag() returns a TsparseMatrix.

Author(s)

Martin Maechler, built on a version posted by Berton Gunter to R-help; earlier versions have been posted by other authors, notably Scott Chasalow to S-news. Doug Bates’s faster implementation builds on TsparseMatrix objects.

See Also

Diagonal for constructing matrices of class diagonalMatrix, or kronecker which also works for "Matrix" inheriting matrices.

bandSparse constructs a banded sparse matrix from its non-zero sub-/super - diagonals.

Note that other CRAN R packages have own versions of bdiag() which return traditional matrices.

Examples

```r
bdiag(matrix(1:4, 2), diag(3))
# combine "Matrix" class and traditional matrices:
bdiag(Diagonal(2), matrix(1:3, 3, 4), diag(3:2))

mlist <- list(1, 2:3, diag(x=5:3), 27, cbind(1:3:6), 100:101)
bdiag(mlist)
stopifnot(identical(bdiag(mlist),
                    bdiag(lapply(mlist, as.matrix)))))

ml <- c(as(matrix((1:24)%x% 11 == 0, 6, 4),"nMatrix"),
         rep(list(Diagonal2, x=TRUE), 3))
mln <- c(ml, Diagonal(x = 1:3))
stopifnot(is(bdiag(ml), "lsparseMatrix"),
           is(bdiag(mln),"dsparseMatrix"))
```

---

**Bunch-Kaufman Decomposition Methods**

Description

The Bunch-Kaufman Decomposition of a square symmetric matrix \( A \) is \( A = PLDL'P' \) where \( P \) is a permutation matrix, \( L \) is unit-lower triangular and \( D \) is block-diagonal with blocks of dimension \( 1 \times 1 \) or \( 2 \times 2 \).

Usage

BunchKaufman(x, ...)
Arguments

x a symmetric square matrix.

... potentially further arguments passed to methods.

Value

an object of class BunchKaufman, which can also be used as a (triangular) matrix directly.

Methods

Currently, only methods for dense numeric symmetric matrices are implemented.

x = "dspMatrix" uses Lapack routine dsytrf,

x = "dsyMatrix" uses Lapack routine dsytrf, computing the Bunch-Kaufman decomposition.

References

The original LAPACK source code, including documentation; http://www.netlib.org/lapack/double/dsytrf.f and http://www.netlib.org/lapack/double/dsptrf.f

See Also

The resulting class, BunchKaufman. Related decompositions are the LU, lu, and the Cholesky, chol (and for sparse matrices, Cholesky).

Examples

data(CAex)
dim(CAex)
isSymmetric(CAex)# TRUE

CAS <- as(CAex, "symmetricMatrix")
if(FALSE) # no method defined yet for *sparse* :

bk <- BunchKaufman(CAS)
## does apply to *dense* symmetric matrices:
bkCA <- BunchKaufman(as(CAS, "denseMatrix"))
bkCA

image(bkCA)# shows how sparse it is, too

str(R.CA <- as(bkCA, "sparseMatrix"))
## an upper triangular 72x72 matrix with only 144 non-zero entries

CAex

Albers' example Matrix with "Difficult" Eigen Factorization

Description

An example of a sparse matrix for which eigen() seemed to be difficult, an unscaled version of this has been posted to the web, accompanying an E-mail to R-help (https://stat.ethz.ch/mailman/listinfo/r-help), by Casper J Albers, Open University, UK.

Usage

data(CAex)
Format

This is a $72 \times 72$ symmetric matrix with 216 non-zero entries in five bands, stored as sparse matrix of class `dgCMatrix`.

Details

In some versions of R, `eigen(Caex)` fell into an infinite loop (whereas `eigen(Caex, EISPACK=TRUE)` has been okay).

Examples

data(Caex)
str(Caex) # of class "dgCMatrix"

image(Caex)# -> it's a simple band matrix with 5 bands
## and the eigen values are basically 1 (42 times) and 0 (30 x):
zapsmall(ev <- eigen(Caex, EISPACK=TRUE, only.values=TRUE)$values)
## i.e., the matrix is symmetric, hence
sCA <- as(Caex, "symmetricMatrix")
## and
stopifnot(class(sCA) == "dsCMatrix",
 as(sCA, "matrix") == as(Caex, "matrix"))

Description

The base functions `cbind` and `rbind` are defined for an arbitrary number of arguments and hence have the first formal argument `. . .`. For that reason, S4 methods cannot easily be defined for binding together matrices inheriting from `Matrix`.

For that reason, `cbind2` and `rbind2` have been provided for binding together two matrices, and we have defined methods for these and the 'Matrix'-matrices.

As a substitute for S4-enabled versions of `cbind` and `rbind`, you can use `cbind` and `rbind` with identical syntax and semantic in order to bind together multiple matrices ("matrix" or "Matrix" and vectors.

Usage

cBind(..., deparse.level = 1)
rBind(..., deparse.level = 1)

Arguments

... matrix-like R objects to be bound together, see `cbind` and `rbind`.
deparse.level integer determining under which circumstances column and row names are built from the actual arguments’ ‘expression’, see `cbind`.
Details

The implementation of these is recursive, calling `cbind2` or `rbind2` respectively, where these have methods defined and so should dispatch appropriately.

Value

typically a ‘matrix-like’ object of a similar class as the first argument in . . .

Note that sometimes by default, the result is a `sparseMatrix` if one of the arguments is (even in the case where this is not efficient). In other cases, the result is chosen to be sparse when there are more zero entries is than non-zero ones (as the default sparse in `Matrix()`).

Author(s)

Martin Maechler

See Also

cbind2, cbind, Methods.

Examples

(a <- matrix(c(2:1,1:2), 2,2))
`cbind(0, rBind(a, 7))` # remains traditional matrix

D <- Diagonal(2)
`cBind(4, a, D, -1, D, 0)` # a sparse Matrix

---

CHMfactor-class

**CHOLMOD-based Cholesky Factorizations**

Description

The virtual class "CHMfactor" is a class of CHOLMOD-based Cholesky factorizations of symmetric, sparse, compressed, column-oriented matrices. Such a factorization is simplicial (virtual class "CHMSimplex") or supernodal (virtual class "CHMSuper"). Objects that inherit from these classes are either numeric factorizations (classes "dCHMSimplex" and "dCHMSuper") or symbolic factorizations (classes "nCHMSimplex" and "nCHMSuper").

Usage

```r
isLDL(x)
```

## S4 method for signature 'CHMfactor'
`update(object, parent, mult = 0, ...)`
`.updateCHMfactor(object, parent, mult, mult)

## and many more methods, notably,
## solve(a, b, system = c("A","LDLt","LD","DLt","L","Lt","D","P","Pt"), ...)
## ----- see below
Arguments

- `x`, `object`, a "CHMfactor" object (almost always the result of `Cholesky()`).
- `parent` a "dsCMatrix" or "dgCMatrix" matrix object with the same nonzero pattern as the matrix that generated object. If `parent` is symmetric, of class "dsCMatrix", then object should be a decomposition of a matrix with the same nonzero pattern as `parent`. If `parent` is not symmetric then object should be the decomposition of a matrix with the same nonzero pattern as `tcrossprod(parent)`.
  
  Since Matrix version 1.0-8, other "sparseMatrix" matrices are coerced to `dsparseMatrix` and `CsparseMatrix` if needed.
- `mult` a numeric scalar (default 0). `mult` times the identity matrix is (implicitly) added to `parent` or `tcrossprod(parent)` before updating the decomposition `object`.
- ... potentially further arguments to the methods.

Objects from the Class

Objects can be created by calls of the form `new("dCHMsuper", ...) but are more commonly created via `Cholesky()`, applied to `dsCMatrix` or `lsCMatrix` objects.

For an introduction, it may be helpful to look at the `expand()` method and examples below.

Slots

of "CHMfactor" and all classes inheriting from it:

- `perm`: An integer vector giving the 0-based permutation of the rows and columns chosen to reduce fill-in and for post-ordering.
- `colcount`: Object of class "integer" ....
- `type`: Object of class "integer" ....

Slots of the non virtual classes "[dl]CHM(supersimpl)"

- `p`: Object of class "integer" of pointers, one for each column, to the initial (zero-based) index of elements in the column. Only present in classes that contain "CHMsimpl".
- `i`: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix. Only present in classes that contain "CHMsimpl".
- `x`: For the "ds*" classes: "numeric" - the non-zero elements of the matrix.

Methods

- `isLDL(x)` returns a `logical` indicating if `x` is an `LDL'` decomposition or (when FALSE) an `LL'` one.
- `coerce` signature(from = "CHMfactor", to = "sparseMatrix") Returns the lower triangular factor `L` from the `LL'` form of the Cholesky factorization. Note that (currently) the factor from the `LL'` form is always returned, even if the "CHMfactor" object represents an `LDL'` decomposition. Furthermore, this is the factor after any fill-reducing permutation has been applied. See the `expand()` method for obtaining both the permutation matrix, `P`, and the lower Cholesky factor, `L`.
- `coerce` signature(from = "CHMfactor", to = "pMatrix") Returns the permutation matrix, `P`, representing the fill-reducing permutation used in the decomposition.
**expand** signature(x = "CHMfactor") Returns a list with components \( P \), the matrix representing the fill-reducing permutation, and \( L \), the lower triangular Cholesky factor. The original positive-definite matrix \( A \) corresponds to the product \( A = P'LL'P \). Because of fill-in during the decomposition the product may apparently have more non-zeros than the original matrix, even after applying `drop0` to it. However, the extra 'non-zeros' should be very small in magnitude.

**image** signature(x = "CHMfactor") Plot the image of the lower triangular factor, \( L \), from the decomposition. This method is equivalent to `image(as(x, "sparseMatrix"))` so the comments in the above description of the `coerce` method apply here too.

**solve** signature(a = "CHMfactor", b = "ddenseMatrix"), system = *:
The `solve` methods for a "CHMfactor" object take an optional third argument `system` whose value can be one of the character strings "A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P" or "P'." This argument describes the system to be solved. The default, "A", is to solve \( Ax = b \) for \( x \) where \( A \) is the sparse, positive-definite matrix that was factored to produce \( a \). Analogously, `system = "L"` returns the solution \( x \), of \( Lx = b \). Similarly, for all system codes but "P" and "P'" where, e.g., \( x \leftarrow solve(a, b, system="P") \) is equivalent to \( x \leftarrow P^-1b \). See also `solve-methods`.

**determinant** signature(x = "CHMfactor", logarithm = "logical") returns the determinant (or the logarithm of the determinant, if `logarithm = TRUE`, the default) of the factor \( L \) from the \( LL' \) decomposition (even if the decomposition represented by \( x \) is of the \( LDL' \) form (!)). This is the square root of the determinant (half the logarithm of the determinant when `logarithm = TRUE`) of the positive-definite matrix that was decomposed.

**update** signature(object = "CHMfactor"), parent. The `update` method requires an additional argument parent, which is either a "dsCMATRIX" object, say \( A \), (with the same structure of nonzeros as the matrix that was decomposed to produce object) or a general "dgCMatrix", say \( M \), where \( A := MM' \) (using `tcrossprod(parent)`) is used for \( A \). Further it provides an optional argument `mult`, a numeric scalar. This method updates the numeric values in object to the decomposition of \( A + mI \) where \( A \) is the matrix above (either the parent or \( MM' \)) and \( m \) is the scalar `mult`. Because only the numeric values are updated this method should be faster than creating and decomposing \( A + mI \). It is not uncommon to want, say, the determinant of \( A + mI \) for many different values of \( m \). This method would be the preferred approach in such cases.

See Also

Cholesky, also for examples; class `dgCMatrix`.

Examples

```r
## An example for the expand() method
n <- 1000; m <- 200; nnz <- 2000
set.seed(1)
M1 <- spMatrix(n, m,
               i = sample(n, nnz, replace = TRUE),
               j = sample(m, nnz, replace = TRUE),
               x = round(rnorm(nnz),1))
XX <- crossprod(M1)  # M1'M1 = M'M where M <- t(M1)
CX <- Cholesky(XX)
isLDL(CX)
str(CX)  # a "dCHMsimpl" object
r <- expand(CX)
L.P <- with(r, crossprod(L,P))  # == L'P
PLL.P <- crossprod(L.P)  # == (L'P)' L'P == P'LL'P
```
b <- sample(m)
stopifnot(all.equal.PLLP, XX),
    all(as.vector(solve(CX, b, system="P")) == r$r %*% b),
    all(as.vector(solve(CX, b, system="Pt")) == t(r$r) %*% b) )

u1 <- update(CX, XX, mult=pi)
if(FALSE) ## fails ___ FIXME ? ___
u2 <- update(CX, t(M), mult=pi)

## [ See help(Cholesky) for more examples ]
## ---------------------

chol

Choleski Decomposition - 'Matrix' S4 Generic and Methods

Description

Compute the Choleski factorization of a real symmetric positive-definite square matrix.

Usage

    chol(x, ...)

    ## S4 method for signature 'dsCMatrix'
    chol(x, pivot = FALSE, ...)

Arguments

    x
        a (sparse or dense) square matrix, here inheriting from class Matrix; if x is not
        positive definite, an error is signalled.

    pivot
        logical indicating if pivoting is to be used.

    ... 
        potentially further arguments passed to methods.

Value

    a matrix of class Cholesky, i.e., upper triangular: R such that R'R = x.

Methods

Use showMethods(chol) to see all; some are worth mentioning here:

    chol signature(x = "dgeMatrix"): works via "dpoMatrix", see class dpoMatrix.
    chol signature(x = "dpoMatrix"): Returns (and stores) the Cholesky decomposition of x, via
        LAPACK routines dlacpy and dptrf.
    chol signature(x = "dppMatrix"): Returns (and stores) the Cholesky decomposition via LA-
        PACK routine dpptrf.
    chol signature(x = "dsCMatrix", pivot = "logical"): Returns (and stores) the Cholesky
        decomposition of x. If pivot is TRUE (the default) the Approximate Minimal Degree (AMD)
        algorithm is used to create a reordering of the rows and columns of x so as to reduce fill-in.
References

See Also

The default from base, chol.

Examples

```r
showMethods(chol, inherited = FALSE) # show different methods

str(c2)

## An example where chol() can't work
(sy3 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, -1, 2, -7)))
try(chol(sy3)) # error, since it is not positive definite

## A sparse example --- exemplifying 'pivot'
(mm <- toeplitz(as(c(10, 0, 1, 0, 3), "sparseVector"))) # 5 x 5
(R <- chol(mm)) ## default: pivot = FALSE
R2 <- chol(mm, pivot=FALSE)
stopifnot(identical(R, R2), all.equal(crossprod(R), mm) )
(R. <- chol(mm, pivot=TRUE))## nice band structure,
## but of course crossprod(R.) is *NOT* equal to mm
## --> see Cholesky() and its examples, for the pivot structure & factorization
stopifnot(all.equal(sqrt(det(mm)), det(R)),
all.equal(prod(diag(R)), det(R)),
all.equal(prod(diag(R.)), det(R)))

## a second, even sparser example:
(M2 <- toeplitz(as(c(1,.5, rep(0,12), -.1), "sparseVector")))
c2 <- chol(M2)
C2 <- chol(M2, pivot=TRUE)
## check the caching of the factorizations:
spd <- as(M2@factors[['spdCholesky']], "Matrix")
sPd <- as(M2@factors[['sPdCholesky']], "Matrix")
stopifnot(identical(t(spd), c2),
all.equal(t(sPd), C2, tol=0))## FIXME -- why not identical()?
```

Description

Invert a symmetric, positive definite square matrix from its Choleski decomposition. Equivalently, compute \((X'X)^{-1}\) from the \((R)\) part of the QR decomposition of \(X\).

Even more generally, given an upper triangular matrix \(R\), compute \((R'R)^{-1}\).
Methods

- x = "ANY" the default method from base, see chol2inv, for traditional matrices.
- x = "dtrMatrix" method for the numeric triangular matrices, built on the same LAPACK dpotri function as the base method.
- x = "denseMatrix" if x is coercable to a triangularMatrix, call the "dtrMatrix" method above.
- x = "sparseMatrix" if x is coercable to a triangularMatrix, use solve() currently.

See Also

chol (for Matrix objects); further, chol2inv (from the base package), solve.

Examples

```r
(M <- Matrix(cbind(1, 1:3, c(1,3,7))))
(cm <- chol(M)) # a "Cholesky" object, inheriting from "dtrMatrix"
chol2inv(cm) %*% M # the identity
stopifnot(all(chol2inv(cm) %*% M - Diagonal(nrow(M))) < 1e-10)
```

---

Cholesky Decomposition of a Sparse Matrix

Description

Computes the Cholesky decomposition of a sparse, symmetric, positive-definite matrix. However, typically chol() should rather be used unless you are interested in the different kinds of sparse Cholesky decompositions.

Usage

Cholesky(A, perm = TRUE, LDL = !super, super = FALSE, Imult = 0, ...)

Arguments

- A: sparse symmetric matrix. No missing values or IEEE special values are allowed.
- perm: logical scalar indicating if a fill-reducing permutation should be computed and applied to the rows and columns of A. Default is TRUE.
- LDL: logical scalar indicating if the decomposition should be computed as LDL' where L is a unit lower triangular matrix. The alternative is LL’ where L is lower triangular with arbitrary diagonal elements. Default is TRUE. Setting it to NA leaves the choice to a CHOLMOD-internal heuristic.
- super: logical scalar indicating is a supernodal decomposition should be created. The alternative is a simplicial decomposition. Default is FALSE. Setting it to NA leaves the choice to a CHOLMOD-internal heuristic.
- Imult: numeric scalar which defaults to zero. The matrix that is decomposed is $A + m \times I$ where $m$ is the value of Imult and I is the identity matrix of order ncol(A).
- ... further arguments passed to or from other methods.
Details

This is a generic function with special methods for different types of matrices. Use `showMethods("Cholesky")` to list all the methods for the `Cholesky` generic.

The method for class `dsCMatrix` of sparse matrices — the only one available currently — is based on functions from the CHOLMOD library.

Again: If you just want the Cholesky decomposition of a matrix, you should probably rather use `chol()`.

Value

an object inheriting from either "CHMsuper", or "CHMsimple", depending on the super argument; both classes extend "CHMfactor" which extends "MatrixFactorization".

In other words, the result of `Cholesky()` is not a matrix, and if you want one, you should probably rather use `chol()`.

References

See Also

Class definitions `CHMfactor` and `dsCMatrix` and function `expand`. Note the extra `solve(*, system = .)` options in `CHMfactor`.

Note that `chol()` returns matrices (inheriting from "Matrix") whereas `Cholesky()` returns a "CHMfactor" object, and hence a typical user will rather use `chol()`.

Examples

data(KNex)
mtm <- with(KNex, crossprod(mm))
str(mtm@factors) # empty list()
(C1 <- Cholesky(mtm)) # uses show(<MatrixFactorization>)
str(mtm@factors) # 'sPDCholesky' (simple)
(Cm <- Cholesky(mtm, super = TRUE))
c(C1 = isLDL(C1), Cm = isLDL(Cm))
str(mtm@factors) # 'sPDCholesky' *and* 'SPDCholesky'
str(cml <- as(C1, "sparseMatrix"))
str(cmat <- as(Cm, "sparseMatrix"))# hmm: super is *less* sparse here
cm[1:20, 1:20]

b <- matrix(c(rep(0, 711), 1), nc = 1)
## solve(Cm, b) by default solves Ax = b, where A = Cm'Cm (= mtm)!
## hence, the identical() check *should* work, but fails on some GOTOblas:
x <- solve(Cm, b)
stopifnot(identical(x, solve(Cm, b, system = "A")),
          all.equal(x, solve(mtm, b)))

Cn <- Cholesky(mtm, perm = FALSE)# no permutation -- much worse:
sizes <- c(simple = object.size(C1),
          super = object.size(Cm),
## Cholesky-class

### Description

The "Cholesky" class is the class of Cholesky decompositions of positive-semidefinite, real dense matrices. The "Bunch-Kaufman" class is the class of Bunch-Kaufman decompositions of symmetric, real matrices. The "pCholesky" and "pBunchKaufman" classes are their packed storage versions.

### Objects from the Class

Objects can be created by calls of the form `new("Cholesky", ...)` or `new("BunchKaufman", ...),` etc, or rather by calls of the form `chol(pm)` or `BunchKaufman(pm)` where `pm` inherits from the "dpoMatrix" or "dsyMatrix" class or as a side-effect of other functions applied to "dpoMatrix" objects (see `dpoMatrix`).
A Cholesky decomposition extends class `MatrixFactorization` but is basically a triangular matrix extending the "dtrMatrix" class.

uplo: inherited from the "dtrMatrix" class.
diag: inherited from the "dtrMatrix" class.
x: inherited from the "dtrMatrix" class.
Dim: inherited from the "dtrMatrix" class.
Dimnames: inherited from the "dtrMatrix" class.

A Bunch-Kaufman decomposition also extends the "dtrMatrix" class and has a perm slot representing a permutation matrix. The packed versions extend the "dtpMatrix" class.

**Extends**

Class "MatrixFactorization" and "dtrMatrix", directly. Class "dgeMatrix", by class "dtrMatrix". Class "Matrix", by class "dtrMatrix".

**Methods**

Both these factorizations can directly be treated as (triangular) matrices, as they extend "dtrMatrix", see above. There are currently no further explicit methods defined with class "Cholesky" or "BunchKaufman" in the signature.

**Note**

1. Objects of class "Cholesky" typically stem from `chol(D)`, applied to a dense matrix D. On the other hand, the function `Cholesky(S)` applies to a sparse matrix S, and results in objects inheriting from class `CHMfactor`.

2. For traditional matrices m, chol(m) is a traditional matrix as well, triangular, but simply an $n \times n$ numeric matrix. Hence, for compatibility, the "Cholesky" and "BunchKaufman" classes (and their "pX" packed versions) also extend triangular Matrix classes (such as "dtrMatrix"). Consequently, determinant(R) for R <- chol(A) returns the determinant of R, not of A. This is in contrast to class `CHMfactor` objects C, where determinant(C) gives the determinant of the original matrix A, for C <- Cholesky(A), see also the determinant method documentation on the class `CHMfactor` page.

**See Also**

Classes `dtrMatrix`, `dpoMatrix`; function `chol`.

Function `Cholesky` resulting in class `CHMfactor` objects, not class "Cholesky" ones, see the section 'Note'.

**Examples**

```r
(sm <- as(as(Matrix(diag(5) + 1), "dsyMatrix"), "dspMatrix"))
signif(csm <- chol(sm), 4)

(pm <- crossprod(Matrix(rnorm(18), nrow = 6, ncol = 3)))
(ch <- chol(pm))
if (toupper(ch@uplo) == "U") # which is TRUE
crossprod(ch)
```
Description
Form row and column sums and means for `Matrix` objects.

Usage

```r
colSums(x, na.rm = FALSE, dims = 1, ...)
rowSums(x, na.rm = FALSE, dims = 1, ...)
colMeans(x, na.rm = FALSE, dims = 1, ...)
rowMeans(x, na.rm = FALSE, dims = 1, ...)
```

## S4 method for signature 'CsparseMatrix'
colSums(x, na.rm = FALSE, 
dims = 1, sparseResult = FALSE)

## S4 method for signature 'CsparseMatrix'
rowSums(x, na.rm = FALSE, 
dims = 1, sparseResult = FALSE)

## S4 method for signature 'CsparseMatrix'
colMeans(x, na.rm = FALSE, 
dims = 1, sparseResult = FALSE)

## S4 method for signature 'CsparseMatrix'
rowMeans(x, na.rm = FALSE, 
dims = 1, sparseResult = FALSE)

Arguments

- `x`: a Matrix, i.e., inheriting from `Matrix`.
- `na.rm`: logical. Should missing values (including NaN) be omitted from the calculations?
- `dims`: completely ignored by the `Matrix` methods.
- `...`: potentially further arguments, for method `<>` generic compatibility.
- `sparseResult`: logical indicating if the result should be sparse, i.e., inheriting from class `sparseVector`.

Value
returns a numeric vector if `sparseResult` is `FALSE` as per default. Otherwise, returns a `sparseVector`.

See Also

`colSums` and the `sparseVector` classes.
Examples

```r
(M <- bdiag(Diagonal(2), matrix(1:3, 3, 4), diag(3:2))) # 7 x 8
colSums(M)
d <- Diagonal(10, c(0,0,10,0,2,rep(0,5)))
MM <- kronecker(d, M)
dim(MM) # 70 80
length(MM@x) # 160, but many are '0'; drop those:
MM <- drop0(MM)
length(MM@x) # 32
scm <- colSums(MM)
stopifnot(is(scm, "sparseVector"),
  identical(scm, as.numeric(scm)))
rowSums(MM, sparseResult = TRUE) # 16 of 70 are not zero
colMeans(MM, sparseResult = TRUE)
## Since we have no 'NA's, these two are equivalent :
stopifnot(identical(rowMeans(MM, sparseResult = TRUE),
  rowMeans(MM, sparseResult = TRUE, na.rm = TRUE)),
  rowMeans(Diagonal(16)) == 1/16,
  colSums(Diagonal(7)) == 1)
```

compMatrix-class

Class "compMatrix" of Composite (Factorizable) Matrices

Description

Virtual class of composite matrices; i.e., matrices that can be factorized, typically as a product of simpler matrices.

Objects from the Class

A virtual Class: No objects may be created from it.

Slots

- **factors**: Object of class "list" - a list of factorizations of the matrix. Note that this is typically empty, i.e. `list()`, initially and is updated automagically whenever a matrix factorization is computed.

- **Dim**,

- **Dimnames**: inherited from the `Matrix` class, see there.

Extends

Class "Matrix", directly.
Compute Approximate CONDition number and 1-Norm of (Large) Matrices

Description

“Estimate”, i.e. compute approximately the CONDition number of a (potentially large, often sparse) matrix A. It works by apply a fast approximation of the 1-norm, \( \text{norm}(A, "1") \), through \( \text{nrmestHBQBI} \).

Usage

\[
\text{condest}(A, t = \min(n, 5), \text{normA} = \text{norm}(A, "1"), \\
\text{silent} = \text{FALSE}, \text{quiet} = \text{TRUE}) \]

\[
\text{nformest}(A, t = \min(n, 5), A.x, A.t.x, n, \\
\text{silent} = \text{FALSE}, \text{quiet} = \text{false}, \\
\text{iter.max} = 10, \text{eps} = 4 * \text{Machine}\$\text{double.e}
\]

Arguments

- **A**: a square matrix, optional for \( \text{nformest}() \), where instead of A, A.x and A.t.x can be specified, see there.
- **t**: number of columns to use in the iterations.
- **normA**: number; (an estimate of) the 1-norm of A, by default \( \text{norm}(A, "1") \); may be replaced by an estimate.
- **silent**: logical indicating if warning and (by default) convergence messages should be displayed.
- **quiet**: logical indicating if convergence messages should be displayed.
- **A.x, A.t.x**: when A is missing, these two must be given as functions which compute A \( \%\%\ x \), or \( t(A) \%\%\ x \), respectively.
- **n**: \( \equiv \text{ncol}(A) \), only needed when A is not specified.
- **iter.max**: maximal number of iterations for the 1-norm estimator.
- **eps**: the relative number that is deemed irrelevant.

Value

Both functions return a **list**, \( \text{nformest}() \) with components,

- **est**: a number > 0, the estimated \( \text{norm}(A, "1") \). 
- **v**: the maximal AX column.

The function \( \text{condest}() \) returns a list with components,

- **est**: a number > 0, the estimated condition number \( \hat{\kappa} \); when \( r := \text{rcond}(A), 1/\hat{\kappa} \approx r \).
- **v**: integer vector length n, with an 1 at the index j with maximal column A[,j] in A.
- **w**: numeric vector, the largest Ax found.
- **iter**: the number of iterations used.
CsparseMatrix-class

Author(s)

This is based on octave’s condest() and onenormest() implementations with original author Jason Riedy, U Berkeley; translation to R and adaptation by Martin Maechler.

References

See Also

norm, rcond.

Examples

data(KNex)
mtm <- with(KNex, crossprod(mm))
system.time(ce <- condest(mtm))
## reciprocal
1 / ce$est
system.time(rc <- rcond(mtm)) # takes ca 3 x longer
rc
all.equal(rc, 1/ce$est) # TRUE -- the approximation was good

CsparseMatrix-class Class “CsparseMatrix” of Sparse Matrices in Column-compressed Form

Description

The "CsparseMatrix" class is the virtual class of all sparse matrices coded in sorted compressed column-oriented form. Since it is a virtual class, no objects may be created from it. See showClass("CsparseMatrix") for its subclasses.

Slots

i: Object of class “integer” of length nnzero (number of non-zero elements). These are the 0-based row numbers for each non-zero element in the matrix, i.e., i must be in 0:(nrow(.)-1).

p: integer vector for providing pointers, one for each column, to the initial (zero-based) index of elements in the column. .@p is of length ncol(.) + 1, with p[1] == 0 and p[length(p)] == nnzero, such that in fact, diff(.@p) are the number of non-zero elements for each column.

In other words, m@p[1:ncol(m)] contains the indices of those elements in m@x that are the first elements in the respective column of m.

Dim, Dimnames: inherited from the superclass, see the sparseMatrix class.

Extends

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

\textbf{tril} \quad \text{signature(x = "CsparseMatrix"):\ldots}
\textbf{triu} \quad \text{signature(x = "CsparseMatrix"):\ldots}
Note

All classes extending CsparseMatrix have a common validity (see validObject) check function. That function additionally checks the i slot for each column to contain increasing row numbers. In earlier versions of Matrix (<= 0.999375-16), validObject automatically re-sorted the entries when necessary, and hence new() calls with somewhat permuted i and x slots worked, as new(...) (with slot arguments) automatically checks the validity.

Now, you have to use sparseMatrix to achieve the same functionality or know how to use .validateCsparse() to do so.

ddiMatrix-class

Class "ddiMatrix" of Diagonal Numeric Matrices

Description

The class "ddiMatrix" of numerical diagonal matrices.

Note that diagonal matrices now extend sparseMatrix, whereas they did extend dense matrices earlier.

Objects from the Class

Objects can be created by calls of the form `new("ddiMatrix", ...)` but typically rather via `Diagonal`.

Slots

- `x`: numeric vector. For an \( n \times n \) matrix, the \( x \) slot is of length \( n \) or \( 0 \), depending on the `diag` slot:
  - `diag`: "character" string, either "U" or "N" where "U" denotes unit-diagonal, i.e., identity matrices.
- `Dim,Dimnames`: matrix dimension and `dimnames`, see the `Matrix` class description.

Extends

Class "diagonalMatrix", directly. Class "dMatrix", directly. Class "sparseMatrix", indirectly, see `showClass("ddiMatrix")`.

Methods

- `%*%` signature(`x = "ddiMatrix", y = "ddiMatrix": ...`

See Also

Class `diagonalMatrix` and function `Diagonal`.

Examples

```
(d2 <- Diagonal(x = c(10, 1)))
str(d2)
## slightly larger in internal size:
str(as(d2, "sparseMatrix"))
M <- Matrix(cbind(1, 2:4))
M %*% d2 # 'fast' multiplication
col(d2) # trivial
stopifnot(is(cd2 <- chol(d2), "ddiMatrix"),
  all.equal(cd2@x, c(sqrt(10), 1)))
```
denseMatrix-class

Virtual Class "denseMatrix" of All Dense Matrices

Description
This is the virtual class of all dense (S4) matrices. It is the direct superclass of ddenseMatrix, ldenseMatrix.

Extends
class "Matrix" directly.

Slots
exactly those of its superclass "Matrix".

Methods
Use showMethods(class = "denseMatrix", where = "package:Matrix") for an overview of methods. Extraction ("[" methods, see [-methods.

See Also
colSums, kronecker, and other such methods with own help pages. Its superclass Matrix, and main subclasses, ddenseMatrix and sparseMatrix.

Examples
showClass("denseMatrix")

dgCMatrix-class

Compressed, sparse, column-oriented numeric matrices

Description
The dgCMatrix class is a class of sparse numeric matrices in the compressed, sparse, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order. dgCMatrix is the "standard" class for sparse numeric matrices in the Matrix package.

Objects from the Class
Objects can be created by calls of the form new("dgCMatrix", ...) or often more easily via Matrix(*, sparse = TRUE).

Slots
x: Object of class "numeric" - the non-zero elements of the matrix.
... all other slots are inherited from the superclass "CsparseMatrix".
Methods

coerce signature(from = "matrix", to = "dgCMatrix")
coerce signature(from = "dgCMatrix", to = "matrix")
coerce signature(from = "dgCMatrix", to = "dgTMatrix")
crossprod signature(x = "dgCMatrix", y = "missing") returns t(x) %*% x as an dsCMatrix object.
crossprod signature(x = "dgCMatrix", y = "matrix"): ...
crossprod signature(x = "dgCMatrix", y = "numeric"): ...
diag signature(x = "dgCMatrix"): returns the diagonal of x
dim signature(x = "dgCMatrix"): returns the dimensions of x
image signature(x = "dgCMatrix"): plots an image of x using the levelplot function
solve signature(a = "dgCMatrix", b = ") see solve-methods, notably the extra argument sparse.
l u signature(x = "dgCMatrix"): computes the LU decomposition of a square dgCMatrix object

See Also

Classes dsCMatrix, dtCMatrix, lu

Examples

(m <- Matrix(c(0,0,2;0), 3,5))
str(m)
m[,1]

dgeMatrix-class

Class "dgeMatrix" of Dense Numeric (S4 Class) Matrices

Description

A general numeric dense matrix in the S4 Matrix representation. dgeMatrix is the "standard" class for dense numeric matrices in the Matrix package.

Objects from the Class

Objects can be created by calls of the form new("dgeMatrix", ...) or, more commonly, by coercion from the Matrix class (see Matrix) or by Matrix(.).

Slots

x: Object of class "numeric" - the numeric values contained in the matrix, in column-major order.
Dim: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.
Dimnames: a list of length two - inherited from class Matrix.
factors: Object of class "list" - a list of factorizations of the matrix.
Methods

The are group methods (see, e.g., *Arith*)

*Arith* signature(e1 = "dgeMatrix", e2 = "dgeMatrix"): ...

*Arith* signature(e1 = "dgeMatrix", e2 = "numeric"): ...

*Arith* signature(e1 = "numeric", e2 = "dgeMatrix"): ...

*Math* signature(x = "dgeMatrix"): ...

*Math2* signature(x = "dgeMatrix", digits = "numeric"): ...

and other matrix methods available:

```r
%*% signature(x = "dgeMatrix", y = "dgeMatrix"): Matrix multiplication; ditto for several other signature combinations, see `showMethods("%*%", class = "dgeMatrix")`.
```

*Schur* signature(x = "dgeMatrix", vectors = "logical"): ...

*Schur* signature(x = "dgeMatrix", vectors = "missing"): ...

*chol* signature(x = "dgeMatrix"): see *chol*.

*coerce* signature(from = "dgeMatrix", to = "lgeMatrix"): ...

*coerce* signature(from = "dgeMatrix", to = "matrix"): ...

*coerce* signature(from = "matrix", to = "dgeMatrix"): ...

*colMeans* signature(x = "dgeMatrix"): columnwise means (averages)

*colSums* signature(x = "dgeMatrix"): columnwise sums

*crossprod* signature(x = "dgeMatrix", y = "dgeMatrix"): ditto for several other signatures, use `showMethods("crossprod", class = "dgeMatrix")`, matrix crossproduct, an efficient version of t(x) %*% y.

*diag* signature(x = "dgeMatrix"): ...

*dim* signature(x = "dgeMatrix"): ...

*dimnames* signature(x = "dgeMatrix"): ...

*eigen* signature(x = "dgeMatrix", only.values = "logical"): ...

*eigen* signature(x = "dgeMatrix", only.values = "missing"): ...

*norm* signature(x = "dgeMatrix", type = "character"): ...

*norm* signature(x = "dgeMatrix", type = "missing"): ...

*rcond* signature(x = "dgeMatrix", norm = "character"): ...

*rcond* signature(x = "dgeMatrix", norm = "missing"): ...

*rowMeans* signature(x = "dgeMatrix"): rowwise means (averages)

*rowSums* signature(x = "dgeMatrix"): rowwise sums

*t* signature(x = "dgeMatrix"): ...

See Also

Classes *Matrix, dtrMatrix*, and *dsyMatrix*. 

The `dgRMatrix` class is a class of sparse numeric matrices in the compressed, sparse, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

**Note:** The column-oriented sparse classes, e.g., `dgCMatrix`, are preferred and better supported in the Matrix package.

### Objects from the Class

Objects can be created by calls of the form `new("dgRMatrix", ...).

### Slots

- `j`: Object of class "integer" of length nnzero (number of non-zero elements). These are the column numbers for each non-zero element in the matrix.
- `p`: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.
- `x`: Object of class "numeric" - the non-zero elements of the matrix.
- `Dim`: Object of class "integer" - the dimensions of the matrix.

### Methods

- `coerce` signature(from = "matrix", to = "dgRMatrix")
- `coerce` signature(from = "dgRMatrix", to = "matrix")
- `coerce` signature(from = "dgRMatrix", to = "dgTMatrix")
- `diag` signature(x = "dgRMatrix"): returns the diagonal of x
- `dim` signature(x = "dgRMatrix"): returns the dimensions of x
- `image` signature(x = "dgRMatrix"): plots an image of x using the `levelplot` function

### See Also

the `RsparseMatrix` class, the virtual class of all sparse compressed row-oriented matrices, with its methods. The `dgCMatrix` class (column compressed sparse) is really preferred.
The "dgTMatrix" class is the class of sparse matrices stored as (possibly redundant) triplets. The internal representation is not at all unique, contrary to the one for class dgCMatrix.

Objects from the Class

Objects can be created by calls of the form new("dgTMatrix", ...), but more typically via as(*, "dgTMatrix").

Slots

i: Object of class "integer" - the row indices of non-zero entries in 0-base, i.e., must be in 0:(nrow(.)-1).

j: Object of class "integer" - the column indices of non-zero entries. Must be the same length as slot i and 0-based as well, i.e., in 0:(ncol(.)-1).

x: Object of class "numeric" - the (non-zero) entry at position (i,j). Must be the same length as slot i. If an index pair occurs more than once the corresponding values of slot x are added to form the element of the matrix.

Dim: Object of class "integer" of length 2 - the dimensions of the matrix.

Methods

+ signature(e1 = "dgTMatrix", e2 = "dgTMatrix")

coerce signature(from = "dgTMatrix", to = "dgCMatrix")

coerce signature(from = "dgTMatrix", to = "dgematrix")

crossprod signature(x = "dgTMatrix", y = "matrix"): ...

crossprod signature(x = "dgTMatrix", y = "numeric"): ...

image signature(x = "dgTMatrix"): plots an image of x using the levelplot function

t signature(x = "dgTMatrix"): returns the transpose of x

Note

Triplet matrices are a convenient form in which to construct sparse matrices after which they can be coerced to dgCMatrix objects.
Diagonal

Create Diagonal Matrix Object

Description
Create a diagonal matrix object, i.e., an object inheriting from `diagonalMatrix`.

Usage
```
Diagonal(n, x = NULL)

.symDiagonal(n, x = rep.int(1, n), uplo = "U")
.sparseDiagonal(n, x = 1, uplo = "U",
  shape = if(missing(cols)) "t" else "g",
  unitri, kind, cols = if(n) 0:(n - 1L) else integer(0))
```

Arguments

- **n**: integer specifying the dimension of the (square) matrix. If missing, `length(x)` is used.
- **x**: numeric or logical; if missing, a `unit` diagonal $n \times n$ matrix is created.
- **uplo**: for `.symDiagonal`, the resulting sparse `symmetricMatrix` will have slot `uplo` set from this argument, either "U" or "L". Only rarely will it make sense to change this from the default.
- **shape**: string of 1 character, one of c("t", "s", "g"), to chose a triangular, symmetric or general result matrix.
- **unitri**: optional logical indicating if a triangular result should be “unit-triangular”, i.e., with `diag = "U"` slot, if possible. The default, `missing`, is the same as TRUE.
- **kind**: string of 1 character, one of c("d", "l", "n"), to chose the storage mode of the result, from classes `dsparseMatrix`, `lsparseMatrix`, or `nsparseMatrix`, respectively.
- **cols**: integer vector with values from 0:(n-1), denoting the columns to subselect conceptually, i.e., get the equivalent of `Diagonal(n,)[, cols + 1]`.

Examples
```
m <- Matrix(0:1:28, nrow = 4)
m[-3, c(2,4,5,7)] <- m[3, 1:4] <- m[1:3, 6] <- 0
(mT <- as(m, "dgTMatrix"))
str(mT)
mT[1,]
mT[4, drop = FALSE]
stopifnot(identical(mT[lower.tri(mT)],
  m[lower.tri(m) ]))
mT[lower.tri(mT, diag=TRUE)] <- 0
mT
```

See Also
Class `dgCMatrix` or the superclasses `dsparseMatrix` and `TsparseMatrix`;

Create Diagonal Matrix Object
Value

Diagonal() returns an object of class ddiMatrix or ldiMatrix (with “superclass” diagonalMatrix).

.symDiagonal() returns an object of class dsCMatrix or lsCMatrix, i.e., a sparse symmetric matrix. This can be more efficient than Diagonal(n) when the result is combined with further symmetric (sparse) matrices, however not for matrix multiplications where Diagonal() is clearly preferred.

.sparseDiagonal(), the workhorse of .symDiagonal returns a CsparseMatrix (the resulting class depending on shape and kind) representation of Diagonal(n), or, when cols are specified, of Diagonal(n)[, cols+1].

Author(s)

Martin Maechler

See Also

the generic function diag for extraction of the diagonal from a matrix works for all “Matrices”. bandSparse constructs a banded sparse matrix from its non-zero sub-/super - diagonals. band(A) returns a band matrix containing some sub-/super - diagonals of A. Matrix for general matrix construction; further, class diagonalMatrix.

Examples

Diagonal(3)
Diagonal(x = 10*(3:1))
Diagonal(x = (1:4) >= 2)#-> "ldiMatrix"

## Use Diagonal() + kronecker() for "repeated-block" matrices:
M1 <- Matrix(0*0:5, 2,3)
(M <- kronecker(Diagonal(3), M1))

(S <- crossprod(Matrix(rbinom(60, size=1, prob=0.1), 10,6)))
(SI <- S + 10*.symDiagonal(6)) # sparse symmetric still
stopifnot(is(SI, "dsCMatrix"))
(I4 <- .sparseDiagonal(4, shape="t"))# now (2012-10) unittriangular
stopifnot(I4@diag == "U", all(I4 == diag(4)))

---

diagonalMatrix-class  Class "diagonalMatrix" of Diagonal Matrices

description

Class "diagonalMatrix" is the virtual class of all diagonal matrices.

Objects from the Class

A virtual Class: No objects may be created from it.
diagonalMatrix-class

Slots

diag: code character string, either "U" or "N", where "U" means ‘unit-diagonal’.
Dim: matrix dimension, and
Dimnames: the dimnames, a list, see the Matrix class description. Typically list(NULL,NULL) for diagonal matrices.

Extends

Class "sparseMatrix", directly.

Methods

These are just a subset of the signature for which defined methods. Currently, there are (too) many explicit methods defined in order to ensure efficient methods for diagonal matrices.

coerce signature(from = "matrix", to = "diagonalMatrix"): ...
coerce signature(from = "Matrix", to = "diagonalMatrix"): ...
coerce signature(from = "diagonalMatrix", to = "generalMatrix"): ...
coerce signature(from = "diagonalMatrix", to = "triangularMatrix"): ...
coerce signature(from = "diagonalMatrix", to = "nMatrix"): ...
coerce signature(from = "diagonalMatrix", to = "matrix"): ...
coerce signature(from = "diagonalMatrix", to = "sparseVector"): ...
t signature(x = "diagonalMatrix"): ...
  %*% signature(x = "dgeMatrix", y = "diagonalMatrix"): ...
  %*% signature(x = "matrix", y = "diagonalMatrix"): ...
  %*% signature(x = "diagonalMatrix", y = "matrix"): ...
  %*% signature(x = "diagonalMatrix", y = "dgeMatrix"): ...
crossprod signature(x = "diagonalMatrix", y = "dgeMatrix"): ...
  and many more methods
solve signature(a = "diagonalMatrix", b, ...): is trivially implemented, of course; see also solve-methods.

which signature(x = "nMatrix"), semantically equivalent to base function which(x, arr.ind).

* signature(e1 = "ddiMatrix", e2="denseMatrix"): arithmetic and other operators from the Ops group have a few dozen explicit method definitions, in order to keep the results diagonal in many cases, including the following:
  / signature(e1 = "ddiMatrix", e2="denseMatrix"): the result is from class ddiMatrix which is typically very desirable. Note that when e2 contains off-diagonal zeros or NAs, we implicitly use 0/x = 0, hence differing from traditional R arithmetic (where 0/0 \rightarrow NaN), in order to preserve sparsity.

summary (object = "diagonalMatrix"): Returns an object of S3 class "diagSummary" which is the summary of the vector object@x plus a simple heading, and an appropriate print method.

See Also

Diagonal() as constructor of these matrices, and isDiagonal. ddiMatrix and ldiMatrix are “actual” classes extending "diagonalMatrix".
Examples

```r
I5 <- Diagonal(5)
D5 <- Diagonal(x = 10^(1:5))
## trivial (but explicitly defined) methods:
stopifnot(identical(crossprod(I5), I5),
          identical(tcrossprod(I5), I5),
          identical(crossprod(I5, D5), D5),
          identical(tcrossprod(D5, I5), D5),
          identical(solve(D5), solve(D5, I5)),
          all.equal(D5, solve(solve(D5), tol = 1e-12),
            solve(D5)# efficient as is diagonal

# an unusual way to construct a band matrix:
rbind2(cbind2(I5, D5), cbind2(D5, I5))
```

Description

Transform a triangular matrix `x`, i.e., of `class "triangularMatrix"`, from (internally!) unit triangular ("unitriangular") to "general" (`diagU2N(x)`) or back (`diagN2U(x)`). Note that the latter, `diagN2U(x)`, also sets the diagonal to one in cases where `diag(x)` was not all one.

`.diagU2N(x)` assumes but does not check that `x` is a `triangularMatrix` with `diag` slot "U", and should hence be used with care.

Usage

```r
diagN2U(x, cl = getClassDef(class(x)), checkDense = FALSE)
diagU2N(x, cl = getClassDef(class(x)), checkDense = FALSE)
```

Arguments

- `x` a `triangularMatrix`, often sparse.
- `cl` (optional, for speedup only:) class (definition) of `x`.
- `checkDense` logical indicating if dense (see `denseMatrix`) matrices should be considered at all; i.e., when false, as per default, the result will be sparse even when `x` is dense.

Details

The concept of unit triangular matrices with a `diag` slot of "U" stems from LAPACK.

Value

A triangular matrix of the same `class` and (semantically) with identical entries as `x`, but with a different `diag` slot.
Note

Such internal storage details should rarely be of relevance to the user. Hence, these functions really are rather *internal* utilities.

See Also

"triangularMatrix", "dtCMatrix".

Examples

```r
(T <- Diagonal(7) + triu(Matrix(rpois(49, 1/4), 7, 7), k = 1))
(uT <- diagN2U(T)) # "unitriangular"
(t.u <- diagN2U(10*T))# changes the diagonal!
stopifnot(all(T == uT), diag(t.u) == 1,
          identical(T, diagU2N(uT)))
T[upper.tri(T)] <- 5
T <- diagN2U(as(T, "triangularMatrix"))
stopifnot(T@diag == "U")
dT <- as(T, "denseMatrix")
dt. <- diagN2U(dT)
dtU <- diagN2U(dT, checkDense=TRUE)
stopifnot(is(dtU, "denseMatrix"), is(dt., "sparseMatrix"),
          all(dT == dt.), all(dt == dtU),
          dt.@diag == "U", dtU@diag == "U")
```

---

**dMatrix-class**

*(Virtual) Class “dMatrix” of “double” Matrices*

Description

The `dMatrix` class is a virtual class contained by all actual classes of numeric matrices in the `Matrix` package. Similarly, all the actual classes of logical matrices inherit from the `lMatrix` class.

Slots

Common to *all* matrix object in the package:

- **Dim**: Object of class “integer” - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

- **Dimnames**: list of length two; each component containing NULL or a `character` vector length equal the corresponding `Dim` element.

Methods

There are (relatively simple) group methods (see, e.g., `Arith`)

- **Arith** signature(e1 = "dMatrix", e2 = "dMatrix"): ...

- **Arith** signature(e1 = "dMatrix", e2 = "numeric"): ...

- **Arith** signature(e1 = "numeric", e2 = "dMatrix"): ...

- **Math** signature(x = "dMatrix"): ...

- **Math2** signature(x = "dMatrix", digits = "numeric"): this group contains `round()` and `signif()`.
**dpoMatrix-class**

**Compare** signature(e1 = "numeric", e2 = "dMatrix"): ...

**Compare** signature(e1 = "dMatrix", e2 = "numeric"): ...

**Compare** signature(e1 = "dMatrix", e2 = "dMatrix"): ...

**Summary** signature(x = "dMatrix"): The "Summary" group contains the seven functions `max()`, `min()`, `range()`, `prod()`, `sum()`, `any()`, and `all()`.

The following methods are also defined for all double matrices:

- **coerce** signature(from = "dMatrix", to = "matrix"): ...
- **expm** signature(x = "dMatrix"): computes the "Matrix Exponential", see `expm`.
- **zapsmall** signature(x = "dMatrix"): ...

The following methods are defined for all logical matrices:

- **which** signature(x = "lsparseMatrix") and many other subclasses of "lMatrix": as the **base** function `which(x, arr.ind)` returns the indices of the `TRUE` entries in `x`; if `arr.ind` is true, as a 2-column matrix of row and column indices.

**See Also**

The nonzero-pattern matrix class `nMatrix`, which can be used to store non-NA logical matrices even more compactly.

The numeric matrix classes `dgeMatrix`, `dgCMatrix`, and `Matrix`.

- `drop0(x, tol=1e-10)` is sometimes preferable to (and more efficient than) `zapsmall(x, digits=10).

**Examples**

```
showClass("dMatrix")

set.seed(10)
round(Matrix(rnorm(28), 4,7), 2)
M <- Matrix(rlnorm(56, sd=10), 4, 14)
(M. <- zapsmall(M))
table(as.logical(M. == 0))
```

---

**dpoMatrix-class**  
*Positive Semi-definite Dense Numeric Matrices*

**Description**

The "dpoMatrix" class is the class of positive-semidefinite symmetric matrices in nonpacked storage. The "dppMatrix" class is the same except in packed storage. Only the upper triangle or the lower triangle is required to be available.

The "corMatrix" class extends "dpoMatrix" with a slot `sd`.

**Objects from the Class**

Objects can be created by calls of the form `new("dpoMatrix", ...)` or from `crossprod` applied to an "dgeMatrix" object.
Slots

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
x: Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.
Dim: Object of class "integer". The dimensions of the matrix which must be a two-element vector of non-negative integers.
Dimnames: inherited from class "Matrix"
factors: Object of class "list". A named list of factorizations that have been computed for the matrix.
sd: (for "corMatrix") a numeric vector of length n containing the (original) \( \sqrt{\text{var}(.)} \) entries which allow reconstruction of a covariance matrix from the correlation matrix.

Extends

Class "dsyMatrix", directly.
Classes "dgeMatrix", "symmetricMatrix", and many more by class "dsyMatrix".

Methods

chol signature(x = "dpoMatrix"): Returns (and stores) the Cholesky decomposition of x, see chol.
determinant signature(x = "dpoMatrix"): Returns the determinant of x, via chol(x), see above.
rcond signature(x = "dpoMatrix", norm = "character"): Returns (and stores) the reciprocal of the condition number of x. The norm can be "O" for the one-norm (the default) or "I" for the infinity-norm. For symmetric matrices the result does not depend on the norm.
solve signature(a = "dpoMatrix", b = ". . ."), and
solve signature(a = "dppMatrix", b = ". . .") work via the Cholesky composition, see also the Matrix solve-methods.

Arith signature(e1 = "dpoMatrix", e2 = "numeric") (and quite a few other signatures): The result of ("elementwise" defined) arithmetic operations is typically not positive-definite anymore. The only exceptions, currently, are multiplications, divisions or additions with positive length(. ) == 1 numbers (or logicals).

See Also

Classes dsyMatrix and dgeMatrix; further, Matrix, rcond, chol, solve, crossprod.

Examples

h6 <- Hilbert(6)
rcond(h6)
str(h6)
h6 * 27720 # is "integer"
solve(h6)
str(h6p6 <- as(h6, "dppMatrix"))

### Note that as(*, "corMatrix") *scales* the matrix
(ch6 <- as(h6, "corMatrix"))
drop0

Drop "Explicit Zeroes" from a Sparse Matrix

Description
Returns a sparse matrix with no “explicit zeroes”, i.e., all zero or FALSE entries are dropped from the explicitly indexed matrix entries.

Usage

drop0(x, tol = 0, is.Csparse = NA)

Arguments

- **x**: a Matrix, typically sparse, i.e., inheriting from `spMatrix`.
- **tol**: non-negative number to be used as tolerance for checking if an entry $x_{i,j}$ should be considered to be zero.
- **is.Csparse**: logical indicating prior knowledge about the “Csparseness” of x. This exists for possible speedup reasons only.

Value

a Matrix like x but with no explicit zeros, i.e., !any(x@x == 0), always inheriting from `CsparseMatrix`.

Note

When a sparse matrix is the result of matrix multiplications, you may want to consider combining `drop0()` with `zapsmall()`, see the example.

See Also

`spMatrix`, class `sparseMatrix`

Examples

```r
m <- spMatrix(10,20, i=1:8, j=2:9, x = c(0:2,3:-1))
m
drop0(m)

## A larger example:
t5 <- new("dtCMatrix", Dim = c(5L, 5L), uplo = "L",
    x = c(10, 1, 3, 10, 1, 10, 1, 10, 10),
    i = c(0L, 2L, 4L, 1L, 3L, 2L, 4L, 3L, 4L),
    p = c(0L, 3L, 5L, 7:9))
TT <- kronecker(t5, kronecker(kronecker(t5,t5), t5))
IT <- solve(TT)
```
dsCMatrix-class

Description

The dsCMatrix class is a class of symmetric, sparse numeric matrices in the compressed, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order.

The dsTMatrix class is the class of symmetric, sparse numeric matrices in triplet format.

Objects from the Class

Objects can be created by calls of the form new("dsCMatrix", ...) or new("dsTMatrix", ...) or (for dsCMatrix) also automatically from Matrix(.)

Slots

uplo: A character object indicating if the upper triangle ("U") or the lower triangle ("L") is stored.
i: Object of class "integer" of length nnZ (half number of non-zero elements). These are the row numbers for each non-zero element in the lower triangle of the matrix.
p: (only in class "dsCMatrix"): an integer vector for providing pointers, one for each column, see the detailed description in CsparseMatrix.
j: (only in class "dsTMatrix"): Object of class "integer" of length nnZ (as i). These are the column numbers for each non-zero element in the lower triangle of the matrix.
x: Object of class "numeric" of length nnZ – the non-zero elements of the matrix (to be duplicated for full matrix).
factors: Object of class "list" - a list of factorizations of the matrix.
Dim: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

Extends

Both classes extend classes and symmetricMatrix dsparseMatrix directly; dsCMatrix further directly extends CsparseMatrix, where dsTMatrix does TsparseMatrix.

Methods

solve signature(a = "dsCMatrix", b = "..."): x <- solve(a,b) solves Ax = b for x; see solve-methods.

chol signature(x = "dsCMatrix", pivot = "logical"): Returns (and stores) the Cholesky decomposition of x, see chol.

Cholesky signature(A = "dsCMatrix", ...): Computes more flexibly Cholesky decompositions, see Cholesky.
**d Determinant** signature(x = "dsCMatrix", logarithm = "missing"): Evaluate the determinant of x on the logarithm scale. This creates and stores the Cholesky factorization.

**d Determinant** signature(x = "dsCMatrix", logarithm = "logical"): Evaluate the determinant of x on the logarithm scale or not, according to the logarithm argument. This creates and stores the Cholesky factorization.

**t** signature(x = "dsCMatrix"): Transpose. As for all symmetric matrices, a matrix for which the upper triangle is stored produces a matrix for which the lower triangle is stored and vice versa, i.e., the uplo slot is swapped, and the row and column indices are interchanged.

**t** signature(x = "dsTMatrix"): Transpose. The uplo slot is swapped from "U" to "L" or vice versa, as for a "dsCMatrix", see above.

**coerce** signature(from = "dsCMatrix", to = "dgTMatrix")

**coerce** signature(from = "dsCMatrix", to = "dgeMatrix")

**coerce** signature(from = "dsCMatrix", to = "matrix")

**coerce** signature(from = "dsTMatrix", to = "dgeMatrix")

**coerce** signature(from = "dsTMatrix", to = "dsCMatrix")

**coerce** signature(from = "dsTMatrix", to = "dsyMatrix")

**coerce** signature(from = "dsTMatrix", to = "matrix")

---

**See Also**

Classes `dgCMatrix`, `dgTMatrix`, `dgeMatrix` and those mentioned above.

**Examples**

```r
mm <- Matrix(toeplitz(c(10, 0, 1, 0, 3)), sparse = TRUE)
mm # automatically dsCMatrix
str(mm)
```

```r
## how would we go from a manually constructed Tsparse* :
mt <- as(mm, "dgTMatrix")
```

```r
## Either
(symM <- as(mt, "symmetricMatrix")) # dsT
(symC <- as(symM, "CsparseMatrix")) # dsC
## or
sC <- Matrix(mt, sparse=TRUE, forceCheck=TRUE)
```

```r
sym2 <- as(symC, "TsparseMatrix")
## --> the same as 'symM', a "dsTMatrix"
```

---

**d DeterminateMatrix-class Virtual Class "d DeterminateMatrix" of Numeric Sparse Matrices**

**Description**

The Class "d DeterminateMatrix" is the virtual (super) class of all numeric sparse matrices.
Slots

- **Dim**: the matrix dimension, see class "Matrix".
- **Dimnames**: see the "Matrix" class.
- **x**: a numeric vector containing the (non-zero) matrix entries.

Extends

Class "dMatrix" and "sparseMatrix", directly.
Class "Matrix", by the above classes.

See Also

the documentation of the (non virtual) sub classes, see showClass("dsparseMatrix"); in particular, dgTMatrix, dgCMatrix, and dgRMatrix.

Examples

showClass("dsparseMatrix")

---

**dsRMMatrix-class**  
**Symmetric Sparse Compressed Row Matrices**

Description

The dsRMMatrix class is a class of symmetric, sparse matrices in the compressed, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

Objects from the Class

These "..RMMatrix" classes are currently still mostly unimplemented!

Objects can be created by calls of the form `new("dsRMMatrix", ...).

Slots

- **uplo**: A character object indicating if the upper triangle ("U") or the lower triangle ("L") is stored. At present only the lower triangle form is allowed.
- **j**: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.
- **p**: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.
- **factors**: Object of class "list" - a list of factorizations of the matrix.
- **x**: Object of class "numeric" - the non-zero elements of the matrix.
- **Dim**: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.
- **Dimnames**: List of length two, see **Matrix**.
dsyMatrix-class

Extends

Classes RsparseMatrix, dsparseMatrix and symmetricMatrix, directly.
Class "dMatrix", by class "dsparseMatrix", class "sparseMatrix", by class "dsparseMatrix" or "RsparseMatrix"; class "compMatrix" by class "symmetricMatrix" and of course, class "Matrix".

Methods

forceSymmetric signature(x = "dsRMMatrix", uplo = "missing"): a trivial method just returning x

forceSymmetric signature(x = "dsRMMatrix", uplo = "character"): if uplo == x@uplo, this trivially returns x; otherwise t(x).

coerce signature(from = "dsCMatrix", to = "dsRMMatrix")

See Also

the classes dgCMatrix, dgTMmatrix, and dgeMatrix.

Examples

(m0 <- new("dsRMMatrix"))
m2 <- new("dsRMMatrix", Dim = c(2L,2L),
    x = c(3,1), j = c(1L,1L), p = 0:2)
m2
stopifnot(colSums(as(m2, "TsparseMatrix")) == 3:4)
str(m2)
(ds2 <- forceSymmetric(diag(2))) # dsy*
dR <- as(ds2, "RsparseMatrix")
dR # dsRMMatrix

---

dsyMatrix-class symmetric Dense Numeric Matrices

Description

The "dsyMatrix" class is the class of symmetric, dense matrices in non-packed storage and "dspMatrix" is the class of symmetric dense matrices in packed storage. Only the upper triangle or the lower triangle is stored.

Objects from the Class

Objects can be created by calls of the form new("dsyMatrix", ...).

Slots

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
x: Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.
Dim,Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), see the Matrix.
factors: Object of class "list". A named list of factorizations that have been computed for the matrix.

Extends

"dsyMatrix" extends class "dgeMatrix", directly, whereas "dspMatrix" extends class "ddenseMatrix", directly.

Both extend class "symmetricMatrix", directly, and class "Matrix" and others, indirectly, use `showClass("dsyMatrix")`, e.g., for details.

Methods

- `coerce` signature(from = "ddenseMatrix", to = "dgeMatrix")
- `coerce` signature(from = "dspMatrix", to = "matrix")
- `coerce` signature(from = "dsyMatrix", to = "matrix")
- `coerce` signature(from = "dsyMatrix", to = "dspMatrix")
- `coerce` signature(from = "dspMatrix", to = "dsyMatrix")
- `norm` signature(x = "dspMatrix", type = "character")
- `norm` signature(x = "dsyMatrix", type = "character")
- `norm` signature(x = "dspMatrix", type = "missing")
- `norm` signature(x = "dsyMatrix", type = "missing")
- `solve` signature(a = "dspMatrix", b = "...") and
- `solve` signature(a = "dsyMatrix", b = "..."): x <- solve(a,b) solves $Ax = b$ for x; see `solve-methods`.
- `t` signature(x = "dsyMatrix"): Transpose; swaps from upper triangular to lower triangular storage, i.e., the uplo slot from "U" to "L" or vice versa, the same as for all symmetric matrices.

See Also

Classes `dgeMatrix` and `Matrix`; `solve`, `norm`, `rcond`, `t`

Examples

```r
## Only upper triangular part matters (when uplo == "U" as per default)
(sy2 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, NA, 32, 77)))
str(t(sy2)) # uplo = "L", and the lower tri. (i.e. NA is replaced).

chol(sy2) #-> "Cholesky" matrix
(sp2 <- pack(sy2)) # a "dspMatrix"

## Coercing to `dpoMatrix` gives invalid object:
sy3 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, -1, 2, -7))
try(as(sy3, "dpoMatrix")) # -> error: not positive definite
```
Description

The "dtCMatrix" class is a class of triangular, sparse matrices in the compressed, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order. The "dtTMatrix" class is a class of triangular, sparse matrices in triplet format.

Objects from the Class

Objects can be created by calls of the form new("dtCMatrix", ...) or calls of the form new("dtTMatrix", ...), but more typically automatically via Matrix() or coercion such as as(x, "dtCMatrix").

Slots

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

diag: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see triangularMatrix.

p: (only present in "dtCMatrix"); an integer vector for providing pointers, one for each column, see the detailed description in CsparseMatrix.

i: Object of class "integer" of length n nonzero (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.

j: Object of class "integer" of length n nonzero (number of non-zero elements). These are the column numbers for each non-zero element in the matrix. (Only present in the dtTMatrix class.)

x: Object of class "numeric" - the non-zero elements of the matrix.

Dim, Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the Matrix, see there.

Extends

Class "dgCMatrix", directly. Class "triangularMatrix", directly. Class "dMatrix", "sparseMatrix", and more by class "dgCMatrix" etc, see the examples.

Methods

coerce signature(from = "dtCMatrix", to = "dgTMatrix")

coerce signature(from = "dtCMatrix", to = "dgeMatrix")

coerce signature(from = "dtTMatrix", to = "dgeMatrix")

coerce signature(from = "dtTMatrix", to = "dtrMatrix")

coerce signature(from = "dtTMatrix", to = "matrix")

solve signature(a = "dtCMatrix", b = "...."): sparse triangular solve (aka "backsolve" or "forwardsolve"), see solve-methods.

t signature(x = "dtCMatrix"): returns the transpose of x

t signature(x = "dtTMatrix"): returns the transpose of x
See Also

Classes \texttt{dgCMatrix}, \texttt{dgTMatrix}, \texttt{dgeMatrix}, and \texttt{dtrMatrix}.

Examples

```r
showClass("dTCMatrix")

showClass("dTMMatrix")
t1 <- new("dTMMatrix", x = c(3,7), i = 0:1, j=3:2, Dim = as.integer(c(4,4)))
t1
## from 0-diagonal to unit-diagonal (low-level step):
tu <- t1; tu@diag <- "U"
tu
cu <- as(tu, "dTCMatrix")
str(cu)# only two entries in @i and @x
stopifnot(cu@i == 1:0,
  all(2 * symmpart(cu) == Diagonal(4) + forceSymmetric(cu)))
t1[1,2:3] <- -1:2
diag(t1) <- 10*c(1:2,3:2)
t1 # still triangular
(it1 <- solve(t1))
t1. <- solve(it1)
all(abs(t1 - t1.) < 10 * .Machine$double.eps)
## 2nd example
U5 <- new("dTCMatrix", i= c(1L, 0:3), p=c(0L,0L,0:2, 5L), Dim = c(5L, 5L),
  x = rep(1, 5), diag = "U")
U5
(iu <- solve(U5))# contains one '0'
validObject(iu2 <- solve(U5, Diagonal(5)))# failed in earlier versions
I5 <- iu #%U5 # should equal the identity matrix
i5 <- iu2 #%U5
asDiag <- function(M) as(drop0(M), "diagonalMatrix")
stopifnot(
  all.equal(Diagonal(5), asDiag(I5), tol=1e-14)
)
```

---

\textbf{dtpMatrix-class}  

\textit{Packed Triangular Dense Matrices - "dtpMatrix"}

**Description**

The "dtpMatrix" class is the class of triangular, dense, numeric matrices in packed storage. The "dtrMatrix" class is the same except in nonpacked storage.

**Objects from the Class**

Objects can be created by calls of the form \texttt{new("dtpMatrix", \ldots)} or by coercion from other classes of matrices.
Slots

`uplo`: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

`diag`: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see `triangularMatrix`.

`x`: Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order. For a packed square matrix of dimension \(d \times d\), \(\text{length}(x)\) is of length \(d(d+1)/2\) (also when `diag` == "U"!).

`dim`, `dimnames`: The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the `Matrix`, see there.

Extends

Class "ddenseMatrix", directly. Class "triangularMatrix", directly. Class "dMatrix" and more by class "ddenseMatrix" etc, see the examples.

Methods

```r
%*% signature(x = "dtpMatrix", y = "dgeMatrix"): Matrix multiplication; ditto for several other signature combinations, see `showMethods("%*%", class = "dtpMatrix")).

coerce signature(from = "dtpMatrix", to = "dtrMatrix")

coerce signature(from = "dtpMatrix", to = "matrix")

determinant signature(x = "dtpMatrix", logarithm = "logical"): the `determinant(x)` trivially is \(\text{prod(diag}(x)))\), but computed on log scale to prevent over- and underflow.

diag signature(x = "dtpMatrix"): ...

norm signature(x = "dtpMatrix", type = "character"): ...

rcond signature(x = "dtpMatrix", norm = "character"): ...

solve signature(a = "dtpMatrix", b = "..."): efficiently using internal backsolve or forwardsolve, see `solve-methods`.

t signature(x = "dtpMatrix"): \(t(x)\) remains a "dtpMatrix", lower triangular if \(x\) is upper triangular, and vice versa.
```

See Also

Class `dtrMatrix`

Examples

```r
showClass("dtrMatrix")

example("dtrMatrix-class", echo=FALSE)
(p1 <- as(T2, "dtpMatrix"))
str(p1)
(pp <- as(T, "dtpMatrix"))
ipl <- solve(p1)
stopifnot(length(p1@x) == 3, length(pp@x) == 3,
  p1 @ uplo == T2 @ uplo, pp @ uplo == T @ uplo,
  identical(t(pp), p1), identical(t(p1), pp),
  all(l.d <- p1 - T2) == 0L, is(l.d, "dtpMatrix"),
  all(u.d <- pp - T) == 0L, is(u.d, "dtpMatrix"),
```

The dtRMatrix class is a class of triangular, sparse matrices in the compressed, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

Objects from the Class

This class is currently still mostly unimplemented!

Objects can be created by calls of the form `new("dtRMatrix", ...)`

Slots

- `uplo`: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. At present only the lower triangle form is allowed.
- `diag`: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see `triangularMatrix`.
- `j`: Object of class "integer" of length `nnzero(.)` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.
- `p`: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row. (Only present in the dsRMatrix class.)
- `x`: Object of class "numeric" - the non-zero elements of the matrix.
- `Dim`: The dimension (a length-2 "integer")
- `Dimnames`: corresponding names (or NULL), inherited from the `Matrix`, see there.

Extends

Class "dgRMatrix", directly. Class "dsparseMatrix", by class "dgRMatrix". Class "dMatrix", by class "dgRMatrix". Class "sparseMatrix", by class "dgRMatrix". Class "Matrix", by class "dgRMatrix".

Methods

No methods currently with class "dsRMatrix" in the signature.

See Also

Classes `dgCMATRIX, dgTMatrix, dgeMatrix`
Examples

```r
(m0 <- new("dtrMatrix"))
(m2 <- new("dtrMatrix", Dim = c(2L, 2L),
          x = c(5, 1:2), p = c(0L, 2:3), j = c(0:1,1L)))
str(m2)
(m3 <- as(Diagonal(2), "RsparseMatrix")) # --> dtrMatrix
```

---

### Description

The "dtrMatrix" class is the class of triangular, dense, numeric matrices in nonpacked storage. The "dtpMatrix" class is the same except in packed storage.

### Objects from the Class

Objects can be created by calls of the form `new("dtrMatrix", ...)`.

### Slots

- **uplo**: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- **diag**: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see `triangularMatrix`.
- **x**: Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.
- **Dim**: Object of class "integer". The dimensions of the matrix which must be a two-element vector of non-negative integers.

### Extends

Class "ddenseMatrix", directly. Class "triangularMatrix", directly. Class "Matrix" and others, by class "ddenseMatrix".

### Methods

- `%*%` signature(x = "dtrMatrix", y = "matrix") and other signatures (use `showMethods("%*%", class="dtrMatrix")`): matrix multiplication. Multiplication of (matching) triangular matrices now should remain triangular (in the sense of class `triangularMatrix`).
- `crossprod,tcrossprod` signature(x = "dtrMatrix", y = "matrix") and other signatures, see "%*%" above.
- `coerce` signature(from = "dgeMatrix", to = "dtrMatrix")
- `coerce` signature(from = "dtrMatrix", to = "matrix")
- `coerce` signature(from = "dtrMatrix", to = "ltrMatrix")
- `coerce` signature(from = "dtrMatrix", to = "matrix")
- `coerce` signature(from = "matrix", to = "dtrMatrix")
\begin{verbatim}
norm signature(x = "dtrMatrix", type = "character")
recond signature(x = "dtrMatrix", norm = "character")
solve signature(a = "dtrMatrix", b = "....")efficiently use a “forwardsolve” or
backsolve for a lower or upper triangular matrix, respectively, see also solve-methods.
+,-,*,...,==,>=,... all the Ops group methods are available. When applied to two triangular
matrices, these return a triangular matrix when easily possible.

See Also
Classes ddenseMatrix, dtpMatrix, triangularMatrix

Examples
(m <- rbind(2:3, 0:-1))
(M <- as(m, "dgeMatrix"))
(T <- as(M, "dtrMatrix"))  ## upper triangular is default
(T2 <- as(t(M), "dtrMatrix"))
stopifnot(T@uplo == "U", T2@uplo == "L", identical(T2, t(T)))
\end{verbatim}

\textbf{Description}

Expands decompositions stored in compact form into factors.

\textbf{Usage}

expand(x, ...)

\textbf{Arguments}

\begin{itemize}
\item \texttt{x} a matrix decomposition.
\item \texttt{...} further arguments passed to or from other methods.
\end{itemize}

\textbf{Details}

This is a generic function with special methods for different types of decompositions, see
\texttt{showMethods} (expand) to list them all.

\textbf{Value}

The expanded decomposition, typically a list of matrix factors.

\textbf{Note}

Factors for decompositions such as \texttt{lu} and \texttt{qr} can be stored in a compact form. The function expand
allows all factors to be fully expanded.
See Also

The LU `lu`, and the Cholesky decompositions which have expand methods; `facmul`.

Examples

```r
(x <- Matrix(round(rnorm(9),2), 3, 3))
(ex <- expand(lux <- lu(x)))
```

---

### Description

Compute the exponential of a matrix.

### Usage

```r
expm(x)
```

### Arguments

- **x**: a matrix, typically inheriting from the `dMatrix` class.

### Details

The exponential of a matrix is defined as the infinite Taylor series

\[
\expm(A) = I + A + A^2/2! + A^3/3! + \ldots
\]

(although this is definitely not the way to compute it). The method for the `dgeMatrix` class uses Ward's diagonal Pade' approximation with three step preconditioning.

### Value

The matrix exponential of `x`.

### Note

The `expm` package contains newer (partly faster and more accurate) algorithms for `expm()` and includes `logm` and `sqrtm`.

### Author(s)

This is a translation of the implementation of the corresponding Octave function contributed to the Octave project by A. Scottedward Hodel <A.S.Hodel@Eng.Auburn.EDU>. A bug in there has been fixed by Martin Maechler.

### References

See Also

Schur: additionally, expm, logm, etc in package expm.

Examples

```r
(m1 <- Matrix(c(1,0,1), nc = 2))
e1 <- expm(m1) ; e <- exp(1)
stifnot(all.equal(e@x, c(e,0,e,e), tol = 1e-15))
(m2 <- Matrix(c(-49, -64, 24, 31), nc = 2))
e2 <- expm(m2)
(m3 <- Matrix(cbind(0,rbind(6*diag(3),0))))# sparse!
e3 <- expm(m3)) # upper triangular
```

Description

Read matrices stored in the Harwell-Boeing or MatrixMarket formats or write sparseMatrix objects to one of these formats.

Usage

```r
readHB(file)
readMM(file)
writeMM(obj, file, ...)
```

Arguments

- `obj`: a real sparse matrix
- `file`: for writeMM - the name of the file to be written. For readHB and readMM the name of the file to read, as a character scalar. The names of files storing matrices in the Harwell-Boeing format usually end in "rue" or "rsa". Those storing matrices in the MatrixMarket format usually end in " mtx".
- `...`: alternatively, readHB and readMM accept connection objects. Optionally additional arguments. Currently none are used in any methods.

Value

The readHB and readMM functions return an object that inherits from the "Matrix" class. Methods for the writeMM generic functions usually return NULL and, as a side effect, the matrix obj is written to file in the MatrixMarket format (writeMM).

Note

The Harwell-Boeing format is older and less flexible than the MatrixMarket format. The function writeHB was deprecated and has now been removed. Please use writeMM instead.

A very simple way to export small sparse matrices S, is to use summary(S) which returns a data.frame with columns i, j, and possibly x, see summary in sparseMatrix-class, and an example below.
References

http://math.nist.gov/MatrixMarket
http://www.cise.ufl.edu/research/sparse/matrices

Examples

```r
str(pores <- readMM(system.file("external/pores_1.mtx", package = "Matrix")))
str(utm <- readHB(system.file("external/utm300.rua", package = "Matrix")))
str(lundA <- readMM(system.file("external/lund_a.mtx", package = "Matrix")))
str(lundA <- readHB(system.file("external/lund_a.rsa", package = "Matrix")))
## Not run:
## NOTE: The following examples take quite some time
## even on a fast internet connection:
if(FALSE) # the URL has been corrected, but we need an un-tar step!
  str(sm <-
    readHB(gzcon(url("http://www.cise.ufl.edu/research/spare/KB/Boeing/msc00726.tar.gz"))))

str(jgl009 <-
readMM(gzcon(url("ftp://math.nist.gov/pub/MatrixMarket2/Harwell-Boeing/couterx/jgl009.mtx.gz"))))
## End(Not run)
data(KNex)
writeMM(KNex$mm, "mmmm.mtx")
## very simple export - in triplet format - to text file:
data(CAex)
s.CA <- summary(CAex)
message("writing to ", outf <- tempfile())
write.table(s.CA, file = outf, row.names=FALSE)
## and read it back -- showing off sparseMatrix():
dd <- read.table(outf, header=TRUE)
mm <- do.call(sparseMatrix, dd)
stopifnot(all.equal(mm, CAex, tol=1e-15))
```

facmul

**Multiplication by Decomposition Factors**

Description

Performs multiplication by factors for certain decompositions (and allows explicit formation of those factors).

Usage

`facmul(x, factor, y, transpose, left, ...)"
forceSymmetric

Arguments

x  a matrix decomposition. No missing values or IEEE special values are allowed.
factor  an indicator for selecting a particular factor for multiplication.
y  a matrix or vector to be multiplied by the factor or its transpose. No missing values or IEEE special values are allowed.
transpose  a logical value. When FALSE (the default) the factor is applied. When TRUE the transpose of the factor is applied.
left  a logical value. When TRUE (the default) the factor is applied from the left. When FALSE the factor is applied from the right.
...  the method for "qr.Matrix" has additional arguments.

Value

the product of the selected factor (or its transpose) and y

NOTE

Factors for decompositions such as lu and qr can be stored in a compact form. The function facmul allows multiplication without explicit formation of the factors, saving both storage and operations.

References

Examples

```r
library(Matrix)
x <- Matrix(rnorm(9), 3, 3)
## Not run:
qrx <- qr(x)  # QR factorization of x
y <- rnorm(3)
facmul(qrx, factor = "Q", y)  # form Q y
## End(Not run)
```

forceSymmetric  Force a Matrix to 'symmetricMatrix' Without Symmetry Checks

Description

Force x (inheriting from Matrix class) to symmetricMatrix, without a symmetry check (which is applied for all as(x, "symmetricMatrix") alikes).

Usage

forceSymmetric(x, uplo)
Arguments

- **x**: a (classed) square matrix.
- **uplo**: optional string, “U” or “L”. The default is “U” unless `x` already has a `uplo` slot (i.e., when it is `symmetricMatrix`, or `triangularMatrix`), where the default will be `x@uplo`.

Value

A square matrix inheriting from class `symmetricMatrix`.

See Also

`symmpart` for the symmetric part, or the coercions `as(x, <symmetricMatrix class>).`

Examples

```r
## Hilbert matrix
i <- 1:6
h6 <- 1/outer(i - 1, i, "+")
sd <- sqrt(diag(h6))
sh <- t(h6/sd)/sd # theoretically symmetric
isSymmetric(sh, tol=0) # FALSE; hence
try(as(sh, "symmetricMatrix") ) # fails, but this works fine:
H6 <- forceSymmetric(sh)

## result can be pretty surprising:
(M <- Matrix(1:36, 6))
forceSymmetric(M) # symmetric, hence very different in lower triangle
(tm <- tril(M))
forceSymmetric(tm)
```

formatSparseM

Formatting Sparse Numeric Matrices Utilities

Description

Utilities for formatting sparse numeric matrices in a flexible way. These functions are used by the `format` and `print` methods for sparse matrices and can be applied as well to standard R matrices. Note that all arguments but the first are optional.

`formatSparseM()` is the main “workhorse” of `formatSpMatrix`, the format method for sparse matrices.

`.formatSparseSimple()` is a simple helper function, also dealing with (short/empty) column names construction.

Usage

```r
formatSparseM(x, zero.print = ".", align = c("fancy", "right"),
  m = as(x,"matrix"), asLogical=NULL, digits=NULL,
  cx, iN0, dn = dimnames(m))

.formatSparseSimple(m, asLogical=FALSE, digits=NULL,
  col.names, note.dropping.colnames = TRUE,
  dn=dimnames(m))
```
Arguments

- **x**: an R object inheriting from class `sparseMatrix`.
- **zero.print**: character which should be used for *structural* zeroes. The default "." may occasionally be replaced by " " (blank); using "\(\theta\)" would look almost like `print()`ing of non-sparse matrices.
- **align**: a string specifying how the `zero.print` codes should be aligned, see `formatSpMatrix`.
- **m (optional)**: a (standard R) `matrix` version of `x`.
- **asLogical**: should the matrix be formatted as a logical matrix (or rather as a numeric one); mostly for `formatSparseM()`.
- **digits**: significant digits to use for printing, see `print.default`.
- **cx (optional)**: (character) matrix; a formatted version of `x`, still with strings such as "\(0,\theta\)" for the zeros.
- **inN0 (optional)**: an integer vector, specifying the location of the non-zeroes of `x`.
- **col.names, note.dropping.colnames**: see `formatSpMatrix`.
- **dn**: `dimnames` to be used; a list (of length two) with row and column names (or NULL).

Value

A character matrix like `cx`, where the zeros have been replaced with (padded versions of) `zero.print`. As this is a *dense* matrix, do not use these functions for really large (really) sparse matrices!

Author(s)

Martin Maechler

See Also

- `formatSpMatrix` which calls `formatSparseM()` and is the `format` method for sparse matrices.
- `printSpMatrix` which is used by the (typically implicitly called) `show` and `print` methods for sparse matrices.

Examples

```r
m <- suppressWarnings(matrix(c(0, 3.2, 0, 0, 11,0,0,0,0, -7,0), 4, 9))
fM <- formatSparseM(m)
noquote(fM)
## nice, but this is nicer :
print(fM, quote=FALSE, right=TRUE)
## and "the same" as :
Matrix(m)

## align = "right" is cheaper -- the "." are not aligned:
noquote(f2 <- formatSparseM(m,align="r"))
stopifnot(f2 == fM | m == 0, dim(f2) == dim(m),
  (f2 == ".") == (m == 0))
```
Class "generalMatrix" of General Matrices

Description

Virtual class of "general" matrices; i.e., matrices that do not have a known property such as symmetric, triangular, or diagonal.

Objects from the Class

A virtual Class: No objects may be created from it.

Slots

- factors ,
- Dim ,
- Dimnames: all slots inherited from compMatrix; see its description.

Extends

Class "compMatrix", directly. Class "Matrix", by class "compMatrix".

See Also

Classes compMatrix, and the non-general virtual classes: symmetricMatrix, triangularMatrix, diagonalMatrix.

Generate a Hilbert matrix

Description

Generate the n by n symmetric Hilbert matrix. Because these matrices are ill-conditioned for moderate to large n, they are often used for testing numerical linear algebra code.

Usage

Hilbert(n)

Arguments

- n a non-negative integer.

Value

the n by n symmetric Hilbert matrix as a "dpoMatrix" object.

See Also

the class dpoMatrix
Methods for function `image` in package `Matrix`. An image of a matrix simply color codes all matrix entries and draws the $n \times m$ matrix using an $n \times m$ grid of (colored) rectangles.

**Usage**

```r
## S4 method for signature 'dgTMatrix'
image(x, 
  xlim = .5 + c(0, di[2]),
  ylim = .5 + c(di[1], 0), aspect = "iso",
  sub = sprintf("Dimensions: %d x %d", di[1], di[2]),
  xlab = "Column", ylab = "Row", cuts = 15,
  useRaster = FALSE,
  useAbs = NULL, colorkey = !useAbs,
  col.regions = NULL,
  lwd = NULL, ...)
```

**Arguments**

- `x`: a Matrix object, i.e., fulfilling `is(x, "Matrix")`.
- `xlim`, `ylim`: x- and y-axis limits; may be used to “zoom into” matrix.
- `aspect`: aspect ratio specified as number (y/x) or string; see `levelplot`.
- `sub`, `xlab`, `ylab`: axis annotation with sensible defaults; see `plot.default`.
- `cuts`: number of levels the range of matrix values would be divided into.
- `useRaster`: logical indicating if raster graphics should be used (instead of the tradition rectangle vector drawing). If true, `panel.levelplot.raster` (from `lattice` package) is used, and the colorkey is also done via rasters, see also `levelplot` and possibly `grid.raster`.
  Note that using raster graphics may often be faster, but can be slower, depending on the matrix dimensions and the graphics device (dimensions).
- `useAbs`: logical indicating if `abs(x)` should be shown; if TRUE, the former (implicit) default, the default `col.regions` will be `grey` colors (and no colorkey drawn). The default is FALSE unless the matrix has no negative entries.
- `colorkey`: logical indicating if a color key aka ‘legend’ should be produced. Default is to draw one, unless `useAbs` is true. You can also specify a `list`, see `levelplot`, such as `list(raster=TRUE)` in the case of rastering.
- `col.regions`: vector of gradually varying colors; see `levelplot`.
- `lwd`: non-negative number or `NULL` (default), specifying the line-width of the rectangles of each non-zero matrix entry (drawn by `grid.rect`). The default depends on the matrix dimension and the device size.
further arguments passed to methods and `levelplot`, notably at for specifying (possibly non equidistant) cut values for dividing the matrix values (superseding cuts above).

**Methods**

All methods currently end up calling the method for the `dgTMatrix` class. Use `showMethods(image)` to list them all.

**Examples**

```r
showMethods(image)
# If you want to see all the methods' implementations:
showMethods(image, incl=TRUE, inherit=FALSE)

data(CAex)
image(CAex, main = "image(CAex)")
image(CAex, useAbs=TRUE, main = "image(CAex, useAbs=TRUE)"

cCA <- Cholesky(crossprod(CAex), Imult = .01)
image(cCA, main="Cholesky(crossprod(CAex), Imult = .01)")
image(cCA, useAbs=TRUE)

data(USCounties)
image(USCounties)# huge
image(sign(USCounties))## just the pattern
    # how the result looks, may depend heavily on
    # the device, screen resolution, antialiasing etc
    # e.g. x11(type="Xlib") may show very differently than cairo-based

## Drawing borders around each rectangle;
    # again, viewing depends very much on the device:
image(USCounties[1:400,1:200], lwd=.1)
image(USCounties[1:200,1:200], lwd=.5)
image(USCounties[1:200,1:200], lwd=.01)

if(doExtras <- interactive() || nzchar(Sys.getenv("R_MATRIX_CHECK_EXTRA")) ||
    identical("true", unname(Sys.getenv("_PKG_CHECKING_doExtras")))) {
    ## Using raster graphics: For PDF this would give a 77 MB file,
    ## however, for such a large matrix, this is typically considerably
    ## *slower* (than vector graphics rectangles) in most cases:
    if(doPNG <- !dev.interactive())
        png("image-USCounties-raster.png", width=3200, height=3200)
    image(USCounties, useRaster = TRUE) # should not suffer from anti-aliasing
    if(doPNG)
        dev.off()
    ## and now look at the *.png image in a viewer you can easily zoom in and out
}#only if(doExtras)
```

---

**Virtual Class "index" - Simple Class for Matrix Indices**
Description

The class "index" is a virtual class used for indices (in signatures) for matrix indexing and sub-assignment of "Matrix" matrices.

In fact, it is currently implemented as a simple class union (setClassUnion) of "numeric", "logical" and "character".

Objects from the Class

Since it is a virtual Class, no objects may be created from it.

See Also

[-methods, and
Subassign-methods, also for examples.

Examples

showClass("index")

indMatrix-class

Index matrices

Description

The "indMatrix" class is the class of index matrices, stored as 1-based integer index vectors. An index matrix is a matrix with exactly one non-zero entry per row. Index matrices are useful for mapping observations to unique covariate values, for example.

Matrix (vector) multiplication with index matrices is equivalent to replicating and permuting rows, or "sampling rows with replacement", and is implemented that way in the Matrix package, see the 'Details' below.

Details

Matrix (vector) multiplication with index matrices from the left is equivalent to replicating and permuting rows of the matrix on the right hand side. (Similarly, matrix multiplication with the transpose of an index matrix from the right corresponds to selecting columns.) The crossproduct of an index matrix $M$ with itself is a diagonal matrix with the number of entries in each column of $M$ on the diagonal, i.e., $M'M = \text{Diagonal(x=table(M@perm))}$.

Permutation matrices (of class pMatrix) are special cases of index matrices: They are square, of dimension, say, $n \times n$, and their index vectors contain exactly all of $1:n$.

While "row-indexing" (of more than one row or using drop=FALSE) stays within the "indMatrix" class, all other subsetting/indexing operations ("column-indexing", including diag) on "indMatrix" objects treats them as nonzero-pattern matrices ("ngTMatrix" specifically), such that non-matrix subsetting results in logical vectors. Sub-assignment ($M[i,j] <- v$) is not sensible and hence an error for these matrices.

Objects from the Class

Objects can be created by calls of the form new("indMatrix", ...) or by coercion from an integer index vector, see below.
**Slots**

- **perm**: An integer, 1-based index vector, i.e., an integer vector of length Dim[1] whose elements are taken from 1:Dim[2].
- **Dim**: Object of class "integer". The dimensions of the matrix which must skinny, i.e., the first dimension has to be at least as large as the second.
- **Dimnames**: list of length two; each component containing NULL or a character vector length equal the corresponding Dim element.

**Extends**

Class "sparseMatrix" and "generalMatrix", directly.

**Methods**

- `signature(x = "matrix", y = "indMatrix")` and other signatures (use `showMethods("%*%", class="indMatrix")`): ...
- `signature(from = "integer", to = "indMatrix")`: This enables typical "indMatrix" construction, given an index vector from elements in 1:Dim[2], see the first example.
- `signature(from = "numeric", to = "indMatrix")`: a user convenience, to allow as(perm, "indMatrix") for numeric perm with integer values.
- `signature(from = "list", to = "indMatrix")`: The list must have two (integer-valued) entries: the first giving the index vector with elements in 1:Dim[2], the second giving Dim[2]. This allows "indMatrix" construction for cases in which the values represented by the rightmost column(s) are not associated with any observations, i.e., in which the index does not contain values Dim[2], Dim[2]-1, Dim[2]-2, ...
- `signature(from = "indMatrix", to = "matrix")`: coercion to a traditional FALSE/TRUE matrix of mode logical.
- `signature(from = "indMatrix", to = "ngTMatrix")`: coercion to sparse logical matrix of class ngTMatrix.
- `signature(x = "indMatrix")`: return the transpose of the index matrix (which is no longer an indMatrix, but of class ngTMatrix).
- `signature(x = "indMatrix")`: return the column or row sums or means.
- `signature(x = "indMatrix", y = "indMatrix")`: a fast method for rowwise catenation of two index matrices (with the same number of columns).
- `signature(X = "indMatrix", Y = "indMatrix")`: return the kronecker product of two index matrices, which corresponds to the index matrix of the interaction of the two.

**Author(s)**

Fabian Scheipl <...@uni-muenchen.de> building on existing "pMatrix", after a nice hike’s conversation with Martin Maechler and tweaks by the latter.

**See Also**

The permutation matrices pMatrix are special index matrices. The “pattern” matrices, nMatrix and its subclasses.
Examples

```r
pl <- as(c(2,3,1), "pMatrix")
(sm1 <- as(rep(c(2,3,1), e=3), "indMatrix")
stopifnot(all(sm1 == pl[rep(1:3, each=3)]))

## row-indexing of a <pMatrix> turns it into an <indMatrix>:
class(pl[rep(1:3, each=3)])

set.seed(12) # so we know '10' is in sample
## random index matrix for 30 observations and 10 unique values:
(s10 <- as(sample(10, 30, replace=TRUE), "indMatrix"))

## Sample rows of a numeric matrix:
(mm <- matrix(1:10, nrow=10, ncol=3))
s10 %*% mm

set.seed(27)
IM1 <- as(sample(1:20, 100, replace=TRUE), "indMatrix")
IM2 <- as(sample(1:18, 100, replace=TRUE), "indMatrix")
(c12 <- crossprod(IM1, IM2))
## same as cross-tabulation of the two index vectors:
stopifnot(all(c12 - unclass(table(IM1@perm, IM2@perm)) == 0))

# 3 observations, 4 implied values, first does not occur in sample:
as(2:4, "indMatrix")
# 3 observations, 5 values, first and last do not occur in sample:
as(list(2:4, 5), "indMatrix")
as(sm1, "ngTMatrix")
s10[1:7, 1:4] # gives an "ngTMatrix" (most economic!)
s10[1:4, ] # preserves "indMatrix"-class

I1 <- as(c(5:1,6:4,7:3), "indMatrix")
I2 <- as(7:1, "pMatrix")
(I12 <- rBind(I1, I2))
stopifnot(is(I12, "indMatrix"),
  colSums(I12) == c(2L,2:4,4:2))
```

invPerm

**Inverse Permutation Vector**

### Description

From a permutation vector `p`, compute its inverse permutation vector.

### Usage

```r
invPerm(p, zero.p = FALSE, zero.res = FALSE)
```

### Arguments

- `p` an integer vector of length, say, `n`.
- `zero.p` logical indicating if `p` contains values `0:(n-1)` or rather (by default, `zero.p = FALSE`) `1:n`.
is.na-methods

zero.res logical indicating if the result should contain values 0:(n-1) or rather (by default, zero.res = FALSE) 1:n.

Value

an integer vector of the same length (n) as p. By default, (zero.p = FALSE, zero.res = FALSE), invPerm(p) is the same as order(p) or sort.list(p) and for that case, the function is equivalent to invPerm <- function(p) { p[p] <- seq_along(p) ; p }.

Author(s)

Martin Maechler

See Also

the class of permutation matrices, pMatrix.

Examples

  p <- sample(10) # a random permutation vector
  ip <- invPerm(p)
  p[ip] # == 1:10
  # they are indeed inverse of each other:
  stopifnot(
    identical(p[ip], 1:10),
    identical(ip[p], 1:10),
    identical(invPerm(ip), p)
  )

Description

Methods for function is.na(), is.infinite(), and is.infinite() for all Matrices (objects extending the Matrix class):

  x = "denseMatrix" returns a "nMatrix" object of same dimension as x, with TRUE's whenever x is NA, finite, or infinite, respectively.
  x = "sparseMatrix" ditto.

Usage

  ## S4 method for signature 'sparseMatrix'
  is.na(x)
  ## S4 method for signature 'dSpMatrix'
  is.infinite(x)
  ## S4 method for signature 'ddenseMatrix'
  is.infinite(x)
  ## ...
## Arguments

- `x` sparse or dense matrix or sparse vector (here; any R object in general).

## See Also

`NA`, `is.na`, `is.finite`, `is.infinite`; `nMatrix`, `denseMatrix`, `sparseMatrix`

The `sparseVector` class.

## Examples

```r
M <- Matrix(1:6, nrow=4, ncol=3,
            dimnames = list(c("a", "b", "c", "d"), c("A", "B", "C")))
stopifnot(all(is.na(M)))
M[2:3,2] <- NA
is.na(M)
if(exists("anyNA", mode="function"))
anyNA(M)

A <- spMatrix(10,20, i = c(1,3:8),
              j = c(2,9,6:10),
              x = 7 * (1:7))
stopifnot(all(is.na(A)))

inA <- is.na(A)
stopifnot(sum(inA) == 1+1+5)
```

---

## Description

Are the dimnames `dn` NULL-like?

`is.null.DN(dn)` is less strict than `is.null(dn)`, because it is also true (`TRUE`) when the dimnames `dn` are “like” `NULL`, or `list(NULL, NULL)`, as they can easily be for the traditional R matrices (`matrix`) which have no formal `class` definition, and hence much freedom in how their `dimnames` look like.

## Usage

`is.null.DN(dn)`
**Arguments**

- **dn**: `dimnames()` of a matrix-like R object.

**Value**

A logical value `TRUE` or `FALSE`.

**Note**

This function is really to be used on “traditional” matrices rather than those inheriting from `Matrix`, as the latter will always have `dimnames` list(`NULL,NULL`) exactly, in such a case.

**Author(s)**

Martin Maechler

**See Also**

- `is.null`, `dimnames`, `matrix`

**Examples**

```r
m <- matrix(round(100 * rnorm(6)), 2, 3); m1 <- m2 <- m3 <- m4 <- m
dimnames(m1) <- list(NULL, NULL)
dimnames(m2) <- list(NULL, character())
dimnames(m3) <- rev(dimnames(m2))
dimnames(m4) <- rep(list(character()),2)

m4 ## prints absolutely identically to m
stopifnot(m == m1, m1 == m2, m2 == m3, m3 == m4,
  identical(capture.output(m) -> cm,
        capture.output(m1)),
  identical(cm, capture.output(m2)),
  identical(cm, capture.output(m3)),
  identical(cm, capture.output(m4)))
```

**Description**

`isSymmetric(M)` returns a `logical` indicating if `M` is a symmetric matrix. This is a base function with a default method for the traditional matrices of class "matrix". Methods here are defined for virtual Matrix classes such that it works for all objects inheriting from class `Matrix`.

**See Also**

- `forceSymmetric`, `symmpart`, and the formal class (and subclasses) "symmetricMatrix".
isTriangular

Examples

```r
isSymmetric(Diagonal(4)) # TRUE of course
M <- Matrix(c(1,2,0,1), 2,2)
isSymmetric(M) # TRUE (*and* of formal class "dsyMatrix")
isSymmetric(as(M, "dgeMatrix")) # still symmetric, even if not "formally"
isSymmetric(triu(M)) # FALSE
```

Description

isTriangular(M) returns a logical indicating M is a triangular matrix. Analogously, isDiagonal(M) is true iff M is a diagonal matrix.

Contrary to isSymmetric(), these two functions are generically from Matrix package, and hence also define methods for traditional (class "matrix") matrices.

Usage

```r
isDiagonal(object)
isTriangular(object, ...)
## S4 method for signature 'CsparseMatrix'
isTriangular(object, upper = NA)
```

Arguments

- **object**: any R object, typically a matrix (traditional or Matrix package).
- **upper**: logical, one of NA (default), FALSE, or TRUE where the last two cases require a lower or upper triangular object to result in TRUE.
- **...**: potentially further arguments for other methods.

Value

a ("scalar") logical, TRUE or FALSE, never NA.

See Also

isSymmetric; formal class (and subclasses) "triangularMatrix" and "diagonalMatrix".

Examples

```r
isTriangular(Diagonal(4))
## is TRUE: a diagonal matrix is also (both upper and lower) triangular
(M <- Matrix(c(1,2,0,1), 2,2))
isTriangular(M) # TRUE (*and* of formal class "dtrMatrix")
isTriangular(as(M, "dgeMatrix")) # still triangular, even if not "formally"
isTriangular(crossprod(M)) # FALSE

isDiagonal(matrix(c(2,0,0,1), 2,2)) # TRUE
```
**Description**

Computes Khatri-Rao products for any kind of matrices.

The Khatri-Rao product is a column-wise Kronecker product. Originally introduced by Khatri and Rao (1968), it has many different applications, see Liu and Trenkler (2008) for a survey. Notably, it is used in higher-dimensional tensor decompositions, see Bader and Kolda (2008).

**Usage**

```r
KhatriRao(X, Y = X, FUN = "*", make.dimnames = FALSE)
```

**Arguments**

- `X, Y` matrices of with the same number of columns.
- `FUN` the (name of the) function to be used for the column-wise Kronecker products, see `kronecker`, defaulting to the usual multiplication.
- `make.dimnames` logical indicating if the result should inherit `dimnames` from `X` and `Y` in a simple way.

**Value**

a "`CsparseMatrix"", say `R`, the Khatri-Rao product of `X (n × k)` and `Y (m × k)`, is of dimension `(n · m) × k`, where the j-th column, `R[,j]` is the kronecker product `kronecker(X[,j], Y[,j])`.

**Note**

The current implementation is efficient for large sparse matrices.

**Author(s)**

Michael Cysouw, Univ. Marburg; minor tweaks by Martin Maechler.

`kronecker`. 
Examples

```r
## Example with very small matrices:
m <- matrix(1:12,3,4)
d <- diag(1:4)
KhatRao(m,d)
KhatRao(d,m)
dimnames(m) <- list(LETTERS[1:3], letters[1:4])
KhatRao(m,d, make.dimnames=TRUE)
KhatRao(d,m, make.dimnames=TRUE)
dimnames(d) <- list(NULL, paste0("D", 1:4))
KhatRao(m,d, make.dimnames=TRUE)
KhatRao(d,m, make.dimnames=TRUE)
dimnames(d) <- list(paste0("d", 10*1:4), paste0("D", 1:4))
KhatRao(m,d, make.dimnames=TRUE)
KhatRao(d,m, make.dimnames=TRUE)

nm <- as(m, "nMatrix")
nm <- as(d, "nMatrix")
KhatRao(nm,nd, make.dimnames=TRUE)
KhatRao(nd,nm, make.dimnames=TRUE)

stopifnot(dim(KhatRao(m,d)) == c(nrow(m)*nrow(d), ncol(d)))
```

KNx

Koenker-Ng Example Sparse Model Matrix and Response Vector

Description

A model matrix \( m \) and corresponding response vector \( y \) used in an example by Koenker and Ng. The matrix \( m \) is a sparse matrix with 1850 rows and 712 columns but only 8758 non-zero entries. It is a "dgCMatrix" object. The vector \( y \) is just numeric of length 1850.

Usage

data(KNex)

References

Examples

data(KNex)
class(KNex$mm)
dim(KNex$mm)
image(KNex$mm)
str(KNex)

```r
system.time( # a fraction of a second
    sparse.sol <- with(KNex, solve(crossprod(mm), crossprod(mm, y))))
head(round(sparse.sol,3))
```
## kronecker-methods

### Description

Computes Kronecker products for objects inheriting from "\texttt{Matrix}".

In order to preserve sparseness, we treat $0 \times NA$ as $0$, not as NA as usually in R (and as used for the \texttt{base} function \texttt{kronecker}).

### Methods

- \texttt{kronecker} signature(X = "Matrix", Y = "ANY")
- \texttt{kronecker} signature(X = "ANY", Y = "Matrix")
- \texttt{kronecker} signature(X = "diagonalMatrix", Y = "ANY")
- \texttt{kronecker} signature(X = "sparseMatrix", Y = "ANY")
- \texttt{kronecker} signature(X = "TsparseMatrix", Y = "TsparseMatrix")
- \texttt{kronecker} signature(X = "dgTMatrix", Y = "dgTMatrix")
- \texttt{kronecker} signature(X = "dtTMatrix", Y = "dtTMatrix")
- \texttt{kronecker} signature(X = "indMatrix", Y = "indMatrix")

### Examples

```r
(t1 <- spMatrix(5, 4, x = c(3,2,-7,11), i= 1:4, j=4:1)) # 5 x 4
t2 <- kronecker(Diagonal(3, 2:4), t1)                # 15 x 12

## should also work with special-cased logical matrices
l3 <- upper.tri(matrix(3,3))
M <- Matrix(l3)
N <- as(M, "nsparseMatrix")
N2 <- as(N, "generalMatrix")
MM <- kronecker(M,M)
NN <- kronecker(N,N)
NN2 <- kronecker(N2,N2)
stopifnot(identical(NN,MM),
           is(NN, "triangularMatrix"))
```

```r
## Compare with QR-based solution ("more accurate, but slightly slower"):
system.time(
  sp.sol2 <- with(KNex, qr.coef(qr(mm), y))
)

tag.all.equal(sparse.sol, sp.sol2, tol = 1e-13) # TRUE
```
ldenseMatrix-class  

Virtual Class "ldenseMatrix" of Dense Logical Matrices

Description

ldenseMatrix is the virtual class of all dense logical (S4) matrices. It extends both denseMatrix and lMatrix directly.

Slots

x: logical vector containing the entries of the matrix.

Dim, Dimnames: see Matrix.

Extends

Class "lMatrix", directly. Class "denseMatrix", directly. Class "Matrix", by class "lMatrix". Class "Matrix", by class "denseMatrix".

Methods

%*%  signature(x = "lsparseMatrix", y = "ldenseMatrix"): ...
%*%  signature(x = "ldenseMatrix", y = "lsparseMatrix"): ...
coerce  signature(from = "matrix", to = "ldenseMatrix"): ...
coerce  signature(from = "ldenseMatrix", to = "matrix"): ...
crossprod  signature(x = "lsparseMatrix", y = "ldenseMatrix"): ...
crossprod  signature(x = "ldenseMatrix", y = "lsparseMatrix"): ...
as.vector  signature(x = "ldenseMatrix", mode = "missing"): ...
which  signature(x = "ldenseMatrix"), semantically equivalent to base function which(x, arr.ind); for details, see the lMatrix class documentation.

ldiMatrix-class

Class "ldiMatrix" of Diagonal Logical Matrices

Description

The class "ldiMatrix" of logical diagonal matrices.

Objects from the Class

Objects can be created by calls of the form `new("ldiMatrix", ...)` but typically rather via `Diagonal`.

Slots

- `x`: "logical" vector.
- `diag`: "character" string, either "U" or "N", see `ddiMatrix`.
- `Dim,Dimnames`: matrix dimension and `dimnames`, see the `Matrix` class description.

Extends

Class "diagonalMatrix" and class "Matrix", directly.
Class "sparseMatrix", by class "diagonalMatrix".

See Also

Classes `ddiMatrix` and `diagonalMatrix`: function `Diagonal`.

Examples

```r
lm <- Diagonal(x = c(TRUE, FALSE, FALSE))
str(lm)#> gory details (slots)
crossprod(lm) # numeric
(nm <- as(lm, "nMatrix"))# -> sparse (not formally "diagonal")
crossprod(nm) # logical sparse
```

lgeMatrix-class

Class "lgeMatrix" of General Dense Logical Matrices

Description

This is the class of general dense `logical` matrices.

Slots

- `x`: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.
- `Dim,Dimnames`: The dimension (a length-2 "integer") and corresponding names (or NULL), see the `Matrix` class.
- `factors`: Object of class "list". A named list of factorizations that have been computed for the matrix.
2108

lsparseMatrix-classes

Extends

Class "ldenseMatrix", directly. Class "lMatrix", by class "ldenseMatrix". Class "denseMatrix", by class "ldenseMatrix". Class "Matrix", by class "ldenseMatrix". Class "Matrix", by class "ldenseMatrix".

Methods

Currently, mainly t() and coercion methods (for as(.)); use, e.g., showMethods(class="lgeMatrix") for details.

See Also

Non-general logical dense matrix classes such as ltrMatrix, or lsyMatrix; sparse logical classes such as lgCMatrix.

Examples

showClass("lgeMatrix")
str(new("lgeMatrix"))
set.seed(1)
(lM <- Matrix(matrix(rnorm(28), 4,7) > 0))# a simple random lgeMatrix
set.seed(11)
(lC <- Matrix(matrix(rnorm(28), 4,7) > 0))# a simple random lgCMatrix
as(lM, "lgCMatrix")

lsparseMatrix-classes  Sparse logical matrices

Description

The lsparseMatrix class is a virtual class of sparse matrices with TRUE/FALSE entries. Only the positions of the elements that are TRUE are stored. These can be stored in the “triplet” form (classes lgMMatrix, lsMMatrix, and ltMMatrix which really contain pairs, not triplets) or in compressed column-oriented form (classes lgMMatrix, lsMMatrix, and ltMMatrix) or in compressed row-oriented form (classes lgRMMatrix, lsRMMatrix, and ltRMMatrix). The second letter in the name of these non-virtual classes indicates general, symmetric, or triangular.

Objects from the Class

Objects can be created by calls of the form new("lgCMMatrix", ...) and so on. More frequently objects are created by coercion of a numeric sparse matrix to the logical form for use in the symbolic analysis phase of an algorithm involving sparse matrices. Such algorithms often involve two phases: a symbolic phase wherein the positions of the non-zeros in the result are determined and a numeric phase wherein the actual results are calculated. During the symbolic phase only the positions of the non-zero elements in any operands are of interest, hence any numeric sparse matrices can be treated as logical sparse matrices.
lsparseMatrix-classes

Slots

x: Object of class "logical", i.e., either TRUE, NA, or FALSE.

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. Present in the triangular and symmetric classes but not in the general class.

diag: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The implicit diagonal elements are not explicitly stored when diag is "U". Present in the triangular classes only.

p: Object of class "integer" of pointers, one for each column (row), to the initial (zero-based) index of elements in the column. Present in compressed column-oriented and compressed row-oriented forms only.

i: Object of class "integer" of length nnzero (number of non-zero elements). These are the row numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.

j: Object of class "integer" of length nnzero (number of non-zero elements). These are the column numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.

Dim: Object of class "integer" - the dimensions of the matrix.

Methods

coerce signature(from = "dgCMatrix", to = "lgCMatrix")

t signature(x = "lgCMatrix"): returns the transpose of x

which signature(x = "lsparseMatrix"), semantically equivalent to base function which(x, arr.ind); for details, see the lMatrix class documentation.

the class dgCMatrix

Examples

(m <- Matrix(c(0,0,2:0), 3,5, dimnames=list(LETTERS[1:3],NULL)))
(lm <- (m > 1)) # lgC
!lm  # no longer sparse
stopifnot(is(lm,"lsparseMatrix"),
          identical(!lm, m <= 1))

data(KNex)

str(mmG.1 <- (KNex $ mm) > 0.1)# "lgC..."

table(mmG.10x)# however with many "non-structural zeros"

## from logical to nz_pattern -- okay when there are no NA's :

nmG.1 <- as(mmG.1, "nMatrix") # <<< has "TRUE" also where mmG.1 had FALSE

## from logical to "double"

dmG.1 <- as(mmG.1, "dMatrix") # has '0' and back:

lmG.1 <- as(dmG.1, "lMatrix") # has no extra FALSE, i.e. drop0() included

stopifnot(identical(nmG.1, as((KNex $ mm) != 0,"nMatrix")),
          validObject(lmG.1), all(lmG.1@x),
          # same "logical" but lmG.1 has no 'FALSE' in x slot:
          all(lmG.1 == mmG.1))

class(xnx <- crossprod(nmG.1))# "nsC..."
class(xlx <- crossprod(dmG.1))# "dsC..." : numeric
is0 <- (xlx == 0)
mean(as.vector(is0))  # 99.3% zeros: quite sparse, but
table(xlx0x == 0)  # more than half of the entries are (non-structural!) 0
stopifnot(isSymmetric(xlx), isSymmetric(xnx),
  ## compare xnx and xlx: have the *same* non-structural 0s:
sapply(slotNames(xnx),
  function(n) identical(slot(xnx, n), slot(xlx, n)))

isyMatrix-class  Symmetric Dense Logical Matrices

Description

The "isyMatrix" class is the class of symmetric, dense logical matrices in non-packed storage and "ispMatrix" is the class of these in packed storage. In the packed form, only the upper triangle or the lower triangle is stored.

Objects from the Class

Objects can be created by calls of the form new("isyMatrix", ...).

Slots

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
x: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.
dim, dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), see the Matrix class.
factors: Object of class "list". A named list of factorizations that have been computed for the matrix.

Extends

Both extend classes "ldenseMatrix" and "symmetricMatrix", directly; further, class "Matrix" and others, indirectly. Use showClass("isyMatrix"), e.g., for details.

Methods

Currently, mainly t() and coercion methods (for as(.)); use, e.g., showMethods(class="dsyMatrix") for details.

See Also

lgeMatrix, Matrix, t

Examples

(M2 <- Matrix(c(TRUE, NA, FALSE, FALSE), 2, 2)) # logical dense (ltr)
str(M2)
  # can
(sM <- M2 | t(M2)) # "lge"
as(sM, "isyMatrix")
str(sM <- as(sM, "ispMatrix")) # packed symmetric
**ltrMatrix-class**

**Triangular Dense Logical Matrices**

**Description**

The "ltrMatrix" class is the class of triangular, dense, logical matrices in nonpacked storage. The "ltrpMatrix" class is the same except in packed storage.

**Slots**

- **x**: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.
- **uplo**: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- **diag**: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see triangularMatrix.
- **Dim**, **Dimnames**: The dimension (a length-2 "integer") and corresponding names (or NULL), see the Matrix class.
- **factors**: Object of class "list". A named list of factorizations that have been computed for the matrix.

**Extends**

Both extend classes "ldenseMatrix" and "triangularMatrix", directly; further, class "Matrix", "lMatrix" and others, indirectly. Use `showClass("ltrMatrix")`, e.g., for details.

**Methods**

Currently, mainly `t()` and coercion methods (for `as()``; use, e.g., `showMethods(class="ltrMatrix")` for details.

**See Also**

Classes `lgeMatrix`, `Matrix`; function `t`

**Examples**

```r
showClass("ltrMatrix")
str(new("ltrpMatrix"))
{lutr <- as(upper.tri(matrix(4,4), "ltrMatrix"))
 str(lutr <- as(lutr, "ltrpMatrix")) # packed matrix: only 10 = (4+1)*4/2 entries
 !lutr ## the logical negation (is *not* logical triangular !)
 ## but this one is:
 stopifnot(all.equal(lutr, as(!lutr, "ltrpMatrix")))
```
(Generalized) Triangular Decomposition of a Matrix

Description
Computes (generalized) triangular decompositions of square (sparse or dense) and non-square dense matrices.

Usage
```
lu(x, ...)  # S4 method for signature 'matrix'
lu(x, warnSing = TRUE, ...)  # S4 method for signature 'dgeMatrix'
lu(x, warnSing = TRUE, ...)  # S4 method for signature 'dgCMatrix'
lu(x, errSing = TRUE, order = TRUE, tol = 1, ...)
```

Arguments
- `x`: a dense or sparse matrix, in the latter case of square dimension. No missing values or IEEE special values are allowed.
- `warnSing`: (when `x` is a "denseMatrix") logical specifying if a warning should be signalled when `x` is singular.
- `errSing`: (when `x` is a "sparseMatrix") logical specifying if an error (see `stop`) should be signalled when `x` is singular. When `x` is singular, `lu(x, errSing=FALSE)` returns `NA` instead of an LU decomposition. No warning is signalled and the user should be careful in that case.
- `order`: logical or integer, used to chose which will-reducing permutation technique will be used internally. Do not change unless you know what you are doing.
- `tol`: positive number indicating the pivoting tolerance used in `cs_lu`. Do only change with much care.
- `...`: further arguments passed to or from other methods.

Details
`lu()` is a generic function with special methods for different types of matrices. Use `showMethods("lu")` to list all the methods for the `lu` generic.

The method for class `dgeMatrix` (and all dense matrices) is based on LAPACK’s "dgetrf" subroutine. It returns a decomposition also for singular and non-square matrices.

The method for class `dgCMatrix` (and all sparse matrices) is based on functions from the CSparse library. It signals an error (or returns `NA`, when `errSing = FALSE`, see above) when the decomposition algorithm fails, as when `x` is (too close to) singular.

Value
An object of class "LU", i.e., "denseLU" (see its separate help page), or "sparseLU", see `sparseLU`; this is a representation of a triangular decomposition of `x`. 
LU-class

Class definitions LU and sparseLU and function expand; qr, chol.

Examples

```r
##--- Dense ---------------------
x <- Matrix(rnorm(9), 3, 3)
lu(x)
dim(x2) <- round(10 * x[, -3])  # non-square
expand(lu2 <- lu(x2))
##--- Sparse (see more in "sparseLU-class")------ % ./sparseLU-class.Rd
pm <- as(readMM(system.file("external/pores_1.mtx",
                          package = "Matrix")),
       "CsparseMatrix")
str(pmLU <- lu(pm))  # p is a 0-based permutation of the rows
                      # q is a 0-based permutation of the columns
## permute rows and columns of original matrix
ppm <- pm[pmLU@p + 1L, pmLU@q + 1L]
pLU <- drop0(pmLU@L)  # L is upper triangular, not dropping extra zeros
## equal up to "rounding"
ppm[1:14, 1:5]
pLU[1:14, 1:5]
```

LUs-

Description

The "LU" class is the virtual class of LU decompositions of real matrices. "denseLU" the class of LU decompositions of dense real matrices.

Details

The decomposition is of the form

\[ A = PLU \]

where typically all matrices are of size \( n \times n \), and the matrix \( P \) is a permutation matrix, \( L \) is lower triangular and \( U \) is upper triangular (both of class dtrMatrix).

Note that the dense decomposition is also implemented for a \( m \times n \) matrix \( A \), when \( m \neq n \).

If \( m < n \) ("wide case"), \( U \) is \( m \times n \), and hence not triangular.

If \( m > n \) ("long case"), \( L \) is \( m \times n \), and hence not triangular.
Objects from the Class

Objects can be created by calls of the form `new("denseLU", ...)`. More commonly the objects are created explicitly from calls of the form `lu(mm)` where `mm` is an object that inherits from the "dgeMatrix" class or as a side-effect of other functions applied to "dgeMatrix" objects.

Extends

"LU" directly extends the virtual class "MatrixFactorization".

"denseLU" directly extends "LU".

Slots

- **x**: object of class "numeric". The "L" (unit lower triangular) and "U" (upper triangular) factors of the original matrix. These are stored in a packed format described in the Lapack manual, and can retrieved by the `expand()` method, see below.
- **perm**: Object of class "integer" - a vector of length `min(dim)` that describes the permutation applied to the rows of the original matrix. The contents of this vector are described in the Lapack manual.
- **Dim**: the dimension of the original matrix; inherited from class `MatrixFactorization`.

Methods

- **expand**
  
signature(x = "denseLU"): Produce the "L" and "U" (and "P") factors as a named list of matrices, see also the example below.

- **solve**
  
signature(a = "denseLU", b = "missing"): Compute the inverse of A, A⁻¹. `solve(A)` using the LU decomposition, see also `solve-methods`.

See Also

class `sparseLU` for LU decompositions of sparse matrices; further, class `dgeMatrix` and functions `lu, expand`.

Examples

```r
set.seed(1)
mm <- Matrix(round(rnorm(9),2), nrow = 3)
mm
str(lum <- lu(mm))
e lu <- expand(lum)
e lu # three components: "L", "U", and "P", the permutation
e lu$L %*% elu$U
(m2 <- with(e lu, P %*% L %*% U)) # the same as 'mm'
stopifnot(all.equal(as(mm, "matrix"),
    as(m2, "matrix")))
```
Construct a Classed Matrix

Description

Construct a Matrix of a class that inherits from Matrix.

Usage

```r
Matrix(data=NA, nrow=1, ncol=1, byrow=FALSE, dimnames=NULL,
       sparse = NULL, doDiag = TRUE, forceCheck = FALSE)
```

Arguments

data an optional numeric data vector or matrix.
nrow when data is not a matrix, the desired number of rows
ncol when data is not a matrix, the desired number of columns
byrow logical. If FALSE (the default) the matrix is filled by columns, otherwise the matrix is filled by rows.
dimnames a dimnames attribute for the matrix: a list of two character components. They are set if not NULL (as per default).
sparse logical or NULL, specifying if the result should be sparse or not. By default, it is made sparse when more than half of the entries are 0. Note that when the resulting matrix is diagonal ("mathematically"), sparse=FALSE results in a diagonalMatrix, unless doDiag=FALSE as well, see the first examples.
doDiag only when sparse = FALSE, logical indicating if a diagonalMatrix object should be considered (default). Otherwise, in such a case, a dense (symmetric) matrix will be returned.
forceCheck logical indicating if the checks for structure should even happen when data is already a "Matrix" object.

Details

If either of nrow or ncol is not given, an attempt is made to infer it from the length of data and the other parameter. Further, Matrix() makes efforts to keep logical matrices logical, i.e., inheriting from class lMatrix, and to determine specially structured matrices such as symmetric, triangular or diagonal ones. Note that a symmetric matrix also needs symmetric dimnames, e.g., by specifying dimnames = list(NULL,NULL), see the examples.

Most of the time, the function works via a traditional (full) matrix. However, Matrix(0, nrow, ncol) directly constructs an “empty” sparseMatrix, as does Matrix(FALSE, *).

Although it is sometime possible to mix unclassed matrices (created with matrix) with ones of class "Matrix", it is much safer to always use carefully constructed ones of class "Matrix".

Value

Returns matrix of a class that inherits from "Matrix". Only if data is not a matrix and does not already inherit from class Matrix are the arguments nrow, ncol and byrow made use of.
### Matrix-class

#### Description

The Matrix class is a class contained by all actual classes in the Matrix package. It is a “virtual” class.

#### Slots

Common to all matrix objects in the package:

- **Dim**: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.
- **Dimnames**: list of length two; each component containing NULL or a character vector length equal the corresponding Dim element.

---

### Examples

```r
Matrix(0, 3, 2)  # 3 by 2 matrix of zeros -> sparse
Matrix(0, 3, 2, sparse=FALSE) -> 'dense'
Matrix(0, 2, 2, sparse=FALSE) -> diagonal
Matrix(0, 2, 2, sparse=FALSE, doDiag=FALSE) -> dense
Matrix(1:6, 3, 2)  # a 3 by 2 matrix (+ integer warning)
Matrix(1:6 + 1, nrow=3)

## logical ones:
Matrix(diag(4) > 0) -> "ldiMatrix" with diag = "U"
Matrix(diag(4) > 0, sparse=TRUE) -> sparse...
Matrix(diag(4) >= 0) -> "lsyMatrix" (of all TRUE)

## triangular
13 <- upper.tri(matrix(1:3))
M <- Matrix(13)) # -> "ltCMatrix"
Matrix(! 13) -> "ltrMatrix"
as(13, "CsparseMatrix")

Matrix(1:9, nrow=3,
  dimnames = list(c("a", "b", "c"), c("A", "B", "C")))
(I3 <- Matrix(diag(3)))# identity, i.e., unit "diagonalMatrix"
str(I3) # note the empty 'x' slot

(A <- cbind(a=c(2,1), b=1:2))# symmetric *apart* from dimnames
Matrix(A)                 # hence 'dgeMatrix'
(As <- Matrix(A, dimnames = list(NULL,NULL)))# -> symmetric
stopifnot(is(As, "symmetricMatrix"),
          is(Matrix(0, 3, 3), "sparseMatrix"),
          is(Matrix(FALSE, 1,1), "sparseMatrix"))
```

---

### See Also

The classes Matrix, symmetricMatrix, triangularMatrix, and diagonalMatrix; further, matrix.

Special matrices can be constructed, e.g., via sparseMatrix (sparse), bdiag (block-diagonal), bandSparse (banded sparse), or Diagonal.
Methods

determinant signature(x = "Matrix", logarithm = "missing"): and
determinant signature(x = "Matrix", logarithm = "logical"): compute the (log) determinant of x. The method chosen depends on the actual Matrix class of x. Note that det also works for all our matrices, calling the appropriate determinant() method. The Matrix::det is an exact copy of base::det, but in the correct namespace, and hence calling the S4-aware version of determinant().

diff signature(x = "Matrix"): As diff() for traditional matrices, i.e., applying diff() to each column.

dim signature(x = "Matrix"): extract matrix dimensions dim.

dim<- signature(x = "Matrix", value = "ANY"): where value is integer of length 2. Allows to reshape Matrix objects, but only when prod(value) == prod(dim(x)).

dimnames signature(x = "Matrix"): extract dimnames.

dimnames<- signature(x = "Matrix", value = "list"): set the dimnames to a list of length 2, see dimnames<-

length signature(x = "Matrix"): simply defined as prod(dim(x)) (and hence of mode "double").

show signature(object = "Matrix"): show method for printing.

image signature(object = "Matrix"): draws an image of the matrix entries, using levelplot() from package lattice.

head signature(object = "Matrix"): return only the “head”, i.e., the first few rows.

tail signature(object = "Matrix"): return only the “tail”, i.e., the last few rows of the respective matrix.

as.matrix, as.array signature(x = "Matrix"): the same as as(x, "matrix"); see also the note below.

as.vector signature(x = "Matrix", mode = "missing"): as.vector(m) should be identical to as.vector(as(m,"matrix")), implemented more efficiently for some subclasses.

as(x, "vector"), as(x, "numeric") etc, similarly.

There are many more methods that (conceptually should) work for all "Matrix" objects, e.g., colSums, rowMeans. Even base functions may work automatically (if they first call as.matrix() on their principal argument), e.g., apply, eigen, svd or kappa all do work via coercion to a “traditional” (dense) matrix.

Note

Loading the Matrix namespace “overloads” as.matrix and as.array in the base namespace by the equivalent of function(x) as(x, "matrix"). Consequently, as.matrix(m) or as.array(m) will properly work when m inherits from the "Matrix" class — also for functions in package base and other packages. E.g., apply or outer can therefore be applied to "Matrix" matrices.

dgeMatrix, dgCMatrix, and function Matrix for construction (and examples).

Methods, e.g., for kronecker.
Examples

```r
slotNames("Matrix")

c1 <- getClass("Matrix")
names(c1@subclasses) # more than 40 ..

showClass("Matrix") #> output with slots and all subclasses

(M <- Matrix(c(0,1,0,0), 6, 4))
dim(M)
diag(M)
cm <- M[1:4,] + 10*Diagonal(4)
diff(M)
## can reshape it even :
dim(M) <- c(2, 12)
M
stopifnot(identical(M, Matrix(c(0,1,0,0), 2,12)),
  all.equal(det(cm),
    determinant(as(cm,"matrix"), log=FALSE)$modulus,
    check.attr=FALSE))
```

MatrixFactorization-class

Class "MatrixFactorization" of Matrix Factorizations

Description

The class "MatrixFactorization" is the virtual (super) class of (potentially) all matrix factorizations of matrices from package Matrix.

The class "CholeskyFactorization" is the virtual class of all Cholesky decompositions from Matrix (and trivial sub class of "MatrixFactorization").

Objects from the Class

A virtual Class: No objects may be created from it.

Slots

Dim: Object of class "integer" - the dimensions of the original matrix - must be an integer vector with exactly two non-negative values.

Methods

`dim` (x) simply returns x@dim, see above.

`expand` signature(x = "MatrixFactorization"): this has not been implemented yet for all matrix factorizations. It should return a list whose components are matrices which when multiplied return the original Matrix object.

`show` signature(object = "MatrixFactorization"): simple printing, see show.

`solve` signature(a = "MatrixFactorization", b = .): solve $Ax = b$ for $x$; see solve-methods.
**ndenseMatrix-class**

**See Also**

classes inheriting from "MatrixFactorization", such as LU, Cholesky, CHMfactor, and sparseQR.

**Examples**

```r
showClass("MatrixFactorization")
getClass("CholeskyFactorization")
```

---

**ndenseMatrix-class  Virtual Class "ndenseMatrix" of Dense Logical Matrices**

**Description**

ndenseMatrix is the virtual class of all dense logical (S4) matrices. It extends both denseMatrix and lMatrix directly.

**Slots**

- `x`: logical vector containing the entries of the matrix.
- `Dim`, `Dimnames`: see Matrix.

**Extends**

Class "nMatrix", directly. Class "denseMatrix", directly. Class "Matrix", by class "nMatrix". Class "Matrix", by class "denseMatrix".

**Methods**

```r
%*% signature(x = "nsparseMatrix", y = "ndenseMatrix"): ...
%*% signature(x = "denseMatrix", y = "nsparseMatrix"): ...
coerce signature(from = "matrix", to = "ndenseMatrix"): ...
coerce signature(from = "ndenseMatrix", to = "matrix"): ...
crossprod signature(x = "nsparseMatrix", y = "ndenseMatrix"): ...
crossprod signature(x = "ndenseMatrix", y = "nsparseMatrix"): ...
as.vector signature(x = "ndenseMatrix", mode = "missing"): ...
diag signature(x = "ndenseMatrix"): extracts the diagonal as for all matrices, see the generic diag()
which signature(x = "ndenseMatrix"). semantically equivalent to base function which(x, arr.ind); for details, see the lMatrix class documentation.
```

**See Also**

Class ngeMatrix and the other subclasses.

**Examples**

```r
showClass("ndenseMatrix")

as(diag(3) > 0, "ndenseMatrix")# -> "nge"
```
nearPD

Nearest Positive Definite Matrix

Description

Compute the nearest positive definite matrix to an approximate one, typically a correlation or variance-covariance matrix.

Usage

`nearPD(x, corr = FALSE, keepDiag = FALSE, do2eigen = TRUE, 
doSym = FALSE, doDykstra = TRUE, only.values = FALSE, 
ensureSymmetry = !isSymmetric(x), 
eig.tol = 1e-06, conv.tol = 1e-07, posd.tol = 1e-08, 
maxit = 100, conv.norm.type = "I", trace = FALSE)`

Arguments

`x` numeric $n \times n$ approximately positive definite matrix, typically an approximation to a correlation or covariance matrix. If `x` is not symmetric (and `ensureSymmetry` is not false), `symmpart(x)` is used.

`corr` logical indicating if the matrix should be a correlation matrix.

`keepDiag` logical, generalizing `corr`: if TRUE, the resulting matrix should have the same diagonal (`diag(x)`) as the input matrix.

`do2eigen` logical indicating if a `posdefify()` eigen step should be applied to the result of the Higham algorithm.

`doSym` logical indicating if `X <- (X + t(X))/2` should be done, after `X <- tcrossprod(Qd, Q)`: some doubt if this is necessary.

`doDykstra` logical indicating if Dykstra’s correction should be used; true by default. If false, the algorithm is basically the direct fixpoint iteration $Y_k = P_t(P_S(Y_{k-1}))$.

`only.values` logical; if TRUE, the result is just the vector of eigenvalues of the approximating matrix.

`ensureSymmetry` logical; by default, `symmpart(x)` is used whenever `isSymmetric(x)` is not true. The user can explicitly set this to TRUE or FALSE, saving the symmetry test. Beware however that setting it FALSE for an asymmetric input `x`, is typically nonsense!

`eig.tol` defines relative positiveness of eigenvalues compared to largest one, $\lambda_1$. Eigen values $\lambda_k$ are treated as if zero when $\lambda_k/\lambda_1 \leq \text{eig.tol}$.

`conv.tol` convergence tolerance for Higham algorithm.

`posd.tol` tolerance for enforcing positive definiteness (in the final `posdefify` step when `do2eigen` is TRUE).

`maxit` maximum number of iterations allowed.

`conv.norm.type` convergence norm type (`norm(*, type)`) used for Higham algorithm. The default is "I" (infinity), for reasons of speed (and back compatibility); using "F" is more in line with Higham’s proposal.

`trace` logical or integer specifying if convergence monitoring should be traced.
Details

This implements the algorithm of Higham (2002), and then (if do2eigen is true) forces positive definiteness using code from posdefify. The algorithm of Knol DL and ten Berge (1989) (not implemented here) is more general in (1) that it allows constraints to fix some rows (and columns) of the matrix and (2) to force the smallest eigenvalue to have a certain value.

Note that setting corr = TRUE just sets diag(.) <- 1 within the algorithm.

Higham (2002) uses Dykstra’s correction, but the version by Jens Oehlschlaegel did not use it (accidentally), and has still lead to good results; this simplification, now only via doDykstra = FALSE, was active in nearPD() upto Matrix version 0.999375-40.

Value

If only.values = TRUE, a numeric vector of eigen values of the approximating matrix; Otherwise, as by default, an S3 object of class "nearPD", basically a list with components

- mat: a matrix of class dpoMatrix, the computed positive-definite matrix.
- eigenvalues: numeric vector of eigen values of mat.
- corr: logical, just the argument corr.
- normF: the Frobenius norm \( \text{norm}(x-X, \ "F") \) of the difference between the original and the resulting matrix.
- iterations: number of iterations needed.
- converged: logical indicating if iterations converged.

Author(s)

Jens Oehlschlaegel donated a first version. Subsequent changes by the Matrix package authors.

References

See Also

A first version of this (with non-optional corr=TRUE) has been available as nearcor(); and more simple versions with a similar purpose posdefify(), both from package sfsmisc.

Examples

```r
## Higham(2002), p.334f - simple example
A <- matrix(1, 3, 3); A[1,3] <- A[3,1] <- 0
n.A <- nearPD(A, corr=TRUE, do2eigen=FALSE)
n.A[c("mat", "normF")]
stopifnot(all.equal(n.A$mat[1,2], 0.760689917),
  all.equal(n.A$normF, 0.52778033, tol=1e-9))

set.seed(27)
```
m <- matrix(round(rnorm(25),2), 5, 5)
m <- m + t(m)
diag(m) <- pmax(0, diag(m)) + 1
(m <- round(cov2cor(m), 2))

str(near.m <- nearPD(m, trace = TRUE))
round(near.m$mat, 2)
norm(m - near.m$mat) # 1.102 / 1.08

if(require("sfsmisc")) {
m2 <- posdefify(m) # a simpler approach
norm(m - m2) # 1.185, i.e., slightly "less near"
}

round(nearPD(m, only.values=TRUE), 9)

## A longer example, extended from Jens' original,
## showing the effects of some of the options:

pr <- Matrix(c(1, 0.477, 0.644, 0.478, 0.651, 0.826,
               0.477, 1, 0.516, 0.233, 0.682, 0.75,
               0.644, 0.516, 1, 0.599, 0.581, 0.742,
               0.478, 0.233, 0.599, 1, 0.741, 0.8,
               0.651, 0.682, 0.581, 0.741, 1, 0.798,
               0.826, 0.75, 0.742, 0.8, 0.798, 1),
nrow = 6, ncol = 6)

nc. <- nearPD(pr, conv.tol = 1e-7) # default
nc.$iterations # 2
nc.1 <- nearPD(pr, conv.tol = 1e-7, corr = TRUE)
nc.1$iterations # 11 / 12 (!)
str(ncr) # still 2 iterations
ncr.1 <- nearPD(pr, conv.tol = 1e-15)
ncr.1 $ iterations # 27 / 30 !

ncF <- nearPD(pr, conv.tol = 1e-15, conv.norm = "F")
stopifnot(all.equal(ncr, ncF)) # norm type does not matter at all in this example

## But indeed, the 'corr = TRUE' constraint did ensure a better solution;
## cov2cor() does not just fix it up equivalently:
norm(pr - cov2cor(ncr$mat)) # = 0.09994
norm(pr - ncr.1$mat) # = 0.08746 / 0.08805

## ngeMatrix-class

Class "ngeMatrix" of General Dense Nonzero-pattern Matrices

Description

This is the class of general dense nonzero-pattern matrices, see nMatrix.

Slots

x: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.
**nMatrix-class**

Dim, Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), see the `Matrix` class.

factors: Object of class "list". A named list of factorizations that have been computed for the matrix.

**Extends**

Class "ndenseMatrix", directly. Class "lMatrix", by class "ndenseMatrix". Class "denseMatrix", by class "ndenseMatrix". Class "Matrix", by class "ndenseMatrix". Class "matrix", by class "ndenseMatrix".

**Methods**

Currently, mainly `t()` and coercion methods (for `as()`); use, e.g., `showMethods(class="ngeMatrix")` for details.

**See Also**

Non-general logical dense matrix classes such as `ntrMatrix`, or `nsyMatrix`; sparse logical classes such as `ngCMatrix`.

**Examples**

```r
showClass("ngeMatrix")
## "lgeMatrix" is really more relevant
```

---

**nMatrix-class**  
Class "nMatrix" of Non-zero Pattern Matrices

**Description**

The `nMatrix` class is the virtual "mother" class of all non-zero pattern (or simply pattern) matrices in the `Matrix` package.

**Slots**

Common to all matrix object in the package:

- **Dim**: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

- **Dimnames**: list of length two; each component containing NULL or a character vector length equal the corresponding **Dim** element.

**Methods**

There is a bunch of coercion methods (for `as()`), e.g.,

```r
coerce signature(from = "nMatrix", to = "matrix"): ...  
coerce signature(from = "nMatrix", to = "dMatrix"): ...  
coerce signature(from = "nMatrix", to = "lMatrix"): ...
```
nnzero

The Number of Non-Zero Values of a Matrix

Description

Returns the number of non-zero values of a numeric-like \( \mathbb{R} \) object, and in particular an object \( x \) inheriting from class \texttt{Matrix}.

Usage

\[
\text{nnzero}(x, \text{na.counted} = \text{NA})
\]

Arguments

\begin{itemize}
\item \( x \): an \( \mathbb{R} \) object, typically inheriting from class \texttt{Matrix} or \texttt{numeric}.
\item \( \text{na.counted} \): a \texttt{logical} describing how \texttt{NAs} should be counted. There are three possible settings for \texttt{na.counted}:
\begin{itemize}
\item \texttt{TRUE} \texttt{NAs} are counted as non-zero (since “they are not zero”).
\item \texttt{NA} (default) the result will be \texttt{NA} if there are \texttt{NA}’s in \( x \) (since “\texttt{NA}’s are not known, i.e., \textit{may be zero}”).
\item \texttt{FALSE} \texttt{NAs} are \textit{omitted} from \( x \) before the non-zero entries are counted.
\end{itemize}
\end{itemize}
Value

the number of non zero entries in x (typically integer).

Note that for a symmetric sparse matrix S (i.e., inheriting from class symmetricMatrix), nnzero(S) is typically twice the length(S@x).

Methods

signature(x = "ANY") the default method for non-Matrix class objects, simply counts the number 0s in x, counting NA's depending on the na.counted argument, see above.

signature(x = "denseMatrix") conceptually the same as for traditional matrix objects, care has to be taken for "symmetricMatrix" objects.

signature(x = "diagonalMatrix"), and signature(x = "indMatrix") fast simple methods for these special "sparseMatrix" classes.

signature(x = "sparseMatrix") typically, the most interesting method, also carefully taking "symmetricMatrix" objects into account.

See Also

The Matrix class also has a length method; typically, length(M) is much larger than nnzero(M) for a sparse matrix M, and the latter is a better indication of the size of M.

Examples

m <- Matrix(0+1:28, nrow = 4)
(mT <- as(m, "dgTMatrix"))
nnzero(mT)
(S <- crossprod(mT))
nnzero(S)
str(S) # slots are smaller than nnzero()
stopifnot(nnzero(S) == sum(as.matrix(S) != 0))# failed earlier

data(KNex)
M <- KNex$mm
class(M)
dim(M)
length(M); stopifnot(length(M) == prod(dim(M)))
nnzero(M) # more relevant than length
## the above are also visible from
str(M)

Description

Computes a matrix norm of x, using Lapack for dense matrices. The norm can be the one norm, the infinity norm, the Frobenius norm, or the maximum modulus among elements of a matrix, as determined by the value of type.
Usage

```
norm(x, type, ...)
```

Arguments

- **x**: a real or complex matrix.
- **type**: A character indicating the type of norm desired. "0", "o" or "t" specifies the one norm, (maximum absolute column sum); "i" or "i" specifies the infinity norm (maximum absolute row sum); "f" or "f" specifies the Frobenius norm (the Euclidean norm of x treated as if it were a vector); and "m" or "m" specifies the maximum modulus of all the elements in x.

The default is "0". Only the first character of type[1] is used.

... further arguments passed to or from other methods.

Details

For dense matrices, the methods eventually call the Lapack functions dange, dansy, dantr, zange, zansy, and zantr.

Value

A numeric value of class "norm", representing the quantity chosen according to type.

References

Examples

```
x <- Hilbert(9)
norm(x, "I")
norm(x, "I")
norm(x, "f")
norm(x, "M")
```

nsparseMatrix-classes  Sparse "pattern" Matrices

Description

The nsparseMatrix class is a virtual class of sparse "pattern" matrices, i.e., binary matrices conceptually with TRUE/FALSE entries. Only the positions of the elements that are TRUE are stored. These can be stored in the "triplet" form (classes ngTMatrix, nsTMatrix, and ntTMatrix which really contain pairs, not triplets) or in compressed column-oriented form (classes ngCMatrix, nsCMatrix, and ntCMatrix) or in compressed row-oriented form (classes ngRMatrix, nsRMatrix, and ntRMatrix). The second letter in the name of these non-virtual classes indicates general, symmetric, or triangular.
Objects from the Class

Objects can be created by calls of the form `new("ngMatrix", ...)` and so on. More frequently objects are created by coercion of a numeric sparse matrix to the pattern form for use in the symbolic analysis phase of an algorithm involving sparse matrices. Such algorithms often involve two phases: a symbolic phase wherein the positions of the non-zeros in the result are determined and a numeric phase wherein the actual results are calculated. During the symbolic phase only the positions of the non-zero elements in any operands are of interest, hence numeric sparse matrices can be treated as sparse pattern matrices.

Slots

`uplo`: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. Present in the triangular and symmetric classes but not in the general class.

`diag`: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The implicit diagonal elements are not explicitly stored when `diag` is "U". Present in the triangular classes only.

`p`: Object of class "integer" of pointers, one for each column (row), to the initial (zero-based) index of elements in the column. Present in compressed column-oriented and compressed row-oriented forms only.

`i`: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.

`j`: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the column numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.

`dim`: Object of class "integer" - the dimensions of the matrix.

Methods

`coerce` signature(`from = "dgCMatrix", to = "ngCMatrix"`), and many similar ones; typically you should coerce to "nCMatrix" (or "nMatrix"). Note that coercion to a sparse pattern matrix records all the potential non-zero entries, i.e., explicit ("non-structural") zeroes are coerced to TRUE, not FALSE, see the example.

`t` signature(`x = "ngCMatrix"`): returns the transpose of `x`

`which` signature(`x = "lsCMatrix"`), semantically equivalent to `base` function `which(x, arr.ind)`: for details, see the `lMatrix` class documentation.

See Also

the class `dgCMatrix`

Examples

```r
(m <- Matrix(c(0,0,2:0), 3,5, dimnames=list(LETTERS[1:3],NULL)))
## extract the nonzero-pattern of (m) into an mMatrix'
mnm <- as(m, "nsparseMatrix")
str(nnm) # no 'x' slot
nnm <- !nm # no longer sparse
(nnm <- as(nnm, "sparseMatrix"))# lgCMatrix
## consistency check:
stopifnot(xor(as(nm, "matrix"),
```
nsyMatrix-class

Description

The "nsyMatrix" class is the class of symmetric, dense nonzero-pattern matrices in non-packed storage and "nspMatrix" is the class of of these in packed storage. Only the upper triangle or the lower triangle is stored.

Objects from the Class

Objects can be created by calls of the form new("nsyMatrix", ...).

Slots

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

x: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

dim, dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), see the Matrix class.

factors: Object of class "list". A named list of factorizations that have been computed for the matrix.

Extends

"nsyMatrix" extends class "ngeMatrix", directly, whereas "nspMatrix" extends class "ndenseMatrix", directly.

Both extend class "symmetricMatrix", directly, and class "Matrix" and others, indirectly, use showClass("nsyMatrix"), e.g., for details.

Methods

Currently, mainly t() and coercion methods (for as(.); use, e.g., showMethods(class="dsyMatrix") for details.

See Also

ngeMatrix, Matrix, t
Examples

```r
(s0 <- new("nsyMatrix"))

(M2 <- Matrix(c(TRUE, NA, FALSE, FALSE), 2, 2)) # logical dense (ltr)
(M2 <- Matrix(c(TRUE, NA, FALSE, FALSE), 2, 2)) # ltr
(M2 <- t(M2)) # ltr

class(sM <- as(sM, "nMatrix")) # -> "nge"
(sM <- as(sM, "nsyMatrix")) # -> "nsy"
str (sM <- as(sM, "nsyMatrix")) # -> "nsp": packed symmetric
```

### ntrMatrix-class

*Triangular Dense Logical Matrices*

#### Description

The "ntrMatrix" class is the class of triangular, dense, logical matrices in nonpacked storage. The "ntpMatrix" class is the same except in packed storage.

#### Slots

- **x**: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.
- **uplo**: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- **diag**: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see `triangularMatrix`.
- **Dim,Dimnames**: The dimension (a length-2 "integer") and corresponding names (or NULL), see the `Matrix` class.
- **factors**: Object of class "list". A named list of factorizations that have been computed for the matrix.

#### Extends

"ntrMatrix" extends class "ngeMatrix", directly, whereas "ntpMatrix" extends class "ndenseMatrix", directly.

Both extend Class "triangularMatrix", directly, and class "denseMatrix", "lMatrix" and others, indirectly, use `showClass("nsyMatrix")`, e.g., for details.

#### Methods

Currently, mainly `t()` and coercion methods (for `as(.)`; use, e.g., `showMethods(class="nsyMatrix")` for details.

#### See Also

Classes `ngeMatrix, Matrix`; function `t`
Examples

```r
showclass("ntrMatrix")
str(new("ntpMatrix"))
nutr <- as(upper.tri(matrix(c,4,4), "ntrMatrix"))
str(ntup <- as(nutr, "ntpMatrix"))  # packed matrix: only 10 = (4+1)*4/2 entries
!ntup  # the logical negation (is *not* logical triangular !)
## but this one is:
stopifnot(all.equal(ntup, as(!ntup, "ntpMatrix")))
```

number-class

**Class "number" of Possibly Complex Numbers**

Description

The class "number" is a virtual class, currently used for vectors of eigen values which can be "numeric" or "complex".

It is a simple class union (**setClassUnion**) of "numeric" and "complex".

Objects from the Class

Since it is a virtual Class, no objects may be created from it.

Examples

```r
showClass("number")
stopifnot(is(li, "number"), is(pi, "number"), is(1:3, "number") )
```

pMatrix-class

**Permutation matrices**

Description

The "pMatrix" class is the class of permutation matrices, stored as 1-based integer permutation vectors.

Matrix (vector) multiplication with permutation matrices is equivalent to row or column permutation, and is implemented that way in the **Matrix** package, see the ‘Details’ below.

Details

Matrix multiplication with permutation matrices is equivalent to row or column permutation. Here are the four different cases for an arbitrary matrix \( M \) and a permutation matrix \( P \) (where we assume matching dimensions):

\[
MP = M \, \%\% \, P = M[, i(p)] \\
P M = P \, \%\% \, M = M[ p, ] \\
P^T M = \text{crossprod}(P, M) (\approx t(P) \, \%\% \, M) = M[i(p), ] \\
M P^T = \text{tcrossprod}(M, P) (\approx M \, \%\% \, t(P)) = M[ , p ]
\]
where \( p \) is the “permutation vector” corresponding to the permutation matrix \( P \) (see first note), and \( i(p) \) is short for \( \text{invPerm}(p) \).

Also one could argue that these are really only two cases if you take into account that inversion (\( \text{solve} \)) and transposition (\( t \)) are the same for permutation matrices \( P \).

**Objects from the Class**

Objects can be created by calls of the form `new("pMatrix", ...)` or by coercion from an integer permutation vector, see below.

**Slots**

- **perm**: An integer, 1-based permutation vector, i.e. an integer vector of length \( \text{dim}[1] \) whose elements form a permutation of \( 1:\text{dim}[1] \).
- **Dim**: Object of class "integer". The dimensions of the matrix which must be a two-element vector of equal, non-negative integers.
- **Dimnames**: list of length two; each component containing NULL or a character vector length equal the corresponding \( \text{dim} \) element.

**Extends**

Class "\text{indMatrix}\), directly.

**Methods**

- `%*%` signature(\( x = "\text{matrix}" \), \( y = "\text{pMatrix}" \)) and other signatures (use `showMethods("%*%", class="pMatrix")`): ...

- **coerce** signature(from = "integer", to = "\text{pMatrix}\): This enables typical "\text{pMatrix}\” construction, given a permutation vector of \( 1:n \), see the first example.

- **coerce** signature(from = "numeric", to = "\text{pMatrix}\): a user convenience, to allow \( \text{as}(\text{perm}, "\text{pMatrix}\”) \) for numeric \( \text{perm} \) with integer values.

- **coerce** signature(from = "\text{pMatrix}\”, to = "\text{matrix}\): coercion to a traditional FALSE/TRUE matrix of mode logical. (in earlier version of \text{Matrix}, it resulted in a 0/1-integer matrix; logical makes slightly more sense, corresponding better to the “natural” sparse\text{Matrix} counterpart, "\text{ngTMatrix}\”.)

- **coerce** signature(from = "\text{pMatrix}\”, to = "\text{ngTMatrix}\): coercion to sparse logical matrix of class \text{ngTMatrix}.

- **determinant** signature(\( x = "\text{pMatrix}\”, \text{logarithm}="\text{logical}\”\)): Since permutation matrices are orthogonal, the determinant must be +1 or -1. In fact, it is exactly the sign of the permutation.

- **solve** signature(\( a = "\text{pMatrix}\”, b = "\text{missing}\”\): return the inverse permutation matrix; note that \( \text{solve}(P) \) is identical to \( t(P) \) for permutation matrices. See \text{solve-methods} for other methods.

- **t** signature(\( x = "\text{pMatrix}\”\): return the transpose of the permutation matrix (which is also the inverse of the permutation matrix).
Note

For every permutation matrix \( P \), there is a corresponding permutation vector \( p \) (of indices, 1:n), and these are related by

\[
P \leftarrow \text{as}(p, "pMatrix")
p \leftarrow P@perm
\]

see also the ‘Examples’.

“Row-indexing” a permutation matrix typically returns an “indMatrix”. See “indMatrix” for all other subsetting/indexing and subassignment (A[..] <- v) operations.

See Also

\texttt{invPerm}(p) computes the inverse permutation of an integer (index) vector \( p \).

Examples

\[
(pm1 \leftarrow \text{as}(\text{as.integer(c(2,3,1)), "pMatrix"}))
t(pm1) \# is the same as
\text{solve}(pm1)
\]

\[
m1 \%*% t(m1) \# check that the transpose is the inverse
\text{stopifnot}(\text{all(diag(3) == as(m1 %*% t(m1), "matrix")),}
is.logical(as(m1, "matrix")))
\]

set.seed(1)
## random permutation matrix :
(p10 \leftarrow \text{as}(\text{sample(10),"pMatrix"}))

## Permute rows / columns of a numeric matrix :
(mm \leftarrow \text{round}(\text{array(rnorm(3 * 3), c(3, 3), 2))}
m1 \%*% mm
\text{try(as(as.integer(c(3,3,1)), "pMatrix"))) # Error: not a permutation}

\text{as}(m1, "ngTMMatrix")
p10[1:7, 1:4] \# gives an "ngTMMatrix" (most economic!)

## row-indexing of a <pMatrix> keeps it as an <indMatrix>:
p10[1:3, ]

printSpMatrix

Format and Print Sparse Matrices Flexibly

Description

Format and print sparse matrices flexibly. These are the “workhorses” used by the \texttt{format}, \texttt{show} and \texttt{print} methods for sparse matrices. If \( x \) is large, \texttt{printSpMatrix}(\( x \)) calls \texttt{printSpMatrix}() twice, namely, for the first and the last few rows, suppressing those in between, and also suppresses columns when \( x \) is too wide.

\texttt{printSpMatrix}() basically prints the result of \texttt{formatSpMatrix}().
printSpMatrix

Usage

formatSpMatrix(x, digits = NULL, maxp = 1e9,
  cld = getClassDef(class(x)), zero.print = ".",
  col.names, note.dropping.colnames = TRUE,
  align = c("fancy", "right"))

printSpMatrix(x, digits = NULL, maxp = OPTION("max.print"),
  cld = getClassDef(class(x)),
  zero.print = ".", col.names, note.dropping.colnames = TRUE,
  col.trailer = "",
  align = c("fancy", "right"))

printSpMatrix2(x, digits = NULL, maxp = OPTION("max.print"),
  zero.print = ".", col.names, note.dropping.colnames = TRUE,
  suppRows = NULL, suppCols = NULL,
  col.trailer = if(suppCols) "......." else ",",
  align = c("fancy", "right"))

Arguments

x 
an R object inheriting from class sparseMatrix.

digits 
significant digits to use for printing, see print.default, the default, NULL, corresponds to using getOption("digits").

maxp 
integer, default from options(max.print), influences how many entries of large matrices are printed at all.

cld 
the class definition of x; must be equivalent to getClassDef(class(x)) and exists mainly for possible speedup.

zero.print 
character which should be printed for structural zeroes. The default "." may occasionally be replaced by " " (blank); using "0" would look almost like print()ing of non-sparse matrices.

col.names 
logical or string specifying if and how column names of x should be printed, possibly abbreviated. The default is taken from options("sparse.colnames") if that is set, otherwise FALSE unless there are less than ten columns. When TRUE the full column names are printed.

When col.names is a string beginning with "abb" or "sub" and ending with an integer n (i.e., of the form "abb... <n>"), the column names are abbreviate()d or substring()ed to (target) length n, see the examples.

note.dropping.colnames 
logical specifying, when col.names is FALSE if the dropping of the column names should be noted, TRUE by default.

col.trailer 
a string to be appended to the right of each column; this is typically made use of by show(<sparseMatrix>) only, when suppressing columns.

suppRows, suppCols 
logicals or NULL, for printSpMatrix2() specifying if rows or columns should be suppressed in printing. If NULL, sensible defaults are determined from dim(x) and options(c("width", "max.print"). Setting both to FALSE may be a very bad idea.

align 
a string specifying how the zero.print codes should be aligned, i.e., padded as strings. The default, "fancy", takes some effort to align the typical zero.print = "." with the position of 0, i.e., the first decimal (one left of
decimal point) of the numbers printed, whereas align = "right" just makes
use of `print(*, right = TRUE)`.

Details

**formatSpMatrix**: If `x` is large, only the first rows making up the approximately first `maxp` entries
is used, otherwise all of `x`. `.formatSparseSimple()` is applied to (a dense version of) the
matrix. Then, `formatSpMatrix` is used, unless in trivial cases or for sparse matrices without `x`
slot.

Value

`formatSpMatrix()`

returns a character matrix with possibly empty column names, depending on
col.names etc, see above.

`printSpMatrix()`

return `x` invisibly, see `invisible`.

Author(s)

Martin Maechler

See Also

the virtual class `sparseMatrix` and the classes extending it; maybe `sparseMatrix` or `spMatrix` as
simple constructors of such matrices.

The underlying utilities `formatSparseM` and `.formatSparseSimple()` (on the same page).

Examples

```r
f1 <- gl(5, 3, labels = LETTERS[1:5])
X <- as(f1, "sparseMatrix")
X ## ==> show(X) ==> print(X)
t(X) ## shows column names, since only 5 columns

X2 <- as(gl(12, 3, labels = paste(LETTERS[1:12],"c",sep=".")),
   "sparseMatrix")
X2
## less nice, but possible:
print(X2, col.names = TRUE) # use [,1] [,2] .. => does not fit

t(X2) # suppressing column names
print(t(X2), col.names=TRUE)
print(t(X2), zero.print = ",", col.names="abbr. 1")
print(t(X2), zero.print = "-", col.names="substring 2")
```
Description

The "Matrix" package provides methods for the QR decomposition of special classes of matrices. There is a generic function which uses qr as default, but methods defined in this package can take extra arguments. In particular there is an option for determining a fill-reducing permutation of the columns of a sparse, rectangular matrix.

Usage

qr(x, ...)  
qrR(qr, complete=FALSE, backPermute=TRUE)

Arguments

x  
a numeric or complex matrix whose QR decomposition is to be computed. Logical matrices are coerced to numeric.

qr  
a QR decomposition of the type computed by qr.

complete  
logical indicating whether the R matrix is to be completed by binding zero-value rows beneath the square upper triangle.

backPermute  
logical indicating if the rows of the R matrix should be back permuted such that qrR()’s result can be used directly to reconstruct the original matrix X.

...  
further arguments passed to or from other methods

Methods

x = "dgCMatrix"  
QR decomposition of a general sparse double-precision matrix with nrow(x) ≥ ncol(x). Returns an object of class "sparseQR".

x = "sparseMatrix"  
works via "dgCMatrix".

See Also

qr; then, the class documentations, mainly sparseQR, and also dgCMatrix.

Examples

### example of pivoting -- from base’ qraux.Rd  
X <- Matrix(cbind(int = 1,  
b1=rep(1:0, each=3), b2=rep(0:1, each=3),  
c1=rep(c(1,0,0), 2), c2=rep(c(0,1,0), 2), c3=rep(c(0,0,1),2)),  
sparse=TRUE)  
X  
# is singular, columns "b2" and "c3" are "extra"  
(qx <- qr(X))  
# both @p and @q are non-trivial permutations  
drop0(R. <- qr.R(qx), tol=1e-15)  
# columns are int b1 c1 c2 b2 c3  
Q. <- qr.Q(qx)  
qI < - sort.list(qx@q)  
# the inverse 'q' permutation  
(X. <- drop0(Q. %*% R.[, qI], tol=1e-15))## just = X
Description

Compute ‘the’ matrix rank, a well-defined functional in theory, somewhat ambiguous in practice. We provide several methods, the default corresponding to Matlab’s definition.

Usage

```r
rankMatrix(x, tol = NULL, meth = c("tolNorm2", "qrLINPACK", "useGrad", "maybeGrad"), sval = svd(x, 0, 0)$d, warn.t = TRUE)
```

Arguments

- `x` numeric matrix, of dimension `n × m`, say.
- `tol` nonnegative number specifying a tolerance for “practically zero” with specific meaning depending on method; by default, `max(dim(x)) * .Machine$double.eps * abs(max(sval))` is according to Matlab’s default (for its only method “tolNorm2”).
- `meth` a character string specifying the computational method, can be abbreviated:
  - `tolNorm2` the number of singular values >= `tol`;
  - `qrLINPACK` this is the rank of `qr(x, tol, LAPACK=FALSE)`, which is `qr(...)$rank` for a dense matrix, and the rank of `R` for sparse `x` (where `qr` uses a “sparseQR” method, see `qr-methods`, and not LINPACK). This used to be the recommended way to compute a matrix rank for a while in the past. For this method, `sval` are not used (nor computed), which may be crucially important for a large sparse matrix `x`.
  - `useGrad` considering the “gradient” of the (decreasing) singular values, the index of the smallest gap.
  - `maybeGrad` choosing method "useGrad" only when that seems reasonable; otherwise using "tolNorm2".
- `sval` numeric vector of non-increasing singular values of `x`; typically unspecified and computed from `x` when needed, i.e., unless `meth = "qrLINPACK"`.
- `warn.t` logical indicating if `rankMatrix()` should warn when it needs `t(x)` instead of `x`. Currently, for `meth = "qrLINPACK"` only.

Value

positive integer in `1:dim(x)`, with attributes detailing the method used.

Note

For large sparse matrices `x`, unless you can specify `sval` yourself, currently `meth = "qrLINPACK"` may be the only feasible one, as the others need `sval` and call `svd()` which currently coerces `x` to a `denseMatrix` which may be very slow or impossible, depending on the matrix dimensions.
Estimate the Reciprocal Condition Number

Description

Estimate the reciprocal of the condition number of a matrix.

This is a generic function with several methods, as seen by `showMethods(rcond)`. 

Usage

```r
rcond(x, norm, ...) 
``` 

## S4 method for signature 'sparseMatrix,character'
```r
rcond(x, norm, useInv=FALSE, ...) 
```
Arguments

- **x**: an R object that inherits from the `Matrix` class.
- **norm**: Character indicating the type of norm to be used in the estimate. The default is "0" for the 1-norm ("0" is equivalent to "1"). The other possible value is "1" for the infinity norm, see also `norm`.
- **useInv**: logical (or `matrix` containing `solve(x)`). If not false, compute the reciprocal condition number as $1/(\|x\| \cdot \|x^{-1}\|)$, where $x^{-1}$ is the inverse of $x$, `solve(x)`. This may be an efficient alternative (only) in situations where `solve(x)` is fast (or known), e.g., for (very) sparse or triangular matrices.
  
  Note that the result may differ depending on `useInv`, as per default, when it is false, an approximation is computed.

  ... further arguments passed to or from other methods.

Value

An estimate of the reciprocal condition number of $x$.

BACKGROUND

The condition number of a regular (square) matrix is the product of the `norm` of the matrix and the norm of its inverse (or pseudo-inverse).

More generally, the condition number is defined (also for non-square matrices $A$) as

$$\kappa(A) = \frac{\max_{\|v\|=1} \|Av\|}{\min_{\|v\|=1} \|Av\|}.$$ 

Whenever $x$ is not a square matrix, in our method definitions, this is typically computed via `rcond(qr.R(qr(X)), ...,)` where $X$ is $x$ or $t(x)$.

The condition number takes on values between 1 and infinity, inclusive, and can be viewed as a factor by which errors in solving linear systems with this matrix as coefficient matrix could be magnified.

`rcond()` computes the *reciprocal* condition number $1/\kappa$ with values in $[0, 1]$ and can be viewed as a scaled measure of how close a matrix is to being rank deficient (aka "singular").

Condition numbers are usually estimated, since exact computation is costly in terms of floating-point operations. An (over) estimate of reciprocal condition number is given, since by doing so overflow is avoided. Matrices are well-conditioned if the reciprocal condition number is near 1 and ill-conditioned if it is near zero.

References

See Also

`norm`, `kappa()` from package `base` computes an *approximate* condition number of a “traditional” matrix, even non-square ones, with respect to the $p = 2$ (Euclidean) `norm`. `solve`.

`condest`, a newer approximate estimate of the (1-norm) condition number, particularly efficient for large sparse matrices.
Examples

```r
x <- Matrix(rnorm(9), 3, 3)
rcond(x)
## typically "the same" (with more computational effort):
1 / (norm(x) * norm(solve(x)))
rcond(Hilbert(9))  # should be about 9.1e-13

## For non-square matrices:
rcond(x1 <- cbind(1:1:10)) 0.05278
rcond(x2 <- cbind(x1, 2:11))# practically 0, since x2 does not have full rank

## sparse
(S1 <- Matrix(rbind(0:1, 0, diag(3:-2))))
rcond(S1)
m1 <- as(S1, "denseMatrix")
all.equal(rcond(S1), rcond(m1))

## wide and sparse
rcond(Matrix(cbind(0, diag(2:-1))))

## Large sparse example -----------
m <- Matrix(c(3,0,2), 2,2)
M <- bdiag(kronecker(Diagonal(2), m), kronecker(m,m))
36*(IM <- solve(M)) # still sparse
MM <- kronecker(Diagonal(10), kronecker(Diagonal(5),kronecker(m,M)))
dim(M3 <- kronecker(bdiag(M,M),MM)) # 12^800 ^ 2
if(interactive()) ## takes about 2 seconds
  system.time(r <- rcond(M3))
## whereas this is *fast* even though it computes solve(M3)
system.time(r. <- rcond(M3, useInv=TRUE))
if(interactive()) ## the values are not the same
c(r, r.)  # 0.05555 0.013888
```

---

**rep2abI**

Replicate Vectors into 'abIndex' Result

**Description**

rep2abI(x, times) conceptually computes rep.int(x, times) but with an abIndex class result.

**Usage**

rep2abI(x, times)

**Arguments**

- `x` numeric vector
- `times` integer (valued) scalar: the number of repetitions

**Value**

a vector of class abIndex
See Also

rep.int(), the base function; abIseq, abIndex.

Examples

(ab <- rep2ab1(2:7, 4))
stopifnot(identical(as(ab, "numeric"),
rep(2:7, 4)))

replValue-class Virtual Class "replValue" - Simple Class for subassignment Values

Description

The class "replValue" is a virtual class used for values in signatures for sub-assignment of "Matrix" matrices.
In fact, it is a simple class union (setClassUnion) of "numeric" and "logical" (and maybe "complex" in the future).

Objects from the Class

Since it is a virtual Class, no objects may be created from it.

See Also

Subassign-methods, also for examples.

Examples

showClass("replValue")

rleDiff-class Class "rleDiff" of rle(diff(.)) Stored Vectors

Description

Class "rleDiff" is for compactly storing long vectors which mainly consist of linear stretches. For such a vector x, diff(x) consists of constant stretches and is hence well compressable via rle().

Objects from the Class

Objects can be created by calls of the form new("rleDiff", ...).
Currently experimental, see below.

Slots

first: A single number (of class "numLike", a class union of "numeric" and "logical").
rle: Object of class "rle", basically a list with components "lengths" and "values". see rle(). As this is used to encode potentially huge index vectors, lengths may be of type double here.
Methods

There is a simple `show` method only.

Note

This is currently an *experimental* auxiliary class for the class `abIndex`, see there.

See Also

`rle`, `abIndex`.

Examples

```r
showClass("rleDiff")
ab <- c(abIs(2, 100), abIs(20, -2))
ab@rleD  # is "rleDiff"
```

Description

The "RsparseMatrix" class is the virtual class of all sparse matrices coded in sorted compressed row-oriented form. Since it is a virtual class, no objects may be created from it. See `showClass("RsparseMatrix")` for its subclasses.

Slots

- `j`: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.
- `p`: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.

`Dim, Dimnames`: inherited from the superclass, see `sparseMatrix`.

Extends

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

Methods

Only few methods are defined currently on purpose, since we rather use the `CsparseMatrix` in `Matrix`. Recently, more methods were added but *beware* that these typically do *not* return "RsparseMatrix" results, but rather `Csparse*` or `Tsparse*` ones.

```r
t signature(x = "RsparseMatrix")
coerce signature(from = "RsparseMatrix", to = "CsparseMatrix")
coerce signature(from = "RsparseMatrix", to = "TsparseMatrix")
```
See Also

its superclass, `sparseMatrix`, and, e.g., class `dgRMatrix` for the links to other classes.

Examples

```r
showClass("RsparseMatrix")
```

---

**Schur Decomposition of a Matrix**

**Description**

Computes the Schur decomposition and eigenvalues of a square matrix; see the BACKGROUND information below.

**Usage**

```r
Schur(x, vectors, ...)
```

**Arguments**

- `x` numeric square Matrix (inheriting from class "Matrix") or traditional `matrix`. Missing values (NAs) are not allowed.
- `vectors` logical. When TRUE (the default), the Schur vectors are computed, and the result is a proper `MatrixFactorization` of class `Schur`.
- `...` further arguments passed to or from other methods.

**Details**

Based on the Lapack subroutine `dgees`.

**Value**

If `vectors` are TRUE, as per default: If `x` is a `Matrix` an object of class `Schur`, otherwise, for a traditional `matrix` `x`, a `list` with components `T, Q, and EVValues`.

If `vectors` are FALSE, a `list` with components

- `T` the upper quasi-triangular (square) matrix of the Schur decomposition.
- `EVValues` the vector of numeric or complex eigen values of `T` or `A`.

**BACKGROUND**

If `A` is a square matrix, then `A = Q · T · Q^T`, where `Q` is orthogonal, and `T` is upper block-triangular (nearly triangular with either 1 by 1 or 2 by 2 blocks on the diagonal) where the 2 by 2 blocks correspond to (non-real) complex eigenvalues. The eigenvalues of `A` are the same as those of `T`, which are easy to compute. The Schur form is used most often for computing non-symmetric eigenvalue decompositions, and for computing functions of matrices such as matrix exponentials.

**References**

Examples
Schur(Hilbert(9))  # Schur factorization (real eigenvalues)

(A <- Matrix(round(rnorm(5*5, sd = 100)), nrow = 5))
(Sch.A <- Schur(A))

eTA <- eigen(Sch.A@T)
str(SchA <- Schur(A, vectors=FALSE))# no 'T' ==> simple list
stopifnot(all.equal(eTA$values, eigen(A)$values, tol = 1e-13),
  all.equal(eTA$values,
    local((z <- Sch.A@EValues
      z[order(Mod(z), decreasing=TRUE)]), tol = 1e-13),
    identical(SchA$T, Sch.A@T),
    identical(SchA@EValues, Sch.A@EValues))

## For the faint of heart, we provide Schur() also for traditional matrices:

a.m <- function(M) unname(as(M, "matrix"))
a <- a.m(A)
Sch.a <- Schur(a)
stopifnot(identical(Sch.a, list(Q = a.m(Sch.A @ Q),
  T = a.m(Sch.A @ T),
  EValues = Sch.A@EValues)),
  all.equal(a, with(Sch.a, a %*% T %*% t(Q))))

---

Schur-class

Class "Schur" of Schur Matrix Factorizations

Description
Class "Schur" is the class of Schur matrix factorizations. These are a generalization of eigenvalue (or "spectral") decompositions for general (possibly asymmetric) square matrices, see the Schur() function.

Objects from the Class
Objects of class "Schur" are typically created by Schur().

Slots
"Schur" has slots
T: Upper Block-triangular Matrix object.
Q: Square orthogonal "Matrix".
EValues: numeric or complex vector of eigenvalues of T.
Dim: the matrix dimension: equal to c(n,n) of class "integer".

Extends
Class "MatrixFactorization", directly.
Methods for function `solve` to solve a linear system of equations, or equivalently, solve for \( X \) in

\[
AX = B
\]

where \( A \) is a square matrix, and \( X, B \) are matrices or vectors (which are treated as 1-column matrices), and the \( R \) syntax is

\[
X \leftarrow \text{solve}(A, B)
\]

In `solve(a,b)` in the \texttt{Matrix} package, \( a \) may also be a \texttt{MatrixFactorization} instead of directly a matrix.

### Usage

```r
## S4 method for signature 'CHMfactor,ddenseMatrix'
solve(a, b, 
    system = c("A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P", "Pt"), ...)
```

```r
## S4 method for signature 'dgCMatrix, matrix'
solve(a, b, sparse = FALSE, tol = .Machine$double.eps, ...)
```

```r
solve(a, b, ...) # the* two-argument version, almost always preferred to
# solve(a)        # the *rarely* needed one-argument version
```

### Arguments

- \( a \) : a square numeric matrix, \( A \), typically of one of the classes in \texttt{Matrix}. Logical matrices are coerced to corresponding numeric ones.

- \( b \) : numeric vector or matrix (dense or sparse) as RHS of the linear system \( Ax = b \).

- \( \text{system} \) : only if \( a \) is a \texttt{CHMfactor}: character string indicating the kind of linear system to be solved, see below. Note that the default, "A", does not solve the triangular system (but "L" does).
sparse: only when `a` is a `sparseMatrix`, i.e., typically a `dgCMatrix`: logical specifying if the result should be a (formally) sparse matrix.

tol: only used when `a` is sparse, in the `isSymmetric(a, tol=+)` test, where that applies.

... potentially further arguments to the methods.

Methods

signature(a = "ANY", b = "ANY") is simply the `base` package’s S3 generic `solve`.

signature(a = "CHMfactor", b = "...."), `system` * The `solve` methods for a "CHMfactor" object take an optional third argument `system` whose value can be one of the character strings "A", "DLt", "LD", "DLt", "L", "Lt", "D", "P" or "Pt". This argument describes the system to be solved. The default, "A", is to solve `Ax = b` for `x` where `A` is sparse, positive-definite matrix that was factored to produce `a`. Analogously, `system = "L"` returns the solution `x` of `Lx = b`; similarly, for all system codes but "P" and "Pt" where, e.g., `x <- solve(a, b, system="P")` is equivalent to `x <- P %*% b`.

If `b` is a `sparseMatrix`, `system` is used as above the corresponding sparse CHOLMOD algorithm is called.

signature(a = "ddenseMatrix", b = "....") (for all b) work via as(a, "dgeMatrix"), using the its methods, see below.

signature(a = "denseLU", b = "missing") basically computes uses triangular forward- and back-solve.

signature(a = "dgCMatrix", b = "matrix") , and

signature(a = "ddenseMatrix", b = "ddenseMatrix") with extra argument list ( `sparse = FALSE`, `tol = .Machine$double.eps` ) : Uses the sparse `lu(a)` decomposition (which is cached in `a`’s factor slot). By default, `sparse=FALSE`, returns a `denseMatrix`, since `U^{-1} L^{-1} B` may not be sparse at all, even when `L` and `U` are.

If `sparse=TRUE`, returns a `sparseMatrix` (which may not be very sparse at all, even if `a` was sparse).

signature(a = "dgCMatrix", b = "dsparseMatrix") , and

signature(a = "dgCMatrix", b = "missing") with extra argument list ( `sparse=FALSE`, `tol = .Machine$double.eps` ) : Checks if `a` is symmetric, and in that case, coerces it to "symmetricMatrix", and then computes a `sparse` solution via sparse Cholesky factorization, independently of the sparse argument. If `a` is not symmetric, the sparse `lu` decomposition is used and the result will be sparse or dense, depending on the `sparse` argument, exactly as for the above (b = "ddenseMatrix") case.

signature(a = "dgeMatrix", b = "....") solve the system via internal LU, calling LAPACK routines `dgetri` or `dgetrs`.

signature(a = "diagonalMatrix", b = "matrix") and other bs: Of course this is trivially implemented, as `D^{-1}` is diagonal with entries `1/D[i,i]`.

signature(a = "dpoMatrix", b = "....Matrix") , and

signature(a = "dppMatrix", b = "....Matrix") The Cholesky decomposition of `a` is calculated (if needed) while solving the system.

signature(a = "dsCMatrix", b = "....") All these methods first try Cholmod’s Cholesky factorization; if that works, i.e., typically if `a` is positive semi-definite, it is made use of. Otherwise, the sparse LU decomposition is used as for the “general” matrices of class "dgCMatrix".

signature(a = "dspMatrix", b = "....") , and
signature(a = "dsyMatrix", b = ". . .") all end up calling LAPACK routines dsptri, dsytrs, dsytrs and dsytri.

signature(a = "dTCMatrix", b = "CsparseMatrix"),

signature(a = "dTCMatrix", b = "dgeMatrix") , etc sparse triangular solve, in traditional S/R also known as backsolve, or forwardsolve. solve(a,b) is a sparseMatrix if b is, and hence a denseMatrix otherwise.

signature(a = "dtrMatrix", b = "ddenseMatrix") , and

signature(a = "dtpMatrix", b = "matrix") , and similar b, including "missing", and "diagonalMatrix":

all use LAPACK based versions of efficient triangular backsolve, or forwardsolve.

signature(a = "Matrix", b = "diagonalMatrix") works via as(b, "CsparseMatrix").

signature(a = "sparseQR", b = "ANY") simply uses qr.coef(a, b).

signature(a = "pMatrix", b = ". . .") these methods typically use crossprod(a,b), as the inverse of a permutation matrix is the same as its transpose.

signature(a = "TsparseMatrix", b = "ANY") all work via as(a, "CsparseMatrix").

See Also

solve, lu, and class documentations CHMfactor, sparseLU, and MatrixFactorization.

Examples

### A close to symmetric example with "quite sparse" inverse:

n1 <- 7; n2 <- 3
dd <- data.frame(a = gl(n1,n2), b = gl(n2,1,n1*n2)) balanced 2-way
X <- sparse.model.matrix(~ -1 + a + b, dd)# no intercept --> even sparser
XXt <- tcrossprod(X)
diag(XXt) <- rep(c(0,0,1,1), length.out = nrow(XXt))

n <- nrow(ZZ <- kronecker(XXt, Diagonal(x=c(4,1))))
image(a <- 2*Diagonal(n) + ZZ %*% Diagonal(x=c(10, rep(1, n-1))))
issymmetric(a) # FALSE
image(drop0(skewpart(a)))
image(iA0 <- solve(a)) # checker board, dense [but really, a is singular!] try(solve(a, sparse=TRUE))##-> error [ TODO: assertError ]

ia. <- solve(a, sparse=TRUE, tol = 1e-19)##-> *no* error stopifnot(all.equal(as.matrix(ia.), as.matrix(iA0)))
a <- a + Diagonal(n)
iad <- solve(a)

ias <- solve(a, sparse=TRUE)
I. <- iad %*% a ; image(I.)
I0 <- drop0(zapsmall(I.)); image(I0)
stopifnot( all.equal(as(I0,"diagonalMatrix"), Diagonal(n)) )

Construct Sparse Design / Model Matrices

Description

Construct a Model or “Design” Matrix
Usage

```r
sparse.model.matrix(object, data = environment(object),
    contrasts.arg = NULL, xlev = NULL, transpose = FALSE,
    drop.unused.levels = FALSE, row.names = TRUE,
    verbose = FALSE, ...)```

Arguments

- **object**: an object of an appropriate class. For the default method, a model formula or terms object.
- **data**: a data frame created with `model.frame`. If another sort of object, `model.frame` is called first.
- **contrasts.arg**: A list, whose entries are contrasts suitable for input to the `contrasts` replacement function and whose names are the names of columns of data containing factors.
- **xlev**: to be used as argument of `model.frame` if data has no "terms" attribute.
- **transpose**: logical indicating if the transpose should be returned; if the transposed is used anyway, setting transpose = TRUE is more efficient.
- **drop.unused.levels**: should factors have unused levels dropped? (This used to be true, implicitly in versions of `Matrix` up to July 2010; the default has been changed for compatibility with R's standard (dense) `model.matrix`.)
- **row.names**: logical indicating if row names should be used.
- **verbose**: logical or integer indicating if (and how much) progress output should be printed.
- **...**: further arguments passed to or from other methods.

Value

a sparse matrix extending `CsparseMatrix`.

Note that `model.Matrix(*, sparse=TRUE)` from package `MatrixModels` may be often be preferable to `sparse.model.matrix()` nowadays, as `model.Matrix()` returns `modelMatrix` objects with additional slots `assign` and `contrasts` which relate back to the variables used.

Author(s)

Doug Bates and Martin Maechler, with initial suggestions from Tim Hesterberg.

See Also

- `model.matrix` in standard R's package `stats`.
- `model.Matrix` which calls `sparse.model.matrix` or `model.matrix` depending on its sparse argument may be preferred to `sparse.model.matrix`.
- `as(f, "sparseMatrix")` (see `coerce(from = "factor", ..)`) in the class doc `sparseMatrix` produces the transposed sparse model matrix for a single factor f (and no contrasts).
Examples

dd <- data.frame(a = gl(3,4), b = gl(4,1,12))# balanced 2-way options("contrasts") # the default: "contr.treatment" sparse.model.matrix(~ a + b, dd) sparse.model.matrix(~ -1+ a + b, dd)# no intercept --> even sparser sparse.model.matrix(~ a + b, dd, contrasts = list(a="contr.sum")) sparse.model.matrix(~ a + b, dd, contrasts = list(b="contr.SAS"))

## Sparse method is equivalent to the traditional one :
stopifnot(all(sparse.model.matrix(~ a + b, dd) ==
    Matrix(model.matrix(~ a + b, dd), sparse=TRUE)),
    all(sparse.model.matrix(~ 0+ a + b, dd) ==
    Matrix(model.matrix(~ 0+ a + b, dd), sparse=TRUE)))

---

**sparseLU-class**  
Sparse LU decomposition of a square sparse matrix

Description

Objects of this class contain the components of the LU decomposition of a sparse square matrix.

Objects from the Class

Objects can be created by calls of the form `new("sparseLU", ...)` but are more commonly created by function `lu()` applied to a sparse matrix, such as a matrix of class `dgCMatrix`.

Slots

- `L`: Object of class "dtCMatrix", the lower triangular factor from the left.
- `U`: Object of class "dtCMatrix", the upper triangular factor from the right.
- `p`: Object of class "integer", permutation applied from the left.
- `q`: Object of class "integer", permutation applied from the right.
- `Dim`: the dimension of the original matrix; inherited from class `MatrixFactorization`.

Extends

Class "LU", directly. Class "MatrixFactorization", by class "LU".

Methods

- **expand**  
  `signature(x = "sparseLU")` Returns a list with components `P`, `L`, `U`, and `Q`, where `P` and `Q` represent fill-reducing permutations, and `L`, and `U` the lower and upper triangular matrices of the decomposition. The original matrix corresponds to the product `PLUQ`.

Note

The decomposition is of the form

\[ A = P'LUQ, \]

or equivalently \( PAQ' = LU \), where all matrices are sparse and of size \( n \times n \). The matrices \( P \) and \( Q \), and their transposes \( P' \) and \( Q' \) are permutation matrices, \( L \) is lower triangular and \( U \) is upper triangular.
See Also

lu, solve, dgCMatrix

Examples

```r
## Extending the one in examples(lu), calling the matrix A, 
## and confirming the factorization identities:
A <- as(readMM(system.file("external/pores_1.mtx", 
  package = "Matrix")), 
  "CsparseMatrix")
str(luA <- lu(A)) # p is a 0-based permutation of the rows
# q is a 0-based permutation of the columns
xA <- expand(luA)
## which is simply doing
stopifnot(identical(xA$L, luA$L), 
  identical(xA$U, luA$U), 
  identical(xA$P, as(luA$p +1L, "pMatrix")), 
  identical(xA$Q, as(luA$q +1L, "pMatrix")))

P.LUQ <- with(xA, t(P) %%% L %%% %*% U %%% Q)
stopifnot(all.equal(A, P.LUQ, tol = 1e-12))
## permute rows and columns of original matrix
pa <- A[luA$p +1L, luA$q +1L]
stopifnot(identical(pa, with(xA, P %%% A %%% t(Q))))

plU <- drop@((luA$L %%% luA$U) # L %%% U -- dropping extra zeros
  stopifnot(all.equal(pa, plU)))
```

---

**Description**

Methods for coercion from and to sparse matrices from package **SparseM** are provided here, for ease of porting functionality to the **Matrix** package, and comparing functionality of the two packages.

**Methods**

```r
from = "matrix.csr", to = "dgRMatrix" ...
from = "matrix.csc", to = "dgCMatrix" ...
from = "matrix.coo", to = "dgTMatrix" ...
from = "dgRMatrix", to = "matrix.csr" ...
from = "dgCMatrix", to = "matrix.csc" ...
from = "dgTMatrix", to = "matrix.coo" ...
from = "sparseMatrix", to = "matrix.csr" ...
from = "matrix.csr", to = "dgCMatrix" ...
from = "matrix.csc", to = "Matrix" ...
from = "matrix.coo", to = "Matrix" ...
```

The documentation in package SparseM, such as SparseM.ontology, and one important class, matrix.csr.

sparseMatrix  General Sparse Matrix Construction from Nonzero Entries

Description

User friendly construction of a compressed, column-oriented, sparse matrix, inheriting from class CsparseMatrix, from locations (and values) of its nonzero entries.

This is the recommended user interface rather than direct new("***Matrix", ...) calls.

Usage

sparseMatrix(i = ep, j = ep, p, x, dims, dimnames,
             symmetric = FALSE, index1 = TRUE,
             giveCsparse = TRUE, check = TRUE)

Arguments

- **i, j**: integer vectors of the same length specifying the locations (row and column indices) of the non-zero (or non-TRUE) entries of the matrix.
- **p**: numeric (integer valued) vector of pointers, one for each column (or row), to the initial (zero-based) index of elements in the column (or row). Exactly one of i, j or p must be missing.
- **x**: optional values of the matrix entries. If specified, must be of the same length as i / j, or of length one where it will be recycled to full length. If missing, the resulting matrix will be a 0/1 pattern matrix, i.e., extending class nsparseMatrix.
- **dims**: optional, non-negative, integer, dimensions vector of length 2. Defaults to c(max(i), max(j)).
- **dimnames**: optional list of dimnames; if not specified, none, i.e., NULL ones, are used.
- **symmetric**: logical indicating if the resulting matrix should be symmetric. In that case, only the lower or upper triangle needs to be specified via (i/j/p).
- **index1**: logical scalar. If TRUE, the default, the index vectors i and/or j are 1-based, as is the convention in R. That is, counting of rows and columns starts at 1. If FALSE the index vectors are 0-based so counting of rows and columns starts at 0; this corresponds to the internal representation.
- **giveCsparse**: logical indicating if the result should be a CsparseMatrix or a TsparseMatrix. The default, TRUE is very often more efficient subsequently, but not always.
- **check**: logical indicating if a validity check is performed; do not set to FALSE unless you know what you’re doing!
### Details

Exactly one of the arguments \( i \), \( j \) and \( p \) must be missing.

In typical usage, \( p \) is missing, \( i \) and \( j \) are vectors of positive integers and \( x \) is a numeric vector. These three vectors, which must have the same length, form the triplet representation of the sparse matrix.

If \( i \) or \( j \) is missing then \( p \) must be a non-decreasing integer vector whose first element is zero. It provides the compressed, or “pointer” representation of the row or column indices, whichever is missing. The expanded form of \( p, \text{rep(seq_along(dp), dp)} \) where \( dp \leftarrow \text{diff(p)} \), is used as the (1-based) row or column indices.

The values of \( i, j, p \) and \( \text{index1} \) are used to create 1-based index vectors \( i \) and \( j \) from which a \text{TsparseMatrix} is constructed, with numerical values given by \( x \), if non-missing. The \text{TsparseMatrix} derived from this triplet form is returned.

The reason for returning a \text{TsparseMatrix} object instead of the triplet format by default is that the compressed column form is easier to work with when performing matrix operations. In particular, if there are no zeros in \( x \) then a \text{TsparseMatrix} is a unique representation of the sparse matrix.

### Value

A sparse matrix, by default (see \text{giveCsparse}) in compressed, column-oriented form, as an \text{R} object inheriting from both \text{CsparseMatrix} and \text{generalMatrix}.

### See Also

\text{Matrix}(*, sparses=TRUE) for the more usual constructor of such matrices; further \text{bdiaq} and \text{Diagonal} for (block-)diagonal and \text{bandSparse} for banded sparse matrix constructors.

The standard \text{R} \text{xtabs}(*, sparses=TRUE), for sparse tables and \text{sparse.model.matrix}() for building sparse model matrices.

Consider \text{TsparseMatrix} and similar class definition help files.

### Examples

```r
## simple example
i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)
(A <- sparseMatrix(i, j, x = x))
summary(A)
str(A) # note that *internally* 0-based row indices are used
## AA can be larger than the maximum row or column indices
(AA <- sparseMatrix(c(1,3:8), c(2,9,6:10), x = 7 * (1:7), dims = c(10,20)))
summary(AA)
## i, j and x can be in an arbitrary order, as long as they are consistent
set.seed(1); (perm <- sample(1:7))
(A1 <- sparseMatrix(i[perm], j[perm], x = x[perm]))
stopifnot(identical(A, A1))
## the (i,j) pairs can be repeated, in which case the x's are summed
(args <- data.frame(i = c(i, 1), j = c(j, 2), x = c(x, 2)))
(Aa <- do.call(sparseMatrix, args))
dn <- list(LETTERS[1:3], letters[1:5])
## pointer vectors can be used, and the (i,x) slots are sorted if necessary:
```
m <- sparseMatrix(i = c(3,1, 3:2, 2:1), p = c(0:2, 4,4,6), x = 1:6, dimnames = dn)

m
str(m)
stopifnot(identical(dimnames(m), dn))

sparseMatrix(x = 2.72, i=1:3, j=2:4) # recycling x
sparseMatrix(x = TRUE, i=1:3, j=2:4) # recycling x, |--> "lgCMatrix"

## no 'x' --> patter*n* matrix:
(n <- sparseMatrix(i=1:6, j=rev(2:7)))-> ngCMatrix

## an empty sparse matrix:
(e <- sparseMatrix(dims = c(4,6), i=(), j=()))

## a symmetric one:
(sy <- sparseMatrix(i= c(2,4,3:5), j= c(4,7:5,5), x = 1:5,
dims = c(7,7), symmetric=TRUE))
stopifnot(isSymmetric(sy),
    identical(sy, ## switch i <-> j (and transpose )
t( sparseMatrix(j= c(2,4,3:5), i= c(4,7:5,5), x = 1:5,
dims = c(7,7), symmetric=TRUE))))

    stopifnot(identical(X., X.), identical(X., X2))
Virtual Class "sparseMatrix" — Mother of Sparse Matrices

Description

Virtual Mother Class of All Sparse Matrices

Slots

Dim: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

Dimnames: a list of length two - inherited from class Matrix, see Matrix.

Extends

Class "Matrix", directly.

Methods

show (object = "sparseMatrix"): The show method for sparse matrices prints "structural" zeroes as "." using printSpMatrix() which allows further customization.

print signature(x = "sparseMatrix"), ....

The print method for sparse matrices by default is the same as show() but can be called with extra optional arguments, see printSpMatrix().

format signature(x = "sparseMatrix"), ....

The format method for sparse matrices, see formatSpMatrix() for details such as the extra optional arguments.

summary (object = "sparseMatrix"): Returns an object of S3 class "sparseSummary" which is basically a data.frame with columns (i,j,x) (or just (i,j) for nsparseMatrix class objects) with the stored (typically non-zero) entries. The print method resembles Matlab's way of printing sparse matrices, and also the MatrixMarket format, see writemm.

cbind2 (x = *, y = *): several methods for binding matrices together, column-wise, see the basic cbind and rbind functions.

Note that the result will typically be sparse, even when one argument is dense and larger than the sparse one.

rbind2 (x = *, y = *): binding matrices together row-wise, see cbind2 above.

determinant (x = "sparseMatrix", logarithm=TRUE): determinant() methods for sparse matrices typically work via Cholesky or lu decompositions.

diag (x = "sparseMatrix"): extracts the diagonal of a sparse matrix.

dim< signature(x = "sparseMatrix", value = "ANY"): allows to reshape a sparse matrix to a sparse matrix with the same entries but different dimensions. value must be of length two and fulfill prod(value) == prod(dim(x)).

coerce signature(from = "factor", to = "sparseMatrix"): Coercion of a factor to "sparseMatrix" produces the matrix of indicator rows stored as an object of class "dgCMatrix". To obtain columns representing the interaction of the factor and a numeric covariate, replace the "x" slot of the result by the numeric covariate then take the transpose. Missing values (NA) from the factor are translated to columns of all 0s.

See also colSums, norm, ... for methods with separate help pages.
Note

In method selection for multiplication operations (i.e. `%*%` and the two-argument form of `crossprod`) the sparseMatrix class takes precedence in the sense that if one operand is a sparse matrix and the other is any type of dense matrix then the dense matrix is coerced to a `dgeMatrix` and the appropriate sparse matrix method is used.

See Also

`sparseMatrix`, and its references, such as `xtabs(*, sparse=TRUE)`, or `sparse.model.matrix()`, for constructing sparse matrices.

Examples

```r
showClass("sparseMatrix") ## and look at the help() of its subclasses
M <- Matrix(0, 10000, 100)
M[1,1] <- M[2,3] <- 3.14
M ## show(.) method suppresses printing of the majority of rows
data(CAex); dim(CAex) # 72 x 72 matrix
determinant(CAex) # works via sparse lu(.)

## factor --> t( <sparse design matrix> ) :
(fact <- gl(5, 3, 30, labels = LETTERS[1:5]))
(Xt <- as(fact, "sparseMatrix")) # indicator rows

## missing values --> all-0 columns:
f.mis <- fact
i.mis <- c(3:5, 17)
is.na(f.mis) <- i.mis
Xt !=(X. <- as(f.mis, "sparseMatrix")) # differ only in columns 3:5,17
stopifnot(all(X.[,i.mis] == 0), all(Xt[,-i.mis] == X.[,-i.mis]))
```

---

**sparseQR-class**

Sparse QR decomposition of a sparse matrix

**Description**

Objects class "sparseQR" represent a QR decomposition of a sparse $n \times p$ rectangular matrix $X$, typically resulting from `qr()`

**Details**

The decomposition is of the form $A[p+1,] = Q \ %*% R$, if the q slot is of length 0 or $A[p+1,q+1] = Q \ %*% R$ where $A$ is a sparse $m \times n$ matrix ($m \geq n$), $R$ is an $m \times n$ matrix that is zero below the main diagonal. The p slot is a 0-based permutation of 1:m applied to the rows of the original matrix. If the q slot has length n it is a 0-based permutation of 1:n applied to the columns of the original matrix to reduce the amount of “fill-in” in the matrix $R$.

The matrix $Q$ is a "virtual matrix". It is the product of $n$ Householder transformations. The information to generate these Householder transformations is stored in the $V$ and $beta$ slots.
The "sparseQR" methods for the qr.* functions return objects of class "dgeMatrix" (see \( \text{dgeMatrix} \)). Results from qr.coef, qr.resid and qr.fitted (when \( k = ncol(R) \)) are well-defined and should match those from the corresponding dense matrix calculations. However, because the matrix \( Q \) is not uniquely defined, the results of qr.qy and qr.qty do not necessarily match those from the corresponding dense matrix calculations.

Also, the results of qr.qy and qr.qty apply to the permuted column order when the \( q \) slot has length \( n \).

**Objects from the Class**

Objects can be created by calls of the form `new("sparseQR", ...)` but are more commonly created by function `qr` applied to a sparse matrix such as a matrix of class \( \text{dgCMatrix} \).

**Slots**

- \( V \): Object of class "\( \text{dgCMatrix} \)". The columns of \( V \) are the vectors that generate the Householder transformations of which the matrix \( Q \) is composed.
- \( \beta \): Object of class "numeric", the normalizing factors for the Householder transformations.
- \( p \): Object of class "integer": Permutation (of \( 0:(n-1) \)) applied to the rows of the original matrix.
- \( R \): Object of class "\( \text{dgCMatrix} \)". An upper triangular matrix of dimension \( n \).
- \( q \): Object of class "integer": Permutation applied from the right. Can be of length 0 which implies no permutation.

**Methods**

- **qr.R** signature(qr = "sparseQR"): compute the upper triangular \( R \) matrix of the QR decomposition. Note that this currently warns because of possible permutation mismatch with the classical \( qr.R() \) result, and you can suppress these warnings by setting `options()` either "Matrix.quick.qr.R" or (the more general) either "Matrix.quick" to `TRUE`.

- **qr.Q** signature(qr = "sparseQR"): compute the orthogonal \( Q \) matrix of the QR decomposition.

- **qr.coef** signature(qr = "sparseQR", y = "\( \text{ddenseMatrix} \)"):

- **qr.coef** signature(qr = "sparseQR", y = "\( \text{matrix} \)"):

- **qr.coef** signature(qr = "sparseQR", y = "numeric"):

- **qr.fitted** signature(qr = "sparseQR", y = "\( \text{ddenseMatrix} \)"):

- **qr.fitted** signature(qr = "sparseQR", y = "\( \text{matrix} \)"):

- **qr.fitted** signature(qr = "sparseQR", y = "numeric"):

- **qr.qty** signature(qr = "sparseQR", y = "\( \text{ddenseMatrix} \)"):

- **qr.qty** signature(qr = "sparseQR", y = "\( \text{matrix} \)"):

- **qr.qty** signature(qr = "sparseQR", y = "numeric"):

- **qr.qy** signature(qr = "sparseQR", y = "\( \text{ddenseMatrix} \)"):

- **qr.qy** signature(qr = "sparseQR", y = "\( \text{matrix} \)"):

- **qr.qy** signature(qr = "sparseQR", y = "numeric"):

- **qr.resid** signature(qr = "sparseQR", y = "\( \text{ddenseMatrix} \)"):

- **qr.resid** signature(qr = "sparseQR", y = "\( \text{matrix} \)"):

- **qr.resid** signature(qr = "sparseQR", y = "numeric"):

- **solve** signature(a = "sparseQR", b = "ANY"): For `solve(a,b)`, simply uses `qr.coef(a,b)`.

str(mmQR <- qr(mm))

Example 1:

sparseVector

Sparse Vector Construction from Nonzero Entries

Description

User friendly construction sparse vectors, i.e., objects inheriting from class sparseVector, from indices and values of its nonzero entries.

Usage

sparseVector(x, i, length)

Arguments

x vector of the non zero entries.
i integer vector (of the same length as x) specifying the indices of the non-zero (or non-TRUE) entries of the sparse vector.
length length of the sparse vector.

Details

zero entries in x are dropped automatically, analogously as drop() acts on sparse matrices.

Value

a sparse vector, i.e., inheriting from class sparseVector.

Author(s)

Martin Maechler

See Also

sparseMatrix() constructor for sparse matrices; the class sparseVector.

Examples

str(sv <- sparseVector(x = 1:10, i = sample(999, 10), length = 1000))

Example 2:

sx <- c(0, 0, 3, 3.2, 0, 0, 0, -3:1, 0, 0, 2, 0, 0, 5, 0, 0)
ss <- as(sx, "sparseVector")
stopifnot(identical(ss,
    sparseVector(x = c(2, -1, -2, 3, 1, -3, 5, 3.2),
    i = c(15L, 10:9, 3L, 12L, 8L, 18L, 4L), length = 20L)))
Sparse Vector Classes: The virtual mother class "sparseVector" has the five actual daughter classes "dsparseVector", "isparsivector", "lsparseVector", "nsparseVector", and "zsparseVector", where we’ve mainly implemented methods for the d*, l*, and n* ones.

Slots

- `length`: class "numeric" - the length of the sparse vector. Note that "numeric" can be considerably larger than the maximal "integer", `.Machine$integer.max`, on purpose.
- `i`: class "numeric" - the (1-based) indices of the non-zero entries. Must not be NA and strictly sorted increasingly.
  Note that "integer" is “part of” "numeric", and can (and often will) be used for non-huge sparseVectors.
- `x`: (for all but "nsparseVector"): the non-zero entries. This is of class "numeric" for class "dsparseVector", "logical" for class "lsparseVector", etc.
  Note that "nsparseVector"s have no `x` slot. Further, mainly for ease of method definitions, we’ve defined the class union (see `setClassUnion`) of all sparse vector classes which have an `x` slot, as class "xsparsesVector".

Methods

- `length`: signature(x = "sparseVector"): simply extracts the length slot.
- `show`: signature(object = "sparseVector"): The show method for sparse vectors prints "structural" zeroes as "." using the non-exported `prSpVector` function which allows further customization such as replacing "." by " " (blank).
  Note that `options(max.print)` will influence how many entries of large sparse vectors are printed at all.
- `as.vector`: signature(x = "sparseVector", mode = "character"): coerces sparse vectors to "regular", i.e., atomic vectors. This is the same as as(x, "vector").
- `as`: see coerce below
- `coerce`: signature(from = "sparseVector", to = "sparseMatrix"), and
  `coerce`: signature(from = "sparseMatrix", to = "sparseVector"), etc: coercions to and from sparse matrices ("sparseMatrix") are provided and work analogously as in standard R, i.e., a vector is coerced to a 1-column matrix.
- `dim<-`: signature(x = "sparseVector", value = "integer") coerces a sparse vector to a sparse Matrix, i.e., an object inheriting from `sparseMatrix`, of the appropriate dimension.
- `head`: signature(x = "sparseVector"): as with R’s (package `util`) `head`, `head(x,n)` (for n >= 1) is equivalent to x[1:n], but here can be much more efficient, see the example.
- `tail`: signature(x = "sparseVector"): analogous to `head`, see above.
- `toeplitz`: signature(x = "sparseVector"): as `toeplitz(x)`, produce the n x n Toeplitz matrix from x, where n = length(x).
- `rep`: signature(x = "sparseVector"): repeat x, with the same argument list (x, times, length.out, each,...) as the default method for rep().
Ops signature(e1 = "sparseVector", e2 = ":") define arithmetic, compare and logic operations, (see Ops).

Summary signature(x = "sparseVector"): define all the Summary methods.

[ signature(x = "atomicVector", i = ...): not only can you subset (aka "index into") sparseVectors x[i] using sparseVectors i, but we also support efficient subsetting of traditional vectors x by logical sparse vectors (i.e., i of class "nsparseVector" or "lsparseVector").

is.na, is.finite, is.infinite (x = "sparseVector"), and

is.na, is.finite, is.infinite (x = "nsparseVector"): return logical or "nsparseVector" of the same length as x, indicating if/where x is NA (or NaN), finite or infinite, entirely analogously to the corresponding base R functions.

See Also

sparseVector() for friendly construction of sparse vectors (apart from as(*, "sparseVector")).

Examples

gclass("sparseVector")
gclass("dsparseVector")
gclass("xsparseVector")# those with an 'x' slot
sx <- c(0,0,3, 3.2, 0,0,0,-3:1,0,0,2,0,0,5,0,0)

\item \texttt{nrow, ncol} \hspace{1cm} integers specifying the desired number of rows and columns.
\item \texttt{i, j} \hspace{1cm} integer vectors of the same length specifying the locations of the non-zero (or non-TRUE) entries of the matrix.
\item \texttt{x} \hspace{1cm} atomic vector of the same length as \texttt{i} and \texttt{j}, specifying the values of the non-zero entries.
\end{itemize}
\item[\textbf{Value}] A sparse matrix in triplet form, as an \texttt{R} object inheriting from both \texttt{TsparseMatrix} and \texttt{generalMatrix}.
\end{description}

The matrix \( M \) will have \( M[i[k], j[k]] = x[k] \), for \( k = 1, 2, \ldots, n \), where \( n = \text{length}(i) \) and \( M[i', j'] = 0 \) for all other pairs \((i', j')\).
**See Also**

`Matrix(*, sparse=TRUE)` for the more usual constructor of such matrices; similarly, `sparseMatrix` which is a bit more general than `spMatrix()` and returns a `CsparseMatrix` which is often slightly more desirable. Further, `bdiag` and `Diagonal` for (block-)diagonal matrix constructors.

Consider `tsparseMatrix` and similar class definition help files.

**Examples**

```r
## simple example
A <- spMatrix(10, 20, i = c(1:3:8),
            j = c(2, 9:6:10),
            x = 7 * (1:7))
A # a "dgTMatrix"
summary(A)
str(A) # note that *internally* 0-based indices (i,j) are used

L <- spMatrix(9, 30, i = rep(1:9, 3), 1:27,
              (1:27) %% 4 != 1)
L # an "lgTMatrix"

### This is a useful utility, to be used for experiments:

rSpMatrix <- function(nrow, ncol, nnz,
            rand.x = function(n) round(rnorm(nnz), 2))
{
  ## Purpose: random sparse matrix
  ## --------------------------------------------
  ## Arguments: (nrow,ncol): dimension
  ## nnz : number of non-zero entries
  ## rand.x: random number generator for 'x' slot
  ## --------------------------------------------
  ## Author: Martin Maechler, Date: 14.-16. May 2007
  stopifnot(nnz <- as.integer(nnz)) >= 0,
  nrow >= 0, ncol >= 0,
  nnz <= nrow * ncol
  spMatrix(nrow, ncol,
           i = sample(nrow, nnz, replace = TRUE),
           j = sample(ncol, nnz, replace = TRUE),
           x = rand.x(nnz))
}

M1 <- rSpMatrix(100000, 20, nnz = 200)
summary(M1)
```

**Description**

The virtual class of symmetric matrices, "`symmetricMatrix`", from the package `Matrix` contains numeric and logical, dense and sparse matrices, e.g., see the examples.

The main use is in methods (and C functions) that can deal with all symmetric matrices.
symmpart

Slots

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

Dim, Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the Matrix, see there.

factors: a list of matrix factorizations, also from the Matrix class.

Extends

Class "Matrix", directly.

Methods

There’s a C function symmetricMatrix_validity() called by the internal validity checking functions.

See Also

isSymmetric which has efficient methods (isSymmetric-methods) for the Matrix classes. Classes triangularMatrix, and, e.g., dsyMatrix for numeric dense matrices, or lscMatrix for a logical sparse matrix class.

Examples

showClass("symmetricMatrix")

## The names of direct subclasses:
scl <- getClass("symmetricMatrix")@subclasses
directly <- sapply(lapply(scl, slot, "by"), length) == 0
names(scl)[directly]

 symmpart Symmetric Part and Skew(symmetric) Part of a Matrix

Description

symmpart(x) computes the symmetric part \((x + t(x))/2\) and skewpart(x) the skew symmetric part \((x - t(x))/2\) of a square matrix \(x\), more efficiently for specific Matrix classes.

Note that \(x == symmpart(x) + skewpart(x)\) for all square matrices – apart from extraneous NA values in the RHS.

Usage

symmpart(x)
skewpart(x)

Arguments

\(x\) a square matrix; either “traditional” of class "matrix", or typically, inheriting from the Matrix class.
Details

These are generic functions with several methods for different matrix classes, use e.g., `showMethods(symmpart)` to see them.

Value

`symmpart()` returns a symmetric matrix, inheriting from `symmetricMatrix` iff `x` inherited from `Matrix`.

`skewpart()` returns a skew-symmetric matrix, typically of the same class as `x` (or the closest "general" one, see `generalMatrix`).

Examples

```r
m <- Matrix(1:4, 2, 2)
symmpart(m)
skewpart(m)

stopifnot(all(m == symmpart(m) + skewpart(m)))
```

```r
## investigate the current methods:
showMethods(skewpart, include = TRUE)
```

## Cross-product of transpose

### Description

Take the cross-product of the transpose of a matrix. `tcrossprod(x)` is formally equivalent to, but faster than, the call `x %*% t(x)`, and so is `tcrossprod(x, y)` instead of `x %*% t(y)`.

### Usage

`tcrossprod(x, y = NULL)`

### Arguments

- **x**: a matrix-like object
- **y**: a matrix-like object or `NULL` (by default); the latter case is formally equivalent to `y = x`.

### Details

For some classes in the Matrix package, such as `dgCMatrix`, it is much faster to calculate the cross-product of the transpose directly instead of calculating the transpose first and then its cross-product.

### Value

An object of an appropriate symmetric matrix class.

### Methods

- `x = "dgCMatrix"` method for compressed, sparse, column-oriented matrices.
triangularMatrix-class

Virtual Class of Triangular Matrices in package: Matrix

Description

The virtual class of triangular matrices, "triangularMatrix", from the package Matrix contains numeric and logical, dense and sparse matrices, e.g., see the examples. The main use will be in methods (and C functions) that can deal with all triangular matrices.

Slots

uplo: String (of class "character"). Must be either "U", for upper triangular, and "L", for lower triangular.

diag: String (of class "character"). Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The diagonal elements are not accessed internally when diag is "U". For denseMatrix classes, they need to be allocated though, i.e., the length of the x slot does not depend on diag.

Dim, Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the Matrix, see there.

Extends

Class "Matrix", directly.

Methods

There’s a C function triangularMatrix_validity() called by the internal validity checking functions. Currently, Schur, isSymmetric and as() (i.e. coerce) have methods with triangularMatrix in their signature.
See Also

isTriangular() for testing any matrix for triangularity; classes symmetricMatrix, and, e.g.,
dtrMatrix for numeric dense matrices, or 1tCMatrix for a logical sparse matrix subclass of
"triangularMatrix".

Examples

showClass("triangularMatrix")

### The names of direct subclasses:
scl <- getClass("triangularMatrix")@subclasses
directly <- sapply(lapply(scl, slot, "by"), length) == 0
names(scl)[directly]

---

TsparseMatrix-class  Class "TsparseMatrix" of Sparse Matrices in Triplet Form

Description

The "TsparseMatrix" class is the virtual class of all sparse matrices coded in triplet form. Since
it is a virtual class, no objects may be created from it. See showClass("TsparseMatrix") for its
subclasses.

Slots

Dim, Dimnames: from the "Matrix" class.

i: Object of class "integer" - the row indices of non-zero entries in 0-base, i.e., must be in
0:(nrow(.)-1).

j: Object of class "integer" - the column indices of non-zero entries. Must be the same length
as slot i and 0-based as well, i.e., in 0:(ncol(.)-1). For numeric Tsparse matrices, (i,j)
pairs can occur more than once, see dgTMatrix.

Extends

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

Methods

Extraction ("[" methods, see [methods.

Note

Most operations with sparse matrices are performed using the compressed, column-oriented or
CsparseMatrix representation. The triplet representation is convenient for creating a sparse ma-
trix or for reading and writing such matrices. Once it is created, however, the matrix is generally
coerced to a CsparseMatrix for further operations.

For convenience, methods for some operations such as **%** and crossprod are defined
for TsparseMatrix objects. These methods simply coerce the TsparseMatrix object to a
CsparseMatrix object then perform the operation.
See Also

its superclass, `sparseMatrix`, and the `dgTMatrix` class, for the links to other classes.

Examples

```r
showClass("TsparseMatrix")
## or just the subclasses' names
names(getClass("TsparseMatrix")@subclasses)
```
Examples

showMethods("unpack")
(cp4 <- chol(Hilbert(4))) # is triangular
tp4 <- as(cp4,"dtMatrix")# [t]riangular [p]acked
str(tp4)
(unpack(tp4))
stopifnot(identical(tp4, pack(unpack(tp4))))

(s <- crossprod(matrix(sample(15), 5,3))) # traditional symmetric matrix
(sp <- pack(s))
mt <- as.matrix(tt <- tril(s))
(pt <- pack(mt))
stopifnot(identical(pt, pack(tt)),
  dim(s ) == dim(sp), all(s == sp),
  dim(mt) == dim(pt), all(mt == pt), all(mt == tt))
showMethods("pack")

Unused-classes Virtual Classes Not Yet Really Implemented and Used

Description

iMatrix is the virtual class of all integer (S4) matrices. It extends the Matrix class directly.

zMatrix is the virtual class of all complex (S4) matrices. It extends the Matrix class directly.

Examples

showClass("iMatrix")
showClass("zMatrix")

Description

Up- and Down-Dating a Cholesky Decomposition

Usage

updown(update, C, L)

Arguments

update logical (TRUE or FALSE) or "+" or "-" indicating if an up- or a down-date is to be computed.

C any R object, coercable to a sparse matrix (i.e., of subclass of sparseMatrix).

L a Cholesky factor, specifically, of class "CHMfactor".
Value

an updated Cholesky factor, of the same dimension as \(L\). Typically of class "dCHMsimp1" (a sub class of "CHMfactor").

Methods

signature(update = "character", C = "mMatrix", L = "CHMfactor") ..
signature(update = "logical", C = "mMatrix", L = "CHMfactor") ..

Examples

dn <- list(LETTERS[1:3], letters[1:5])
## pointer vectors can be used, and the (i,x) slots are sorted if necessary:
m <- sparseMatrix(i = c(3, 1, 3:2, 2:1), p = c(0:2, 4,4,6), x = 1:6, dimnames = dn)
cA <- Cholesky(A <- crossprod(m) + Diagonal(5))
166 * as(cA,"Matrix") ^ 2
uc1 <- updown(“+", Diagonal(5), cA)
## Hmm: this loses positive definiteness:
uc2 <- updown("-", 2*Diagonal(5), cA)
image(show(as(cA, "Matrix")))
image(show(c2 <- as(uc2,"Matrix")))## severely negative entries
##---> Warning

USCounties

USCounties Contiguity Matrix

Description

This matrix represents the contiguities of 3111 US counties using the Queen criterion of at least a single shared boundary point. The representation is as a row standardised spatial weights matrix transformed to a symmetric matrix (see Ord (1975), p. 125).

Usage

data(USCounties)

Format

A 3111^2 symmetric sparse matrix of class dsCMatrix with 9101 non-zero entries.
Details

The data were read into R using `read.gal`, and row-standardised and transformed to symmetry using `nb2listw` and `similar.listw`. This spatial weights object was converted to class `dsCMatrix` using `as_dsTMatrix_listw` and coercion.

Source

The data were retrieved from http://sal.uiuc.edu/weights/zips/usc.zip, files “usc.txt” and “usc_q.GAL”, with permission for use and distribution from Luc Anselin.

[-methods

Methods for "[": Extraction or Subsetting in Package 'Matrix'

Description

Methods for "[", i.e., extraction or subsetting mostly of matrices, in package Matrix.
Methods

There are more than these:

- \( x = \text{"Matrix"}, i = \text{"missing"}, j = \text{"missing"}, \text{drop} = \text{"ANY"} \)
- \( x = \text{"Matrix"}, i = \text{"numeric"}, j = \text{"missing"}, \text{drop} = \text{"missing"} \)
- \( x = \text{"Matrix"}, i = \text{"missing"}, j = \text{"numeric"}, \text{drop} = \text{"missing"} \)
- \( x = \text{"dsparseMatrix"}, i = \text{"missing"}, j = \text{"numeric"}, \text{drop} = \text{"logical"} \)
- \( x = \text{"dsparseMatrix"}, i = \text{"numeric"}, j = \text{"missing"}, \text{drop} = \text{"logical"} \)
- \( x = \text{"dsparseMatrix"}, i = \text{"numeric"}, j = \text{"numeric"}, \text{drop} = \text{"logical"} \)

See Also

\(<-\text{-methods}\) for subassignment to "Matrix" objects. \texttt{Extract} about the standard extraction.

Examples

```r
str(m <- Matrix(round(rnorm(7*4),2), nrow = 7))
stopifnot(identical(m, m[3]))
 m[2, 3] # simple number
 m[2, 3:4] # simple numeric of length 2
 m[2, 3:4, drop=FALSE] # sub matrix of class 'dgeMatrix'
## rows or columns only:
 m[1,]  # first row, as simple numeric vector
 m[1:2] # sub matrix of first two columns
```

```
showMethods("[", inherited = FALSE)
```

Description

Methods for "\(<-\)", i.e., extraction or subsetting mostly of matrices, in package \texttt{Matrix}.

Note: Contrary to standard \texttt{matrix} assignment in base \texttt{R}, in \texttt{x[\ldots] <- val} it is typically an \texttt{error} (see \texttt{stop}) when the \texttt{type} or \texttt{class} of \texttt{val} would require the class of \texttt{x} to be changed, e.g., when \texttt{x} is logical, say "\texttt{isparseMatrix}" , and \texttt{val} is numeric.

Methods

There are \textit{many many} more than these:

- \( x = \text{"Matrix"}, i = \text{"missing"}, j = \text{"missing"}, \text{value} = \text{"ANY"} \) is currently a simple fallback method implementation which ensures "readable" error messages.
- \( x = \text{"Matrix"}, i = \text{"ANY"}, j = \text{"ANY"}, \text{value} = \text{"ANY"} \) currently gives an error
- \( x = \text{"denseMatrix"}, i = \text{"index"}, j = \text{"missing"}, \text{value} = \text{"numeric"} \)
- \( x = \text{"denseMatrix"}, i = \text{"index"}, j = \text{"index"}, \text{value} = \text{"numeric"} \)
- \( x = \text{"denseMatrix"}, i = \text{"missing"}, j = \text{"index"}, \text{value} = \text{"numeric"} \)
See Also

[-methods for subsetting "Matrix" objects; the index class; Extract about the standard subset assignment (and extraction).

Examples

```r
set.seed(101)
(a <- m <- Matrix(round(rnorm(7*4),2), nrow = 7))

a[] <- 2.2 # <- replaces **every** entry
a
## as do these:
a[,] <- 3 ; a[TRUE,] <- 4

m[2, 3] <- 3.14 # simple number
m[3, 3:4] <- 3:4 # simple numeric of length 2

## sub matrix assignment:
m[-(4:7), 3:4] <- cbind(1:2:4) #-> upper right corner of 'm'
m[3:5, 2:3] <- 0
m[6:7, 1:2] <- Diagonal(2)
m

## rows or columns only:
m[1,] <- 10
m[,2] <- 1:7
m[-(1:6), ] <- 3:0 # not the first 6 rows, i.e. only the 7th as(m, "sparseMatrix")
```
Chapter 18

The boot package

---

**abc.ci**  
*Nonparametric ABC Confidence Intervals*

### Description

Calculate equi-tailed two-sided nonparametric approximate bootstrap confidence intervals for a parameter, given a set of data and an estimator of the parameter, using numerical differentiation.

### Usage

```r
abc.ci(data, statistic, index=1, strata=rep(1, n), conf=0.95, 
eps=0.001/n, ...)
```

### Arguments

- **data**  
  A data set expressed as a vector, matrix or data frame.

- **statistic**  
  A function which returns the statistic of interest. The function must take at least 2 arguments; the first argument should be the data and the second a vector of weights. The weights passed to statistic will be normalized to sum to 1 within each stratum. Any other arguments should be passed to abc.ci as part of the ...() argument.

- **index**  
  If statistic returns a vector of length greater than 1, then this indicates the position of the variable of interest within that vector.

- **strata**  
  A factor or numerical vector indicating to which sample each observation belongs in multiple sample problems. The default is the one-sample case.

- **conf**  
  A scalar or vector containing the confidence level(s) of the required interval(s).

- **eps**  
  The value of epsilon to be used for the numerical differentiation.

- **...**  
  Any other arguments for statistic. These will be passed unchanged to statistic each time it is called within abc.ci.
Details

This function is based on the function abcnon written by R. Tibshirani. A listing of the original function is available in DiCiccio and Efron (1996). The function uses numerical differentiation for the first and second derivatives of the statistic and then uses these values to approximate the bootstrap BCa intervals. The total number of evaluations of the statistic is \(2n+2+2\times\text{length}(\text{conf})\) where \(n\) is the number of data points (plus calculation of the original value of the statistic). The function works for the multiple sample case without the need to rewrite the statistic in an artificial form since the stratified normalization is done internally by the function.

Value

A \(\text{length}(\text{conf})\) by 3 matrix where each row contains the confidence level followed by the lower and upper end-points of the ABC interval at that level.

References

- `boot.ci`

Examples

```r
# 90% and 95% confidence intervals for the correlation
# coefficient between the columns of the bigcity data
abc.ci(bigcity, corr, conf=c(0.90,0.95))

# A 95% confidence interval for the difference between the means of
# the last two samples in gravity
mean.diff <- function(y, w)
  { gp1 <- 1:table(as.numeric(y$series))[1]
    sum(y[gp1, 1] * w[gp1]) - sum(y[-gp1, 1] * w[-gp1])
  }
grav1 <- gravity[as.numeric(gravity[, 2]) >= 7, ]
abc.ci(grav1, mean.diff, strata = grav1$series)
```

Description

The `acme` data frame has 60 rows and 3 columns.

The excess return for the Acme Cleveland Corporation are recorded along with those for all stocks listed on the New York and American Stock Exchanges were recorded over a five year period. These excess returns are relative to the return on a risk-less investment such a U.S. Treasury bills.
Description

The aids data frame has 570 rows and 6 columns.

Although all cases of AIDS in England and Wales must be reported to the Communicable Disease Surveillance Centre, there is often a considerable delay between the time of diagnosis and the time that it is reported. In estimating the prevalence of AIDS, account must be taken of the unknown number of cases which have been diagnosed but not reported. The data set here records the reported cases of AIDS diagnosed from July 1983 and until the end of 1992. The data are cross-classified by the date of diagnosis and the time delay in the reporting of the cases.

Usage

aids

Format

This data frame contains the following columns:

year  The year of the diagnosis.
quarter  The quarter of the year in which diagnosis was made.
delay  The time delay (in months) between diagnosis and reporting. 0 means that the case was reported within one month. Longer delays are grouped in 3 month intervals and the value of delay is the midpoint of the interval (therefore a value of 2 indicates that reporting was delayed for between 1 and 3 months).
An indicator of censoring. These are categories for which full information is not yet available and the number recorded is a lower bound only.

time The time interval of the diagnosis. That is the number of quarters from July 1983 until the end of the quarter in which these cases were diagnosed.

y The number of AIDS cases reported.

**aircondit**

*Failures of Air-conditioning Equipment*

Description

Proschan (1963) reported on the times between failures of the air-conditioning equipment in 10 Boeing 720 aircraft. The *aircondit* data frame contains the intervals for the ninth aircraft while *aircondit7* contains those for the seventh aircraft.

Both data frames have just one column. Note that the data have been sorted into increasing order.

Usage

`aircondit`

Format

The data frames contain the following column:

hours The time interval in hours between successive failures of the air-conditioning equipment

Source

The data were taken from

References

Description

The amis data frame has 8437 rows and 4 columns.

In a study into the effect that warning signs have on speeding patterns, Cambridgeshire County Council considered 14 pairs of locations. The locations were paired to account for factors such as traffic volume and type of road. One site in each pair had a sign erected warning of the dangers of speeding and asking drivers to slow down. No action was taken at the second site. Three sets of measurements were taken at each site. Each set of measurements was nominally of the speeds of 100 cars but not all sites have exactly 100 measurements. These speed measurements were taken before the erection of the sign, shortly after the erection of the sign, and again after the sign had been in place for some time.

Usage

amis

Format

This data frame contains the following columns:

speed  Speeds of cars (in miles per hour).
period  A numeric column indicating the time that the reading was taken. A value of 1 indicates a reading taken before the sign was erected, a 2 indicates a reading taken shortly after erection of the sign and a 3 indicates a reading taken after the sign had been in place for some time.
warning  A numeric column indicating whether the location of the reading was chosen to have a warning sign erected. A value of 1 indicates presence of a sign and a value of 2 indicates that no sign was erected.
pair  A numeric column giving the pair number at which the reading was taken. Pairs were numbered from 1 to 14.

Source

The data were kindly made available by Mr. Graham Amis, Cambridgeshire County Council, U.K.

Remission Times for Acute Myelogenous Leukaemia

Description

The `aml` data frame has 23 rows and 3 columns.

A clinical trial to evaluate the efficacy of maintenance chemotherapy for acute myelogenous leukaemia was conducted by Embury et al. (1977) at Stanford University. After reaching a stage of remission through treatment by chemotherapy, patients were randomized into two groups. The first group received maintenance chemotherapy and the second group did not. The aim of the study was to see if maintenance chemotherapy increased the length of the remission. The data here formed a preliminary analysis which was conducted in October 1974.

Usage

`aml`

Format

This data frame contains the following columns:

- `time`: The length of the complete remission (in weeks).
- `cens`: An indicator of right censoring. 1 indicates that the patient had a relapse and so `time` is the length of the remission. 0 indicates that the patient had left the study or was still in remission in October 1974, that is the length of remission is right-censored.
- `group`: The group into which the patient was randomized. Group 1 received maintenance chemotherapy, group 2 did not.

Note

Package `survival` also has a dataset `aml`. It is the same data with different names and with `group` replaced by a factor `x`.

The beaver data frame has 100 rows and 4 columns. It is a multivariate time series of class "ts" and also inherits from class "data.frame".

This data set is part of a long study into body temperature regulation in beavers. Four adult female beavers were live-trapped and had a temperature-sensitive radio transmitter surgically implanted. Readings were taken every 10 minutes. The location of the beaver was also recorded and her activity level was dichotomized by whether she was in the retreat or outside of it since high-intensity activities only occur outside of the retreat.

The data in this data frame are those readings for one of the beavers on a day in autumn.

This data frame contains the following columns:

<table>
<thead>
<tr>
<th>day</th>
<th>The day number. The data includes only data from day 307 and early 308.</th>
</tr>
</thead>
<tbody>
<tr>
<td>time</td>
<td>The time of day formatted as hour-minute.</td>
</tr>
<tr>
<td>temp</td>
<td>The body temperature in degrees Celsius.</td>
</tr>
<tr>
<td>activ</td>
<td>The dichotomized activity indicator. 1 indicates that the beaver is outside of the retreat and therefore engaged in high-intensity activity.</td>
</tr>
</tbody>
</table>

The data were obtained from

bigcity

**Population of U.S. Cities**

**Description**

The bigcity data frame has 49 rows and 2 columns.

The city data frame has 10 rows and 2 columns.

The measurements are the population (in 1000's) of 49 U.S. cities in 1920 and 1930. The 49 cities are a random sample taken from the 196 largest cities in 1920. The city data frame consists of the first 10 observations in bigcity.

**Usage**

bigcity

**Format**

This data frame contains the following columns:

u  The 1920 population.

x  The 1930 population.

**Source**

**References**

---

**boot**

**Bootstrap Resampling**

**Description**

Generate R bootstrap replicates of a statistic applied to data. Both parametric and nonparametric resampling are possible. For the nonparametric bootstrap, possible resampling methods are the ordinary bootstrap, the balanced bootstrap, antithetic resampling, and permutation. For nonparametric multi-sample problems stratified resampling is used: this is specified by including a vector of strata in the call to boot. Importance resampling weights may be specified.

**Usage**

\[
\text{boot(data, statistic, R, sim = "ordinary", stype = c("i", "f", "w"), strata = rep(1,n), L = NULL, m = 0, weights = NULL, ran.gen = function(d, p) d, mle = NULL, simple = FALSE, ..., parallel = c("no", "multicore", "snow"), ncpus =getOption("boot.ncpus", 1L), cl = NULL)}
\]
Arguments

data
A vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one multivariate observation.

statistic
A function which when applied to data returns a vector containing the statistic(s) of interest. When sim = "parametric", the first argument to statistic must be the data. For each replicate a simulated dataset returned by ran.gen will be passed. In all other cases statistic must take at least two arguments. The first argument passed will always be the original data. The second will be a vector of indices, frequencies or weights which define the bootstrap sample. Further, if predictions are required, then a third argument is required which would be a vector of the random indices used to generate the bootstrap predictions. Any further arguments can be passed to statistic through the ... argument.

R
The number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case R would be a vector of integers where each component gives the number of resamples from each of the rows of weights.

sim
A character string indicating the type of simulation required. Possible values are "ordinary" (the default), "parametric", "balanced", "permutation", or "antithetic". Importance resampling is specified by including importance weights; the type of importance resampling must still be specified but may only be ordinary or "balanced" in this case.

stype
A character string indicating what the second argument of statistic represents. Possible values of stype are "i" (indices - the default), "f" (frequencies), or "w" (weights). Not used for sim = "parametric".

strata
An integer vector or factor specifying the strata for multi-sample problems. This may be specified for any simulation, but is ignored when sim = "parametric". When strata is supplied for a nonparametric bootstrap, the simulations are done within the specified strata.

L
Vector of influence values evaluated at the observations. This is used only when sim is "antithetic". If not supplied, they are calculated through a call to empinf. This will use the infinitesimal jackknife provided that stype is "w", otherwise the usual jackknife is used.

m
The number of predictions which are to be made at each bootstrap replicate. This is most useful for (generalized) linear models. This can only be used when sim is "ordinary". m will usually be a single integer but, if there are strata, it may be a vector with length equal to the number of strata, specifying how many of the errors for prediction should come from each strata. The actual predictions should be returned as the final part of the output of statistic, which should also take an argument giving the vector of indices of the errors to be used for the predictions.

weights
A vector or matrix of importance weights. If a vector then it should have as many elements as there are observations in data. When simulation from more than one set of weights is required, weights should be a matrix where each row of the matrix is one set of importance weights. If weights is a matrix then R must be a vector of length nrow(weights). This parameter is ignored if sim is not "ordinary" or "balanced".

ran.gen
This function is used only when sim = "parametric" when it describes how random values are to be generated. It should be a function of two arguments.
The first argument should be the observed data and the second argument consists of any other information needed (e.g. parameter estimates). The second argument may be a list, allowing any number of items to be passed to ran.gen. The returned value should be a simulated data set of the same form as the observed data which will be passed to statistic to get a bootstrap replicate. It is important that the returned value be of the same shape and type as the original dataset. If ran.gen is not specified, the default is a function which returns the original data in which case all simulation should be included as part of statistic. Use of sim = "parametric" with a suitable ran.gen allows the user to implement any types of nonparametric resampling which are not supported directly.

mle
The second argument to be passed to ran.gen. Typically these will be maximum likelihood estimates of the parameters. For efficiency mle is often a list containing all of the objects needed by ran.gen which can be calculated using the original data set only.

simple
logical, only allowed to be TRUE for sim = "ordinary", stype = "i", n = 0 (otherwise ignored with a warning). By default a n by R index array is created: this can be large and if simple = TRUE this is avoided by sampling separately for each replication, which is slower but uses less memory.

... Other named arguments for statistic which are passed unchanged each time it is called. Any such arguments to statistic should follow the arguments which statistic is required to have for the simulation. Beware of partial matching to arguments of boot listed above, and that arguments named X and FUN cause conflicts in some versions of boot (but not this one).

parallel
The type of parallel operation to be used (if any). If missing, the default is taken from the option "boot.parallel" (and if that is not set, "no").

ncpus
integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.

cl
An optional parallel or snow cluster for use if parallel = "snow". If not supplied, a cluster on the local machine is created for the duration of the boot call.

Details
The statistic to be bootstrapped can be as simple or complicated as desired as long as its arguments correspond to the dataset and (for a nonparametric bootstrap) a vector of indices, frequencies or weights. statistic is treated as a black box by the boot function and is not checked to ensure that these conditions are met.

The first order balanced bootstrap is described in Davison, Hinkley and Schechtman (1986). The antithetic bootstrap is described by Hall (1989) and is experimental, particularly when used with strata. The other non-parametric simulation types are the ordinary bootstrap (possibly with unequal probabilities), and permutation which returns random permutations of cases. All of these methods work independently within strata if that argument is supplied.

For the parametric bootstrap it is necessary for the user to specify how the resampling is to be conducted. The best way of accomplishing this is to specify the function ran.gen which will return a simulated data set from the observed data set and a set of parameter estimates specified in mle.

Value
The returned value is an object of class "boot", containing the following components:

t0
The observed value of statistic applied to data.
t  A matrix with \( \text{sum}(R) \) rows each of which is a bootstrap replicate of the result of calling \text{statistic}.  

R  The value of \( R \) as passed to \text{boot}.  

data  The data as passed to \text{boot}.  

seed  The value of \text{.Random.seed} when \text{boot} was called.  

statistic  The function \text{statistic} as passed to \text{boot}.  

sim  Simulation type used.  

stype  Statistic type as passed to \text{boot}.  

call  The original call to \text{boot}.  

strata  The strata used. This is the vector passed to \text{boot}, if it was supplied or a vector of ones if there were no strata. It is not returned if \text{sim} is "parametric".  

weights  The importance sampling weights as passed to \text{boot} or the empirical distribution function weights if no importance sampling weights were specified. It is omitted if \text{sim} is not one of "ordinary" or "balanced".  

pred.i  If predictions are required (\( m > 0 \)) this is the matrix of indices at which predictions were calculated as they were passed to \text{statistic}. Ommitted if \( m \) is 0 or \text{sim} is not "ordinary".  

L  The influence values used when \text{sim} is "antithetic". If no such values were specified and \text{stype} is not "w" then \( L \) is returned as consecutive integers corresponding to the assumption that data is ordered by influence values. This component is omitted when \text{sim} is not "antithetic".  

ran.gen  The random generator function used if \text{sim} is "parametric". This component is omitted for any other value of \text{sim}.  

mle  The parameter estimates passed to \text{boot} when \text{sim} is "parametric". It is omitted for all other values of \text{sim}.  

There are \text{c.plot} and \text{print} methods for this class.  

Parallel operation  

When \text{parallel} = "multicore" is used (not available on Windows), each worker process inherits the environment of the current session, including the workspace and the loaded namespaces and attached packages (but not the random number seed: see below).  

More work is needed when \text{parallel} = "snow" is used: the worker processes are newly created \text{R} processes, and \text{statistic} needs to arrange to set up the environment it needs: often a good way to do that is to make use of lexical scoping since when \text{statistic} is sent to the worker processes its enclosing environment is also sent. (E.g. see the example for \text{jack.after.boot} where ancillary functions are nested inside the \text{statistic} function.) \text{parallel} = "snow" is primarily intended to be used on multi-core Windows machine where \text{parallel} = "multicore" is not available.  

For most of the \text{boot} methods the resampling is done in the master process, but not if \text{simple} = TRUE nor \text{sim} = "parametric". In those cases (or where \text{statistic} itself uses random numbers), more care is needed if the results need to be reproducible. Resampling is done in the worker processes by \text{censboot} (\text{sim} = "wierd") and by most of the schemes in \text{tsboot} (the exceptions being \text{sim} = "fixed" and \text{sim} = "geom" with the default \text{ran.gen}).  

Where random-number generation is done in the worker processes, the default behaviour is that each worker chooses a separate seed, non-reproducibly. However, with \text{parallel} = "multicore" or \text{parallel} = "snow" using the default cluster, a second approach is used if \text{RNGkind}("L'Ecuyer-CMRG") has been selected. In that approach each worker gets a different
subsequence of the RNG stream based on the seed at the time the worker is spawned and so
the results will be reproducible if ncpus is unchanged, and for parallel = "multicore" if
parallel::mc.reset.stream() is called: see the examples for mclapply.

  out
}
air.boot <- boot(aircondit, air.fun, R = 999, sim = "parametric", ran.gen = air.rg, mle = mean(aircondit$hours))

# The bootstrap p-value can then be approximated by
sum(abs(air.boot$t[,2]-1) > abs(air.boot$t0[2]-1))/(1+air.boot$R)

---

### boot.array

**Bootstrap Resampling Arrays**

**Description**

This function takes a bootstrap object calculated by one of the functions `boot`, `censboot`, or `tilt.boot` and returns the frequency (or index) array for the bootstrap resamples.

**Usage**

`boot.array(boot.out, indices)`

**Arguments**

- **boot.out**: An object of class "boot" returned by one of the generation functions for such an object.
- **indices**: A logical argument which specifies whether to return the frequency array or the raw index array. The default is `indices=FALSE` unless `boot.out` was created by `tsboot` in which case the default is `indices=TRUE`.

**Details**

The process by which the original index array was generated is repeated with the same value of `.Random.seed`. If the frequency array is required then `freq.array` is called to convert the index array to a frequency array.

A resampling array can only be returned when such a concept makes sense. In particular it cannot be found for any parametric or model-based resampling schemes. Hence for objects generated by `censboot` the only resampling scheme for which such an array can be found is ordinary case resampling. Similarly if `boot.out$sim` is "parametric" in the case of `boot` or "model" in the case of `tsboot` the array cannot be found. Note also that for post-blackened bootstraps from `tsboot` the indices found will relate to those prior to any post-blackening and so will not be useful.

Frequency arrays are used in many post-bootstrap calculations such as the jackknife-after-bootstrap and finding importance sampling weights. They are also used to find empirical influence values through the regression method.

**Value**

A matrix with `boot.out$R` rows and `n` columns where `n` is the number of observations in `boot.out$data`. If `indices` is `FALSE` then this will give the frequency of each of the original observations in each bootstrap resample. If `indices` is `TRUE` it will give the indices of the bootstrap resamples in the order in which they would have been passed to the statistic.
Side Effects

This function temporarily resets .Random.seed to the value in boot.out$seed and then returns it to its original value at the end of the function.

See Also

boot.ci, censboot, freq.array, tilt.boot, tsboot

Examples

# A frequency array for a nonparametric bootstrap
city.boot <- boot(city, corr, R = 40, stype = "w")
boot.array(city.boot)

perm.cor <- function(d,i) cor(d$x,d$y[i])
city.perm <- boot(city, perm.cor, R = 40, sim = "permutation")
boot.array(city.perm, indices = TRUE)

Arguments

boot.out An object of class "boot" containing the output of a bootstrap calculation.
conf A scalar or vector containing the confidence level(s) of the required interval(s).
type A vector of character strings representing the type of intervals required. The value should be any subset of the values c("norm", "basic", "stud", "perc", "bca") or simply "all" which will compute all five types of intervals.
index

This should be a vector of length 1 or 2. The first element of index indicates the position of the variable of interest in boot.out$t0 and the relevant column in boot.out$.t. The second element indicates the position of the variance of the variable of interest. If both var.t0 and var.t are supplied then the second element of index (if present) is ignored. The default is that the variable of interest is in position 1 and its variance is in position 2 (as long as there are 2 positions in boot.out$t0).
If supplied, a value to be used as an estimate of the variance of the statistic for the normal approximation and studentized intervals. If it is not supplied and \( \text{length(index)} \) is 2 then \( \text{var.t0} \) defaults to \( \text{boot.out$t@0[index[2]]} \) otherwise \( \text{var.t0} \) is undefined. For studentized intervals \( \text{var.t0} \) must be defined. For the normal approximation, if \( \text{var.t0} \) is undefined it defaults to \( \text{var.t0} \). If a transformation is supplied through the argument \( h \) then \( \text{var.t0} \) should be the variance of the transformed statistic.

This is a vector (of length \( \text{length(index)} \)) of variances of the bootstrap replicates of the variable of interest. It is used only for studentized intervals. If it is not supplied and \( \text{length(index)} \) is 2 then \( \text{var.t} \) defaults to \( \text{boot.out$t@[,index[2]]} \), otherwise its value is undefined which will cause an error for studentized intervals. If a transformation is supplied through the argument \( h \) then \( \text{var.t} \) should be the variance of the untransformed bootstrap statistics.

The observed value of the statistic of interest. The default value is \( \text{boot.out$t@0[index[1]]} \). Specification of \( \text{t0} \) and \( \text{t} \) allows the user to get intervals for a transformed statistic which may not be in the bootstrap output object. See the second example below. An alternative way of achieving this would be to supply the functions \( h, hdot \), and \( hinv \) below.

The bootstrap replicates of the statistic of interest. It must be a vector of length \( \text{length(R)} \). It is an error to supply one of \( t0 \) or \( t \) but not the other. Also if studentized intervals are required and \( t0 \) and \( t \) are supplied then so should be \( \text{var.t0} \) and \( \text{var.t} \). The default value is \( \text{boot.out$t@[,index]} \).

The empirical influence values of the statistic of interest for the observed data. These are used only for BCa intervals. If a transformation is supplied through the parameter \( h \) then \( L \) should be the influence values for \( t \); the values for \( h(t) \) are derived from these and \( hdot \) within the function. If \( L \) is not supplied then the values are calculated using \( \text{empinf} \) if they are needed.

A function defining a transformation. The intervals are calculated on the scale of \( h(t) \) and the inverse function \( hinv \) applied to the resulting intervals. It must be a function of one variable only and for a vector argument, it must return a vector of the same length, i.e. \( h(c(t1,t2,t3)) \) should return \( c(h(t1),h(t2),h(t3)) \). The default is the identity function.

A function of one argument returning the derivative of \( h \). It is a required argument if \( h \) is supplied and normal, studentized or BCa intervals are required. The function is used for approximating the variances of \( h(t0) \) and \( h(t) \) using the delta method, and also for finding the empirical influence values for BCa intervals. Like \( h \) it should be able to take a vector argument and return a vector of the same length. The default is the constant function 1.

A function, like \( h \), which returns the inverse of \( h \). It is used to transform the intervals calculated on the scale of \( h(t) \) back to the original scale. The default is the identity function. If \( h \) is supplied but \( hinv \) is not, then the intervals returned will be on the transformed scale.

Any extra arguments that \( \text{boot.out$statistic} \) is expecting. These arguments are needed only if BCa intervals are required and \( L \) is not supplied since in that case \( L \) is calculated through a call to \( \text{empinf} \) which calls \( \text{boot.out$statistic} \).

Details

The formulae on which the calculations are based can be found in Chapter 5 of Davison and Hinkley (1997). Function \( \text{boot} \) must be run prior to running this function to create the object to be passed as \( \text{boot.out} \).
Variance estimates are required for studentized intervals. The variance of the observed statistic is optional for normal theory intervals. If it is not supplied then the bootstrap estimate of variance is used. The normal intervals also use the bootstrap bias correction.

Interpolation on the normal quantile scale is used when a non-integer order statistic is required. If the order statistic used is the smallest or largest of the R values in boot.out a warning is generated and such intervals should not be considered reliable.

**Value**

An object of type "bootci" which contains the intervals. It has components

- R
  - The number of bootstrap replicates on which the intervals were based.
- t0
  - The observed value of the statistic on the same scale as the intervals.
- call
  - The call to boot.ci which generated the object.
  - It will also contain one or more of the following components depending on the value of type used in the call to boot.ci.
- normal
  - A matrix of intervals calculated using the normal approximation. It will have 3 columns, the first being the level and the other two being the upper and lower endpoints of the intervals.
- basic
  - The intervals calculated using the basic bootstrap method.
- student
  - The intervals calculated using the studentized bootstrap method.
- percent
  - The intervals calculated using the bootstrap percentile method.
- bca
  - The intervals calculated using the adjusted bootstrap percentile (BCa) method.
  - These latter four components will be matrices with 5 columns, the first column containing the level, the next two containing the indices of the order statistics used in the calculations and the final two the calculated endpoints themselves.

brambles

**Spatial Location of Bramble Canes**

**Description**

The brambles data frame has 823 rows and 3 columns.

The location of living bramble canes in a 9m square plot was recorded. We take 9m to be the unit of distance so that the plot can be thought of as a unit square. The bramble canes were also classified by their age.

**Usage**

brambles
**Format**

This data frame contains the following columns:

- **x** The x coordinate of the position of the cane in the plot.
- **y** The y coordinate of the position of the cane in the plot.
- **age** The age classification of the canes; 0 indicates a newly emerged cane, 1 indicates a one year old cane and 2 indicates a two year old cane.

**Source**

The data were obtained from

**Smoking Deaths Among Doctors**

---

**Description**

The *breslow* data frame has 10 rows and 5 columns. In 1961 Doll and Hill sent out a questionnaire to all men on the British Medical Register enquiring about their smoking habits. Almost 70% of such men replied. Death certificates were obtained for medical practitioners and causes of death were assigned on the basis of these certificates. The *breslow* data set contains the person-years of observations and deaths from coronary artery disease accumulated during the first ten years of the study.

**Usage**

`breslow`

**Format**

This data frame contains the following columns:

- **age** The mid-point of the 10 year age-group for the doctors.
- **smoke** An indicator of whether the doctors smoked (1) or not (0).
- **n** The number of person-years in the category.
- **y** The number of deaths attributed to coronary artery disease.
- **ns** The number of smoker years in the category (`smoke*n`).

**Source**

The data were obtained from

**Calcium Uptake Data**

**Description**

The calcium data frame has 27 rows and 2 columns.

Howard Grimes from the Botany Department, North Carolina State University, conducted an experiment for biochemical analysis of intracellular storage and transport of calcium across plasma membrane. Cells were suspended in a solution of radioactive calcium for a certain length of time and then the amount of radioactive calcium that was absorbed by the cells was measured. The experiment was repeated independently with 9 different times of suspension each replicated 3 times.

**Usage**

`calcium`

**Format**

This data frame contains the following columns:

- `time` The time (in minutes) that the cells were suspended in the solution.
- `calc` The amount of calcium uptake (nmoles/mg).

**Source**

The data were obtained from

**References**

The cane data frame has 180 rows and 5 columns. The data frame represents a randomized block design with 45 varieties of sugar-cane and 4 blocks.

This data frame contains the following columns:

- \( n \) The total number of shoots in each plot.
- \( r \) The number of diseased shoots.
- \( x \) The number of pieces of the stems, out of 50, planted in each plot.
- \( \text{var} \) A factor indicating the variety of sugar-cane in each plot.
- \( \text{block} \) A factor for the blocks.

The aim of the experiment was to classify the varieties into resistant, intermediate and susceptible to a disease called "coal of sugar-cane" (carvao da cana-de-acucar). This is a disease that is common in sugar-cane plantations in certain areas of Brazil.

For each plot, fifty pieces of sugar-cane stem were put in a solution containing the disease agent and then some were planted in the plot. After a fixed period of time, the total number of shoots and the number of diseased shoots were recorded.

The data were kindly supplied by Dr. C.G.B. Demetrio of Escola Superior de Agricultura, Universidade de Sao Paolo, Brazil.

**capability**  
*Simulated Manufacturing Process Data*

**Description**

The capability data frame has 75 rows and 1 columns. The data are simulated successive observations from a process in equilibrium. The process is assumed to have specification limits (5.49, 5.79).

**Usage**

capability

**Format**

This data frame contains the following column:

y  The simulated measurements.

*Weight Data for Domestic Cats*

**Description**

The catsM data frame has 97 rows and 3 columns.  
144 adult (over 2kg in weight) cats used for experiments with the drug digitalis had their heart and body weight recorded. 47 of the cats were female and 97 were male. The catsM data frame consists of the data for the male cats. The full data are in dataset cats in package MASS.

**Usage**

cats
cav

Format

This data frames contain the following columns:

- **Sex**: A factor for the sex of the cat (levels are F and M).
- **Bwt**: Body weight in kg.
- **Hwt**: Heart weight in g.

Source

The data were obtained from

cav

Position of Muscle Caveolae

Description

The cav data frame has 138 rows and 2 columns. The data gives the positions of the individual caveolae in a square region with sides of length 500 units. This grid was originally on a 2.65mm square of muscle fibre. The data are those points falling in the lower left hand quarter of the region used for the dataset caveolae.dat in the spatial package by B.D. Ripley (1994).

Usage

cav

Format

This data frame contains the following columns:

- **x**: The x coordinate of the caveola’s position in the region.
- **y**: The y coordinate of the caveola’s position in the region.

CD4 Counts for HIV-Positive Patients

Description

The cd4 data frame has 20 rows and 2 columns. CD4 cells are carried in the blood as part of the human immune system. One of the effects of the HIV virus is that these cells die. The count of CD4 cells is used in determining the onset of full-blown AIDS in a patient. In this study of the effectiveness of a new anti-viral drug on HIV, 20 HIV-positive patients had their CD4 counts recorded and then were put on a course of treatment with this drug. After using the drug for one year, their CD4 counts were again recorded. The aim of the experiment was to show that patients taking the drug had increased CD4 counts which is not generally seen in HIV-positive patients.

Usage

cd4

Format

This data frame contains the following columns:

baseline The CD4 counts (in 100’s) on admission to the trial.
oneyear The CD4 counts (in 100’s) after one year of treatment with the new drug.

Source

The data were obtained from DiCiccio, T.J. and Efron B. (1996) Bootstrap confidence intervals (with Discussion). *Statistical Science, 11*, 189–228.

Nested Bootstrap of cd4 data

Description

This is an example of a nested bootstrap for the correlation coefficient of the cd4 data frame. It is used in a practical in Chapter 5 of Davison and Hinkley (1997).

References

See Also

cd4
Description

This function applies types of bootstrap resampling which have been suggested to deal with right-censored data. It can also do model-based resampling using a Cox regression model.

Usage

censboot(data, statistic, R, F.surv, G.surv, strata = matrix(1,n,2),
         sim = "ordinary", cox = NULL, index = c(1, 2), ....,
         parallel = c("no", "multicore", "snow"),
         ncpus = getOption("boot.ncpus", 1L), cl = NULL)

Arguments

data The data frame or matrix containing the data. It must have at least two columns, one of which contains the times and the other the censoring indicators. It is allowed to have as many other columns as desired (although efficiency is reduced for large numbers of columns) except for sim = "weird" when it should only have two columns - the times and censoring indicators. The columns of data referenced by the components of index are taken to be the times and censoring indicators.

statistic A function which operates on the data frame and returns the required statistic. Its first argument must be the data. Any other arguments that it requires can be passed using the ... argument. In the case of sim = "weird", the data passed to statistic only contains the times and censoring indicator regardless of the actual number of columns in data. In all other cases the data passed to statistic will be of the same form as the original data. When sim = "weird", the actual number of observations in the resampled data sets may not be the same as the number in data. For this reason, if sim = "weird" and strata is supplied, statistic should also take a numeric vector indicating the strata. This allows the statistic to depend on the strata if required.

R The number of bootstrap replicates.

F.surv An object returned from a call to survfit giving the survivor function for the data. This is a required argument unless sim = "ordinary" or sim = "model" and cox is missing.

G.surv Another object returned from a call to survfit but with the censoring indicators reversed to give the product-limit estimate of the censoring distribution. Note that for consistency the uncensored times should be reduced by a small amount in the call to survfit. This is a required argument whenever sim = "cond" or when sim = "model" and cox is supplied.

strata The strata used in the calls to survfit. It can be a vector or a matrix with 2 columns. If it is a vector then it is assumed to be the strata for the survival distribution, and the censoring distribution is assumed to be the same for all observations. If it is a matrix then the first column is the strata for the survival distribution and the second is the strata for the censoring distribution. When sim = "weird" only the strata for the survival distribution are used since the
censoring times are considered fixed. When \( \text{sim} = "\text{ordinary}" \), only one set of strata is used to stratify the observations, this is taken to be the first column of strata when it is a matrix.

**sim**  
The simulation type. Possible types are "ordinary" (case resampling), "model" (equivalent to "ordinary" if cox is missing, otherwise it is model-based resampling), "weird" (the weird bootstrap - this cannot be used if cox is supplied), and "cond" (the conditional bootstrap, in which censoring times are resampled from the conditional censoring distribution).

**cox**  
An object returned from \texttt{coxph}. If it is supplied, then \( F \cdot \text{surv} \) should have been generated by a call of the form \texttt{survfit(cox)}.

**index**  
A vector of length two giving the positions of the columns in \texttt{data} which correspond to the times and censoring indicators respectively.

Other named arguments which are passed unchanged to \texttt{statistic} each time it is called. Any such arguments to \texttt{statistic} must follow the arguments which \texttt{statistic} is required to have for the simulation. Beware of partial matching to arguments of \texttt{censboot} listed above, and that arguments named \texttt{x} and \texttt{fun} cause conflicts in some versions of \texttt{boot} (but not this one).

**parallel, ncpus, cl**  
See the help for \texttt{boot}.

### Details

The various types of resampling are described in Davison and Hinkley (1997) in sections 3.5 and 7.3. The simplest is case resampling which simply resamples with replacement from the observations.

The conditional bootstrap simulates failure times from the estimate of the survival distribution. Then, for each observation its simulated censoring time is equal to the observed censoring time if the observation was censored and generated from the estimated censoring distribution conditional on being greater than the observed failure time if the observation was uncensored. If the largest value is censored then it is given a nominal failure time of \( \text{Inf} \) and conversely if it is uncensored it is given a nominal censoring time of \( \text{Inf} \). This is necessary to allow the largest observation to be in the resamples.

If a Cox regression model is fitted to the data and supplied, then the failure times are generated from the survival distribution using that model. In this case the censoring times can either be simulated from the estimated censoring distribution (\( \text{sim} = "\text{model}" \)) or from the conditional censoring distribution as in the previous paragraph (\( \text{sim} = "\text{cond}" \)).

The weird bootstrap holds the censored observations as fixed and also the observed failure times. It then generates the number of events at each failure time using a binomial distribution with mean 1 and denominator the number of failures that could have occurred at that time in the original data set. In our implementation we insist that there is a least one simulated event in each stratum for every bootstrap dataset.

When there are strata involved and \( \text{sim} \) is either "model" or "cond" the situation becomes more difficult. Since the strata for the survival and censoring distributions are not the same it is possible that for some observations both the simulated failure time and the simulated censoring time are infinite. To see this consider an observation in stratum 1F for the survival distribution and stratum 1G for the censoring distribution. Now if the largest value in stratum 1F is censored it is given a nominal failure time of \( \text{Inf} \), also if the largest value in stratum 1G is uncensored it is given a nominal censoring time of \( \text{Inf} \) and so both the simulated failure and censoring times could be infinite. When this happens the simulated value is considered to be a failure at the time of the largest observed failure time in the stratum for the survival distribution.
When \texttt{parallel = "snow"} and \texttt{cl} is not supplied, \texttt{library(survival)} is run in each of the worker processes.

**Value**

An object of class "boot" containing the following components:

- **t0**: The value of \texttt{statistic} when applied to the original data.
- **t**: A matrix of bootstrap replicates of the values of \texttt{statistic}.
- **R**: The number of bootstrap replicates performed.
- **sim**: The simulation type used. This will usually be the input value of \texttt{sim} unless that was "model" but \texttt{cox} was not supplied, in which case it will be "ordinary".
- **data**: The data used for the bootstrap. This will generally be the input value of \texttt{data} unless \texttt{sim = "weird"}, in which case it will just be the columns containing the times and the censoring indicators.
- **seed**: The value of \texttt{.Random.seed} when \texttt{censboot} was called.
- **statistic**: The input value of \texttt{statistic}.
- **strata**: The strata used in the resampling. When \texttt{sim = "ordinary"} this will be a vector which stratifies the observations, when \texttt{sim = "weird"} it is the strata for the survival distribution and in all other cases it is a matrix containing the strata for the survival distribution and the censoring distribution.
- **call**: The original call to \texttt{censboot}.

**channing**  

**Channing House Data**

**Description**

The `channing` data frame has 462 rows and 5 columns.

Channing House is a retirement centre in Palo Alto, California. These data were collected between the opening of the house in 1964 until July 1, 1975. In that time 97 men and 365 women passed through the centre. For each of these, their age on entry and also on leaving or death was recorded. A large number of the observations were censored mainly due to the resident being alive on July 1, 1975 when the data was collected. Over the time of the study 130 women and 46 men died at Channing House. Differences between the survival of the sexes, taking age into account, was one of the primary concerns of this study.

**Usage**

`channing`
Format

This data frame contains the following columns:

- **sex**: A factor for the sex of each resident ("Male" or "Female").
- **entry**: The residents age (in months) on entry to the centre.
- **exit**: The age (in months) of the resident on death, leaving the centre or July 1, 1975 whichever event occurred first.
- **time**: The length of time (in months) that the resident spent at Channing House. \((time=exit-entry)\)
- **cens**: The indicator of right censoring. 1 indicates that the resident died at Channing House, 0 indicates that they left the house prior to July 1, 1975 or that they were still alive and living in the centre at that date.

Description

The *claridge* data frame has 37 rows and 2 columns.

The data are from an experiment which was designed to look for a relationship between a certain genetic characteristic and handedness. The 37 subjects were women who had a son with mental retardation due to inheriting a defective X-chromosome. For each such mother a genetic measurement of their DNA was made. Larger values of this measurement are known to be linked to the defective gene and it was hypothesized that larger values might also be linked to a progressive shift away from right-handedness. Each woman also filled in a questionnaire regarding which hand they used for various tasks. From these questionnaires a measure of hand preference was found for each mother. The scale of this measure goes from 1, indicating someone who always favours their right hand, to 8, indicating someone who always favours their left hand. Between these two extremes are people who favour one hand for some tasks and the other for other tasks.

Usage

*claridge*

Format

This data frame contains the following columns:

- **dnan**: The genetic measurement on each woman’s DNA.
- **hand**: The measure of left-handedness on an integer scale from 1 to 8.
**Source**

The data were kindly made available by Dr. Gordon S. Claridge from the Department of Experimental Psychology, University of Oxford.
